Figure 33.5: Proportion of Undernourished in Developing Regions. Actual and FAO Baseline Projections. **Source:** FAO/IFAD/WFP (2002: 9).

¹ Legend: SSA: Sub-Saharan Africa; NENA: Near east and North Africa; LAC: Latin America and the Caribbean; S.Asia: South Asia; SEA: East and Southeast Asia.

Furthermore, regional and social differences exist (figure 33.4). Food production has augmented, but at the same time poverty, hunger, and preventive illnesses (HIV/AIDS) increased in several countries, above all in *Sub-Saharan Africa* (SSA). This region has at its disposal today 20 per cent less food than 25 years ago, despite the population increase (UNDP 1998, 1999, 2000, 2001). The SSA countries produced between 2002 and 2003 about 22.89 million tons of cereals; a small increase compared with the 21.55 mt of the previous year. This production is insufficient to feed the population and 15.2 million people are threatened by famine or require international food support (figure 33.5). Causes are complex: in the former grain reserve of the region in Zimbabwe a corrupt government rules; in Congo a civil war is ongoing; and Namibia is confronted with a severe desertification process. In general, severe droughts and disasters have affected food production in many countries, but also the international trade rules are unequal for Africa (Turner 2003).

In SSA the fifth poorest segment of the population obtained only 72 per cent of nutritional requirements, in Latin America 78 per cent, and in the recent independent countries of the former USSR, 80 per cent. The gap among and within countries in Africa and Asia is increasing, and only the fifth wealthiest

will get their nutritional requirements in the near future. These negative results are reinforced by the present policy of cash crops, the food production, and the policy of biofuel controlled by multinational enterprises (MNE).

Tajikistan and probably Azerbaijan will lose their food security without armed conflicts, but the food situation can get worse in the event of political destabilization (chap. 34 by Salih). In sum, with the estimated population growth in poor countries and the present policy of food as a commodity, poor countries will be highly affected by the change of food patterns, and therefore more exposed to hunger and famine. These processes are reinforced by propaganda, where occidental introduced values of food patterns are taking away the few resources able to offer healthy food to poor people.

With a global population of more than 6.5 billion inhabitants, more than one sixth in 70 countries are suffering from hunger (USDA 2005). Natural factors such as loss of fertile soils, salinization of coastal areas and deltas, intrusion of salty water into coastal aquifers, and greater droughts will increase food vulnerability in countries that are today food insecure. These processes will be aggravated by climate change and more frequent hazards.

Table 33.1: Models of World Global Food Consumption by Social Classes. **Source:** Lang/Heaseman (2004 or 2005: 195), modified by Oswald.

Category of consumption	High	Medium	Poor
Diet of social class	1.5 billion people: meat, packed food, bottled drinks	3 billion: grain, clean water	1.8 billion: insufficient grain, polluted water
Transportation	Private cars, planes	Bicycles, buses, cars	Walking, public transportation
Origin of food	Food from far away, supermarkets, shops of specialties, delicatessen	Some food from outside, local shops and markets	Local food, local shops and markets
Materials	Throw away	Durable	Local biomass
Goals	Wide with global horizons	Sufficient, regional horizons	Limited or missing local horizons
Fuels	Gas, gasoline, kerosene	Gasoline, gas	Wood, excrement, organic waste
Environmental Impact	High	Considerable	Low

33.3.1.1 Food Prices and Trade

The export of primary commodities from the poor countries to the world market equals that of 1980, representing 26 per cent of the global trade. Nevertheless, the imports grew from 28 per cent in 1970 to 37 per cent in 1997. The net food imports in the poorest countries have increased by about 50 per cent between 1980 and 1997 (a rise from US\$ 3.9 to US\$ 6 billion). The increase in 19 medium income countries was 40 per cent (from US\$ 9.3 to US\$ 13; see: Kwa 2003: 24). Food distribution is another unequal issue (Sen 1995). Globally, one fifth of the world population has access to 86 per cent of world consumption, compared with the poorest 20 per cent that obtain 1.3 per cent, and consumption in rich countries is still rising.

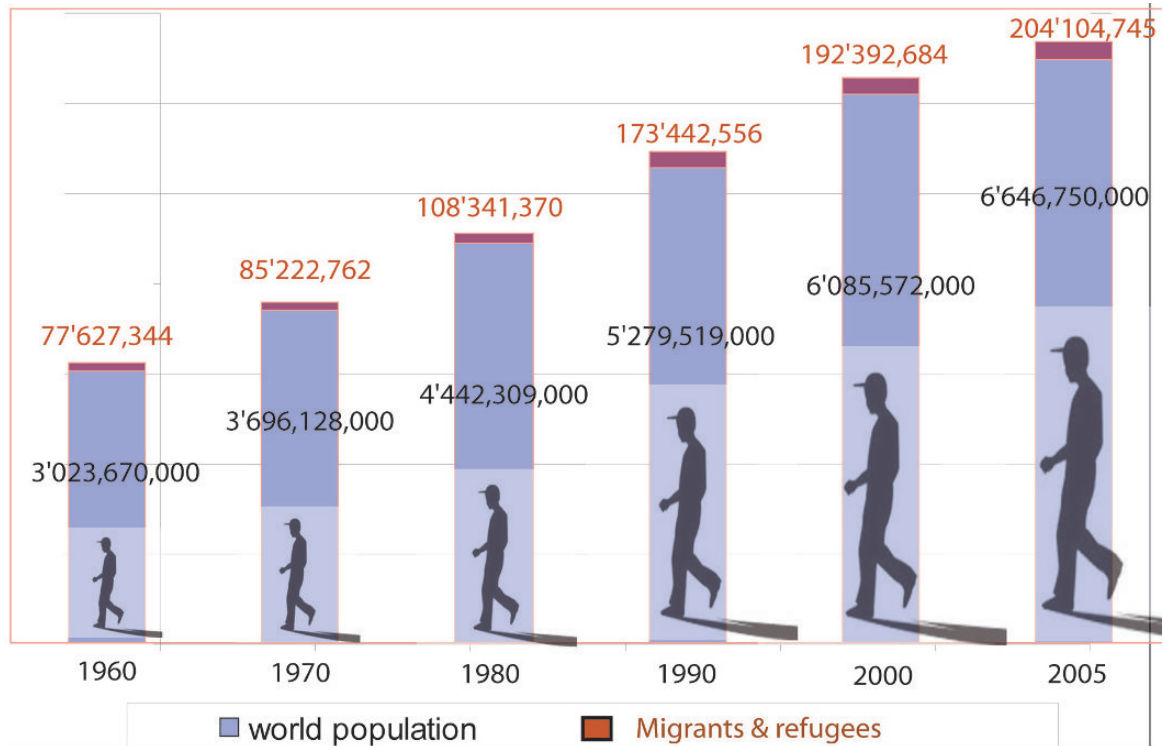

These data show the concentration of food in industrialized countries and a situation of increasing hunger in the poorest nations as a result of missing money, unemployment, low prices for prime material, unjust terms of trade and trade system, low salaries, population growth and corrupt governments, but also missing land and production means for the poorest. Especially women and girls belong to the group of highly vulnerable persons, and are affected by this perverse poverty.²¹ The sum of these factors prevents rural people from getting sufficient food to overcome hunger, and thus many are forced to migrate to slums in cities where environmental, social, and economic deterioration affects again the most vulnerable (Villarreal 2003; Scheitingart 2006).

33.3.1.2 Food Aid and Internal Gaps

During 1996/97, 66 low income countries required 8.5 million tons (mt) of grain from food aid, and in 1998 it increased to 11 mt. The USDA estimated that this aid covered 85 per cent of the projected needs, and the minimal nutritional requirements are 17.6 mt. The FAO (2005b) calculated that the food deficit will grow in 2008, and with the same minimal ingestions, per capita insufficiency will increase by 80 per cent to 19.8 mt, while nutritional deficiency will rise by 65 per cent to 28.4 mt. As a result, 35 poor countries will experience food shortage and 47 countries more must reduce food intake. This implies new subsidies for food surpluses and a greater food power for exporting countries (USA, Canada, EU, Australia). This power is based on highly subsidized prices affecting poor countries and their rural people. TNE obtain a

21 Extreme poverty is better characterized as 'perverse poverty' (Oswald 1990). The perversity lies in the fact that a child before being born, is condemned already to becoming a second class citizen due to brain damage, caused by chronic undernourishment and having an anaemic mother. Later, the child enters into the 'Valley of Death' between 1 and 2½ years of age, because of its fragile immune system. If they survive despite chronic hunger, often the growth, intellectual improvement, and motricity of the child is seriously damaged. During the first year of life a child requires 80 per cent of the nutrients for brain development and growth. Malnutrition causes irreversible intellectual and physical damage. Besides the small size, there are problems for logical learning, altered micro-motricity, and slow reactions.

Figure 33.6: International migrants and refugees (1960-2005). **Source:** UN (2006); at: <<http://esa.un.org/migration/>> (15 October 2006).

major part of these subsidies, and Gorelick (2000) estimated that profits obtained by big companies in the USA in form of subsidies and external support amount to US\$ 2.4 billion dollars, without including environmental costs or health damages. Vandana Shiva (2003) calculated that each kilogramme of food consumed in the USA travels 1,500 miles, generating 10 kg of CO₂, thus contributing to global warming.

These structural inequalities create worldwide prototypes of food consumption, depending on economic possibilities (see table 33.1). It represents a kind of schizophrenic behaviour of upper classes that are damaging to the global environment (see chap. 59 by Dalby/Brauch/Oswald) and their personal health, with their inadequate food intake (Murray/López 1996).²² Middle classes are becoming aware of their health and consume more locally produced organic food, but they also buy fruit and vegetables from outside. The lower classes struggle not only for their food survival, but also for drinking water and other basic services. These social groups create the lowest environmental impact.

This global food pattern is the result of complex and multicausal processes, where local and global activities get negatively reinforced, and where *Free Trade Agreements* (FTA), indiscriminate openness of

agricultural markets in the South, SAP imposed by IMF (Strahm/Oswald 1990; Stiglitz 2002), failed policies by the World Bank (mega-projects of dams and irrigations districts, and modernization of agriculture in hands of agribusiness) have created hunger. This critical situation worsened due to subsidies for agricultural products by industrialized countries, corrupt national governments, and local elites²³, financial monopolies, exports of prime materials at international prices below production costs, debt payments, bank rescues, patriarchal structure inside families and society, lack of peasant support also for organic agriculture, and low agricultural wages. With deteriorated and marginal land, polluted resources and high prices

22 In 2003 more than 40 billion dollars were spent for food advertisements, what is equivalent to 70 per cent of the GDP of poor nations. For each dollar spent by WHO to heal damages caused by inadequate food intake, more than \$500 were spent to support these diets. Three quarter are oriented to promote junk food, empty calories, and a high level of sugar and low nutrients. In Eastern Europe 60 per cent of investment in foreign food are oriented to sweets, jam, and bubble water, and only 10 per cent of food expenses were used for fruit and vegetables (Dalmenry/Hanna/Lobstein 2003).

Figure 33.7: Undernourished Population in Latin America and in the Caribbean. Percentage of Population with Malnutrition (1998-2000). **Source:** The estimates by CEPAL (2004) are based on FAO data.

a) Simple average of 24 countries; b) Statistical weighted average of 24 countries

for agricultural inputs, most peasants are obliged to leave their community and migrate to megacities, and illegally to industrialized countries in search of a livelihood (figure 33.6). The increasing data on migration

and refugees reflect the deep rural crises worldwide (Negrete/Ruiz 1991), affecting the most sustainable and productive food system in the world, i.e. of the peasants (Barraclough 1995; 1995a) thereby transferring food security to transnational agribusiness. All these factors have forced important rural groups to migrate to megacities or leave their country, confronted with a 'survival dilemma' (Brauch 2008c).

Natural disasters and armed conflicts have further accelerated this flight, and in 2005 there were an estimated 37 million environmentally-induced migrants or displaced people (UN 2005a; see figure 33.5; see chap. 15 by Wisner; chap. 18 by Bogardi/Birkmann/Gebert/Setiadi and chap. 19 by Ahmed). Kofi Annan (2005) referred to one billion environmental refugees due to desertification, water scarcity, and soil depletion.

33.3.2 Latin America

The repercussions of the failed development policies in Latin America are affecting vulnerable groups, especially indigenous and rural children, the elderly, and women. The causes of chronic hunger in the most biodiverse countries of the world are complex and are directly related to the unequal income distribution,

23 An aggravating phenomenon for food insecurity is social inequality. Latin America is the region with the highest social gaps. This is a result of the appropriation of surplus by the military, political and economic elites, using repression, in alliance with transnational capital, The Catholic Church and the mass media were instrumental in creating a clientelist and corporative model of government. CEPAL (2004, 2007) compared the economic growth between 1960 and 1980 of 5.5 per cent/year with that of the neo-liberal phase from 1980 to 2000 of 2 per cent when the IMF applied SAP programmes, consolidating the exclusive model of development (UNDP 1990-2005). Most affected by these developments were peasants and indigenous people during these crises years, which were often pushed from their land and natural resources by TNE that imposed a model of capital intensive production when the country had enough human power. As a model of this unsustainable agribusiness a modern chicken farm must produce yearly about 240,000 birds. After paying credit and inputs to the TNE "this prodigious (and inhuman) production left the farmer only US\$12,000, or five cents/bird" (Gorelick 2000: 5).

and as mentioned above as a result of failed policies. In 2007, still 55 million Latinos have suffered from hunger (figure 33.7), affecting particularly the conflict prone regions, such as Haiti and Central America. Several economic crises have concentrated income during 2000 to 2004 in Argentina, Colombia, Panama, Ecuador, Venezuela, Uruguay and Costa Rica, thus increasing the number of poor people. Countries with higher levels of undernourishment are simultaneously affected by political instability or are recovering from civil wars, such as Haiti, Guatemala, Honduras, Bolivia, Peru, Nicaragua, El Salvador, Guyana, and Mexico from a severe economic crisis.

In terms of food intake 50 per cent of the population in Haiti lack basic food; 20–30 per cent in Nicaragua, the Dominican Republic, Guatemala, Bolivia, Venezuela, Honduras; 10–20 per cent in Panama, El Salvador, Guyana, Cuba, Colombia, Peru, Suriname, Brazil, Paraguay, and Trinidad & Tobago (CEPAL 2004). During the last few years, specific governmental programmes have improved the situation of nutrition in El Salvador, Venezuela, Guatemala, Mexico, Argentina and Nicaragua (CEPAL 2004), and recent efforts of integral food programmes (zero hunger) were implemented in Brazil, Venezuela, and Bolivia (CEPAL 2006).

33.3.3 Mexico

Mexico is one of the most unequal countries, with the richest man in the world (Forbes, 10 August 2007). During the 1980's its model of import substitution and stable development was replaced by a neoliberal globalization process (Klein/Fontan/Tremblay 2003). After joining NAFTA in 1994, the effects in rural areas and for the peasant economy were disastrous. The wealth has been even more concentrated (table 33.2).

Table 33.2: Social Vulnerability and Internal Gaps in Wealth and Income in Mexico. **Source:** INEGI (2005) and Bank of Mexico (2004).

Concept	% of population	% of national wealth	% of financial savings
Very rich	0.23	40.3	78.0
Poor	52.7	18.4	10.0

The effects of free trade, promoted by business monopolies, and the rapid openness by government without compensatory processes permitted an evaluation a decade later. The results are complex: economic

growth was below one per cent; the employment policy was unable to offer to more than one million young people a job and the new employments are precarious, without social protection, and with 'white' trade union leaderships that are favouring enterprises. About half of the labour force is (self-) employed in the informal, often illegal sector, salaries declined by 60 per cent since 1982 and during a decade of NAFTA by 23 per cent. The indigenous and peasant economy is in crisis with half of the 80 per cent of poor people living in perverse poverty. More than one million peasants have left agriculture since the signing of NAFTA, and poverty is affecting half of the population (Wise 2003; Nadal/Wise 2004; Ackerman 2005; Calo/Wise 2005).

Half of Mexican children suffer anaemia and 56 per cent of the indigenous children are severely undernourished²⁴ (INNSZ 2005). The indicator of municipal nutritional risk with 14 variables indicates that 70 per cent of the municipalities in the rural areas with a population of 30 per cent have severe undernourishment as a result of regional and social inequality (figures 33.8 and 33.9). The severe undernourishment hardly declined since 1989 due to inflation and economic crises, while the concentration of wealth owned by a tiny elite has increased dramatically.

Women have developed survival strategies for their children and elders, and often they have to pay the debt for the illegal crossing of their husbands. Also feminization of agriculture rose to 35 per cent (INEGI 2006). Food imports affect both countries: the USA due to pollution of agrochemicals to raise yield productivity, and Mexico due to payment of US\$ 72 billion for food importation and job creation in a foreign country (INEGI 2005). Only a small elite representing 0.23 per cent of the population benefits from this type of modern rape capitalism, owning 40.3 per cent of national wealth and 78 per cent of financial savings (table 33.2).

Nevertheless, these global data do not reflect the existing regional disparities. Table 33.3 explains the

24 The indigenous population is especially marginalized. Only 20 per cent have water connections in their houses, 17.2 per cent have no electricity, 31.3 per cent have no schools; 19.9 per cent of men and 12.3 per cent of women have only a basic education, and only 8.1 per cent live more than 65 years. Mexico has a rich cultural diversity with 85 indigenous languages, where Náhuatl, Maya, Mixteco and Zapoteco represent 51.4 per cent. Nevertheless, languages such as Cucapa, Papago and Kilwa are spoken by less than 500 persons and are on the verge of disappearing (INEGI 2000, 2003).

Figure 33.8: Comparison of national surveys on food, nutritional stage of children below 5 years of age, measuring size and weight in relationship to age. **Source:** National Nutritional Survey (INNSZ 1974, 1979, 1989, 1996).

Table 33.3: Nutritional Priority in 2,443 Municipalities in Mexico. **Source:** Chávez/ Ávila/Shamana (2006); based on the National Survey of Nutrition (INNSZ 2005).

Level of marginalization	Municipalities		Level of under-nourishment	Low size/children		Affected municipalities
	Number	%		number	%	
Very low	247	10.1	Very high	50	100	222
Low	417	17.1	High	40	49.9	510
Medium	486	20.0	Medium	30	39.9	365
High	906	37.9	Low	20	29.9	737
Very high	387	15.8	Very Low	10	19.9	369
Total	2,443	100.0	Without priority	0	9.9	240

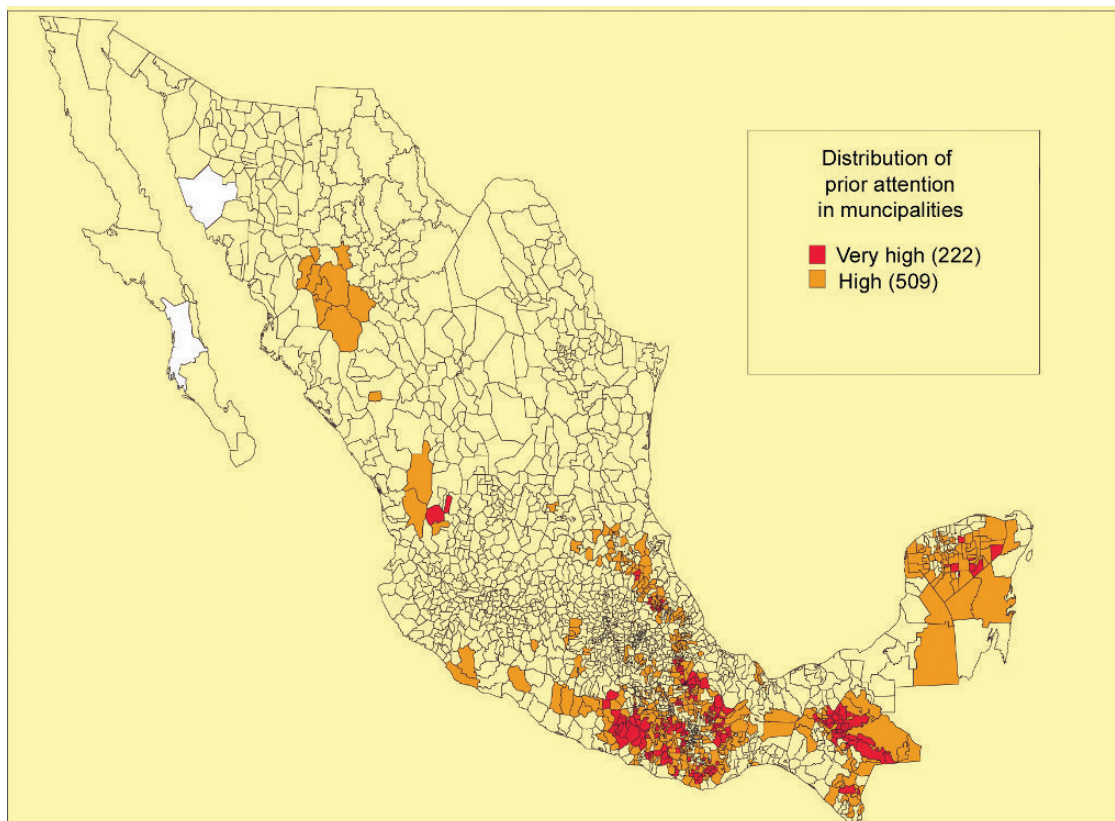

level of marginality of Mexican municipalities where 54 per cent have high levels of poverty. This marginality is directly linked to hunger and low school achievement, mortgaging the future of indigenous and peasant children. There is also a direct relationship among a high level of undernourishment, low size or weight for children under 5 years, with low income in rural marginal municipalities.

Marginality and undernourishment are geographically located in the south of Mexico, where poor peasant and indigenous survive, and also in some indigenous municipalities in the north (figure 33.10). In the last survey on nutrition (2005), the northern states had improved their food access (except the indigenous Tamaulipas) and the traditional poor states in the south, Chiapas, Oaxaca, Guerrero, Veracruz, Yucatán, Hidalgo, Puebla and Campeche, are getting worse

(INNSZ 2005). Regional inequalities are often triggered by internal and interfamilial social and gender discrimination. These processes further aggravate the existing perverse poverty among the most vulnerable within poor families.

The food perspectives for the future are uncertain, and will most likely get worse due to the massive use of corn and oil seeds for biofuel. Furthermore, confronted with climate change, disasters and greater drought, Mexico must take its food security problem seriously, especially if the USA and Canada that presently provide more than 16 million tons of basic grain should become food insecure. Therefore, the term of 'food power', created in 1972 by Henry Kissinger, may generate structural instability, migration, and social riots (figure 33.6).

Figure 33.9: Map of municipalities in Mexico with high and very high needs for nutritional attention. **Source:** Chávez/Ávila/Samanah (2007), based on the National Survey of Nutrition (2005).

Based on global and regional scenarios on temperature rise, precipitation, decline in groundwater, and hydro-meteorological disasters, together with biofuel from cereals, the worldwide supply of basic grain will be reduced drastically. In 2007, still half of the people live in regions with a low level of underground water, including the three large grain producers: China, India, and the USA. Countries such as Mexico, Iran, Israel, Pakistan, Saudi Arabia, Jordan, and Yemen are overexploiting their aquifers and limiting alternatives for the future. Due to projected water scarcity in the next 25 years, cheap grain will disappear from the world market and only very few countries will be able to improve their agricultural production due to climate change. In 2005, the world market price of rice, highly vulnerable to water, increased by 30 per cent reaching US\$ 260/t (USDA 2005). The corn price in Mexico rose between September and December 2006 from 1,500 to 3,500 pesos/ton, as a result of the demand for biofuel for corn in the USA, but also due to speculative practices. Therefore, the future of the world food system is complex and uncertain, and a

new policy of food sovereignty will play an important role in the political stability of many countries.

33.4 Three Models of Food Production

Related to the conceptualization of food security and food sovereignty (see 34.2), three models of food production and commercialization have evolved: a) the *productivity model* based on the green revolution; b) the *life science model* that relies on modern biotechnology and genetics; and c) the *traditional organic or green model*.

33.4.1 The 'Productivity' Model

Throughout the 20th century the productivity model tried to homogenize food crops similar to industry, and during the last two centuries the supply of food and agricultural inputs was in the centre. The green revolution promoted monocultures, intensive use of chemicals, veterinarian drugs, improved seeds, machines, fossil energy, and irrigation systems. Politically, this system relied on high government subsidies (USA,

EU, OCDE, Japan), offering the consumers cheap products. The production was controlled by agronomists, veterinarians, and the chemical industry. Health and environment concerns were marginal. The Ministry of Agriculture managed natural resources such as soils, water, forests, flora, fauna, and fish.

Internationally, this model should have eradicated hunger and given the whole world food security. Until today it remains the basic tool against hunger (FAO 1996a, 2000a, , 2005b, 2005c). High crop yields and 'free markets' were at the centre of the concern and therefore hunger could not be eradicated, owing to the maximization of profit of agribusiness and governmental subsidies in developed countries. Hunger and poverty were considered undesirable side effects for southern countries and for people with a low capacity to modernize. Social, environmental, and cultural factors of diverse food production are only marginally considered. Food is not treated as a cultural good or as a patrimony of thousands of years of human effort. The limits of this model are imposed by negative effects on health (Gallaher 2005) and on the environment (scarcity in water and oil resources).

33.4.2 The 'Life Science' Model

In the 21st century a new model is emerging that establishes links among health, food production, and dietetic habits. It represents the new health safety and food security concerns where individuals with purchasing power are at the centre of attention. Concrete genes were linked to specific illnesses (Nestlé 1999), creating a scientific basis for life or a 'life science' paradigm (Lang/Heasean 2004). This model is demand-oriented and takes into account the consumers and their needs. Productivity is still important. It refers to the balanced daily intake of proteins, carbohydrates, vitamins and minerals, all of them necessary for a healthy life.

This *life science model* integrates the food chain in the form of clusters and relates it to production, transformation, and trade of food. It combines genetic research with field experiments, including biology, engineering, nutrition, pharmacology, health, and mobile field labs. The industries are controlled by multinational food chains. They offer clean, safe, and homogenous products that can stay for weeks on the shelves of supermarkets, thanks to *genetically modified genes and organisms* (GMO). Food is not only modified but also enriched artificially with nutrients to prevent illness, such as enzymes, proteins, minerals, etc. At the centre of concerns is the individual health, improved

by technological proceedings in bio-labs, where specialists are in charge of human lives (Nestle 2002). These processes of 'healthy' food can only be controlled through sophisticated scientific procedures in well-equipped laboratories in universities or research institutes of MNE. The experts are paid by the food MNE, which are simultaneously producers, sellers, and supervisors. When nonconformities arise, due to the complexity of the process, governments rely on these institutions, where those who are interested and involved are both judge and arbiter (Beck 1998; 2000).

Independently of an intensive propaganda in mass media, some undesired effects can not be denied, and NGOs are trying worldwide to carefully educate people on these negative effects. Most evident are genetic modified crops (GMO), which started commercially in 1995. In 2005 more than 80 million hectares were produced in the USA (68 per cent), 22 per cent in Argentina, 6 per cent in Canada, and 3 per cent in China. South Africa, Chile, India, and Brazil are joining this production process. On GMO seeds there exists an oligopoly of four main multinational enterprises. One sole holding (Monsanto) controls 90 per cent of all seeds with two genetic modified properties: a herbicide (roundup) and an insecticide (Bt). Conclusive results are still lacking whether these seeds are innocuous, but there are risks that the recombinant process could produce unknown effects in human and animal health and environment. Unwanted pollution occurred in Canada where wind, water, insects, and other animals have polluted natural crops of canola with GMO ties, destroying the great biodiversity and the natural production of this crop (Schmeiser 2002). Another threat is related to new toxics, new plagues, and insects resistant to GMO and other insecticides. Paediatricians have found a high level of food allergy in babies and therefore baby food is produced without GMO seeds.

In socio-economic terms, eight MNE merged in 2007 into four, able to produce 83 per cent of biotechnological research in the world. This is a threat for the freedom of science and technology in favour of humankind. There is another danger that small farmers may be forced to stop farming due to the expensive productive processes of GMO seeds (40 per cent of cotton production in 2005), what is reinforced through subsidies that are highly concentrated in big enterprises. Finally, these GMO seeds are controlled by patents and the WTO is the arbiter through TRIPS (Heineke 2002; Schmid 2000; Oswald 2000; 2002). The study of FAO (2005a) in different countries has shown that the income of producers in Mexico in-

creased by 12 per cent using cotton GM-seeds from Monsanto, but the benefits were more than three times as high in China where a national research institute produced their own GM-seeds.

The 'life science' paradigm continues with the same model of productivity, but it oriented at the consumers and their health needs. The integration into the food chain is through clusters. This model of production has generated new illnesses (BSE²⁵) and could promote new epidemics such as avian flu, since genetically modified organisms work with virus and bacteria that could have their own dynamism when they are modified and inserted into different plants or animals.

Therefore, the cornucopian vision to resolve by MNE environmental, social, and health problems through science and technology shows its limits, but above all poor people have to pay for the mistakes, and biodiversity can get lost for ever. It is horrific that thousands of peasants have committed suicide when GMO harvests failed and credits could not be paid back (Shiva 2003, 2008, 2009). With regard to food sovereignty there is no doubt. This model of production has enormously increased the costs of production (GM-seeds), and created a monopoly of agrochemicals and the transformation of basic food in the hands of TNEs. These processes are able to concentrate wealth within few hands, increasing poverty not only due to more expensive food, but also due to associated health problems.

33.4.3 'Green Agriculture' Model

The green model generates symbiotic relations and mutual dependence between nature and food production, and therefore uses soft methods of agriculture. They are regionally diverse and utilize polycultivation, association of crops, rotation, mixed agriculture, fixation of nitrogen from air to soil, biopesticides, traditional methods of soil conservation and food, integral management of water, plagues, and environmental services. The combination of traditional and modern

knowledge is consolidating food sovereignty in any region. A biodiverse and regionally adapted use of seeds is conserving diversity of species, and therefore is agro-ecological. This mode of production cannot be globalized. The surplus of production is sold in the local markets and thus reduces environmental pollution and global warming linked to transnational agribusiness and global markets.

Local agricultural production and trade, with access for peasants to water, seeds, credits, as well as technical and financial support could promote this model of agriculture. This green model takes women and peasants as key elements for food issues and agricultural consolidation. It encourages the participation of indigenous, women, and peasants in the national and regional definition of rural policies. It can guarantee women access to land for production and livelihood, and through empowerment they can overcome the violent and patriarchal structures inside families, regions, countries, and the global economic system. It includes the right that peasant organizations have developed their own model of food sovereignty and are now struggling for their right to produce and consume healthy, permanent, and culturally accepted food which is locally produced, sold, cooked, and consumed. Governments have the obligation of protecting their economy from subsidized food imports. They have to establish agricultural prices which are able to cover the production costs and to protect the environment. By linking environmental services with farming, land planning, and participative democracy, this paradigm supports a stable rural development and therefore respects the human right for non-migration. When livelihood in villages and countries is guaranteed with public resources for poverty and hunger alleviation,²⁶ bottom-up efforts can be reinforced. In the medium term, safe ecosystems and stable social relations create synergies and cooperation where safe food and the environment improve public health and cultural diversity at the local level.

This third model reflects the food sovereignty debate. It understands food in a holistic way, where livelihood, sustainability, and culture are the driving elements to maintain the genetic diversity for future generations, offering healthy nutrition and establish-

25 BSE is a result of feeding cows with waste from animals instead of grass. After 15 years research of more than 500 drugs, it was proven that *Bovine Somatropina*, an amino acid able to stimulate growth in cows, is responsible for an increase of 180 per cent of breast cancer in pre-menopausal women and the same number of prostate cancer in men (World Cancer Research Fund 1997). Confronted with avian flu threats, the same MNEs are producing expensive medicaments with dubious results to combat a potential epidemic.

26 Foreign food aid from outside has to be targeted to avoid a distortion of non-market items such as equity, corruption, electoral use, etc., but above all it can destroy the local productive systems. Thus, it must always be an emergency support, limited in time and for specific events.

ing a direct relation among productive, commercialization, and consumption cycles. It represents also an alternative for more than 1.5 billion peasants and small farmers who still depend on their ancient technology. They carefully selected the seeds from the former year that were and are able to guarantee the next harvest. It consolidates the basic right to consume safe, sufficient, and culturally accepted toxic-free food that is locally produced, transformed, and sold.

Thus, in the green agricultural paradigm food is a cultural act of life and more than the intake of proteins and calories. It is until today the only real possibility to overcome existing famine and hunger and offer humankind an opportunity to create justice and well-being all over the world by fulfilling the Universal Declaration of Human Rights in its Art. 25.1. Food sovereignty within the green paradigm represents the rights of people, communities, and countries to define their own ecological, social, economical, and cultural project of the future. Besides maintaining food as a pleasure of life, and not a threat to health and survival, it consolidates the world food culture and consumption for the future.

33.4.4 Food Perspectives: Models of Production, Population Growth, Climate Change, and Environmental Deterioration

'Food security' in the context of the model of agribusiness production or life science has failed to improve the world food situation. It is not a problem of the amount of food and of the knowledge how to produce more, but it is basically a problem of poverty (FAO 2006). Therefore the evidence is that in most poor countries the total number of hungry people has not been reduced, except for China and India and the former countries of USSR. Rather, new threats of food insecurity are rising. This requires the reformulation of the basic assumption of how to reduce hunger and how to achieve the MDGs. The globalization process in its regressive phase has reversed some advances, but in countries with high population growth that are threatened by severe impacts of climate change and disasters, the eradication of hunger is further limited.

Both the 'productivity' and the 'life science' paradigms have also led to higher emissions. Aquifers have collapsed in India and Mexico. Through genetic pollution both models have been destroying the biodiversity of southern countries. Thus, with regard to food

security, but also for the survival of humanity and nature, the present understanding of food security has failed to combat hunger. It has rather increased the threats and risks of more serious famine not only in Africa, but worldwide. Imposing food security instead of food sovereignty, and destroying the traditional green production, could become a boomerang also for northern and developed countries.

From 2000 to 2005 organic food production has grown by 20 to 30 per cent. In Germany organic food products grew annually by 15 per cent. A major increase has also occurred in the US where the *National Organic Programme* (NOP) supports small farmers and promotes the certification of green agriculture where organic products grew from US\$ 1 to 13 billion from 1994 to 2003. In 2005 about 26 million hectares of land were certified and 560,000 farmers were affiliated.²⁷

In most countries, due to the productive model of the political elites, the support for organic agriculture is still limited. Nevertheless, the TNEs have discovered this green option for supermarkets. They are now charging higher prices for naturally grown products. Consumers, confronted with doubts about GMO, are demanding comprehensive labelling, but TNEs have tried to influence national laws to avoid or restrict this. Propaganda on different products is confusing the consumers even more by letting them believe that they determine their own model of life.

Via Campesina has challenged this TNE and has campaigned against gene modified seeds and promoted laws favouring its alternative agricultural model. They insisted that environmental, cultural, and social factors are as important as the economy. Further, economic crises and increasing poverty in rural areas have created among peasants, the indigenous, and women a sense of security that they can manage their own food supply with regional resources and local seeds.

At the international level, FAO has argued that food needs could be linked with a protection of the natural heritage by:

promoting market-based incentives that compensate farmers for their stewardship efforts, thus maintaining their economic viability; replacing polluting agricultural practices with approaches that can reverse the dramatic trends in biodiversity loss; thriving on community par-

27 See: Research and Market, 2005: *Current Organic Agriculture Market Worldwide: A Year in View, 2005*, at: <http://www.researchandmarkets.com/reportinfo.asp?report_id=302678>.

ticipation in land conservation. Meeting food needs while protecting the natural heritage is a challenge shared by all countries of the planet. Organic agriculture can meet this challenge head-on by: promoting market-based incentives that compensate farmers for their stewardship efforts, thus maintaining their economic viability; replacing polluting agricultural practices with approaches that can reverse the dramatic trends in biodiversity loss; thriving on community participation in land conservation (El-Hage Scialabba 2003: 15).

Simultaneously, FAO has also promoted GMO seeds in diverse poor countries, and continues to support the 'green revolution' model. Many existing contradictions are inherent in the three productive models, and reflect the struggle for hegemony. They can be synthesized as follow: the 'productive' model is unsustainable due to the scarcity and pollution of natural resources (water, soil, seeds, and loss of biodiversity). Ministers of agriculture have shifted slowly to the 'life science' model that is supported by ministers of trade who promote free trade and bilateral agreements. Health ministers have supported nutria-genomic research, biosecurity protocols and vaccines that are often produced from genetically modified plants. Productivity concerns dominate over inherent risks and threats for biodiversity and humankind, due to the uncertainty and insecurity of genetic manipulation and nanotechnology. Both could affect the essence of human beings and the future of life (Habermas 2001).

These two models induce a scenario of a 'food war'²⁸ (Lang/Heasman 2004), when multiple factors of aggravation of conflicts intervene: the quality and innocuous food demand, international commerce, governmental regulations, nutritional requirements, control of TNEs, anti-monopoly laws in transportation, financial monopsony, security in food chains, supply of safe food products, coexistence of over- and undernourished people, environmental damages, science and technology (S&T). Arbitration among these many contradictions are often handled by experts associated with TNEs.

But despite the unimaginable advances in S&T; hunger is still increasing and far from being eradicated. Why is this so? There is a second related factor. The model of transnational agribusiness is oriented at

the individual, considering his or her consumption and PPP. As with the modern health system, the individuals become victims and objects of persuasion for food recipes to strengthen their health that are often counterproductive. These two realities have opened for social movements, NGOs, and critical scientists a space for struggle. Confronted with the nutritional and health deterioration, they have denounced these TNEs and often corrupt government allies which try through early alerts and catastrophic predictions about epidemics²⁹ to push the errors and possible consequences of this erroneous productive system to various 'natural' causes.

The global deterioration of life quality and limited progress in hunger alleviation in most developing countries, as well as high levels of obesity and cancer³⁰ in industrialized countries, offer organic agriculture an option for the future. Social movements understood these opportunities and are promoting food sovereignty with native seeds and organic input as a real alternative against hunger and malnutrition.

Table 33.4 summarizes, contrasts, and compares the many advantages and disadvantages of the 'life science' model with those of the 'sustainable organic agricultural' model.

In synthesis, the paradigm of 'science of life' relies on governmental financial resources; however, the consolidation of this model depends on the acceptance by consumers who are induced through advertisements to buy these products. Therefore, the competition among some TNEs could leak information about damages in health through this model of food intake, and strict governmental control can avoid a manipulation of consumers. But often the same pharmaceutical holdings are also selling medicaments, control hospitals through the stock market, and often repel demands to pay compensation for damages caused by unhealthy food. Their treatment (chemo-

28 The authors understand under food war the aggravation of the conflict where a vision between offer and demand of food, new scientific knowledge, unknown technologies, but also global and national policies linked to demographic changes and epidemiological transition could convert food in a generator of illnesses, as a result of private decision-making processes.

29 This has happened with the so-called 'mad cow' disease or Bovine Spongiform Encephalopathy (BSE), an encephalopathy as a variant of the Creutzfeldt-Jakob illness, see chap. 34 by Salih), with the avian flu (SARS), and some chronic degenerative sicknesses plus chronic degenerative processes (strokes to the myocardium, brain stroke, arthritis, osteoporosis, cancer, diabetes, and obesity; US National Institute of Health 1998; Tansley/Worsley 1995; Barker 1992; WHO/FAO 2003; WHO 2003, 2003a; Dalmenry/Hanna/Lobstein 2003; World Cancer Research Fund 1997).

30 45 per cent of deaths from cancer worldwide happens in the industrial countries with less than 20 per cent of the total world population (Times, 15 January 2008: 5).

Table 33.4: Advantages and disadvantages in the food production sectors. **Source:** Compiled by the author.

Concepts	Food Security: <i>'Sciences of Life'</i>	Food Sovereignty: <i>'Sustainable Production'</i>
Food	Scientific: vitamins, proteins, sugar, carbohydrates, synthetic additives of sugar, flavours and colours	Integral, nutritional, natural, empirical and culturally accepted, healthy, regionally produced, diverse and ritual
Food intake	Fast, frozen, homogeneous, pre-prepared, rich in fat and sugar with artificial additives, vitamins and minerals	Elaborated at home, fresh and varied depending on the season of the year and the products available regionally
Hunger	Result of low productivity	Result of poverty, lack of land reform, credits, local markets and governmental support
Food Security	Production and food import (including 'virtual water')	Local and biodiverse production, reinforced by recollection, hunting and environmental services
Land	Big extension of monocultivation	Small plots with orchards, policultivation, mixed agriculture, small livestock
Technology	Highly specialized, heavy machinery, drop system irrigation and by aspersion, agrochemicals to fight against plagues and illnesses, veterinarian medicines, hormones, drugs, capital intensive	Agro-ecological, rotation and association of diverse crops, intensive in human-power, natural combat of plagues and illnesses, natural growing of livestock, horizontal integration of waste for production and recycling
Seeds	GMO protected by TRIPs, animal genetically homogenized	Cultural patrimony of seeds, yearly selected and reproduced during the next cycle, diverse types of livestock
Gender	Patriarchal, male, feminization of paid rural workers	Extensive family integrating men and women, leadership in communities, cooperation, solidarity and mutual help
Market	International with fitosanitary controls, TRIPs, unequal terms of trade, subsidies, dumping	Local and regional with social control and equal terms of trade, social sanction and local saving and redistribution of accumulated capital
Commercialization	TNE are integrated with supermarkets chains, monopolies and oligopolies of nutria-genomics	From farmers to consumers on a small scale
Capital	Financial	Natural, social and cultural
Credit	International and national banks	Public resources, family savings, micro-credits and popular savings and cooperation, economy of solidarity
Transformation	Chains of TNEs inducing artificial proteins, vitamins, minerals and enzymes	In family enterprises with traditional methods
Productive Organization	Contract-agriculture based on paid temporary labour force with temporary unemployment, informal economy	Family unity, diverse, multiple activity during the whole year combined with livestock, forestry, recollection, hunting and environmental services
Environment	GMO induce biodiversity loss, agro-chemical, high pollution, abuse of water, depletion of aquifers, exploitation of natural resources	Sustainable production including integral environmental management, recycling of waste, care about natural resources
Policy	Demand-oriented for international consumer, socialization of pollution	Oriented to cover local supply and demand, minimal environmental impact
Economic Philosophy	Value of change, with maximization of profits and socialization of losses	Value of use with maximization of social relations and collective livelihood

Table 33.4: Advantages and disadvantages in the food production sectors. **Source:** Compiled by the author.

Prices	Artificial international prices due to subsidies, generating <i>dumping</i> in the world market	Local, interchange of products and services fixed by the economy of solidarity and support for the vulnerable
Productive Integration	Monopolies, oligopolies and monopsonies	Local chains of integrated micro-business
Trade organization	Monopsonies integrated in FTA, WTO controls through GATS, TRIPS and international arbitration	Family unity and local market with incipient household transformation, local non-violent conflict resolution
Food disposal	World supply-demand, depending on available capital and prices, speculation with crops, increase of hunger	Proper system of production for local food, family and regional storage
Economy	Free-market	Family and solidarity
Subsidies	Paid to agribusiness in industrialized countries, generating <i>dumping</i> in poor countries	Poverty alleviation programmes, support for green agriculture, care for the environment, job creation at the local level, biodiversity support
Science and Technology	GMO, nutria-genetic, nanotechnology, chemical and genetic conservation, integration of food with pharmaceutical chains, highly specialized	Combination of traditional technology improved with modern natural methods, seed selection, traditional harvests and conservation methods, mixed agriculture
Democracy	Formal electoral, with elements of authoritarianism, vertical and excluding decision-making favouring elites	Democratic and participative decision-making processes favouring majorities and protecting the vulnerable
Future	Inefficient farmers disappear with debts, fusion of enterprises creating <i>holdings</i> , conflicts and violence, authoritarian and vertical model of decision-making, survival dilemma and migration	Political stability, guards of biodiversity and food sovereignty, participative model with direct democracy, care for the vulnerable and good governance

therapy and radiotherapy) creates further collateral effects compensated with other expensive drugs. Their goal is only the maximization of profits by taking away the surplus created by society.³¹ These contradictions in the health, education, and food system were exposed by Ivan Illich (1976).

On the other side, there is the small green production for poor people, peasants, women and minorities. Organizing production and transformation, food diversity, and local markets increase local food security. More governmental support is still lacking, and also scientific and technological efforts to combine traditional and modern knowledge has to be developed, e.g. in New Zealand. There are enough universities that could support green models of production able to facilitate the creation of local jobs and offer

young people an opportunity for employment and a decent life. However, the political and economic elites that benefit from the other two productive models are preventing an enhanced 'food security' combined with 'food sovereignty' and a dignified livelihood (Nord/Andrews/Carlson 2004).

33.5 Conclusions: Food Security with Self-sufficiency, Food Sovereignty, and Cultural Integration

On this dual political and conceptual background, this chapter addressed the following research question: food represents not only a security issue of intake of nutrients, but it forms part of a holistic understanding of life and a constituting element of any civilization. Thus, food includes networks of connectedness, belonging, and relationship of trust, reciprocity, cooperation, solidarity, care, and exchange. It creates social benefits and risk reduction, but also innovative activities through the wider access to infor-

31 The case of old people is often dramatic. They lose their savings for medical treatment and hospitalization. Once without resources they are abandoned and in the best case they go back to the traditional medical sector. However, governmental controls can further limit this alternative.

mation and learning. It is a process of anchoring of personal and group identities (see chap, 88 by Oswald on HUGE; Oswald 2008 a), where social relations reaffirm the integration of a person inside a community establishing rights and obligations, such as access to land, credit, technology, training, market, life quality, and rituals.

Besides guaranteeing physical and cultural survival, 'food sovereignty' creates also new opportunities for people-centred poverty alleviation and new understanding of rurality as a complex social network. It represents a critical response to the accepted development and modernization paradigms, and opens ways for diverse rural life processes where agricultural activities and environmental services coexist with services and industries.

Thus, food is part of a holistic model of life and a constituting element of any civilization. Networks of interrelationships, and processes of identity and social belonging, create relationships of trust, reciprocity, cooperation and exchange. They are at the basis for 'food security' which could evolve into an integral 'food sovereignty'. Confronted with new threats of global environmental change, 'food sovereignty' represents social benefits and contributes to risk reduction through innovative creativity where instant world communication helps to establish new learning processes. During this process of achieving 'food sovereignty', personal and group identity is anchored and social relations may overcome stereotypes by reaffirming the integration of a person or a group within a community. Such a wider understanding of rurality that includes non-agricultural activities facilitates critical responses to historical injustice, abuse and environmental changes, and opens ways for diverse rural-urban life processes, where agricultural activities and environmental services coexist with other services and non-contaminating industries and transportation systems.

The future is getting complex and the world is confronted with unexpected climatic events, generating massive migrations, chaotic urbanization, pollution of natural resources, and loss of biodiversity. The ecological footprint and the size of the 'food footprint' is converted from food consumption by this equation:

$$\frac{\text{FoodQuantity(mt)}}{\text{CropYield(mt/ha)}}$$

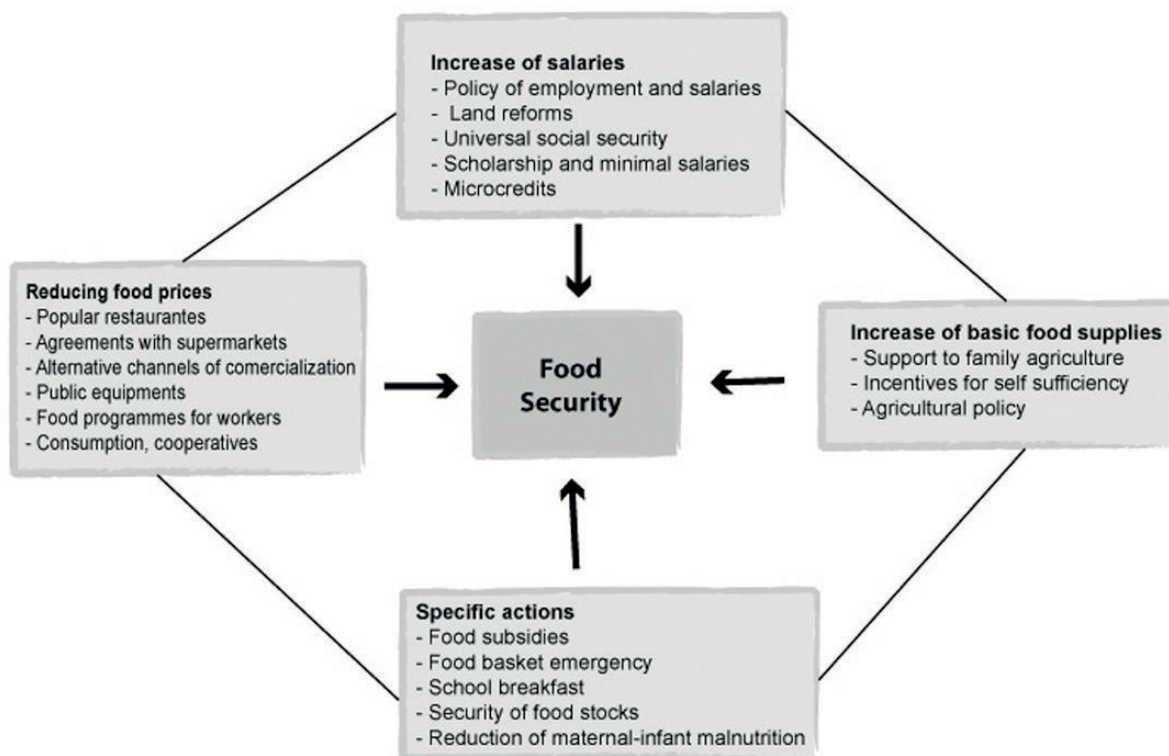

where crop yields are taken from the FAO database (Friends of the Earth 1997). Population growth creates new challenges when billions of young people ask

for dignified employment. On the contrary, the lack of jobs could create complex emergencies. In this multifaceted panorama new agreements among governments at all levels with business and organized civil society should be negotiated where public well-being has to prevail over private interests. This implies to transform through creative activities related to food production, transformation and consumption, the existing monopolies into local chains of micro-enterprises that are able to offer cheap, healthy and, culturally accepted food in a framework of an economy of solidarity.

But market forces are pushing in a contrary direction. The future food sector will experience a competition between the 'life science' and 'sustainable small production' model. New food-related illnesses (e.g. BSE) have created a greater awareness among people, what they are eating. In Europe, some 20 per cent of the population is familiar with the associated risks of agribusiness by TNEs and 80 per cent reject GMO food. Increasing degenerative illnesses and obesity have forced the TNEs to focus on new products, and the culture of 'light' food has been their response. However, only a comprehensive approach with preventive health, vitamins, proteins, iodine, flour, and other microelements for the undernourished will be able to alleviate hunger and create livelihood for all with a distribution of profits. The future will show if the public relations activities by TNEs will be able to counter a wider public awareness on the risks associated with the life science approach or whether small green food production will slowly replace big food monopolies. However, there are some global decision-making processes that may contribute to and speed up a strategic shift aiming at 'food sovereignty' (CLOC 2004):

1. *Global Policy*: The Special Rapporteur of the UN for Food Rights, Jean Ziegler, said in November 2005 that there "are no secrets how to eradicate hunger. There are no new technologies necessary. Simple political will is required to change the existing policies which make the rich richer and the poor poorer".
2. *Poverty Alleviation*: Jeffrey Sachs (2004 or 2005) linked the multidimensional roots of hunger to poverty. In the Kenyan village of Sauri he tried 'the big five' with US\$ 70 per person and year, including retroviral against HIV/AIDS.³²
3. *Support for women in agriculture*: Women are not only more affected by modernization, they represent also an alternative for self-sufficiency and to the food supplies by TNEs. In poor coun-

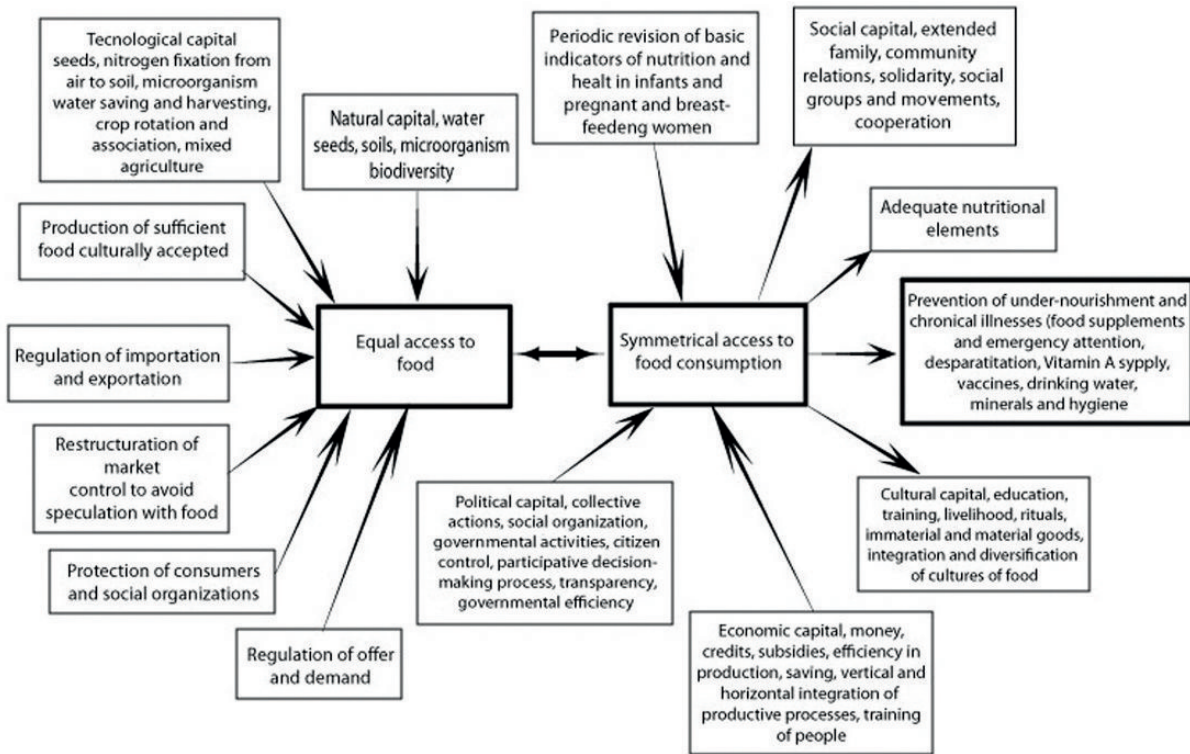

Figure 33.10: Programme 'Fome zero' (without hunger) in Brazil. **Source:** Instituto Cidadania (2001), São Paulo, Brazil.

tries women produce most of the local food (FAO 2002; 2005b).

4. *Regional Food Sovereignty:* Via Campesina, CLOC (2004), MST (2005), and the Peasant University of the South (UNICAM) are promoting an integral model of food with democratic land-reform, credits and local savings, green agriculture, chains of integrated local micro-businesses, an economy of solidarity, and traditional medicine.
 5. *Food policy to alleviate hunger:* Brazil proposed a model of food support for popular sectors linking the small production system with an offer of healthy food, increase of minimal salary of workers, and an urban offer of cheap food for the poor (figure 33.10).
 6. A well developed system of periodic measurement of basic indicators of undernourishment is needed, above all for children below five years, including anthropometric measurements of weight and size related to their age. UNICEF, WHO, and INNSZ have proposed six steps with minimal costs to avoid premature deaths, slow development, and brain damage in infants: Vitamin A complements; a complete scheme of vaccines; nutritional supplements to overcome severe undernourishment; periodic elimination of parasites, complements of iron, iodine, and other minerals (such as flour against caries) depending on the water composition, floors covered with cement, latrines, clean water access, and nutritional education and care (Álvarez/Oswald 1993). Furthermore, the metabolic syndrome of undernourished children with small size should be addressed. They of
-
- 32 1. *Improvement of local food* through a mixed agriculture of fruit trees, plants able to fix nitrogen from the air to the soil, rotation of crops, organic composting, and bio-pesticides; 2. *Community Health Centres* able to treat the most common gastro-intestinal illnesses, malaria, dengue, reproductive health and campaign for vaccination, undesired pregnancy, and sexually transmitted illnesses; 3. *Basic Education:* training in simple technologies for production, and conservation of safe food at the community level, especially for women; 4. *Renewable energies:* solar systems, biogas, oil and other energies able to give children light for studying, energy for water pumps, machines for grain mills, and refrigeration of medicaments and food; 5. *Clean water,* building of latrines, water harvesting, protection of wells, and other simple techniques to conserve safe water and to avoid water-borne illnesses.

Figure 33.11: Food sovereignty: equal access to food and symmetrical access to food consumption. **Source:** Chávez/Ávila/Shamah (2007); modified by Oswald (2007a).

ten rely on a diet that is rich in carbohydrates and fat, and are subsequently frequent victims of obesity, later on diabetes and coronary illnesses.

7. Education, training, and the rescue of traditional elements of food culture are basic requirements to improve the nutritional situation in poor countries. Education and training, especially of women, reduces not only the illnesses in families and premature death, but it opens the cooperation in reproductive health and creates stable livelihood conditions in villages, and colonies, and slums of the urban poor.

Figure 33.11 synthesizes the conjugation of natural, political, social, economic, technological, and cultural capitals (Chávez/Ávila/Shamah 2007; Oswald 2001, 2007a) enabling women, indigenous, and peasants to handle food and nutrition for their families in an integral way, improving their quality of life, and reducing premature death and preventing diseases. Such a new comprehensive security process that combines ‘food security’ with ‘food sovereignty’, and also with ‘water’ and ‘health security’, may be better able to resolve the food problems of the other half of the world population for whom food security has been an issue of daily survival of their families that avoids the overconsump-

tion and loss of life quality with which the food security problems of the OECD world and the elites in the global South are struggling (see chap. 34 by Salih).

The discussion has shown that the evolution of the concept of ‘food security’ within multilateral organizations has failed due to a top-down approach that is neither questioning the demands of the people, nor the interests behind the driving forces of world business. The continuous adaptation of the ‘food security’ concept and model by FAO reflects its basically technocratic approach that is far away from the real problems of hunger and of agribusiness. The FAO has tried to resolve a complex health problem with aspirin (Preker/Feachem/De Ferranti 2000).

Confronted with serious environmental deteriorations and adverse economic conditions resulting from the neoliberal approach, the directly affected people started first with a critical analysis of agricultural and food aid policies from industrialized countries. Greater environmental destruction, new threats due to climate change, and deeper ecological footprints forced organization of civil society to create the new paradigm of ‘food sovereignty’ as a holistic life concept.

This understanding could overcome the limited productive approach, but also the behaviour of converting poor people into victims of their circumstances, when the real causes of their situation of marginalization are precisely the forces of the free market, the political domination and the exploitation of humans and nature for profit. The future is complex and the situation will probably get worse. Then biodiverse and culturally determined approaches to food sovereignty could foster solidarity among human beings and protect their remaining common natural and cultural capital.

34 Governance of Food Security in the 21st Century

M. A. Mohamed Salih

34.1 Introduction

Governance is broadly defined as the exercise of power in an institutional context with the main aim of directing, controlling, and regulating activities concerned with the public interest. It includes but traverses government to denote how people govern themselves in terms of accountability, legitimacy, and transparency. On the other hand, food security denotes access by all people at all times to enough food for an active, healthy life. Its essential elements are the availability of food and ability to acquire it. Conversely, food insecurity is the lack of access to sufficient food and can be either chronic or transitory. Chronic food insecurity is a continuously inadequate diet resulting from lack of resources to produce or acquire food. Transitory food insecurity, however, is a temporary decline in a household's access to enough food. The worst of transitory food insecurity is famine.

Therefore, governance of food security is about the exercise of power within institutional contexts, particularly crafted to direct, control, and regulate activities concerned with food security whereby these institutions are viewed by citizens as legitimate, accountable, and transparent. The ultimate objective of governance of food security is to ensure the availability and ability of the populations to acquire food for an active and healthy life.

However, neither the classic definition of governance as government immune from the scrutiny or global governance, nor the conventional definition of food security as a mere availability and ability to acquire food are sufficiently broad to encompass the requirements of food security governance during the 21st century. At least two factors militate against any non-critical adoption of such narrow definitions:

First, governance of food security during the 21st century differs markedly from that of the pre-Second World War era. Globalization has contributed to a process of increasing integration in the world's econ-

omy and even producing a global culture of consumerism, arts, and music. There is also the integration of global markets, rapid advances of technology, information and communication technologies, highly skilled labour mobility, and flow of investments, global capital and multilaterals operating at a global scale. The globalization of production and products from consumer goods to automobiles, clothes, food, and manufacturing has contributed to an emergence of a dynamic and interdependent world interlocked with vibrant networks and transactions.

One implication of this integration is that globalized food products and production also means the existence of a global network of trade and commerce on a large variety of food products. For example, Coleman, Grant, and Josling (2004: 3) lament,

Despite its rootedness in place and its dependence on the natural rhythms of the seasons, the life cycles of animals and the climate, agriculture is changing rapidly in character as it becomes drawn into globalizing processes in the economy, the world of politics, and culture. As an economic activity, it is losing its exceptionality and becoming one sector among others contributing to economic growth. Politically, the long-standing protective mantle of the nation-state is yielding to new forces, new rules and new constraints defined at regional and global levels.

The emerging governance of food security regime is not only regionally and globally driven, it operates in conjunction with a myriad of powerful institutions, some of which transcend food to health (WHO), intellectual property rights, biodiversity (CBD), trade regime and intellectual property rights (WTO/TRIPS). The new policy space as Coleman, Grant, and Josling describe it is marred with power asymmetries, conflict ridden, and dangerously susceptible to manipulation and high passions engendered by social movements and global justice activism.

So much entangled are food and other security domains that Nestle (2003: 265) warns against the most dreaded scenario linking food safety, food security, and national security. He called "food a biologi-

cal weapon”, with a particular concern being made about the role of biotechnology in developing bioterror weapons. In his words:

The research methods used to transmit desired genes into plants could easily be adapted for nefarious purposes: creating pathogenic bacteria resistant to multiple antibiotics or able to synthesize lethal toxins, or superweeds resistant to herbicides (Nestle 2003).

To be sure, despite its significance, as purported by Nestle above, no area of the current debate on governance has had such a low profile as food security governance, despite the myriad of global food problems which occupy the world’s conscience, from famine to food safety and global food-related disease scares. This omission cannot be explained because of irrelevance or lack of genuine interest in the significance of governance to food security. It certainly cannot be explained on the grounds that a ‘good governance’ regime in food security already exists.¹ It clearly does not. This omission has been the cause of concern for all sectors of society; the economy, political actors, scientists and policy-makers alike, and in particular the impoverished sector of humankind which suffers both chronic and transitory food insecurity.

Second, a notion of food security governance within the context of industrialized, globalized, and highly commercialized food markets by necessity implies more than the mere availability of, entitlement and ability to acquire food. The global food scares which characterized the closing decades of the 20th century (BSE, SARS, Avian Bird Flu, vCJD) are clear signs that while the current level of scientific and technological developments could ensure food availability, the broader objective of food security is difficult to guarantee. The notion that Food Kills by Pennington (2003) offers one of the most succinct descriptions of the history of the most lethal outbreaks of food related diseases such as BSE and vCJD, among others. He warned that the lessons of past outbreaks were not heeded and wondered whether the lessons of recent outbreaks have been learned to prevent them happening in the future.

34.2 Illustration: Food Security as Food Safety

First, Bovine Spongiform Encephalopathy (BSE), popularized as mad cow disease, first appeared in the UK

in 1986, when cattle started to exhibit strange symptoms of nervous collapse. The disease is caused by cows eating other cow meat and bone meal via high protein feed. It caused degeneration of the brain where afflicted cows eventually became uncoordinated and difficult to handle (Wells 1987: 419). The *New Scientist* (29 January 1986) described the disease as belonging to the so-called “unconventional slow viruses, which includes scrapie in sheep and goats, chronic wasting disease in mule and deer and transmissible mink encephalopathy. In a sense, the disease has a wide variety of ways to be transmissible through both domesticated and wild animals, thus affecting the whole food chain.”

The disease struck in Britain again in 1996, considered one of the major outbreaks, and included many countries interlocked in livestock trade, in particular Britain, France, Germany, Canada, the USA, and Japan among others. In 1997 most European countries admitted the existence of BSE, which prompted the EU to issue measures intended to curb the spread of the disease. Import restrictions as well as other quarantine measures and slaughter of animals suspected of having acquired BSE were imposed.

The discovery that BSE is transmissible to humans, and that humans could get a different variant of the disease as 146 patients in the UK alone died of the human form of mad cow disease, known as variant Creutzfeldt-Jakob disease (vCJD), has aggravated an already desperate situation (Coghlan 2004). The interface between what food humans eat and the variety of diseases detectable or undetectable illustrates the increasing vulnerability to food and food-related threats and hazards that fall well within the twin paradigms of food security governance and food safety on a global-scale.

Apart from the fact that BSE and its variant CJD are menacingly dangerous diseases, they can also spread globally in countries that are not really suffering from chronic or transitory food insecurity. It conflates food security and food safety not at the national or regional level, but globally, giving credence to the view that food security in the 21st century requires a more proactive global partnership and networks that transcend government and multilateral organizations and include the currently vibrant global justice movement, activities, and NGOs.

Second, the case of Avian Influenza is well documented and its implications for global food security are horrendous. According to WHO, Avian Influenza (also known as Asian flu from the 1957 outbreak in China) is an infectious disease of birds caused by type

¹ This chapter is inspired by a shorter entry by M. Salih (2005).

A strains of the influenza virus. The disease, first identified in Italy more than 100 years ago, occurs worldwide. Migratory waterfowl – most notably wild ducks – are the natural reservoir of avian influenza viruses, and these birds are also the most resistant to infection. Domestic poultry, including chickens and turkeys, are particularly susceptible to epidemics of rapidly fatal influenza. For example, during the 1983–1984 epidemics, the virus caused a mortality level in poultry approaching 90%. During the 1999–2001 epidemics in Italy, the virus mutated within 9 months to a highly pathogenic form causing the death or destruction of more than 13 million birds.

A subsequent development after so many outbreaks of Avian Flu, the first documented infection of humans with an avian influenza virus occurred in Hong Kong in 1997, when a strain caused severe respiratory disease in 18 humans, of which six died. The killing – within three days – of Hong Kong's entire poultry population, estimated at around 1.5 million birds, reduced opportunities for further direct transmission to humans, and may have averted a pandemic. The most recent cause for alarm occurred in January 2004, when laboratory tests confirmed the presence of avian influenza virus in human cases of severe respiratory disease in the northern part of Vietnam and China.

In essence, in the 21st century (as we have already experienced during the outbreaks of BSE), with the Avian Bird Flu the old notion of food security defined in terms of food availability, access, and quality would increasingly be relegated less emphasis in the broader security debate. It has been argued that the scientific and technological developments during the last century have already mustered the capacity to produce sufficient food to feed the world. But the old regimes of entitlement and access, particularly for the unfortunate sectors of humankind, sadly still loom large.

34.3 Conflating Securities: Human, Food and National

Three plausible interpretations could be put forward as to why food security governance remains on the back seat of the debate, although global food governance institutions do exist. First, it can be explained in relation to two competing definitions of security: human security and national security. For most of the post-Second World War period, particularly during the Cold War, security was predominantly defined as national security. Military security was the dominant

concern of national security, with its evident economic and political connotations. Cold War architects considered national security the defining element of national sovereignty. Concerns with military expenditure predominated over concerns with human security – defined as:

A condition of existence in which basic human needs are met and human dignity, including meaningful participation in the life of community can be realized. At the most basic level, food, shelter, education, and health care are essential for the survival of human beings (Thomas/Wilken 1999: 3).

So food security is essentially part of human security and as such demands a redefinition of the concept of security. This conceptualization was absent during the Cold War, when the heightened ideological divisions between Western and Eastern blocs in many instances sacrificed human security for the sake of achieving national security objectives.

Secondly, it was expected that with the end of the Cold War the emphasis would shift from military to human security. The triumph of multilateralism has contributed to a new and emerging global governance regime, and it was expected that this would foster a new 'humanitarian' understanding and therefore make it possible for humankind to reap the positive outcomes of the democratic peace dividend. Sadly, this has not been the case. Indeed, in some parts of the world, particularly war-torn and famine-stricken countries, the end of the bipolar Cold War has instead produced new forms of polarization (ethnic, religious, economic, regional etc.) that have undermined both state as well as human security (Salih 1999: 132–133).

Thirdly, food security governance should entail the accountability of the governors to the governed through binding commitments, to which most developing countries' leaders are probably fearful of subscribing. The current global mind-set is premised on food trade and competitiveness. Thus commitments to ensure the food security of potential competitors are imperative. These could deter the largest food producing and exporting countries from making concessions in the areas of subsidies and market access to developing countries.

While large food exporting countries and regional entities supply food in complex emergencies – for famine relief and disaster prevention – they are less keen to support long-term food security, including such global visions as food-for-all and a hunger-free world. In short, there are serious food security governance issues at the national, regional, and global

levels, so we must look more closely into the linkages between these and the general debate on governance.

The new forms of polarization could be summarized in terms of food affluence-related food security driven crises – such as food related outbreaks of infectious diseases in the industrially advanced or high-tech modern food production systems – and underdeveloped low food productivity food security problems associated with developing countries.

34.4 Linkages

It might seem from the polarization argument I raised earlier that the 21st century food security governance regime will be highly differentiated according to the level of technology which goes into food production, and it has been translated into food affluence versus food poverty. On the contrary, none of the elements of the conventional definition of food security commonly referred to as “access by all at all times to enough food for an active, healthy life, including availability and the ability to acquire it” has been fully obtained (Reutlinger 1987). The persistence of *‘Famine that Kills’* (de Waal 1996, 2004) and *‘When Food Kills’* (Pennington 2003) has only magnified the problem and made the joints of dualistic vision of two different governance regimes catering for different lives and different needs absurdly cruel and analytically fraudulent.

The current change in the type, patterns, and magnitude of consequences associated with leading healthy life is not just by ensuring food safety, but also by ensuring that an interface between human and non-human diseases is curtailed. This cannot be ensured by subsuming food security under economic governance and financial and market security regimes under which the global market operates – food security is a governance in its own right. Apparently, all four aspects of food security (availability, access, stability, and quality) are matters for a governance regime that underscores the centrality of food as an indispensable part of the support system for human life. In this respect food security encompasses more than the economies of food production, consumption, distribution, and marketing. As such, food security cannot be guaranteed through effective and functioning economic, science, and technology governance institutions alone. Nor can it be ensured through policy reforms dealing merely with economic regulatory frameworks and instruments with societal

and political pressures to ensure that these regulations are acted upon.

In the food security domain, governance is part of a broader context, linking the physical environment health as well as the socio-economic and political aspects of society. This in turn is linked to a global governance regime that has designed policies to respond to global food insecurity. These include buffer stock systems, food price stabilization programmes, food aid, financial food facility schemes, trade policies, and food imports. These conventional food security-cum-safety issues are compounded with recent developments in global trade regimes on food and food products engendered by globalizations (Paarlberg 2002; Roberts/Orden/Josling 2004; Burch/Rickson/Lawrence 1996; Goodman/Watts 1997; Wilson 2001). These developments signalled that there are more non-food entries of food security governance in the 21st century than ever in human history.

Although national and global before food security policies are important for fostering food security, these are often influenced by other non-food policies such as marketing, trade regimes, and transport. Taken on their own they cannot solve problems associated with food entitlement. Obviously, food policies devoid of real concerns with food security have provided poor answers to urgent and critical food needs. Not only have these policies failed to solve food crises, they have miserably failed to ensure long-term food security.

One fallacy associated with the current regime of food governance is that global food security is an aggregate of national food policies designed under the assumption that food self-sufficiency would automatically ensure food security. This argument could be logically constructed, but evidently logic is not always right and here is a case in point. It is not possible to translate food self-sufficiency into food security without a proper agricultural infrastructure, without credit and extension schemes, and without public food distribution policies. The next question is what the main characteristics of food security governance are and how they could contribute to the national and global public policy governance debate.

34.5 Food Security and Democracy

The governance of food security involves many stakeholders – it encompasses both government and society. The significance of multi-stakeholder governance stems from its ability to combine the efforts of all

concerned with food security. It includes government, farmers, environmentalists, the social justice lobby, human rights groups, the 'right to food' activists, food technology producers, and exporters.

The political dimension of food security governance is particularly important because it is only in a democracy that such a regime could be put into practice. This means that for any government to be legitimate, its authority (the legitimate exercise of power) should derive from periodic and regular free, fairly contested elections with inclusive participation. Popular sovereignty is exercised and expressed in the daily practice of political and human rights, guaranteed under constitutional and legal arrangements to restrain the holders of power and to protect those who could be subject to their whim. The holders of political power are held accountable not only to parliament and the state's regulatory institutions but also to the people. The executive branch is also held accountable by law through an independent judiciary and other legal and regulatory frameworks.

Even by the experiences of food-related diseases which were global in nature, it was evident that old democracies (Europe, USA, and Canada) dealt with the case of BSE or mad cow disease and other epidemics more transparently than non-democratic or even new democracies (China, Vietnam, and Russia). Because democracy renders the governors responsive to the governed, old democracies were able to openly inform their populations and the world within a relatively shorter period of time to take the necessary precautions, than for instance in the case of China or Vietnam where disclosures were made only under immense international pressure. One would argue that, thanks to the new democratic dispensation the world is experiencing today, many governments the world over are more prone to push issues of national pride to the side (Pennington 2003; Rowell 2003; Ridely/Baker/Baker).

It is obvious that only in democracies are food policies freely negotiated and binding policies conceived, targets set and implemented, and reviewed in order to gauge compliance with the government's commitments. When governance reflects public preferences it is likely that food will be at the top of the list of priorities. In a sense, governance should be about understanding political institutions' interactions with policy domains such as food security policies and how to make them work effectively also, and largely, for the poor. Those negatively affected by food policies should be able to use the institutions of governance to hold their government responsible. It

is essential that citizens are able to question the record of governments that allow food shortages and famine to ravage their country.

In common with the dominant debate on economic and political governance, food security governance is also about "institutional governance building and supporting cultures of rights and rules that make possible the agreements represented in coalition and common understandings" (March/Olsen 1995). A culture of rights and rules, common understandings and agreements, is as important for the governance of food security as for fostering a polity based on democratic cultures and values. One cannot ensure the one without the other.

So proactive food security governance can be summarized as follows:

- Exerting pressure on government and others involved in food security policies;
- Maintaining accountability and oversight to ensure compliance with commitments made;
- Making corrective measures when policy targets are not met within a specific time frame;
- Establishing an administrative regulatory framework to improve food availability, access, and quality.

A food governance regime needs to ensure the active participation of each layer in this multi-stakeholder approach, otherwise food policies cannot be put into effect. Of course, it is naive to think that there are no vested interests or power structures informing the relationship between the diverse stakeholders. But the fact that an institutional framework has been created for self-governing as well as for negotiating interests is an important step towards breaking the monopoly over critical issues such as national and global food policies.

34.6 Illustration: Food Security, Food Scarcity and Famine

Here I provide two trajectories: one deals with the case of Ethiopia and the other with Zimbabwe in the African continent in order to illustrate the linkages between authoritarianism and famine. First, the case of Ethiopia offers an illustration of the relationship between democracy usurping the contention that democracy is not just about the principles but the practice. During two distinct periods of despotic rule: a) during the 1972-1974 famine, Emperor Haile Selassie's government was hesitant to confront the popula-

tion or declare parts of the country as disaster regions. This famine has among other things contributed to wide discontent and political agitation, which ultimately contributed to a military socialist coup in 1974. Famine struck again during 1984–1988, known in the annals of human consciousness as the “Great Ethiopian famine”, attracting worldwide attention and condemnation of the slow response of Mengistu Haile Mariam’s and his junta. As if famine is not enough, the war against several liberation fronts in Eritrea, Tigre, Afar, Somali, and Oromo populated regions intensified. Because of the authoritarian nature of government, the complete news blackout about the famine, the Ethiopians depended on foreign news sources about the famine in their own country. The forcibly implemented settlement programme as a response to the 1972–1974 famine was a complete disaster and, in fact, the new settlements became hotspots of poverty and in some cases famine.

Since the collapse of the military socialist regime in 1991, Ethiopians have begun to enjoy some democratic rights and have become more vocal in making demands on government to respond to major social problems. The government attitude towards the 2004 famine was different from that of its predecessors. An appeal for famine relief was timely made, NGO operations facilitated, and within a short period of time the situation was contained. The fact that 2005 is an election year also meant that the government will be judged by the electorate on how well it has responded to the famine situation.

I examined the charters or constitutions of the contending political parties in order to attest to whether food security, which is one of the major social problems confronting Ethiopia for millennia, was a major election issue. Unfortunately, the answer is no. Restoring peoples’ dignity by adopting food policies that would ensure food security is somehow subsumed under vague notions of ‘development’, ‘raising the standards of living’, and ‘poverty reduction strategies’. The problem is not that these issues are not important – they are important – the problem is that in authoritarian regimes none of them could be freely debated even when people are not able to attain a minimalist notion of food security, i.e. access by all people at all times to enough food for an active, healthy life.

Second, dictatorship or lack of its dialectical other, i.e. of democracy, can turn a food secure country into food insecure country, such as the case of Zimbabwe. Zimbabwe’s inadequate economic and

political policies have turned it from a regional breadbasket into a famine stricken country. Since the eviction of European Zimbabweans from their farms by the ZANO-PF militia in 2002, it was estimated that at least two million Zimbabweans are in urgent need of food relief. It is also reported that even when relief food is delivered, the government of Zimbabwe uses it as a weapon against its opponents, denying it to those citizens the ruling ZANO-PF party considers as enemies of the state.

Sen (1999) argues that no famine has ever taken place in the history of the world in a functioning democracy, because democratic governments have to win elections and face public criticism, and have a strong incentive to undertake measures to avert famines and other catastrophes. The reverse of this argument is true in the cases of Ethiopia and Zimbabwe. Whereas, the absence of democratic rule during Emperor Haile Selassie and Lt. Mengistu Haile Mariam despotic regimes produced some of the worst famines in the history of Ethiopia, the authoritarian ZANU-PF regime of President Mugabe has transformed Zimbabwe from a food exporting to a famine-stricken country. In the following section I articulate the role of social forces in engendering democratic governance for ensuring food security.

34.7 Harnessing Change

The globalization of food, the exponential development in food technology from biotechnology to genetic modification, and the global competition for farm animal and plant genetic resources carry with them immense risks and probably some potential opportunities. They have the potential to transform what is meant by food security for subsistence producers and indigenous peoples. At the same time it cannot and should not be left to the monopoly of individual states or corporate whim to maintain minimum standards of sustenance.

Naturally the current regime of governance for global food security addresses some of the current concerns. For example, the Food and Agriculture Organization (FAO), the World Food Centre, the Commission for Genetic Resources for Food and Agriculture (GAIN), the Commission on Sustainable Development, the World Food Program (WFP), the Hunger Commission, the WTO Agreement on Trade on Intellectual Property, Food and Biodiversity. There is also a myriad of civil society organizations and NGOs, including the NGOs’ Forum on Food Secu-

rity, the Genome Resources Action International (GRAIN), Rural Advancement International (RAI), and the World Resources Institute etc. However, its direct contribution to alleviating food insecurity for the majority of the world's population is questionable. The gap in perception between global, national, and household food security governance is too great to be bridged by global conventions and treaties alone. It is also doubtful whether the current regime satisfies the requirements for global food security governance set out above.

If politicians felt that their political fortunes are dependent on ensuring food security, food policies in these countries would have acquired a sense of urgency. It is not just an issue for parliamentary committees responsible for oversight. It is more importantly a question of empowering national civil society organizations, NGOs, and pressure groups to exert added pressure on governments to act on food security as a matter of priority.

In the 21st century I contend that governance of food security could then be treated not as a separate and periodic concern, taken seriously only when famine and natural disasters strike, or when outbreaks of epidemics such as BSE and Avian Bird Flu strike, but as an integral part of the overall governance debate. Food safety is no longer a matter for national governments or global corporate power operating in the fields of food science, technology, production and distribution, but also a matter for large and complex institutions reflecting the global-local nexus in this vital arena of human security. But even this broad understanding will not be enough if non-state actors, including the global social justice movement, civil society organizations, NGOs, as well as democracy lobby and advocacy pressure groups and social movements are not able to impress their voice in how food policies are developed and implemented at a global scale. The linkages between human security and food

security can never be more obvious and their implications more complex to comprehend.

The governance of global food security could, however, be hugely aided by democratic governance that is responsive to the immediate concerns of citizens. As voters they can influence policies and priorities and can commit public policy to food security targets. So the relationship between democracy and the quest for transparency, accountability, and public participation cannot be isolated from the debate about food security and its opposite, food insecurity, shortages, and famine.

34.8 Conclusion

I attempted to contribute to the conceptualization of security in the domain of globalized food production and food products, implying certain risks emanating from the intensification of food production through the use of new biotechnologies. The existence of a global food market indicates that food safety issues are no longer country-based but traverse national and regional boundaries. This understanding adds to the complexity of attaining both conventional and new conceptualizations of food security. The former deals with articulating the need for the emergence of regimes of food security governance. They are by necessity informed by the democratic dispensations which characterized the late 20th and early 21st century, whereby governance involves state and non-state actors as well as multilateral, corporate, private and global social movements, social justice networks, and NGOs. Admittedly, food governance regimes are more pro-active in old democracies than new democracies and authoritarian regimes. Reconceptualizing food security governance means giving 'voice' to those forces which could contribute effectively to an efficient and effective integrated governance regime duly conscious of the global-local nexus in the important sphere of human existence.

35 A Research Strategy to Secure Energy, Water, and Food via Developing Sustainable Land and Water Management in Turkey

Selim Kapur, Burcak Kapur, Erhan Akca, Hari Eswaran and Mustafa Aydın

35.1 Introduction

One of the basic contentions of the neo-realist world-view has been the argument that states have to survive in a dangerously competitive and ruthlessly conflictual environment (Waltz 2002: 29). Accordingly, the need to survive in a risky environment forces states to focus on strategies that maximize their power relative to their rivals. In this context, traditional security policy has been concerned primarily with deliberate military attack from certain enemies. However, post-Cold War global processes have been changing the nature of threat and forcing adaptation of basic strategic principles and the patterns of allegiance associated with them. The world's security *problématique* have truly changed in the past decade or two. Our thinking about the *nature* of security must also change, taking account of changes in the nature of threat for survival. There are clearly new and sometimes unexpected linkages between political, security, and economic concerns that challenge the capacity of the state both to recognize and to respond to the new challenges. At the same time, there has been an institutional challenge relating to the adequacy of existing institutions for international action, and to the potential for coordination between state and other non-state (transnational and sub national) forces.

One such area relates to the security of energy, water, and food. It is now increasingly commonplace to securitize formerly non-security-related issues of production of food, ownership of water, and continued supply of energy resources (Brauch 2003). In this context, energy security can be defined as access to steady supply of cheap, clean, and reliable energy resources, while water security refers to continued clean and steady access to potable and useable water; and food security relates to "access to adequate, safe and nutritious food to maintain healthy life", which include freedom from chronic hunger (Collomb 2003: 777). All of these inevitably include the problem of sustain-

ability, which has become more of a problem as a result of realization that neither energy resources, nor food and water, are unlimited commodities in the world, and that their shortages would create security risks. When put together, the security complex of energy, water, and food could be achieved, or at least enhanced, by improvement of integrated programmes for the sustainable management of land, water, and energy resources¹.

Turkey has been one of the countries that experiences energy scarcity, less than self-sufficiency in food production, and an unequal distribution of water throughout the country. There has been increasing concern in Turkey that water availability fluctuates widely among regions, and seasonally within regions. Food self-sufficiency has also become problematic recently with decreasing production, while energy shortage and external dependency creates burdens for the country's economic development. In this context, the ambitious multi-purpose GAP project (Turkish acronym for South-eastern Anatolian Irrigation Development Project), seeks to increase the GNP by 445 per cent, the per capita income by 209 per cent, and to create jobs for 3.5 million people (Tekinel 2001: 13), as well as alleviating Turkey's energy dependency to outside sources, increasing food production and better regulating its water resources. The GAP was launched by the Turkish government with a specific aim in mind: "to develop a strategy for a sustainable and secure production of energy and food" (35.2.). This chapter seeks to present a contextual approach (35.3), i.e. a research programme for developing energy, wa-

1 For extensive scientific definitions of *security* see Brauch (2006); for a Turkish perspective on regional security see Aydın (2006); on *energy security* see the contributions in this volume, part IV, Chapters 23–32; on water security, see the Chapters 41–58 in part VII in this volume; and on food security see the chapters 33–35 in part V of this volume.

ter and food security (35.4) via a *sustainable land and water management* (SLWM) strategy, and to draw policy conclusions (35.5).

A successful SLWM strategy, that anticipates constraints for sustainability and develops action plans to address them, would enable us to deal with security issues beforehand that may otherwise develop to a full-scale crisis. The suggested research strategy for the GAP focuses on technical solutions needed to ensure sustainability, which is needed for any type of planning, as well as creating a security feeling among the larger population for their well-being over the long term. Because the emphasis is on sustainability, system monitoring is considered an essential part of the research strategy. Indicators must be carefully selected prior to project commencement, and they must be monitored during the duration of the research activity. These indicators are used to monitor the system (project area) as a whole and as measures for its quality and health. Socio-economic indicators serve as proxies for such purposes (Scherr 2001: 155; Southgate 2001: 461). Ecosystem indicators are more difficult to determine and require greater effort to monitor. These are as important as the socio-economic indicators when sustainability is being studied (Eswaran/Virmani/ Spivey 1993: 7; Swaminathan 1991: 244).

With food, water, and irrigation security in mind, the GAP is the largest irrigation and hydroelectric power development project undertaken in Turkey. The GAP area (74,000 km²) covers one tenth of the total and one fourth of the irrigable area of the country (figure 35.1), and includes six provinces on the plains formed by the tributaries of the Euphrates and Tigris rivers. It was conceived in the 1960's when productivity and food production was utmost concern². All the research has so far focused on this. There are now considerable data for the management of different production systems for food production. Sustainability emerged as an issue in the 1980's and 1990's, and the integrity of the environment has become an overriding factor. Internationalization of the project and a "security concern" to neighbouring countries also took place at this time (See Aydin in this volume). The established structure that was particularly concerned with enhancing production was ill-prepared to meet the new challenges and paradigm shifts. Though

the agricultural research community appreciates SLWM as a concept, there is still a considerable hesitation launching SLWM-related research activities. The environmental and transnational components still baffle the agricultural scientists. As a result, the progress is slow.

The casual chain that leads to these marked changes in ecosystems of irrigation regions is clear. In several countries they are frequently associated with demands for more land due to the increased rural populations. There is also the impending impact of global climate change depending on the locality. Ecosystem degradation processes are strongly affected by population pressures, poverty, enhanced demand for ecosystem products, and the uncontrolled rates of resource consumption.

The negative effects of ecosystem degradation commence with the imperceptible changes in biodiversity and lead eventually to the process of "desertification" (UNCED 1993). Cropland quality is slowly reduced through land degradation processes. When crop yields reach their marginal utility value or when it is no more economically productive to grow a crop, the land is either abandoned (by shifting cultivation) or used for grazing. A frequent process is overgrazing and an indicator of reduction in land quality is when small ruminants replace large ones. The consequence thereof is a gradual change in the hydrology of the watershed resulting in reduced biomass quality and quantity and leading to reduced carbon sequestration and enhanced albedo³.

Developing new paradigms, designing strategies for the new challenges, and implementing long-term research activities in the area of SLWM are the current needs of Turkey. The GAP provides a unique opportunity for such a programme, addressing various intricate sociopolitical, economic, environmental and security problems at the local, national, and transnational levels. This chapter evaluates the conditions and suggests research areas for implementation.

35.2 The Basis for SLWM

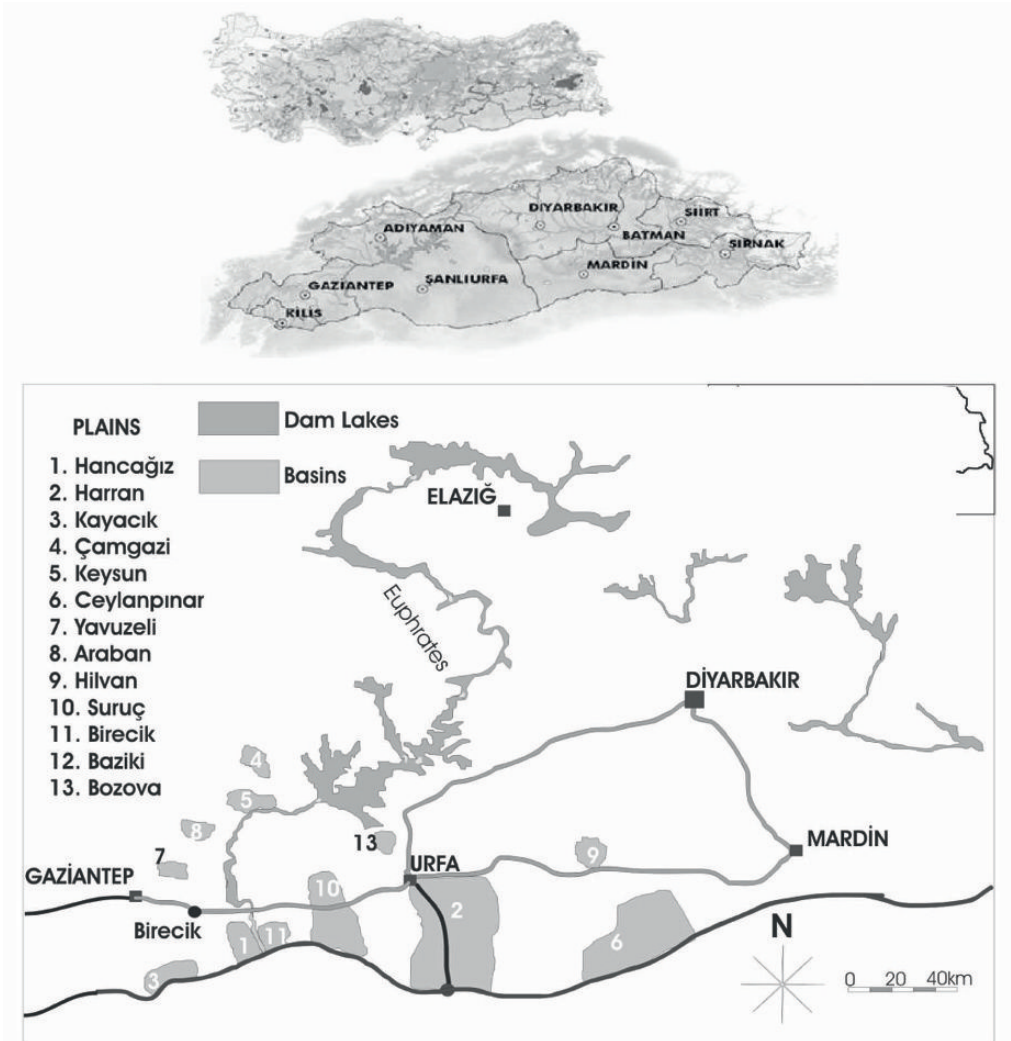

35.2.1 Energy Context

Energy in the GAP is and will continue to be highly crucial with a sectoral distribution of 78 per cent compared to the 15.6 per cent distribution of agriculture

2 In addition to self-sufficiency in food production, various issues related to sustainable economic development, irrigation, social integration of the local population, and political reconstruction of the area were instrumental in launching of the GAP.

3 A measure of reflectivity of a surface or a body in the earth surface.

Figure 35.1: The irrigation basins of the GAP. **Source:** <www.gap.gov.tr (5 May 2005)>.

and 25.5 per cent of tourism according to the reports of 2001. The justification for a colossal project such as the GAP should primarily be considered for energy. The dramatic increase in petroleum imports in the mid 1970's cost US\$ 5.7 billion for a ten-year period. This grew, amounting to US\$ 2.6 billion in 1988 alone, which caused a crisis for energy production growing at 33 per cent, whereas energy consumption increased by 172 per cent. Thus, the Turkish government launched a massive investigation into its hydroelectric potential. Estimates revealed annual run-off figures of 185 bcm for the 21 river basins of Turkey, where 62 bcm is planned to be consumed after the year 2000, leaving 123 bcm for use as hydroelectric power and agriculture (MacQuarrie 2004: 84). Biswas, Kolars, and Murakami (1997: 180) estimated Turkey's hydropower energy potential at 35,618 MW,

or 126,650 GWh. The 400 hydropower plants that were under construction in 2005 are programmed to achieve a production of 63.5 per cent of the estimated potential, and 26 per cent of the estimated electricity needs of Turkey by 2010. The 2001 GAP report indicates that the project contributes nearly half of all hydroelectric energy produced in Turkey, and 9.3 per cent of its total electricity production, with a planned 20 per cent coming from the GAP region by 2010 (MacQuarrie 2004: 84). Tekinel (2001: 13) documents that the added income of the 6 main hydroelectric power plants to the region has been over 690 million US\$/year (11.49 billion kWh), with the immense Atatürk plant contributing 294 million US\$/year (4.9 billion kWh) of the total. Considering an increase of the energy demand by 250-300 per cent for the near future, which brings forward concerns relating de-

pendency to outside sources thus issues of ability to formulate and implement independent foreign and domestic policies, it is highly probable that Turkey will reconsider its plans for managing the Euphrates and Tigris rivers to create relative autonomy in its foreign and domestic policy-making.

35.2.2 Food Quantity and Quality Context: Food Security

The primary task of land management is to enhance productivity of the land with the per capita income which is targeted to reach US\$ 4350 from the previous level of only US\$ 596 (Tekinel 2001: 14) (figure 35.2). But reports have revealed that the 9 per cent added value of agriculture for the Turkish economy in the region had already increased to 12 per cent by the year 2000. Thus, a 2 per cent increase in per capita income was attained from 1985 to 2000. As the Mediterranean region, the GAP area presents a unique suite of soils that has effects on food quality. The high pH and the calcareous nature of most soils, indicates a need for zinc, in addition to nitrogen, phosphorous, and potassium for sustained production. This high pH also immobilizes many trace elements needed for health of both human and animal populations. These elements include selenium, chromium, cobalt, iodine, and fluorine. Currently, these are added as supplements to the feed. Besides the increase obtained in the production of the main crops in the GAP after irrigation (table 35.1), there are opportunities to increase the content of these elements in the grain, and studies are needed in this area (Dinc/Kapur 1991).

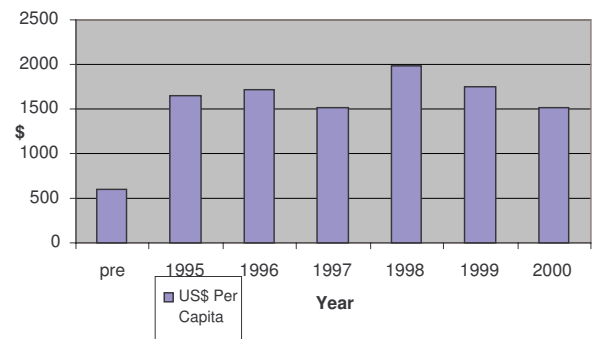

The tremendous increase (table 35.1) in crop production has been a major factor for the income growth in the region. The comparative yield increases with the total production in Turkey highlights the importance of the economic contribution of the region for the overall economy. The changing crop pattern of the GAP region after irrigation shows a trend and demand for increasing cultivated areas for industrial crops, such as cotton.

The main goal of the strategy to achieve food security is to improve soil quality by the carbon sequestration in the soil. C-sequestration improves and sustains biomass and agronomic productivity, which also leads to the reduction in the atmospheric concentration of CO₂. However, irrespective of climate change, the soil organic carbon (SOC) is an extremely valuable natural resource in need of restoration and conservation. Thus, the development of C-management policies, which include regulation based on trading of soil

Table 35.1: Comparison of the whole product in Turkey with increase of some crops after the GAP irrigation.

Crop	Total Production (1986)	GAP Production	(GAP×100)/Turkey
Cotton	580.000	685.402	118
Tobacco	117.529	18.888	11
Sugar Beet	14.304.375	4.098.895	29
Oil seed	1.807.904	1.327.820	73
Maize	1.500.000	117.869	8
Rice	168.000	141.839	84
Vegetable	12.398.950	3.513.842	28
Animal feed	4.836.454	1.092.898	26
Pistachio	23.000	66.458	289
Fruit	1.303.900	660.019	51

Figure 35.2: Agricultural added value in the GAP Per Capita.

carbon, may be successful over a period of 20 to 50 years if strictly implemented, what requires consistent and long-lived subsidies for land users for no till farming (Lal 2004: 1624; Lal/Griffin/Apt/Lave/Morgan 2004: 393).

35.2.3 Water Security Context: Water Availability and Distribution

Water scarcity or unequal distribution of it within the country creates dependency to outside sources, which increases possibility of friction between neighbouring countries when one supplies to the other the resources it needs, either freely or with a charge. The situation is exacerbated when the supplier is also in need of more water, vital for survival. The GAP project, developed in an effort to deal with these problems, includes some 22 dams, 25 irrigation

projects and 19 hydroelectric power plants. It is divided into 13 major subprojects, of which seven are located on the Euphrates and six on the Tigris. On the Euphrates, the Lower Euphrates is the largest subproject, including the Atatürk Dam and Şanlıurfa Tunnels with five smaller subprojects. But despite the enormous amounts of water to be used for the irrigation of projected 1.7 million ha, efficiency of the irrigation system is needed. This has been questioned in many parts of the world. In Turkey, the history of the irrigation projects indicates that success depends, in addition to engineering structures, on the management of the land and water, as well as on human and governance problems. Due to political pressures, many projects have been implemented before their main distribution and drainage networks were completed. The long-term consequences must yet be studied. Water use efficiency is a secondary concern for irrigation engineers. Ad hoc studies have shown water losses of up to 50 per cent in some areas (Tekinel 1993: 4). Inappropriate or inadequate land levelling further reduces the efficiency of water use.

Much of the inadequacy in irrigation systems leads to secondary salinization which is the greatest threat to water security and consequently also to food security. In some of the older projects (Çumra, Menemen, Seyhan) detrimental changes have occurred in the soils as a result of poor drainage facilities. The resultant salinization has discouraged farmers from capitalizing on the irrigation and instead some reverted to dry-land practices. In the Çumra project, it is estimated that 42 per cent of the land is still under fallow. These cannot be corrected without more social and political accountability. Although not directly land related, this is also part of the sustainable land management, i.e. of the security of water and land.

Earlier, a problem of the inadequate amount of water entering a delta was mentioned. With new irrigation projects coming on line and with ever increasing hydroelectric projects, the quantity of fresh water entering the sea will be less. This will affect the salinity of the water on the coastal platforms and have great impact on aquatic life. Further, the irrigation water remains largely on the system (accentuated by poor drainage facilities), evaporates during the hot season and results in salinization of soils. This reduces the soil quality and thus threatens food security. These processes are termed "endoreization" which, if not monitored, has devastating ecological consequences.

35.3 Research Strategy for the GAP Region

The 74,000 km² area presents both a laboratory and a challenge to ensure sustainability of agriculture. In general, the regional climate is similar to the Mediterranean with hot, dry summers and mild and humid winters. The soil moisture regime is xeric⁴ and the soil temperature regime is thermic. A variety of soils, including Cambisols⁵ on the hill slopes in association with shallow Leptosols⁶ and rock outcrops, friable, reddish Luvisols⁷ derived from basic rocks and limestone, are interspersed with sticky, Vertisols⁸. Cambisols are also present but probably were of wider extent in the past. Erosion has decapitated the mollic qualifier⁹ and also reduced the effective thickness of the soils. The water holding capacity of the Luvisols and Cambisols is about 50 to 100 mm/metre while the Vertisols have a higher capacity of about 150 mm/metre of soil. Wind blown sand may cap some of the soils while developing dunes of several metres.

As agriculture is dependent on water, the kind of soil is crucial. A detailed soil map was initiated in 1985. This was complimented with Landsat-3 MSS data, the latter being also used to monitor grain production (Dinç/Kapur 1991). In the last three decades, a large number of agronomic experiments were laid out for several crops. Most were designed to determine crop performance and/or response to management. This research provided databases and experience that assisted in the eventual establishment of the GAP programme. However, as indicated previously, the main focus was on production and not on sustainability.

35.3.1 Elements of a Strategic Plan

Sustainable land management is the system of technologies, with associated objectives, activities, and outcomes, employed to maintain or enhance the quality and productivity of the resource base while prom-

4 Dry conditions in which plant growth may be limited by water shortage

5 Cambisols are typical in temperate or cooler regions, in which soils are either young or, depending on the climate, processes of soil formation occur slowly.

6 Young and shallow soils.

7 Relatively mature fertile soils.

8 Dark soils with high clay contents and characteristic development of cracks.

9 Surface layer of soil that is dark coloured and relatively thick.

ising an improved quality of life and intergenerational equity for the community. Thus, when SLM is evaluated or monitored, these components are considered:

- Quality of life is maintained or enhanced;
- Ecosystem integrity is maintained or enhanced;
- Productivity, including quantity, quality, economics, and acceptance, is also maintained or enhanced.

The following are general considerations in designing SLM projects.

Indicators. The concept of sustainability incorporates a timeframe of decades and SLM ensures the optimal functioning of the system in this period. A most important component of an SLM programme is indicators that are used to monitor the progress of the system. A series of indicators are needed that monitor the stresses (pressure) experienced by the system, the state of the system, and the responses to the stresses. This suite is monitored regularly and analysed to evaluate system behaviour. The *pressure-state-response* matrix becomes a useful tool to evaluate progress. The matrix is applied to all sectors, biophysical, environmental, and socio-economic.

Project design. Since the project deals with a large contiguous area, it must provide for niches for many known plant and animal communities. Preserving biodiversity is as important as the production part of the project. To develop a master plan, the characteristics of the bio-communities, including the needs of migratory birds, must be known or researched. Fragile systems, such as sloping lands or wetlands, must be clearly demarcated and set aside as ecosystem refuges. These fragile systems will be targets for special monitoring as they are most sensitive to changes. This design of the project must be made in consultation with a range of specialists and respected during the implementation phase.

Preserving the heritage. The GAP area has known civilization for more than 5,000 years. Evidence of this is entombed in the soil as burial mounds, *höyük*s or tells, and archaeological fragments. Meeting current food security needs can be done while preserving and protecting the history of mankind. In developing the area for irrigation, a continuous vigilance is necessary for this aspect of sustainability.

Concept ownership. If sustainability remains a research concept, it has minimal impact and the system breaks down. There must be awareness in the community, particularly among land users. They must ac-

cept the notion and this can be achieved through information dissemination and a participatory approach. The added value of biodiversity to agroecosystems can be demonstrated and the land users can be charged to be the guardians of biodiversity.

Economic viability. The economic viability of the farming community is the driver of the sustainability paradigm in the project area. In its absence, the farmers' preoccupation with survival prevents them from contributing to environmental concerns. Appropriate government support, marketing facilities, infrastructures such as road networks, and an efficient extension service assure its viability.

Other Considerations. The GAP area has historically been dominated by a system characterized by grazing by small ruminants and rain-fed grain crops on valley bottoms. Where water was available (tube-wells or aquifers) local irrigated crops were developed and a larger variety of crops (cotton, chickpeas, lentils, tree-crops) were grown. The dramatic increases in performance of irrigation are evident. However, the stability of the system is uncertain. After harvest of grains, the straw is removed as fodder for animals, and small ruminants graze the remaining stubble. A net export of plant nutrients takes place from the fields, as the amount of fertilizers used is minimal. With the establishment of irrigation facilities, and accompanying subsidies available, there is excessive use of agrochemicals to maintain high production. The extent of this has yet to be established.

Water-logging and development of salinity have been experienced in some irrigated areas in Turkey. Both are yield depressing factors as perhaps the greatest hazards of irrigation. Not all soils have the same propensity to develop salinity and thus an important task is to develop maps of the salinity-hazard. An equally important task is to monitor the soils for salinity or to develop early warning indicators. The area is also prone to wind and water erosion. In an irrigated system, ground cover remains for longer time spans and this reduces both kinds of erosion. However, irrigation waters frequently carry high silt loads which when deposited on the soil crusts easily and hampers seedling emergence.

Finally, the success of an irrigation enterprise is strongly governed by its socio-economic milieu. Land tenure is a major issue and this must guarantee to ensure the positive effects not only of productivity but also sustainability of the programme. In addition to land ownership, the project must consolidate and allocate land for its different uses (including biodiver-

sity). A related question relates to the water rights for different users. This must be determined and agreed to from the outset. Finally, there must be adequate support services to ensure help when needed and provide the technical and marketing facilities crucial for the stability of the area

35.3.2 Research Strategy

A good strategy anticipates constraints to sustainability and develops the activities to address them. Although the theme of the paper is sustainable land management, the socio-economic component is critical and in many instances is more important than the technical solutions. Both components are nullified if they do not operate in an appropriate policy environment, from the national to the local level.

The suggested research strategy will focus on the technical solutions needed to ensure sustainability. As the emphasis is on sustainability, system monitoring is considered an essential. The indicators must be carefully selected before the project begins and monitored during its duration. The chosen indicators will supplement data collected in agronomic trials. They are generally monitoring the system (project area) as a whole and are measures of the health of the system. Socio-economic indicators serve as proxies. Ecosystem indicators are more difficult to determine and require greater effort to monitor. Both are equally important for the study of sustainability. Some framing questions for the research strategy are:

1. Has the quality of life of communities in the area been significantly enhanced?
2. What changes can be recommended to maximize profits and minimize risks?
3. What components of the ecosystem are being aided or hampered by irrigation?
4. Is land degradation (or components of it) being changed and in what direction?
5. Is the productivity of the soil resource base being attained and maintained?
6. Is the current pattern and mix of land use the best for the goal of sustainability?

35.3.3 The Harran Project: A Case Study

Thirteen project areas are defined for the GAP programme and the Harran Plain is the first area to be developed. The area of 225,000 ha is confined in the south by Syria and the Tektek, Fatik, and Urfa Mountains in the east, west, and north respectively. Details

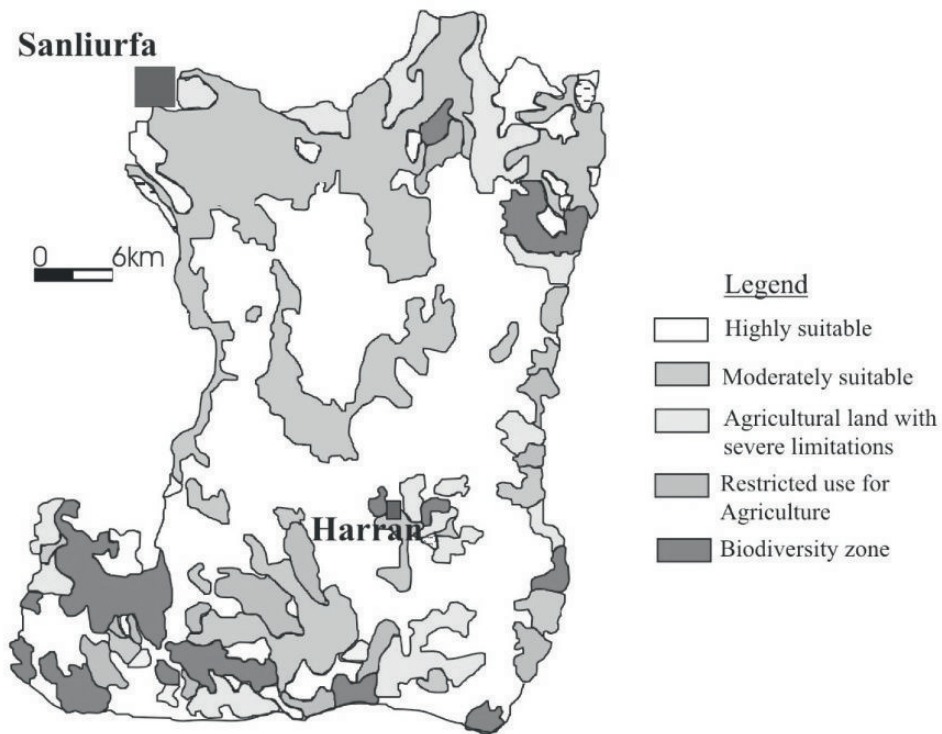

of the soil and physiographic characteristics of the region are given by Dinç and Kapur (1991). A semi-detailed soil survey at a scale of 1:50,000 was made in 1991 and a large number of soils were sampled and analysed for the soil survey programme. The maps were digitized and additional information was included in the attribute files. Using GIS tools, interpretive maps were prepared (figure 35.3), which show the secondary salinization as a major risk for food security that may result from irrigation.

Figure 35.3: Actual and potential salinity of the Harran Plain in 1985. **Sources:** Dinç/Kapur (1991); Şenol/Yeğingil/Dinç/Öztürk (1991); Özkutlu/İnce (1999).

Finally, a land suitability map that demarcated the area for agricultural use (Şenol/Yeğingil/Dinç/Öztürk 1991: 49) was prepared (figure 35.4). This stage of evaluating the baseline conditions was also complemented with socio-economic surveys and demographic information. The Koruklu Agricultural Research Station of the University of Çukurova has been conducting research on farming systems and irrigation. In 2005, project emphasis has been on productivity and developing land for the landless. Since completion of the first project phase sustainability became an issue and a new strategic plan became necessary. Figure 35.5 shows the proposed activity chart for the second project phase. A master plan using the baseline information is being developed. This plan demarcates areas for irrigated agriculture, dryland agriculture and grazing, biodiversity zones, archaeological

Figure 35.4: The land suitability map of the Harran Plain. **Source:** Şenol/Yeğingil/Dinç/Öztürk (1991).

sites to be preserved, and possible sites for new villages. Resource consumption whereby good agricultural lands and anthrosapes¹⁰ are used for urban dwelling is plaguing the country. This is a major long-term sustainability question that must be addressed.

Long-term agronomic sites have been established, following the previous norms of best soils or most extensive soils. Although sites that represent tension zones will also be selected. The latter represent less favourable conditions but actual situations on farmers' fields. Data of farming and cropping systems are now being used in simulation models and as experience in the use of these models increase, they will be used in developing scenarios. The cumulative experience and data will eventually be used to develop decision support systems for farm managers, extension service, and progressive farmers.

The selection of indicators, particularly those on the environment, is difficult to define, and discussions are underway to select appropriate ones. International projects, such as the land quality indicator project of the World Bank, are also working in this area and we will use their recommendations. Impact

monitoring is also being developed by other international organizations and their approach will be adapted for our use. Impact assessment will be made every five years and this provides an opportunity to determine the status of the resource conditions and corrective actions that must be taken if there are weaknesses in the system.

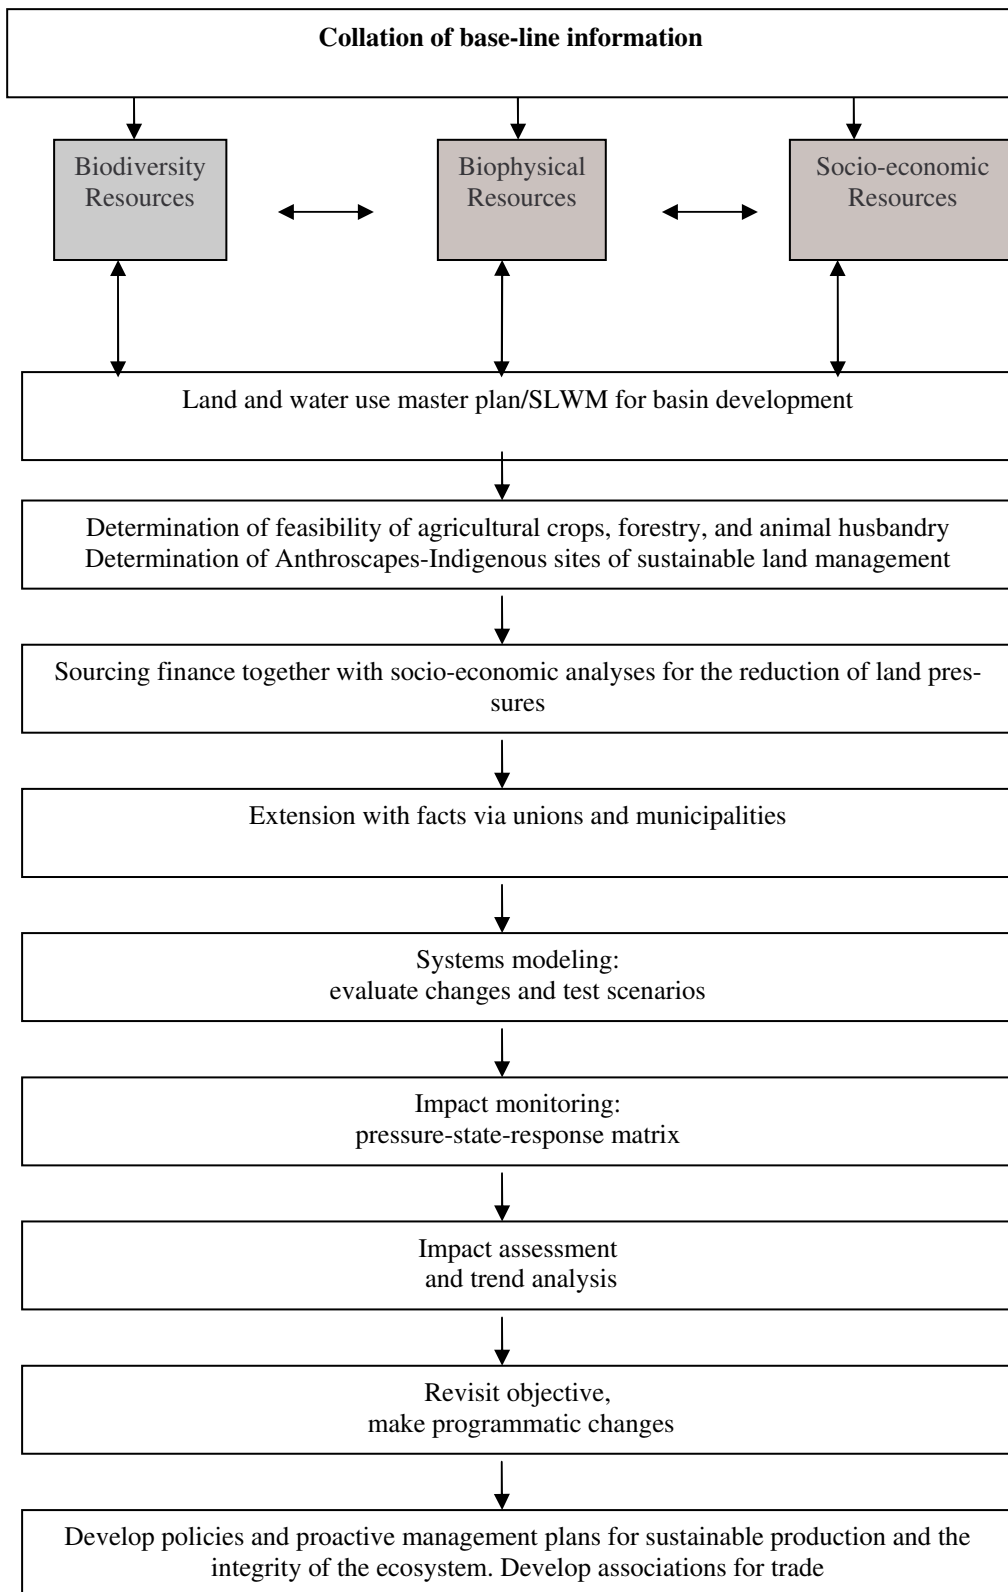

The whole activity is a research area that is new to the authors and we expect it to be an important learning process. There are problems of coordination and communication between specialists from different disciplines. Another conflict area is the desire to accomplish (get the project moving) and the cautious approach of the research scientist. Due to the commitment of national decision-makers, we are confident that progress will be made.

35.4 Conclusion

The paradigm shift that SLWM calls for (as in the water basin development context) is that research must be holistic and systems-based in a basin context. It should include not only agronomic and crop or livestock based observations but also the linkages of these to the ecosystem, the socio-economic and political conditions of the area, and the larger regional

¹⁰ Areas of indigenous and sustainable land use, i.e. inherited human-shaped landscapes.

Figure 35.5: Harran project activity chart. **Source:** modified from Kapur/Eswaran/ Akça/Dingil (2002).

context. It should show specifically how the resource base is maintained or enhanced to provide more energy, food and water security for the whole region, not just for a few people or a single country.

In the final analysis, it should clearly demonstrate that agriculture is environment friendly. The farming community must also demonstrate a paradigm shift as they participate in the programme. Plucknett and Winkelmann (1995: 184) stated that farmers must confront formidable challenges in learning to manage ever more advanced technologies in ways that will increase the productivity of their resources while protecting the environment. They stress that this will be a daunting task in the developing world. In some Mediterranean countries there are still many obstacles against adopting science-based technologies. But this must be the goal of not only national decision-makers but also for any research strategy.

It is clear that sustainability of land and water resources is not only an important input for continued economic development, but also crucial in the long-term survival of regional people. This study demonstrated how an SLWM approach could contribute to that long-term goal. It also highlighted that without such an integrated project, regional as well as national and local long-term survival and short-to-mid-term development would be at risk. This eventuality would inevitably create security problems for regional as well as international levels. To deal with these, the starting point should be the development of a successful SLWM research strategy.

36 Sustainable Livelihood Security. Evolution and Application

Hans-Georg Bohle

36.1 Introduction

The chapter reviews the concept of sustainable livelihood security against the background of the current discourse on human security. It analyses the academic and political context in which the livelihoods approach has emerged and became popular and asks how the concept was utilized by both researchers and practitioners, and to what effect. It focuses on the normative base and the discursive context of the concept.

The chapter argues that the new approach on sustainable livelihood security has emerged as an influential way of thinking on how the rural and urban poor can be identified and targeted, how pro-poor interventions can be planned, and how policy-relevant analysis on local levels can guide research on vulnerability, poverty and development. Analyzing and promoting sustainable livelihood security is closely connected with the concept of human security, putting people at the centre and taking equity, human rights, capabilities and sustainability as its normative basis. New frontiers in livelihoods research are presented in the chapter that seek to compensate for some of the shortcomings of the concept that are outlined in the paper. These include theoretically grounded appraisals of the relationship between structure and agency; politically sensitive analysis of social relations of access and control; and a culturally sensitive recognition of the non-material dimension of sustainable livelihoods security.

36.2 The Concept and its Principles

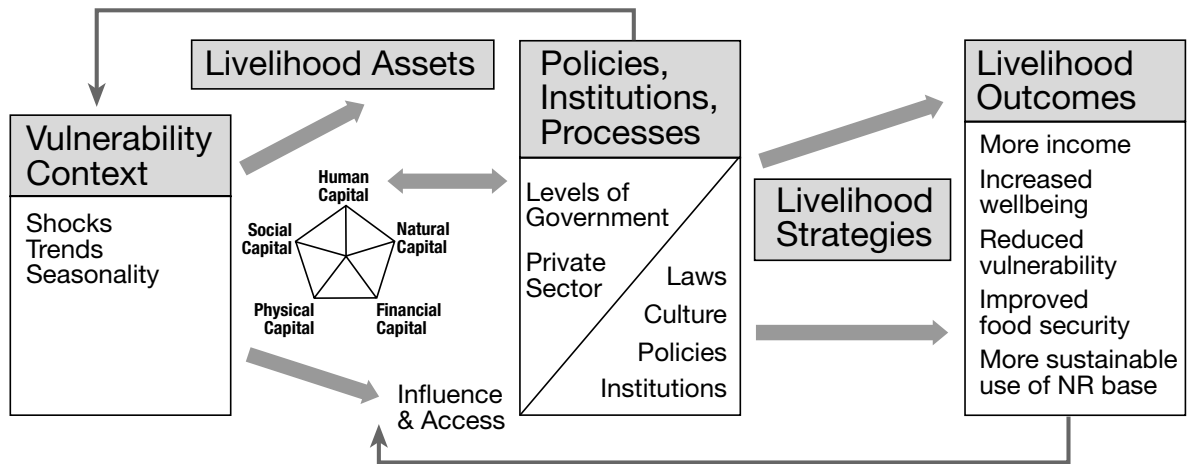

In the late 1990's, development agencies have put reduction, elimination and eradication of poverty as the prime focus of their programmes (AusAID 1997; DFID 1999; UNDP 1999; NZAID 2002; Cahn 2002). The new focus on poverty is also clearly reflected in the UN Millennium Development Goals, which range from halving extreme poverty to providing universal

primary education by the date of 2015. In accordance with this renewed interest in poverty reduction, the livelihoods approach has emerged during the 1990's. It focuses on the everyday life realities of the poor and seeks to identify how the poor secure their living and what it is that can sustain poor households through the stresses and shocks of their lives. The concept of 'Sustainable Livelihood Security' has emerged as a "way of thinking" (Cahn 2002: 1) that can be used as a tool for identifying and targeting the poor, planning pro-poor interventions, reviewing and evaluating poverty-related projects, carrying out policy analysis on local levels, and guiding research on poverty and development. Analyzing and promoting sustainable livelihood security implies putting people at the centre of attention. People-centred approaches to sustainable poverty elimination can only be achieved if analysis and support focus on what really matters to poor people. "Putting the Last First" (Chambers 1983) is thus the guiding principle of analyzing and providing sustainable livelihood security.

Emerging from intensive work at the IDS in Sussex during the 1990's, a set of core principles has been developed which, together, constitute what is now known as the "Sustainable Livelihoods Approach" (Chambers/Conway 1991; Scoones 1998; Carney 1999). This approach was adopted and formalized as the *Sustainable Livelihoods Framework* (SLF) by DFID in 1999 and published in the form of Sustainable Livelihoods Guidance Sheets (DFID 1999, constantly updated).

According to Chambers and Conway (1992), a 'livelihood' comprises the capabilities, assets (including both material and social resources) and activities required for a means of living. 'Livelihood security' refers to secure ownership of, or access to, resources and income-earning activities, including reserves and assets to offset risk, ease shocks and meet contingencies. 'Sustainable' refers to the maintenance or enhancement of resource productivity on a long-term basis. An individual, household or social group may be

Figure 36.1: The Sustainable Livelihood Framework. **Source:** DFID (1999). This figure is in the public domain.

enabled to gain sustainable livelihood security in many ways - through ownership of land, livestock or trees; rights to grazing, fishing, hunting or gathering; through stable employment with adequate remuneration; or through varied repertoires of activities. DFID (1999, glossary) has identified six core principles of the 'Sustainable Livelihoods Approach' in the context of poverty-focused development activities:

- *People-centred:* sustainable poverty elimination will be achieved only if external support focuses on what matters to people, understands the differences between groups of people and works with them in a way that fits in with their current livelihood strategies, social environment and ability to adapt.
- *Responsive and participatory:* poor people must be key actors in identifying and addressing livelihood priorities. Outsiders need processes that enable them to listen and respond to the poor.
- *Multi-level:* poverty elimination is an enormous challenge that will only be overcome by working at multiple levels, ensuring that local-level activity informs the development of policy and an effective enabling environment, and that higher-level policies and institutions support people to build upon their own strengths.
- *Conducted in partnership:* with both the public and the private sector.
- *Sustainable:* there are four key dimensions to sustainability - economic, institutional, social and environmental sustainability. All are important - a balance must be found between them.
- *Dynamic:* external support must recognize the dynamic nature of livelihood strategies, respond flexibly to changes in people's situation, and develop longer-term commitments.

These core principles of the sustainable livelihoods approach should not be confused with the principles of livelihood analysis which relate more specifically to the approaches and activities involved in investigating livelihoods. The core principles of 'Livelihood Analysis' are as follows (DFID 1999; glossary):

- Effort should be devoted to identifying and understanding the livelihood circumstances of marginalized and excluded groups.
- Analysis should take into account important social divides that make a difference to people's livelihoods. For example, it is often appropriate to consider men, women, different age groups, etc. separately. It is not sufficient to take the household as the sole unit of analysis.
- The sustainable livelihood (SL) approach seeks to build upon people's strengths and resourcefulness. When conducting analysis it is important to avoid thinking only about need.
- The SL approach embraces the idea of dynamism. Avoid taking one-off snapshots and instead think about change over time, including concerns about sustainability.
- There will never be a set recipe for which method to use under which circumstances. Flexibility is key. Equally, it is not necessary to produce one definitive 'map' of livelihoods. Different 'maps' may be appropriately used for different purposes.

In order to help understand and analyse the livelihoods of the poor, the Sustainable Livelihoods Frame-

work (SLF) has been developed by Scoones (1998: 4) and made a central part of the Sustainable Livelihoods Guidance Sheets by DFID (1999: 1.1). The framework which is presented in schematic form in figure 36.1 views poor people as operating in a context of vulnerability. Within this context, they have access to certain assets ('capitals') or poverty reducing factors. These gain their meaning and value through the prevailing social, institutional and organization environment. This environment also influences the livelihood strategies – ways of combining and using assets – that are open to people in pursuit of beneficial livelihood outcomes that meet their own livelihood objectives.

36.3 Origins and Evolution of the Concept

The 'Sustainable Livelihoods Approach' was originally developed for the rural poor (Carney 1999: 1). After decades of limited success in eliminating rural poverty, new ideas about pro-poor rural development were emerging in the 1990's, with a remarkable convergence when a number of prominent agencies revised their rural development strategies in broadly similar directions.

The emergence of the so-called livelihood approaches can be regarded as a reaction to the defects of conventional professional analysis and practice in rural development (Chambers/Conway 1992: 2). In social science analysis, and in the practice of rural development, the question of how a vastly larger number of people may gain at least basically decent rural livelihoods in a manner which can be sustained and secure – most of the rural poor living in fragile and marginal environments – had so far been tackled by a conventional conservatism in concepts, values, methods and behaviour. Three modes of thinking in development teaching and analyses had proved singularly resistant to change: production thinking, employment thinking, and poverty-line thinking (Chambers/Conway 1992: 2). In the mode of production thinking, problems defined variously as hunger, malnutrition and famine had been seen as problems of not producing enough food. There is, however, overwhelming evidence that these are much more problems of access and rights, of distribution and entitlements, rather than of production or supply (Sen 1981). In employment thinking, the problems of the rural poor had been seen as lack of employment. The ideal was full employment; the prescription was generating large

numbers of new workplaces. But this misfits much rural reality, in which people are not 'jobless' or 'unemployed', but constantly seeking to put together a living through multifarious repertoires of activities. In poverty-line thinking, deprivation had been defined in terms of a single continuum, the poverty line, which was measured either in terms of incomes or consumption. The aim was to enable more people to rise above this line, and fewer to sink below it. But deprivation and rural poverty, as poor people experience and perceive them, have many dimensions which do not correspond with this measure at all (Jodha 1988). To sum up, these three modes of analysis and development practice share two defects: an industrialized country imprint; and reductionism for ease of measurement (Chambers/Conway 1992: 3).

These ways of thinking clearly reflect the dominant modes of donor support for rural development over the past half century. The defining feature of this support was the tacit equation of 'rural' with 'agricultural' development (Carney 1999: 2). In the 1950's–60's the focus of donor attention fell on increasing the production of staple crops through 'green revolution' strategies, struggling to achieve food self-sufficiency. The emphasis was on import substitution, supply-driven policies and parastatal monopolies of both input supply and output marketing. Although these strategies were highly successful in terms of production-thinking, the benefits tended to be skewed towards richer farmers and more favourable environments (Bohle 1984, 1989, 1999).

The 1970's was the decade of integrated rural development (IRD). This strategy clearly reflected employment and income thinking. Although the complexities of rural life became to be taken into account, IRD projects were driven top-down, often with scant regard to local circumstances and few links to local social and political structures. The 1980's saw efforts to reform or adjust the agricultural sector through economic liberalization and privatization. At the project level, disillusionment with the top-down approach of IRD translated into a new focus on participation, NGO-implemented projects and bottom-up development (Stöhr/Taylor 1981). This created the ground for the emerging sustainable livelihoods approaches of the 1990's with their focus on people-centred, participatory principles. New main themes were the sustainability of the environment, the protection of natural resources, a renewed concern about world food supplies, and an extended access to food for the poorest sections of the population.

Although the sustainable livelihoods approach concentrates on the rural poor, any development strategy for the 21st century has to confront the question of how a vastly increasing number of urban poor people can secure and sustain a livelihood. As in rural development, the focus of pro-poor development of the 1970's and 1980's had clearly been driven by employment, income and poverty-line thinking. This became particularly evident with ILO's approach on promoting the urban informal sector, with an emphasis on supporting informal income opportunities and urban employment (Hart 1973; Bromley/Gerry 1979). Within the urban informal sector approach to urban poverty, new themes have emerged in the 1990's and early 2000's which show a remarkable convergence with livelihoods perspectives; a new focus on the life realities and survival activities in the city (Thomas 1995); attempts to make the 'shadow lives' of the working poor more visible (Chatterjee 1999); and a fresh interest in the livelihoods of the most vulnerable segments in megacities (Chikarmane/Narayan 2000; Köberlein 2003). Accordingly, urban livelihoods also emerged as people-centred approaches to reduce urban poverty (Rakodi/Lloyd-Jones 2002), and an asset vulnerability framework for analyzing urban poverty was developed by the World Bank (Moser 1998).

36.4 The Normative Basis

The livelihoods approach to rural and urban poverty is based normatively on the ideas of rights, security, capabilities, equity, and sustainability. Rights-based approaches to development (DFID 1999: 1.1) take as their foundations the need to promote and protect human rights - the rights that have been recognized by the global community and are protected by international legal instruments. These include economic, social and cultural as well as civil and political rights, all of which are interdependent. Running through the rights-based approach are concerns that constitute central building-blocks of the livelihoods concept: concerns with empowerment and participation, and with the elimination of discrimination on any grounds.

Rights-based and security-driven livelihoods approaches are complementary perspectives that seek to achieve many of the same goals. Concerns with empowerment and participation of the most vulnerable, for example, seek to strengthen the capacity of the poor to achieve stable and secure livelihoods. Although there is a strange absence of explicitly applying the notion of security in the sustainable liveli-

hoods approach, livelihood security is implicitly always present as a precondition of the poor to cope with and adapt to the risks of their lives, to ease shocks and to meet contingencies. While the shortest definition of a livelihood "as a means of securing a living" (Chambers/Conway 1992: 6) strongly underscores security issues, the working definition of sustainable livelihoods by the same authors fails to encompass the notion of security. It has been argued that it was not sustainability, but vulnerability and security that presented Chambers' central concerns when formulating the livelihoods approach (Arce 2003: 202). But it seems that Chambers brilliantly embraced the momentum of the environmental sustainability discussion, then at its height because of the 1992 UN Conference on Environment and Development, and then re-interpreted sustainability as a matter of vulnerability reduction and promotion of human security (de Haan/Zoomers 2005: 30).

In addition to rights-based and security-driven concerns, capability, equity and sustainability were explicitly taken as the normative base to the concept of sustainable livelihoods (Chambers/Conway 1992). The three concepts are again closely linked. Each has two sides, normative and descriptive. And each is also both end and means. Linked together, capability, equity and sustainability can be taken as a framework for development thinking which is both normative and practical. The term capability has been used by Sen (1984, 1987) to refer to the ability of the poor to perform certain basic functions. Quality of life is seen in terms of valued activities and the ability to choose and perform those activities. Within Sen's framework of capability, there is a subset of "livelihood capabilities" (Chambers/Conway 1992: 4) that include being able to find and make use of livelihood opportunities, and being able to cope with stress and shocks (i.e. gaining security). Such capabilities are not just reactive, but also proactive and dynamically adaptable. Equity, in conventional terms, is measured by the way of relative income distribution. But Chambers and Conway (1992: 4) used the word more broadly, to imply a more equal distribution of assets, capabilities and opportunities, and especially enhancement of the livelihoods of the most deprived and vulnerable. Sustainability, in "development prose" (Chambers/Conway 1992: 4), has replaced 'integrated' as a versatile synonym for 'good'. Livelihoods are considered sustainable when they are resilient in the face of external shocks and stresses; are not dependent upon external support; maintain the long-term productivity of natural resources; and do not undermine the livelihoods

opportunities open to others, including future generations (DFID 1999: 1.4). The sustainability of livelihoods raises two questions (Chambers/Conway 1992: 9): whether a livelihood is sustainable environmentally, in its effects on local and global resources and other natural assets; and whether it is sustainable socially, that is, able to cope with stress and shocks, and retain ability to continue and improve the livelihood opportunities of the poor. Sustainability is thus a function of how assets and capabilities are utilized, maintained and enhanced so as to preserve livelihoods.

All these normative bases of the livelihood approach, taken together, bear a remarkable resemblance to the current discourse on human security. Explicit links to this discourse, however, are curiously absent in the discussion on livelihoods. On the contrary, the origins, influences and development of the livelihoods approach are usually only linked to the sustainability discourse. It was in fact the *World Commission on Environment and Development* (WCED 1987a) that put forward sustainable livelihood security as an integrating concept and made it central to its report (WCED 1987). In the further development of the concept, however, the notion of security got lost. Recently, the Millennium Ecosystem Assessment Synthesis Report (2005: vi) has re-addressed security issues when linking ecosystem services with constituents of well being. Security, i.e. personal safety, secure resource access, and security from disasters, is conceptualized exactly in line with the security notions reflected both in the sustainable livelihoods approach and in the human security discourse. Closer scrutiny of the current discourse on human security none the less reveals that most of its debates during the past decade have revolved around the notions of rights, capabilities and equity which are so central to the livelihoods approach.

36.5 The Discursive Context: Human Security

When the notion of human security was introduced as a new paradigm of sustainable human development in the 1994 UNDP Human Development Report (UNDP 1994: 3), the arguments for proposing the concept were much in line with what is now termed the livelihood approach. It was proposed that for most people today, a feeling of insecurity arises more from worry about daily life than from the dread of war or a catastrophic world event. This means that different security concepts are needed for states and

for people, and it acknowledges that even state security will be precarious (and empty) unless based on and consistent with the security of individuals. A new paradigm for human development is thus needed that puts people at the centre and that enables individuals to enlarge their human capabilities to the full (UNDP 1994: 4).

This first discursive strand around human security, initiated by UNDP (1994), applied the languages of safety, protection and freedoms and defined human security basically as ‘freedom from want’ and ‘freedom from fear’. Human security, according to UNDP (1994: 3), means safety from the constant threats of hunger, disease, crime and repression. It also means protection from sudden and hurtful disruptions in the pattern of our daily lives. Loss of human security can thus be a slow, silent process or an abrupt, loud emergency. While ‘human development’ is the process of widening the range of people’s choices, ‘human security’ focuses on how people can exercise these choices freely and safely, and that they can be relatively confident that the opportunities they have today are not lost tomorrow.

This conception of human security is also central to the GECHS (Global Environmental Change and Human Security) programme, an international core project of the International Human Dimensions of Global Environmental Change Programme (IHDP). With foci on conflict, gender and health security in the context of global environmental change, the GECHS Science Plan (1999) has defined human security to be a state that is achieved when and where individuals and communities have the options necessary to end, mitigate or adapt to threats to their human, environmental and social rights; have the capacity and freedom to exercise these options; and actively participate in pursuing these options. While most definitions of human security had so far been based on the concept of ‘freedom from fear’ and ‘freedom from want’, the GECHS definition focuses specifically on freedom to take action on one’s own behalf in response to changing environmental conditions. In particular, it emphasizes the ways that environmental changes contribute to (or exacerbate) pervasive threats and critical situations, while at the same time undermining the capacity to respond to these threats. It interprets environmental change in the context of ongoing social changes, which together may affect the security of some individuals and communities.

A third strand of discussion on human security was initiated by the UN-Commission for Human Rights (2003). It takes a rights-based approach and

also employs the language of freedoms. The requirements for being 'human', in addition to sheer existence, can go far beyond freedoms from want and from fear. According to the Commission for Human Rights (Robinson 2003), "freedom from humiliation, from indignity and from despair" has to be added to fully grasp the notion of human security (Gasper 2005: 225). A fourth discursive strand of the debate on human security revolves around Sen's (2003) capability approach. It is concerned with the stability of the effective (i.e. attainable), valued opportunities that are available to poor people. Instead of addressing freedoms 'from', the capability approach views human security as freedoms 'to', especially the freedoms to act and to attain. In this way, it is very similar to the GECHS approach to human security. A last and currently most important discursive formation within the human security discourse has been stimulated by the Commission on Human Security's report *Human Security Now* (2003). Human security here is to safeguard the 'vital core' of all human lives from critical pervasive threats, without impeding long-term human fulfilment. This commission (known as the Ogata-Sen commission) suggested human security as a fundamental set of human functions related to survival, dignity, and, last not least, livelihood (Alkire 2003: 24). The current discourse on human security brings together the ethics of capabilities, human needs, and human rights, just as the livelihoods approach does. All these types of ethics are closely related and complementary, not competitive: "human security discourse builds on this potential, bringing together what was previously artificially separated" (Gasper 2005: 232).

36.6 Application of the Concept

The livelihood approach has been widely used both in the academic literature and in development practice. The most prominent field of applying the livelihood approach has been in vulnerability analysis. The focus has been on livelihood assets and capital analysis and on the evaluation of livelihood strategies based on the resources identified.

Experience with livelihoods' approaches in vulnerability analysis has shown that the most complex part is probably the analysis of asset portfolios, particularly of intangible resources (Chambers/Conway 1992: 7). The tangible assets commanded (or not commanded) by a household or group can be classified into stores and resources. The intangible assets consist of claims and access. Claims are demands and appeals which

can be made for material, moral or other practical support. Access is the opportunity in practice to use a resource, store or service or to obtain information, material, technology, employment, food or income. The concept of social capital has been widely employed to identify the claims and opportunities that make up livelihoods (Bohle 2005). Institutional analysis has also been utilized (Scoones 1998: 11) to examine the regularized practices that determine the control of livelihood assets and identify the rules and norms that regulate access or exclusion (Bohle/Fünfgeld 2006). On the whole, asset analysis has revealed the complex ways in which the poor and vulnerable combine capitals and dynamically shape and reconfigure their livelihoods' portfolios, and how even narrower forms of assets such as social capital alone are diversified and reconstructed in highly flexible manners, especially in contexts of rapid transformations or violent conflict (Bohle 2006).

In the field of livelihood strategies, vulnerability analysis has shown that wide ranges of activity repertoires, based on complex and dynamic asset portfolios, are being employed to cope with shocks and to adapt to the risks and vagaries of vulnerable livelihoods. In general, coping and adaptation involves "managing resources" (Wisner/Blaikie/Cannon/Davis 2004: 113), but in adverse situations coping and adaptation can include defence mechanisms, active ways of solving livelihoods problems, and methods for handling shocks and stress. In the substantial literature on strategies for coping with stress and shocks (e.g. Ellis 2000), livelihood strategies have been identified to consist of "repertoires" (Chambers/Conway 1992: 7) or "mixes" of stinting, hoarding, protecting, depleting, diversifying, claiming and moving activities (Chambers/Conway 1992: 11). These activities are frequently sequenced in a way that sustainable livelihood security may be protected in the long run, even at the cost of short-term sufferings and losses (Bohle 2001). Sequencing of livelihood activities may also imply the search for establishing a particular livelihood strategy that may serve as a precursor for gaining access to other resources (Scoones 1998: 8).

Livelihood analysis has also become a vital tool in development practice, particularly in terms of participatory vulnerability analysis. DFID, CARE, Oxfam, ACTION AID INTERNATIONAL and UNDP have emerged as the main actors in the field of participatory, livelihoods-based vulnerability analysis. In her attempt to compare the livelihoods approaches employed by DFID, CARE; Oxfam and UNDP, Carney (1999) has provided an outline of each agency's ap-

proach, lessons learnt, and on the differences. She also supplied summary tables on the origins, usage and operational issues of the various approaches, as well as the operationalized frameworks of the agencies involved. It is obvious that the four organizations share much in common, notably the focus on assets and on micro-macro links, as well as common roots in the works of Chambers and Conway (1992). Although commonality certainly exceeds variation (Carney 1999: 17), there is a somewhat different understanding of sustainability between the agencies. Different agencies also put a different level of stress on empowerment. UNDP emerges as the only organization that explicitly stresses technology in its framework.

In their report to DFID, Cannon, Twigg and Rowell (2003) have placed vulnerability analysis and sustainable livelihoods in the context of natural disasters. They argue that the humanitarian policy of DFID is limited in its ability to link relief to long-term sustainability and enhancement of livelihoods, and that the sustainable livelihoods approach offers ample, but underutilized potentials for vulnerability reduction. As such, vulnerability analyses may help to bring humanitarian work in line with DFID's other main objectives and tie it in with the sustainable livelihoods approach (Cannon/Twigg/Rowell 2003: 3). Case studies on *Vulnerability and Capacity Assessment* (VCA) exercises undertaken by IFRC, Oxfam and CARE show that livelihoods-based vulnerability analyses, in the context of disasters, should be capable of directing and targeting development and interventions, seeking ways to enhance and protect people's livelihoods, assist vulnerable populations in their own self-protection and support institutions in their role of disaster prevention (Cannon/Twigg/Rowell 2003: 4).

36.7 Evaluation: New Frontiers in Livelihoods Research

One of the major strengths of the livelihood approach is that it views the poor and vulnerable not as passive victims, but highlights the active or even proactive role to secure their living in contexts of uncertainty, risk, stress and shocks. The livelihood approach clearly marks the shift from the structural perspectives of dependencia and neo-Marxism to actor-oriented perspectives. This new focus on the agency of the poor addressed the everyday-life experiences of the poor, the micro-worlds of their family, community and social networks. As such, it draws fresh attention to issues such as marginalization and exclusion, vulnerabil-

ity and poverty, inequality and powerlessness as key determinants of precarious livelihoods (de Haan/Zoomers 2005: 28).

Contrary to the rather pessimistic outlook of conventional household studies, the new generation of livelihood studies took a more optimistic view and showed how people can mobilize resources to make a living, and how they play active roles in achieving their livelihoods by continuously exploiting opportunities. The livelihoods approach is basically positive in that it first identifies what people have rather than focusing on what the poor do not have (Cahn 2002: 3). The poor are conceived as possessing a lot of agency, and as taking an active role in responding to and enforcing change (de Haan/Zoomers 2003: 38). It has been argued that it was exactly this pro-active, self-help, participatory and optimistic image of the sustainable livelihoods approach that made it so attractive to the UK's development policy under New Labour since 1997 (Solesbury 2003: 2, quoted after de Haan/Zoomers 2005). The improved understanding of the holistic and dynamic meaning of livelihood is certainly an important achievement of the livelihoods approach. However, the worldview of the Sustainable Livelihoods Frameworks in general, and the fresh focus on action and agency, in particular, also poses a number of questions.

A first unresolved problem of the livelihoods approach is the nature of relationships between structure and agency. This is a complex question in development sociology which has been discussed at length in the works of Giddens, especially in his theory of structuration (1984). Here Giddens refers to the "duality of structures" as both constraint and opportunity, and to the dialectic and recursive linkages and feedbacks between (intentional and unintentional; routinized and reflexive) social practice and the social structures that enable and restrict agency. One challenge for livelihoods analysis is therefore to integrate findings from action theory (including Bourdieu's concept of habitus and Luhmann's sociology of risk) into its frameworks to get a sounder understanding of how human agency in the context of livelihood strategies can be understood and explained.

A second problem that has recently been put forward by de Haan and Zoomers (2005) is the relative weight that politics and power play in the livelihood decisions of the poor. They argue that social relations, particularly property relations and configurations of power, play such a major role in determining access to and control over vital livelihoods resources that they cannot be overemphasized. Although transforming

structures, mediating processes, institutions and organizations appear in all livelihood frameworks, there is a tendency within livelihoods studies to downplay these structural features and to focus on agency, capabilities, and opportunities (de Haan/Zoomers 2005: 33). Again, theoretical approaches from political economy, conflict studies and research on power dynamics are needed to integrate questions of access and control, of conflicts and contestations, of struggles and violence into livelihoods analysis.

A third problem is the general neglect of those aspects of livelihoods security that go far beyond the political, economic and material objectives of life. One of the shortcomings of both actor-oriented and structural-functional approaches to livelihoods is the neglect of the role of culture, identity and ideology. As Guyer and Peters (1987: 209 (quoted from de Haan/Zommers 2005: 29) remark, “the socially specific units that approximate ‘households’ are best typified not merely as clusters of task-oriented activities, not merely as places to live/eat/work/reproduce, but as sources of identity and social markers. They are located in structures of cultural meaning and differential power”.

Livelihoods are much more than “a means to secure a living” (Chambers/Conway 1992: 6), much more than getting food and income, a shelter and protection. Livelihoods are equally about the circulation of information, the management of skills, and the affirmation of personal significance, identity and status (Wallmann 1984). Moreover, in the words of Bebbington (1999: 2022, quoted from de Haan/Zoomers 2005: 32),

a person’s assets, such as land, are not merely means with which he or she makes a living: they also give meaning to that person’s world. Assets are not simply resources that people use in building livelihoods: they are assets that give them the capability to be and to act. Assets should not be understood only as things that allow survival, adaptation and poverty alleviation: they are also the basis of agent’s power to act and to reproduce, challenge or change the rules that govern the control, use and transformations of resources.

36.8 Conclusion

The new approach on sustainable livelihood security has emerged as an influential way of thinking on how the rural and urban poor can be identified and targeted, how pro-poor interventions can be planned, and how policy-relevant analysis on local levels can guide research on poverty and development. Analyz-

ing and promoting sustainable livelihood security is very closely connected with the concept of human security, putting people at the centre and taking equity, human rights, capabilities and sustainability as its normative basis. Sustainable livelihood security views poor people as possessing a lot of agency and evaluates the dynamic portfolios of assets and the multifarious repertoires of livelihood activities that vulnerable groups pursue to secure their lives. This new focus on the agency of the poor addresses their everyday-life experiences in participatory modes of enquiry and sheds fresh light on both their livelihood constraints and opportunities.

The new frontiers of livelihoods research address some of the current shortcomings of the approach and involve at least three things. *Firstly*, a theoretically grounded appraisal of the relationship between structure and agency. *Secondly*, a politically sensitive articulation of the social relations of access and control, particularly power relations, that govern the linkages between structure and agency. And *thirdly*, a culturally sensitive recognition of the non-material, needs-based, subjective and psychological dimensions of livelihoods security which, again, cannot be separated from agency, structure and politics. This implies that the basically harmonious, non-political, untheoretical and objectivist worldview of sustainable livelihoods security has to incorporate the experience that the world in which the vulnerable seek to secure a living is a political arena with conflicting interests. It is a world in which livelihoods are contested and negotiated, struggled over, lost and won. And it is a world where it matters a lot what the vulnerable themselves value as sustainability and security.

37 Global Health Security: The WHO Response to Outbreaks Past and Future

Guénaél Rodier and Mary Kay Kindhauser

37.1 Introduction

During the first years of the 21st century, concern about the threat of infectious diseases has rapidly escalated after three dramatic events: a bioterrorist attack, the emergence and international spread of a severe new disease, and the looming threat of an influenza pandemic. Concern has progressively mounted: worst-case scenarios for one outbreak have been replaced by the next. While the three events are distinctly different in their origins and epidemiology, each has delivered a vivid warning that the world is now far more vulnerable to the adverse effects of emerging and epidemic-prone diseases. Together, they have challenged the very notion that an outbreak can be considered 'localized' in a highly mobile, economically interdependent, and electronically interconnected world. Although the number of cases and deaths has been comparatively small (table 37.1), the social and economic consequences have been enormous.

Table 37.1: Cases and deaths from recent outbreaks compared with those from persistent infectious disease threats ^(a) numbers infected in June 2005). **Source:** WHO Statistics; at: <<http://www.who.int/research/en/>>.

Disease	Year	Cases	Deaths
Anthrax	2001	22	5
SARS	2003	8098	774
H5N1 avian influenza	2004 – June 2005	108	54
AIDS	2004	39.4 million ^a	3.1 million
Tuberculosis	2004	8.97 million ^a	1.7 million
Malaria	2004	400 million	1 million

The unprecedented volume of international air travel – airlines now carry 1.6 billion passengers each

year – has opened opportunities for pathogenic agents to be carried to any part of the world within a few hours. The interdependence of economies and commerce means that the disruption caused by an outbreak in one area can likewise spread quickly around the world. Broad access to electronic communications immediately gives outbreaks a large international audience and amplifies the anxiety they provoke, leading to behaviours – avoidance of travel, drops in consumer consumption of certain foods and goods – that further exacerbate the social and economic consequences. Since the start of the 21st century, public perceptions of the severity of outbreaks have been shaped by striking images of investigative squads in full protective gear, masked faces and empty airports, and the mass culling of millions of animals. Politicians, too, now appreciate that outbreaks can have consequences that extend far beyond the health sector. For all these reasons, the risk of further outbreaks, especially when caused by a new pathogen, is increasingly seen as a direct threat to national and international security.

After a brief introduction of the evolution of the health security concept within the WHO (37.2), three health security issues will be discussed for the three outbreaks – anthrax, SARS and H5N1 avian influenza (37.3 and 37.4) – and the specific ways they have altered perceptions of the infectious disease threat (37.5). These changes are then placed in the context of concerns that had been mounting, albeit far more gradually, during the last decades of the previous century (37.6 to 37.8). Changes in concepts of national and international security are discussed in terms of their increased ability to accommodate infectious disease threats (37.9). The remaining sections explain the operational framework put in place by WHO to defend global health security (37.10).

37.2 Evolution of the Health Security Concept within WHO

UNDP (1994) mentioned health security¹ as one of seven dimensions of its suggested human security concept. The concept of a *health security* has been introduced during a WHO Colloquium on Women's Health Security on 5 September 1995 in Beijing as encompassing:

all aspects of the basic human right to health. Health security means the guarantee of accessible and affordable health care to all – men, women and children. Its three cornerstones are equity, choice and partnership. In the case of women, this translates into provision and access to information and education; adequate nutrition; freedom from violence; the right to work in safe environments; and access to appropriate health care

1 This brief section was added by Hans Günter Brauch with the consent of the authors. The new sectoral 'health security' concept is closely related with all five security dimensions: the economic, societal, environmental but also with the political and military. Within the *environmental* dimension of security (ecological security) it is closely linked with 'water security' (referring to the health problems that are generated by *water scarcity* (drought, heat waves), *abundance* (flash floods and inundation) and by *degradation* and *pollution* (water related diseases). In the *societal* and *economic* dimension of security health security refers to totally different discourses in the North (health reform, affordability of public health services for aging societies partly based on solidarity principles) and in the South (bring basic health services to the poor and most vulnerable to both diseases and water related hazards). The health security debate has also acquired a *political* dimension, e.g. due to the use of economic sanctions (e.g. on the health of children in Iraq), and the prevention of scientific assessments of the impact of enriched uranium projectiles during the second Persian Gulf war in 1991 (Haavisto 2003; UNEP 2003, 2003a, 2005, 2007) and a *military* dimension with regard to the impacts of wars (war and post-war periods) but also on the health of combatants and the civilian population (also by the use of both conventional and mass destruction weapons that do not discriminate between both) and more recently primarily of the fear that terrorists may use biological and chemical weapons indiscriminately thus threatening the survival of whole civilian populations in the urban centres of the economically developed world. In the conceptualization of health security differences exist also within the UN system with regard to the referent object. While many have used the state (national security) as the major referent of health security, UNDP (1994) referred to the individual human being, the people or to humankind (human security) as the key referent object.

services. ... Freedom from all forms of violence against women is an essential component of health security. ... WHO calls for governments and health planners to improve their response to the threat to women's physical and mental well-being by regarding violence as an important health issue. ... WHO believes that only through health security, can women have access to quality health care services, and be sure that their health needs will be met from birth to old age.²

The WHO Global Commission on Women's Health adopted at the United Nations' Fourth World Conference on Women a Declaration calling for government action to sustain the realization of women's health security.³ The WHO contributes to *Global Health Security*, and specifically to the concept of *Global Public Health Security*⁴. This is done through WHO Pandemic and Epidemic Alert and Response activities, via a global partnership focusing on three goals: a) contain known risks, b) respond to the unexpected, and c) improve preparedness.⁵

37.3 Anthrax, SARS and an Ominous Influenza Virus

The deliberate use of anthrax to incite terror, which quickly followed the events of 11 September 2001 in the USA, changed the profile of the infectious disease threat in a dramatic and definitive way. Prior to these events, the emergence of new diseases – and most especially, the impact of AIDS on Africa and on economically important nations in Asia – had sharpened concern about the infectious disease threat as a disruptive and destabilizing force, and given it space in national security debates. The reality of bio-terrorism immediately raised the infectious disease threat to the level of a high priority security imperative worthy of attention in defence and intelligence circles. In so doing, it also focused attention on several features of the infectious disease situation that make outbreaks – whatever their cause – an especially ominous threat. As smallpox again became a disease of great concern, both politicians and the public began to comprehend problems, long familiar to public health professionals.

4 The World Health Report 2007. A Safer Future – Global Public Health Security in the 21st Century. World Health Organization. <http://www.who.int/whr/2007/en/index.html>.

These have ranged from silent incubation periods that allow pathogens to cross borders undetected and undeterred, through the finite nature of vaccine manufacturing capacity, to the simple fact that outbreaks have a potential for international spread that transcends the defences of any single country.

Speculations about the consequences of a biological attack with the smallpox virus produced many scenarios about how a new or unfamiliar pathogen might behave in the 21st century. Even in the most advanced countries, the non-specific symptoms of a flu-like illness would create diagnostic confusion. Clinicians, unfamiliar with the disease, would initially miss cases, thus delaying the first alert. Inadequate supplies of vaccines and antiviral drugs would fuel social upheaval. Lacking adequate surge capacity, hospitals and health care systems would be overwhelmed. Authorities would resort to enforced isolation and quarantine. The silent incubation period would facilitate rapid international spread by air travellers. Given broad access to electronic communications, rumours would spread with equal speed. Travel and tourism to affected areas would come to a virtual standstill.

When SARS began to spread internationally in late February 2003, many of these scenarios were played out in reality. Others would take on concrete meaning in 2004, when a highly lethal avian virus began moving the world to the brink of another influenza pandemic. SARS – the first severe new disease of the 21st century – spread rapidly along the routes of international air travel. The disease placed every country with an international airport at risk of an imported case. SARS spread from person to person, required no vector, displayed no particular geographical affinity, mimicked the symptoms of many other diseases, took its heaviest toll on hospital staff, and killed around 10 per cent of those infected. In the absence of a vaccine or cure, isolation and quarantine became the principal control measures. SARS caused great social disruption and economic losses far out of proportion to the number of cases and deaths and well beyond the outbreak sites. News on the disease jolted stock markets. Projections for economic growth were revised downwards. Commerce in distant countries dependent on Asian goods and manufacturing capacity suffered. Schools, hospitals, businesses, and some borders were closed. Broad access to electronic communications and extensive media coverage made the public deeply aware of SARS and worries about its spread. Travel to affected areas plummeted, causing airlines with Asian routes to lose an estimated US\$ 10 billion. Fortunately, these consequences, apparent

early on, brought political support at the highest level and increased pressure to contain the outbreak as the only way to regain economic health (WHO 2003a).

SARS did not change the world, but it did reveal how much the world has changed in terms of increased and universal vulnerability to new disease threats. SARS challenged the assumption that wealthy nations, with their well-equipped hospitals and high standards of living, would be shielded from the amplification of cases seen when new diseases emerged in the developing world. Contrary to expectations, SARS spread most efficiently in sophisticated urban hospitals. SARS redefined national responsibilities for outbreaks in two important ways. *First*, given the international repercussions of outbreaks in an interconnected and mobile world, governments are likely to be held accountable, by the international community as well as by their citizens, for failures in their response to an outbreak. *Second*, broad access to electronic communications – from mobile phones to the internet – has made it increasingly likely that official notification of an unusual disease event will be preempted by rumours, likewise giving national events an immediate international audience. It has also made outbreaks too quickly and highly visible for governments to attempt to conceal them. China's initial denial of its SARS outbreak and prohibition of press reports could not stop mobile phone users from sending a text message about a 'fatal flu' in Guangdong Province more than 45 million times on a single day in early February 2003.⁵

SARS stimulated an emergency response, and a level of media attention, on a scale that may have changed public and political perceptions of the risks associated with emerging and epidemic-prone diseases. Reports in scientific publications and the media and from governmental agencies in several countries generally agree that SARS raised the profile of public health to new heights by demonstrating the severity of adverse effects that a health problem can have on economies, social stability and political careers (National Intelligence Council 2003).

At the peak of the SARS outbreak, many infectious disease experts, asked to comment on the significance of the new disease, used the example of pandemic influenza for comparative purposes. While SARS was certainly a matter for grave concern, the true potential of an infectious disease to wreak havoc in a glo-

5 John Pomfret: "Outbreak gave China's Hu an opening; President responded to pressure inside and outside country on SARS", in: *Washington Post*, 13 May 2003.

alized society would be seen with the arrival of the next influenza pandemic, which would be impossible to stop. Far more contagious, and transmitted during a short incubation period, pandemic influenza would extend the devastating consequences seen with SARS in Asia and Toronto, Canada to the entire world within a matter of months. While SARS infected just under 8,000 people, killing almost 800, many millions of people would unquestionably perish during the next influenza pandemic.

In January 2004, six months after WHO declared the SARS outbreak over, intensified surveillance for a recurrence of cases detected a cluster of patients with severe respiratory disease at a paediatric hospital in Hanoi, Viet Nam (WHO 2005). That event marked the start of an outbreak of human cases of avian influenza, caused by the H₅N₁ strain of the virus, that has brought the world closer to an influenza pandemic than at any time since 1968. The scenarios of how a highly contagious and lethal virus will behave under the unique conditions of the 21st century have begun again, but this time with greater urgency in the face of an imminent catastrophe. No one would question the directness of the threat that pandemic influenza poses to national and international security. Should the case fatality rate be as low as 1 per cent, the highly contagious nature of influenza and the size of the world's population could translate into 30 million deaths, concentrated over a short period of time, if less than half of today's 6.5 billion people were infected. Moreover, the concern with national security is so great that international sharing of limited supplies of vaccines and antiviral drugs is considered exceedingly unlikely; in past pandemics, countries have consistently nationalized manufacturing capacity, allowing exportation of vaccines and drugs only after all national needs had been met. Perhaps most important, differences in the capacity of industrialized and developing countries to respond to outbreaks is now much greater than at the start of the previous century. With health services in many developing countries already overburdened by AIDS, tuberculosis, and malaria, an event such as a pandemic influenza is likely to strain fragile health systems to the point of collapse, further increasing the world's present imbalance.

37.4 Microscopic Adversaries: Well-equipped to Invade, Evade, and Surprise

The source of the evolving infectious disease threat resides in microscopic adversaries that change and adapt with great speed and have the advantages of surprise on their side. During the past 30 years, the infectious disease threat has diverged considerably from previous patterns of epidemiology, drug susceptibility, geographical distribution and severity (Lederberg/Shope/Oaks 1992). Such divergence arises from the naturally volatile behaviour of the microbial world, amplified by recent ecological and demographic trends. Constant evolution and adaptation are the survival mechanisms of the microbial world. Infectious disease agents readily and rapidly multiply, mutate, adapt to new hosts and environments, and evolve to resist drugs. This natural propensity to change has been greatly augmented by the pressure of a crowded, closely interconnected, and highly mobile world, which has given infectious agents unprecedented opportunities to exploit (Rodier/Ryan/Heymann 2000). Vulnerability to the threat is now recognized as universal. As adversaries, microbial pathogens have particular advantages in terms of invisibility, mobility, adaptability, and silent incubation periods that render national borders meaningless.

Changes in the way humanity inhabits the planet have disrupted the delicate equilibrium of the microbial world. Population growth, incursions into previously uninhabited areas, exploitation of the environment, and intensified agricultural and farming practices have disturbed the natural environment in which pathogens, plants, and animals have peacefully coexisted for centuries (Heymann/Rodier 2001). These pressures have given pathogens multiple opportunities to exploit new environments and invade new hosts, including humans. As a result, new diseases, which are poorly understood, difficult to treat, and often initially highly lethal, are now emerging at an unprecedented rate (Woolhouse/Dye 2001). During the past three decades, more than 40 new viruses, bacteria, and other pathogens capable of infecting humans have been identified, and this trend is certain to continue (Heymann 2003).

Apart from favouring the emergence of new diseases, demographic trends have created conditions that allow infectious diseases – whether old or new – to flourish. Populations throughout the world are now larger, older, and more closely crowded in urban centres, often living under squalid conditions. Even

the wealthiest nations have pockets of poverty that act like reservoirs, incubating epidemic-prone diseases linked to poor hygiene and sanitation. The growing numbers of complex emergencies and refugees living in crowded camps also provide fertile breeding grounds for outbreaks of both common and exotic diseases. Wealthy nations, too, can contribute to the emergence of new diseases. The emergence of bovine spongiform encephalopathy, or 'mad cow' disease, has been linked to processed animal feeds; processed foods using lower quality meat are thought to have contributed to the emergence of a related disease in humans which, though rare, is invariably fatal (WHO 2002b). The food chain has likewise become globalized with two results: the investigation of food-borne outbreaks has become enormously complex; recalls of contaminated food can stretch across continents and cost millions of dollars (WHO 2002; Tauxe 1997).

The misuse of antibiotics and other drugs is another ominous trend introducing another universal problem: the rapid development of resistance to front-line drugs, leaving some major diseases with no affordable treatment (WHO 2001a). Healthcare in all countries is now compromised by the shrinking number of effective antimicrobials. Fuelled by co-infection with HIV, the return of tuberculosis as a global menace has been accompanied by the emergence of multi-drug-resistant forms costing up to 100 times more to treat (Kindhauser 2003). Malaria may soon be resistant worldwide to all currently available first-line drugs (Kindhauser 2003). Drug resistance to common bacterial infections is now so pervasive that it raises the spectre of a post-antibiotic era in which many life-saving treatments and routine surgical procedures could become too risky to perform (WHO 2001).

These developments have eroded past confidence that high standards of living and access to powerful medicines could insulate domestic populations from infectious disease threats abroad. They have also restored the historical significance of infectious diseases as a disruptive force – this time cast in a modern setting characterized by close interdependence of nations and instantaneous communications (Heymann 2003a). Within affected countries, the disruptive potential of outbreaks and epidemics is expressed in ways ranging from public panic and population displacement to the interruption of routine functions that occurs when containment requires the emergency immunization of populations numbering in the millions. Disruption can also be measured in economic

terms. Outbreaks are always expensive to contain. Affected countries can experience heavy additional burdens in the form of lost trade and tourism—estimated at US\$ 2 billion during the 1994 outbreak of plague in India (Cash/Narasimham 2002). The losses to Asian economies associated with SARS have been estimated as at least US\$ 30 billion (WHO 2003a). As of May 2005, the total direct losses in gross domestic product accruing from the poultry sector in Asia, damaged by H5N1 avian influenza, were estimated at US\$ 10 billion; indirect costs are still being estimated (Cash/Narasimham 2002). At the global level, some of the most telling efforts to measure economic consequences, in terms of international relations and foreign affairs, have centred on determining what the AIDS epidemic in sub-Saharan Africa means for the economies of wealthy nations. At one extreme, the high mortality caused by this disease and the particular age group it affects has been interpreted as the cost to industrialized countries of lost export markets (Kassalow 2001). At the other extreme, the economic costs of AIDS to the international community have been expressed in terms of the price of drugs and services needed to rescue a continent (Sachs 2001). The human suffering caused by this disease defies calculation in any terms.

37.5 Changing Perceptions of Security

Efforts to understand the security implications of emerging and epidemic-prone diseases have taken place within the context of a reconsideration of what constitutes a security threat in the post-Cold War era. In its traditional meaning, 'security' has long been a strictly national pursuit aimed at defending territorial integrity and ensuring state survival. It is intrinsically self-centred, focused on shielding state citizens from external danger in an international system ruled by anarchy (Burchill 1996). Traditional approaches to the defence of national security are military functions: protecting borders, fighting wars, and deterring aggressors (Ban 2001; CSIS 2000).

Two events have challenged these traditional views. First, the end of the Cold War meant an end to security issues polarized by the ideological conflict and geopolitical interests of the superpowers, and kept on edge by the nuclear arms race. As old threats subsided, more attention focused on threats arising from civil unrest, internal conflicts, mass migration of refugees, and localized wars between neighbouring countries, particularly when these had the capacity to

undermine state stability or contribute to state failure (Nichiporuk 2000; Kelley 2000; Weiner 1992; Price-Smith 2002). The absence of a bipolar power system magnified these threats considerably, as intervention to prop up a failing state of geopolitical strategic interest was no longer assured (Fidler i.p.; Tickner 1995; Cooper 1996). As a result, security issues became broader and more complex, and attention began to focus on ensuring the internal stability of states by addressing the root causes of unrest, conflict, and mass population movement rather than defending national borders against external aggressors (Holsti 1996). In the wake of these changes, a number of factors – from environmental conditions to income, education, and health – were put forward as determinants of internal state stability and therefore of potential relevance to the evolving security debate (Elbe 2002).

In a second event, the forces of globalization demonstrated the porous nature of national borders and eroded traditional notions of state sovereignty. In a closely interconnected and interdependent world, the repercussions of adverse events abroad easily cross borders to intrude on state affairs in ways that cannot be averted through traditional military defences (Ban 2001). For example, in the world's tightly interrelated financial system, a crisis in a distant economy can rapidly spread to affect others.⁶ Many other transnational threats – whether arising from environmental pollution or tobacco advertising – were recognized as having an effect on internal affairs that went beyond the control of strictly national actions. Emerging and epidemic-prone diseases qualified as a transnational threat for obvious reasons: they easily cross borders in ways that defy traditional defences and cannot be deterred by any state acting alone (Ban 2001). In the broadened debate, their disruptive potential gave them added weight as a possible security concern, although this potential differs considerably between industrialized and developing countries (Kelley 2000).

This disruptive potential arises from several general characteristics of outbreaks, which are further defined by the pathogen and the political, economic, and cultural context in which the outbreak occurs. Epidemics are disruptive because of the large number of people they can infect within a short period of time. For example, within a single week in February 2006, the Chikungunya virus disease affected an estimated 22,000 people on the small island of La Réunion in the Indian Ocean. A severe new disease of unknown

cause and epidemiological potential is more alarming for the public than an established epidemic-prone disease that recurs according to well-characterized patterns. These characteristics give outbreaks their potential to cause social disruption and economic losses well beyond health care costs and out of proportion to the true severity of the risk.

First, outbreaks are urgent public health emergencies accompanied by rapid efforts to care for cases, prevent further spread, and bring the outbreak under control. Necessary control measures can be drastic: mass emergency immunization, quarantine, border control, travel restrictions, and mass slaughter of animals.

Second, the behaviour of outbreaks is unpredictable, making it difficult for authorities to reassure the public on such key questions as who is at risk, will the outbreak spread, and will the recommended control measures offer adequate protection. The history of recent outbreaks yields many examples of a sudden surge in cases or spread to another country after an outbreak was thought to have peaked. Such setbacks can arise from a single lapse in infection control at a hospital, a hidden pocket of infection missed by surveillance, smuggled animals, or the simple volume of international air travel. Given the propensity of the microbial world to undergo rapid change, new risks groups can emerge, modes of transmission can change, and treatments can fail if drug resistance develops.

As a third feature, outbreaks are usually alarming events that can elicit great anxiety in the general public. This anxiety can endure even when new knowledge about the outbreak is reassuring. A disease that spreads easily from person-to-person by the airborne route will be more frightening than a disease that requires close contact with an infected person or animal, as these behaviours can theoretically be avoided. Other features likely to amplify public concerns include high fatality in the absence of a vaccine or cure, a propensity to spread internationally, suspicions that a disease has been deliberately introduced, and an amplification of cases in health care facilities, thus diminishing response capacity when it is needed most.

Such public reactions give outbreaks a fourth shared feature: their high political profile. The extreme behaviours that can result are well documented and range from the wearing of masks and avoidance of travel, through fear of hospitals and stigmatization of patients and minority groups, to riots, loss of confidence in governments, and consumer avoidance of certain food items. Such public reactions give out-

6 Thomas Homer-Dixon: "Now comes the real danger", in: *Toronto Globe and Mail*, 12 September 2001.

breaks a fourth shared feature: their high political profile. When public anxiety, social disruption, and economic losses accompany an outbreak, it gains attention at government levels far higher – and more powerful – than public health. Such attention can be a major advantage when it brings full political commitment to outbreak control, supported by adequate resources. At the other extreme, outbreak control can be severely impeded when political authorities, motivated by economic rather than public health concerns, decide to withhold information about an outbreak, downplay its significance, or conceal it altogether. Political conditions can also shape the impact of an outbreak. Countries with a democratic tradition, in which politicians are elected and held accountable for their actions and the press enjoys full freedom, will be expected to issue reliable information about an outbreak, and retain public confidence. More authoritarian governments may be less forthcoming with public information but will have the political power to enforce public compliance with control measures and can thus bring an outbreak under control with impressive speed, albeit frequently without regard for public sentiment or human rights.

All of these features working together give outbreaks yet another shared characteristic: they are nearly always newsworthy events closely followed by the national if not the international press. On the positive side, media coverage can be used effectively, especially near the start of an outbreak, to keep the general public informed and communicate recommended protective measures. Unfortunately, media coverage often fuels public alarm and intensifies the associated economic losses. As one recent example, reports in several European countries of H₅N₁ avian influenza in a small number of wild birds brought immediate drops in poultry consumption of 30 per cent and higher. In France, confirmation of H₅N₁ infection in a single commercial farm cost the poultry industry an estimated US \$ 48 million within a month.

In industrialized countries, an event such as an influenza pandemic, where supplies of vaccines and antiviral drugs are clearly insufficient, has the capacity to destabilize populations, especially when life-saving interventions are made available to only a select few groups. This capacity helps explain why avian influenza and the prospects of another pandemic have been so widely discussed as issues important to national security and foreign affairs. All the implications of the intrusion of public health within the security arena still need to be understood and taken into ac-

count to ensure proper coordination between the two sectors.

While neither the timing nor the severity of the next pandemic can be predicted, history shows that these events consistently bring an explosive surge in the number of illnesses and deaths sufficient to temporarily paralyse public services and economic productivity (WHO 2005). Another consequence will be increased absenteeism in all sectors of the labour force, with capacity temporarily reduced in such essential public services as health care, law enforcement, transportation, utilities, and telecommunications. As SARS so amply demonstrated, a new disease with the right features can have a devastating effect on economic activity in some of the world's most sophisticated cities. Conservative estimates indicate that SARS caused economic losses in Asia alone of around US \$ 30 billion. In November 2005, the World Bank estimated that an influenza pandemic could cost the world economy US \$ 800 billion within a year; these losses would largely arise from the uncoordinated efforts of the public to avoid infection. SARS and pandemic influenza are, however, exceptional diseases. In industrialized countries, outbreaks of the more common infectious diseases are always costly but rarely qualify as socially disruptive.

In developing countries, where economies are fragile and infrastructures weak, outbreaks and epidemics are far more directly and frequently disruptive. In these countries, the destabilizing effect of high-mortality endemic diseases, including malaria and tuberculosis as well as AIDS, is amplified by emerging and epidemic-prone diseases, as they disrupt routine control programs and health services, often for extended periods, due to the extraordinary resources and logistics required for their control (Kindhauser 2003).

For example, outbreaks of epidemic meningitis, which regularly occur in the African 'meningitis belt,' disrupt normal social functions and bring routine health services to the brink of a standstill as containment depends on the emergency vaccination of all populations at risk (Kindhauser 2003). During the recent SARS outbreak in China, programmes for childhood immunization, AIDS, and tuberculosis were halted for months as all staff and resources were diverted to SARS control. The resurgence of African sleeping sickness, which is also a disease of livestock, has disrupted productive patterns of land use and jeopardized food security in remote rural areas (Kindhauser 2003). Recent outbreaks of dengue in Latin America required the assistance of military forces,

sometimes from neighbouring countries, for their containment. The response to the 2005 outbreak of Marburg haemorrhagic fever in Angola likewise drew support from military forces.

Outbreaks of new or unusual diseases can cause public panic to a degree that calls into question government's capacity to protect its population, as happened when the Nipah virus encephalitis began killing pig farmers in Malaysia in 1999. As another example, management of the SARS outbreak jeopardized political careers in several countries. In addition, the dramatic interruption of trade, travel, and tourism that can follow news of an outbreak places a further economic burden on impoverished countries with little capacity to absorb such shocks (Cash/Narasimham 2002).

37.6 New Tools: Real-time Disease Intelligence

In 1995, the Democratic Republic of the Congo experienced its second highly fatal outbreak of Ebola haemorrhagic fever, this time in Kikwit. That outbreak, which smouldered undetected for three months, caught the international community by surprise and demonstrated the urgent need to improve outbreak alert and response capacity in several specific ways (Heymann/Barakamfitiye/Szezeniowski 1999). It underscored the need for stronger infectious disease surveillance and control worldwide, for better international preparedness, and for new and faster systems for gathering disease intelligence at the international level and arranging the logistics of emergency response. It also underscored the need to accommodate the demands of the press and the public for authoritative and continuous information. A need for more broad-based international health regulations, and for electronic information systems connecting all parts of WHO, became evident, as did the realization that timely and adequate outbreak detection and response required coordinated support from a broad coalition of partners. The urgency of the situation was formally acknowledged in May 1995, when the World Health Assembly, in its first resolution on emerging infections, asked WHO to draw up plans and strategies for improving world capacity to recognize and respond to new diseases (WHO 1995).

In 1996, WHO began building up an operational system, supported by a 'virtual' architecture, for meeting these needs. Earlier detection of outbreaks was of utmost importance. To expedite the gathering of epi-

demio intelligence, WHO introduced the *Global Public Health Intelligence Network* (GPHIN) in 1997.⁷ This powerful new tool, developed and maintained for WHO by Health Canada, is a customized search engine that continuously scans open web sites, in six languages, for rumours and reports of suspicious disease events. GPHIN operates as a sensitive real-time early warning system by systematically searching for key words in over 950 news feeds and electronic discussion groups around the world. Human review and computerized text mining are used to filter, organize and classify the more than 18,000 items it picks up every day, of which around 200 merit further analysis by WHO. Apart from its comprehensive and systematic search capacity, GPHIN brought great gains in time over traditional systems in which an alert is sounded only after case reports at the local level progressively filter to the national level and are then notified to WHO (Public Health Agency of Canada/GPHIN 2004; Mawudeku/Lemay/Werker/Andraghetti/St. John 2007).

To broaden international capacity and share the burden of outbreak response, the *Global Outbreak Alert and Response Network* (GOARN) was set up in early 2000 to ensure that a 'strike force' of specialized staff and technical resources could be rapidly assembled and deployed for emergency investigations and on-the-spot assistance. This overarching network currently interlinks, in real time, 120 existing networks and institutes which together possess much of the data, laboratory capacity, specialized skills, and experienced personnel needed to keep the level of international preparedness high. As GOARN partners have a broad geographical base and many have staff within countries frequently affected by outbreaks, this network formally complements GPHIN's 'artificial intelligence' as a first-hand human source of early information about outbreaks (Heymann/Rodier 2001).

The establishment of GOARN solved many longstanding problems. First, by drawing on the resources and expertise of a broad range of technical partners, the network obviated the need - with all its associated expenses - to maintain a permanent staff of dedicated experts in the face of a danger that emerges only sporadically and unpredictably. Second, as outbreaks present widely varying demands for their control, GOARN brought much-needed flexibility and a surge capacity that could be tailored to outbreak needs. The network has a light 'virtual' operational structure,

7 D. Balkisoon: "Canada begins global inspection for infection", in: *Capital News*, 12 March 1999.

overseen by a steering committee outside WHO, and has been kept free of heavy administrative or bureaucratic procedures. The establishment of GOARN also helped ensure that experts from any single country would have frequent opportunities, during international responses, to exercise and sharpen their technical skills. Finally, GOARN introduced a formal mechanism for balancing national and international strategic interests, particularly when the response to an outbreak in one country has implications for the international community at large.

A new system of electronic communications was also set up to make better use of a unique geographical and strategic resource: WHO's 141 country offices, concentrated in the developing world and located within or in close proximity to ministries of health. Although the size of these offices varies according to the disease situation in the country concerned, all offices are staffed with medical experts and often with epidemiologists, and all have the essential logistic equipment, including vehicles and local communications, needed for prompt on-the-scene investigation of outbreaks. During outbreak response, these offices facilitate the arrival of international staff by arranging flights, customs and immigration clearance, and accommodations. By electronically interlinking these offices, WHO added yet another channel for feeding in rapid news about unusual disease events within countries, and allowing those countries to tap the resources of GOARN.

With all these systems bringing in abundant rumours, WHO simultaneously introduced a novel approach for the systematic verification of outbreaks, with the goal of rapidly determining which rumoured outbreaks were of genuine international concern, and then translating the results into action-oriented information for electronic transmission to partners (Grein/Kamara/Rodier/Plant/Bovier/Ryan/Ohyama/Heymann 2000). Procedures for outbreak verification rely on an initial assessment that uses standard epidemiological criteria to determine whether an event meets the definition of an outbreak, and additional criteria, developed by WHO, to determine its international significance. These criteria include unexpectedly high rates of illness and death for a particular geographical area or season, potential for spread beyond national borders, interference with international travel or trade, likely need for international assistance to contain the event, and possible accidental or deliberate release of a pathogen. Once an event has been determined to have potential international importance, the process of verification is initiated. This process relies

on confirmation of details from national health authorities, usually through the WHO country office, and from GOARN partners present in the field. For rapid diagnostic confirmation, especially of unusual or highly pathogenic agents, WHO relies on its network of collaborating laboratories, many of which are specialized in the diagnosis of specific diseases or groups of diseases. An evaluation of the effectiveness of this new system of outbreak verification was conducted after two years and revealed that sources other than official government notifications were by far the most frequent origin of initial information about outbreaks in all geographical areas and for all diseases (Grein/Kamara/Rodier/Plant/Bovier/Ryan/Ohyama/Heymann 2000)

To facilitate the coordination of large-scale international assistance, often involving many agencies from many nations, operational protocols were developed setting out standardized procedures for the alert and verification process, communications, coordination of the response, emergency evacuation, research, evaluation, monitoring, and relations with the media (WHO 2000; 2000a). Other guidelines provide a code of conduct governing the behaviour of foreign nationals during and after field operations in the host country. By setting out a chain of command and executing the containment response in an orderly way, these protocols help protect against the very real risk that samples of a lethal pathogen might be collected – under the often hectic conditions that surround an outbreak – and used for bioterrorist purposes. All of these developments became the driving force for initiating a sweeping revision of the International Health Regulations, which govern international procedures for the reporting of epidemic-prone diseases and the application of measures to prevent their spread (WHO 2002a).

37.7 Tools Refined in Practice

Mechanisms for outbreak detection and response were refined as WHO responded to other infectious disease emergencies or strengthened vigilance for especially worrisome diseases. In 1996, the so-called 'meningitis belt', a group of 18 semi-arid African countries that stretch across the bulge of the continent from Ethiopia in the east to Senegal in the west, experienced the largest recorded outbreak of epidemic meningococcal disease in history (Kindhauser 2003). More than 200,000 cases and 20,000 deaths occurred. Neither countries nor the international com-

munity nor the manufacturers of vaccines and other supplies could cope with the scale of the crisis. The emergency response fully exhausted international vaccine supplies and drew attention to the need to be prepared for future outbreaks on a similar scale. In January 1997, WHO established the *International Coordinating Group on Vaccine Provision for Epidemic Meningitis* (ICG) in partnership with UNICEF, the International Federation of Red Cross and Red Crescent Societies, Médecins Sans Frontières, other agencies, ministries of health in affected nations, and the major vaccine manufacturers and drug suppliers. The ICG worked quickly to replenish vaccine stocks and ensure that these were pre-positioned in countries at greatest risk. To date, more than 20 million doses of meningococcal vaccine have been channelled through the ICG mechanism. It has also accelerated improvements in the surveillance system, as the prospect of assistance is a compelling incentive for countries to report cases (Kindhauser 2003).

The dramatic recent resurgence of yellow fever, especially in West Africa, resulted in similar problems with vaccine supply. The seriousness of the problem became apparent during a yellow fever epidemic that began in 2000 in Guinea, where no routine or catch-up vaccination campaigns had been conducted since the end of the 1950's. Vaccine shortage delayed mass immunization in some areas until four weeks after the epidemic's peak. This situation prompted the ICG to establish a similar mechanism for the stockpiling of 2 million doses of yellow fever vaccine, with priority distribution reserved for outbreaks as opposed to routine immunization. As for epidemic meningitis, this mechanism has left the international community better prepared and better equipped to cope with emergency situations. Even so, the present level of preparedness may not be adequate. For example, in 2001, the first outbreak of urban yellow fever in Africa in 10 years occurred in Abidjan, Côte d'Ivoire, necessitating the emergency vaccination of 2.9 million persons in less than two weeks. Although vaccine reserves were again depleted, the emergency response averted an estimated 30,000 deaths (Kindhauser 2003).

The WHO Global Influenza Surveillance Network, the oldest disease-specific surveillance system at WHO, has also expanded its functions in line with recent public health emergencies. The network, which presently unites 110 laboratories in 84 countries, keeps watch over constant changes in the genetic composition of circulating influenza viruses, which are highly unstable. Apart from guiding the twice-yearly composition of influenza vaccines, as recommended by

WHO for the northern and southern hemispheres, the network operates as an early warning system, keeping the world alert to the emergence of influenza variants and novel strains, including those that might herald the start of a new influenza pandemic. The network was put to the test in 1997, when the highly pathogenic H5N1 avian influenza strain, previously thought to infect only birds and pigs, crossed the species barrier to infect humans, causing 18 cases and 6 deaths in Hong Kong. In the current outbreak of H5N1 avian influenza in Asia, which has already caused more than 100 cases, laboratories in the network are again playing an instrumental role in providing diagnostic support to affected countries and performing the essential 'detective work', at the molecular level, needed to understand the origins of the outbreak and interpret its significance for public health (WHO 2005).

All of these new mechanisms, networks, and procedures were put to the test – under extremely challenging conditions – when severe acute respiratory syndrome began spreading internationally in early 2003. Like the 1995 Ebola outbreak in the Democratic Republic of the Congo, which took the world by surprise. SARS was also a surprise, but the international community was far better prepared to respond. The response to SARS also tested an assumption of fundamental importance to public health: all these safeguards, working at their best, might be able to prevent a new disease from establishing endemicity, and thus spare the world untold suffering and expense. From the outset, this was the goal pursued by WHO in coordinating the activities of many partners. Although the emergence of SARS went undetected and then unreported at the national level, international mechanisms for outbreak alert and response performed well (Heymann/Rodier 2004). The spread of a severe new disease along the routes of international air travel was promptly detected and immediately brought to worldwide attention through two global alerts. The international response worked on two main fronts to manage cases and interrupt transmission at the main outbreak sites, and to seal off opportunities for further international spread.

The possibility of stopping SARS 'dead in its tracks' brought all-out support at levels ranging from heads of state to community volunteers, and in forms ranging from reverse transcriptase PCR assays of virus isolates to mass distribution of thermometers. The interruption of all known chains of transmission was accomplished less than four months later, largely through the use of 19th century public health measures

and 21st century communications tools (Heymann/Rodier 2004). As telling evidence of the importance of accrued experience, the ability to recommend these public health measures, with technical confidence in their efficacy, drew largely on international experience using case detection, isolation, and infection control to contain Ebola outbreaks.

37.8 Revised International Health Regulations: Faster, Stronger, Broader

In May 2005, the 192 member states of WHO unanimously adopted a significantly revised and modernized version of the *International Health Regulations*, which constitute the only legal framework governing the reporting of outbreaks and prevention of their international spread (WHO 2005a). Revisions in the regulations respond to several problems identified by WHO, its GOARN partners, and national authorities during outbreak responses. First, the scope of the previous regulations, in legal force since 1969, was far too narrow, confined as it was to only three diseases: cholera, plague, and yellow fever. The revised regulations recognize that the infectious disease threat has grown in terms of both the number of diseases that need to be watched very closely and the risk that more new diseases will emerge. Scope has been expanded accordingly, and now encompasses all public health emergencies of international concern, including those caused by chemical agents and radio-nuclear materials. Second, reporting requirements and timeframes have been tightened, reflecting the heightened sense of urgency and the greater speed allowed by electronic communications. Third, procedures have been put in place to compensate for weak detection and response capacities in many countries. The kinds of support offered by GOARN response teams are fully recognized. The regulations further acknowledge that strengthened national capacities are the best solution, as they aim to detect and stop an outbreak at the source; core capacity requirements for surveillance and response in individual countries are set out in an annex. The regulations also recognize that media reports may pre-empt official notification of an event, and include provisions for WHO actions in such a situation. Finally, by assigning responsibilities and establishing internationally agreed rules and procedures, the regulations can exert pressure on nations that fail to comply.

37.9 Strengthened Defences, Formidable Foes

Public health emergencies throw into sharp relief the strengths and weaknesses of infrastructures for protecting the public on a daily basis. The outbreaks experienced so far in the early years of the 21st century have underscored the capacity of the microbial world to deliver lethal and disruptive surprises, raising the profile of public health in the eyes of politicians and the public. The anthrax incident, by turning the unthinkable prospect of bioterrorism into a reality, made outbreaks a high-profile security concern (Heymann 2003). SARS vividly demonstrated the far-reaching social and economic costs of a new disease that spread along the routes of international air travel (Heymann/Rodier 2004). These consequences will be far more dramatic when the next influenza pandemic arrives. Ironically, the certainty of a pandemic's direct impact on national security has diminished the prospect of international collaboration that was the hallmark of the SARS response. When every nation is directly threatened by a disease, defence strategies turn distinctly towards national self-interests, especially when essential medical interventions for reducing morbidity and mortality are available in grossly inadequate quantities. Public health, chronically short of resources in even the wealthiest countries, cannot be asked to shoulder the full burden of responsibility for defending the world against diseases that have such severe implications for national and international security.

Nonetheless, few would question that recently developed infrastructures and mechanisms have strengthened collective defences and have performed well under the demanding conditions - particularly favourable to the international spread of diseases - of the 21st century. Adoption of the strengthened International Health Regulations has established the legal framework for increased global security against the threat of emerging and epidemic-prone diseases. GPHIN brings in the intelligence, systematically screening rumours for the first alerts to an outbreak. From January to March 2005, 40 per cent of the initial alerts to outbreaks, subsequently investigated by WHO, came from the media and other non-official sources. GOARN provides the operational mechanism for deploying a strike force when international assistance is needed. From 1 May 2002 to 31 March 2005, WHO detected and verified 760 outbreaks of potential international concern in collaboration with 138 affected countries. International assistance was re-

quested for more than 70 of these events. For more than 50, international teams were deployed to provide on-the-ground support using expertise from WHO and its GOARN partners.

Every outbreak presents a unique set of problems that have to be solved, innovatively and quickly, under emergency conditions. Each outbreak of international concern leaves WHO and its partners with more experience and more technical innovations to draw on when the next event inevitably occurs. For example, experts in medical anthropology were first used during an Ebola outbreak in 2003 to introduce community behaviours conducive to outbreak control. These experts are now a standard part of international teams deployed to control viral haemorrhagic fevers in Africa. The technique of mathematical modelling, first used during the SARS outbreaks, is now a strong component of pandemic influenza risk assessment, forecasting, and testing of strategies for delaying international spread. Risk communication to the public was introduced during the SARS outbreak as a strategy for mitigating the excessive social and economic consequences attributed to an anxious public. It is being used again, now supported by new guidelines, as part of preparedness for the next influenza pandemic.

While these mechanisms and accrued experiences have strengthened the world's collective defences against the infectious disease threat, they cannot provide full protection as long as national capacities to detect outbreaks remain weak. The world's largest and deadliest outbreak of the rare Marburg haemorrhagic fever, which occurred in Angola in early 2005, smouldered undetected for months. Tragically, the outbreak came to the attention of public health officials only after iatrogenic infection in a paediatric ward led to a sudden surge in cases of severe illness and deaths in children hospitalized for other conditions. As is often the case in developing countries, detection of the outbreak at its start was delayed by the large number of other severe infectious diseases that commonly kill young children. On the positive side, the speed and intensity of the international response to this outbreak, including rapid funding of activities and support from more than 100 international staff drawn from GOARN institutions, underscore heightened concern about emerging diseases and illustrate the resources this concern can generate in an emergency situation – even when the threat of international spread and economic disruption is far less than that posed by diseases such as SARS and pandemic influenza or the prospect of a bioterrorist attack (Ndayimirije/Kindhauser 2005).

37.10 Conclusions and Remaining Needs

To make the world more secure against the threat of emerging and epidemic-prone diseases, several activities need to be undertaken. *First*, mechanisms for using international teams to stop an outbreak have proven their effectiveness. Their value as a defence strategy must not, however, be overestimated. Such mechanisms are, at best, a 'fail-safe' operation, specifically compensating for failures to detect and contain an outbreak locally, thus quelling spread at the source. This reality, brought into focus by the revised *International Health Regulations*, has sparked a special WHO effort to strengthen outbreak detection and response capacity in epidemic-prone developing countries. Nor should the success of the SARS response create a false sense of security that WHO teams will always be able to stop new diseases "dead in their tracks". The spread of pandemic influenza to all corners of the world might be delayed somewhat, but never stopped (WHO 2005).

Second, more needs to be done to protect the world against the risk of outbreaks arising from laboratory accidents. This risk has been vividly illustrated by laboratory accidents resulting in SARS infections, some of which were fatal, in Singapore, Taiwan (China), and mainland China, and by the accidental distribution of an influenza virus, responsible for the 1957 pandemic, in test kits sent to hundreds of laboratories around the world.

Finally, when outbreaks and epidemic-prone diseases are regarded as direct threats to national and international security, defence strategies should become a priority for political leaders and government sectors, including finance, trade, and defence, that rank higher than public health and command far more resources. Trends witnessed during the first years of the 21st century are certain to continue, if not intensify. Investment in improved public health infrastructure is the best strategy for defence against this persisting threat. But unlike the response to individual outbreaks, which aims to quickly end an emergency, this investment will need to be ongoing. The threat posed by emerging and epidemic-prone diseases – and the risk to national and international security – cannot be stopped 'dead in its tracks'.

38 Health and Human Security in the 21st Century

Jennifer Leaning

38.1 Introduction¹

Security is a most important concept to human beings and can be seen as applying at the level of the family, the community, the nation-state, the region, and the entire world. Historically, the notion of ‘national security’, founded on military capacity and political projection of the self-interest of the nation-state, has dominated policy discussions of this concept since the end of World War II. In the last half-century, however, worldwide social, economic, political, and environmental changes have forced the recognition that many other elements play into what makes human beings in families, communities, and nations feel secure. These other elements have been approached in policy discussions through more recent conceptualizations of human security and health security.

It is argued here that profound and dramatic accelerations in these global changes over this next century will require vigorous attention to these issues of human and health security (38.2) (CHS 2003; Chen/Leaning/Narasimhan 2003). The overarching framework of human security is advanced as encompassing within it the more specific health and health system elements of what the medical and public health community usually consider to be ‘health security’ (38.3 and 38.4). It is further argued that the newly introduced term of health security, focused on response to international threats of bioterrorism and pandemic disease, is the international enhancement of the traditional concept of ‘national security’, in that the resources of the state (now the international community of states) are marshalled to protect its (their) citizens against external threats (38.4, also chap 37 by Rodier/Kindhauser). A strategy aimed solely at these dangers, however, does not suffice. The weight of evidence regarding near-term risks to human societies suggests

that the 21st century harbours far more disruptive and widespread threats to our individual and collective wellbeing. The concluding sections assess the relevance of the human security framework for addressing these global threats (38.5 and 38.6). This assessment suggests that it will require a most robust and creative application of this framework, on a scale that could only be described as a truly comprehensive international security strategy, to withstand what lies ahead and not lose what we have collectively achieved so far.

38.2 Major Global Issues

The major issues of this century that have particular bearing on human and health security are:

- the underlying dynamics of globalization;
- demographic change (chap. 12 by Lutz);
- environmental change, especially global warming (see preface essay/foreword by Pachauri; chap. 4–7 by Brauch; Kinnas; Bluemel; Issar/Zohar)
- growing disparities between the rich and the poor; and
- migration, especially forced migration from war or desperate economic circumstances (chap. 19 by Ahmed).

38.2.1 Globalization

The chief characteristics of globalization are accelerated trans-national movements of people, ideas, and trade (Held/McGrew/Goldblatt/Parraton 1999; Held/McGrew 2007). These trends are all enhanced and supported by extraordinary advances in information technology (Castells 1996/2000, 1997/2004, 1998/2000). The positive impacts appear as expansions in communication and access to knowledge, which in turn have supported a profusion of diverse social networks variously linked to diffusion of a common culture drawn from myriad sources; the rapid growth in economies that have linked to international

1 The author would like to thank Nicholas Rizzo for his contribution as research assistant to the preparation of this chapter.

Figure 38.1: Population of the World 1950-2050 according to different projection variants. **Source:** Created by the author based on data from: United Nations Population Division, World Population Prospects: The 2006 Revision Population Database. <<http://esa.un.org/unpp/>>.

trade networks and multinational corporations; and the development of international civil society (Kaldor/Anheier/Glasius, 2003). This last development in particular has spurred the elaboration and adoption of important international norms of international law and human rights and raised expectations regarding the reach and responsibility of international institutions.

The negative impacts of globalization have intensified underlying social vulnerabilities and accelerated unwanted trends (Speth 2003; Scholte 2005). Travel, crowding, and interacting proximities now create increasing potential to expose human and animal populations to new, emerging, and re-emerging diseases. Explosive corporate growth in industry and technology can undermine local political authorities and social diversity, hasten environmental degradation, and raise the risk of accidents involving hazardous and deadly materials.

38.2.2 Demographic Change

Demographic changes in the 21st century are projected to have two distinctly different patterns of impact, one on poor countries, who will witness growth, and one on rich countries, who will witness aging. These changes entail a projected stabilization in population growth worldwide to an estimated plateau of 9-12 billion people worldwide by 2050 (UN 2001, 2003, 2005a, 2007; figure 38.1).

Between 2005 and 2030, the population is expected to grow to at least 8.2 billion worldwide. Of this growth, over 90 per cent will be in the less developed regions of the world; and of that growth, 97 per cent will be in already dense urban settlements (UN 2000a, 2002, 2004, 2006a; figure 38.2).

Population growth for the poor countries of the world over this century means intense strain on natural resources, marked escalation in current crises of urban water, sanitation, and other essential services, and enormous physical crowding in vast slum perimeters of current cities of the south. Population change for the rich countries in this same timeframe brings a minimum net growth but marked shift in population age structure, whereby at the end of this century most countries in Europe, as well as China and Japan, will have over 30 per cent of their population over 60 years old (UN 2007a). Predictions for the United States vary depending upon projections in immigration policy and the same could be said for Europe, if the pressing need for an increased young labour force were to cause an easing in current controls on immigration (Lee/Haaga 2002: 5).

38.2.3 Global Environmental Change and Global Warming

Global environmental change, particularly if the trends predicted in global warming go unchecked, will have devastating effects on many human, plant,

Figure 38.2: Urban and rural population of the world, 1950-2030. **Source:** Created by the author based on data from: United Nations Population Division, World Urbanization Prospects: The 2007 Revision Population Database. <<http://esa.un.org/unup/index.asp>>.

and animal populations by the end of this century (Munn 2002, vol. 1-5). Rising sea levels, drought, extreme weather conditions, and floods spell grave loss of inland habitat and coastline, threatening all living creatures with major disruptions in life supports and livelihoods. Independent of global warming, projected current patterns of human interaction with the environment pose serious risks to human welfare throughout the world (Crutzen/Stoermer 2000; Crutzen 2002; Clark/Crutzen/Schellnhuber 2005): encroachment on supplies of fresh water; pollution and contamination of air, water, and land; loss of forest cover; erosion of agricultural terrain; and progressive desertification (MA 2005; Adeel/Bogardi/Brauel/Chasek/Niamir-Fulleer/Gabriels/King/Knabe/Kowsar/Salem/Schaaf/Shepherd/Thomas 2006).

38.2.4 Growing Disparities Between the Rich and the Poor

In 1998, on the occasion of receiving an honorary doctorate at Harvard University, Nelson Mandela stated his belief that the major issue facing the 21st century would be the growing worldwide disparity between the rich and the poor.² This disparity is closely

tied to the three major factors of globalization, environmental change, and demographic trends, all of which, unless modified by a human security framework, will accentuate the gap between the developing and the developed world. The 2006 UN Human Development report places 31 nations in the index category for Low Human Development; 28 of these countries are in Sub-Saharan Africa (UNDP 2006). The same report provides sufficient information to indicate that the observed HDI gap in 1980 has only somewhat improved by 2004 (figure 38.3). According to the latest estimates, over 15 per cent of the world's population live on less than one dollar per day, while more than 40 per cent of the world's population live on less than 2 dollars per day³ (Chen/Ravallion 2007). Statistics abound with which to elaborate upon this picture.

2 This address by President Nelson Mandela of 18 September 1998 can be found at: <<http://www.anc.org.za/ancdocs/history/mandela/1998/nm0918.htm>>.

3 The paper cited as Chen/Ravallion 2007 records the percentage of the population living under \$1 per day as 18.09 per cent and the percentage of the population living under \$2 per day as 47.55 per cent. However, these percentages are based on the population of the less developed world. Therefore, the statistics given above were calculated by the author using the 2004 estimates for the world population from the World Bank; total number of people living in aforementioned conditions divided by total population yielded the percentages given above.

Figure 38.3: Growing Disparities between the Rich and the Poor. **Source:** Based on data from: UNDP (2006: 288-290). In 1980 data were available on fewer countries than in 2004.

Despite some good efforts undertaken in discontinuous steps over the last few decades, as a world community we have lost ground in Africa, made mixed headway in Asia, and probably stabilized most countries of Latin America. The averages belie the misery, however. A significant fraction of the world's population live in desperately poor areas of Africa and Asia, have seen their standard of living and possibilities for the future continue to decline over recent decades (Collier 2007: 3-13), and now stand to experience the greatest increase in population projected over this next century (Population Reference Bureau 2006: 5). If current trends continue, these large populations of very poor people will become increasingly impoverished and increasingly more numerous.

38.2.5 Forced and Distress Migration

Forced migration is the term used to describe population flight from war and disaster. Desperate economic migrants could reasonably be included in this category. However they are classified, the numbers of people who are seeking entry to the perceived safe havens of this world, the West and the North, are very large and growing every year. Many studies have identified the range of options and consequences this phenomenon presents to developed societies, including disruptions of social ecology, challenges to economic relationships, and injection of increasingly diverse political and cultural discourses (Weiner/Russell 2001).

38.3 Human Security

Human security, as an idea and an aspiration, is grounded on a view of the world that centres on people rather than nation-states. The exploration of this idea can be seen in the 1982 Palme Report, *Common*

Security, where international preoccupation with the nuclear arms race was countered with the argument that peace rested in the minds and aspirations of people, not sovereign leaders (Independent Commission on Disarmament and Security Issues 1982). The discussion of human security culminated in the international effort that produced the Human Security report of 2003. A range of socio-economic and civic concerns animates this report, leading to the basic point that the world's security lies not in accumulation of arms or elaboration of international political arrangements but rather in strengthening the foundations that make people healthy and comfortable within their own communities and regions.

The concept of human security invoked here is based on the recognition that human beings share common psycho-social needs of identity, recognition, participation, and autonomy (Amoo 1997). These human needs obtain regardless of economic status or political stability but can best be assessed when absolute minimum requirements for food, shelter, water, and security from grave assault have been met. This concept was developed as an analytic guide to agencies engaged in post-conflict settlement and recovery activities but its components can be seen to apply to the dynamics of communities and societies in a wide range of situations (Leaning/Arie 2001).

The three main components of this concept of human security involve a sense of home, a link to community, and a positive sense of the future, or a sense of hope. Human beings hold strong attachments to place, often laced with memories of physical sensations (a hill in distant view, the tree by the road, domestic scents or sounds, a night sky). A large part of being home, however, means being together with one's family. The presence and strength of close family bonds establishes home, or at least essential ele-

ments of home, for many people who have been forced to leave their geographic homeland.

Links to community include all those relationships that are based on extended kinship or secure economic and social interactions with familiar places, people, markets, schools, and civic institutions. Levels of predictability, reliability, and trust are embedded in these relationships. Large and small transactions, of diverse social and economic import, take place on the basis of these relationships. Shoes are left to be mended; money is exchanged for food; marriages can be arranged; loans are made and repaid; deeds and wills negotiated and copies safely deposited in collective systems of records.

A positive sense of the future has great bearing on whether a person is willing to believe that the future will, in fact, arrive and that efforts expended in the present moment will have impact at some future date. This sense defines a stance towards investment and risk that is ultimately hopeful. A positive sense of the future will promote investment in education, saving seed for the next harvest, letting one plot of land lie fallow for greater harvest in two years, reluctance to engage in short-term behaviours that carry high negative risks.

38.4 Health Security

38.4.1 Health Security: An Issue of International, National and Human Security

Within the medical and public health communities, the concept of 'health security' has long been used to describe the cumulative effect of many different efforts undertaken to ensure the health of a given population or target group (Chen/Leaning/Narasimhan 2003; Chen/Narasimhan 2003: 183-194). In recent years, since the U.S. terrorist events of 9-11 and ensuing anthrax deaths, and then the SARS epidemic and outbreaks of avian influenza, the term health security has been applied to a very particular set of international and national strategies designed to prepare and respond to biological, chemical, and nuclear threats from terrorism and the threat of pandemic influenza.

The Global Health Security Initiative, established in November, 2001, brings together Canada, the UK, the U.S., the European Commission, France, Germany, Italy, Japan, and Mexico to plan coordinated activities in this context.⁴ The World Health Organization serves as the technical advisor to this initiative

and has recently established its own platform for promoting what it terms international health security (WHO 2007; chap. 37 by Rodier/Kindhauser).

These two concepts of health security are very different. The first one, aimed at improving health of individuals and populations through time, rests easily within the larger humanist dimensions of human security. It is people-centered, development oriented, and tied to more broad-scale initiatives that seek to improve the human condition. The second concept, focused on planning to respond to terrorist events using weapons of mass destruction and to mass epidemic disease, particularly pandemic flu, has a tight focus on international and national security that harkens back to the nation-state perspective on world stability and peace that the Palme Report sought to counter.

38.4.2 Health Security from a Human Security Perspective

In the discussion that follows, the emphasis will be on the first concept of health security, the one familiar to medical and public health professionals throughout the world. They may not all use the term but they would understand the meaning - that the health of people rests on policies and programmes that protect populations from harm and promote well-being throughout their life span. The second concept will be invoked in the context of addressing global trends, including the threat of pandemic flu and proliferation of armed conflict.

Health security, in its more traditional sense, can be seen as a subset of human security and as an essential attribute of each of its three elements of home, community, and positive sense of the future. The concept of health, as used here, is an attribute of an individual, described as a state of physical and mental well-being. The WHO definition of health as "a complete state of physical, mental, and social well-being, and not merely the absence of disease or infirmity" (WHO 1948) has struck many engaged in the provision of health care as so visionary as to be elusive as a policy goal. Attaining even an absence of disease or infirmity is far out of reach for millions of people today and may well become even more difficult to attain in the years ahead. Further, the concept of health, as a state of well-being, is also seen to be derivative of many different inputs and processes, all depending upon choices and resources available at the level of in-

4 WHO: "Global Health Security Initiative", at: <www.ghsi.ca/english/index.asp>.

dividual, family, community and nation. Increasingly, as the global trends described above begin to impinge at the regional level, these factors will also prove pivotal to human health.

In this regard, it is argued that health security must be conceptualized within a larger framework of human security. Life is lived in relationships, with other humans and with the environment. Hippocrates had it at least partly right when he said that a physician who knew of the air, water, and wind in the area affecting his patients would know much about their health (Lloyd 1978: 148-149). In other words, health as a state of being is not a unitary, independent, concrete concept that is either present or absent, conferable or not. It is a state of being that can be developed and nurtured but never entirely controlled or predicted. It is not something obtained with fame or fortune; not something proclaimed through fiat; nor can it be won through war.

As a state of being that is diffusely permeable to and susceptible to externalities, health can only be reached in some larger context and framework. It is argued here that the elements of human security provide this larger framework. This argument can perhaps be appreciated most readily in its negative form. Without home, community, or a positive sense of the future, it is exceedingly unlikely that any person can attain a moderate state of physical and mental well-being.

38.4.3 Health Security Issues in the Developing World

Home provides the micro-environment for supports to the basics of individual health, in terms of food, shelter, water, protection from assault, and emotional nurturing and bonding. Many families on earth cannot maintain even this minimum micro-environment. Furthermore, from the perspective of family health, several of these inputs can only be provided at the village level. Yet villages in the developing world often lack accessible sources of safe drinking water, are comprised of people with undifferentiated and meagre skill sets, and lack roads or transport to markets and other services. Young children join the adults in a physical struggle to wrest fuel and sustenance from their surroundings. In many situations the villages are themselves stagnant sources of disease, illness, poor diets, and few options. If the larger towns at the district level lack adequately stocked and manned health posts and schools, the entire region suffers from neglect, underemployment, and high rates of infant mor-

tality from entirely preventable conditions (diarrhoeal illness, respiratory infection, malaria, measles, and parasites). Fully one out of every fifth baby born in these homes and villages of the developing world dies of these causes before he or she reaches the age of five years old. Women in these villages, weakened by anaemia, malnutrition, and sheer hard work, find child birth a life-threatening event. The main causes of maternal mortality (obstructed labour, haemorrhage, or infection) could be addressed with adequate secondary obstetrics at district level hospitals. Many regions in Africa and Asia do not have these services at the district level and so many women die. Maternal mortality ratios (maternal deaths per 100,000 adjusted live births) in the developed world (Norway, UK, US) are 16, 13, 17; in the developing world (Afghanistan, Niger, Chad) are 1,600, 1,100, 1,900 (UNDP 2006).

38.4.4 Health Security Issues in the Developed World

In developed societies (characterized by greater wealth, education, and decades if not centuries of stable improvements in infrastructure, systems, technology, and governance) the human security components of home and community have far greater potential to provide the complex inputs that are required to attain a moderate state of physical and mental well-being. Overall, this potential has been realized in these societies, as reflected in their much higher average health indices of infant mortality, maternal mortality, and life expectancy.

Health in the developed world relies upon and enjoys much tighter and more robust linkages between home and community that serve to create and integrate the many social and economic factors that contribute to the attainment of physical and mental well-being. Families in communities can rely on transport and road systems and technologically stable utility grids to provide safe water and reliable energy for electricity and fuel. Transport and road systems permit access to a wide variety of markets and goods and services, including healthcare facilities.

People in homes and in communities are enmeshed in regulations and monitoring processes that directly and indirectly protect and sustain health: environmental and health and safety regulations, food inspection and safety systems, traffic codes, and school and workplace health assessment and promotion programmes. Homes that fail to provide basic elements of physical and psychological care for their members

may get identified in community systems of surveillance and often community-based groups or individuals can fill some of the gaps that individual homes cannot meet. Aggregations of communities usually manage to make the financial and administrative arrangements for access to an expected array of adequate and appropriate primary care services and referrals to secondary and tertiary care when needed. Although these health care arrangements within and among developed countries vary dramatically in quality and scope, in general the kind of health care available at the community level in rich countries is very difficult to obtain except at best in some of the capital cities of the developing world.

38.4.5 Requirements for Achieving Health Security

All health systems require at the national level a network of law and policy that establishes the financial and administrative systems required to fund and maintain this very complex network of human resources, infrastructure, and technical and social operations. Rich countries have put in place the major components of this underlying law and policy network. Poor countries usually have never done so, or if they had at one time, these components have been destroyed in war or degraded by decades of neglect, poverty, corruption, and mismanagement.

A positive sense of the future is the third core element of human security. Its health security analogue has several aspects. The first is simply and fundamentally an expectation that one may live to old age. The second is that members of your family and your friends may also look forward to long life, so that as you go forward you will not be alone. The third is that these later years may be characterized by continued health and vigour, so that longer life is associated with sustained capacity for enjoyment and ongoing contribution to one's family, community, and society. Much of this multi-layered confidence in one's health future, so to speak, is based on habits, processes, and systems of care put in place when one was young. If you were the product of a full term birth, vaccinated, fed, sheltered, and loved during your early years, trained in healthy habits and educated enough to hold a job, if whenever necessary you found access to adequate health care to treat you when you were injured or ill, it is highly likely that you will reach late middle age in fine form. At that point a process of aging and chance appears to assert itself, in a manner that medical science still has not deciphered, and begins to exert

stronger force on one's prospects for old age and really old age (Olshansky/Carnes/Cassel 1993: 46-52).

38.4.6 Health Security and Social Welfare in North and South

It is also at this phase of your life that the final layer of health security must be in place for you to have full confidence in what remains of your future. This layer is a system of health care and social welfare that is organized and financed to support people through all phases of life and disability. Since older people consume a disproportionate share of health care expenditures, the developed world is now experiencing the increasingly heavy costs of caring for an aging population. The rich countries will soon be joined in this experience by the middle income countries of Asia and Latin America. After several decades of improvements in primary health care and vaccination campaigns, their health care burden has two peaks: the first a residually high but declining level of morbidity among infants and young adults, the decline now slowed by the effects of the HIV/AIDS epidemic; and the second at the other end of the demographic spectrum, where a growing number of people are surviving to reach old age. The situation remains different for the poorest countries of this world, which still have few people surviving into old age. (And those that do have few options for health care so the potential impact of these older people on the national burden of care is not yet being felt.)

38.4.7 Health Security Challenges of Aging Societies

A challenge to health security, for rich and middle income countries alike, is how to structure and pay for the health care costs and social needs of this growing section of their older population. Health care has rarely risen to the top of political agendas in any country at any time, except perhaps for Cuba, whose revolution has been defined and based on provision of health care to all its citizens (Flanz 2004; Hadad/Macintyre 2002: 445-461). Yet it could be argued that a positive sense of the future is pivotal in a society's overall stability and workforce engagement. From that perspective, as the productive members of the wealthier nations begin to confront the uncertainty in national and community arrangements for organizing and financing their later health and welfare needs, it is possible to envision growing tensions between age cohorts, increasing contestation over scarce goods,

and intensifying political debates at the highest level of the nation-state.

The collective challenge to health security, shared by all, is how to address the marked differential in health status and health care capacities between the poor countries and the rest of the world. In the ensuing decades it is certain that first world medicine and clinical science will continue to evolve and continue to bestow benefits on the people fortunate to live within the reach of these innovations. The task is to design and implement policies and services that will help the poorest countries build their own systems of care and raise the level of public health and clinical care for their own populations. Clearly this task has become more difficult with the expanding impact of the HIV/AIDS epidemic, although international attention and funds now attracted by this crisis have already begun to encourage a wider debate on the strategies for improving all forms of health care in these regions.

38.4.8 Priorities of Health Security in the Developing World

The major priorities continue to be reductions in infant and maternal mortality and combating the HIV/AIDS pandemic, malaria, and tuberculosis. The list of what is needed is moderately long and can be categorized by which branches of first world health care must focus on which needs:

Medical science: vaccines, new pharmaceuticals and therapeutic agents, rapid and/or more reliable diagnostic tests suitable for field conditions

Clinical medicine: professional education of students, physicians, nurses, and other health personnel, incentives to keep trained people in the region, and health systems capacity building, including improvements in medical schools, clinics, hospitals, and district level laboratory facilities

Public health: training and education of health professionals and government authorities in public health systems to support vaccination campaigns and routine vaccination of target populations, ongoing monitoring and surveillance of key disease and health indicators, malaria control, access to clean water, reduction in air, water, and ground pollution from all sources, and tobacco control.

The health security perspective has been given added empirical momentum by a recent body of work establishing that improvements in health lead to demonstrable improvements in economic indicators, at the level of national data sets (Bloom/Canning 2000:

1207–1209). The force of this finding is that directly targeting health strategies may prove to be one of the more effective means of encouraging social and economic development, from raising standards of literacy to reductions in unemployment. Although the linkage has not been made explicitly to the human security framework, this research indicates the close ties, in terms of policy and programme, between the two concepts of health security and human security.

38.5 Impact of Global Trends on Health and Human Security

Yet the scope and scale of these challenges to health and human security, grave as they are, do not begin to encompass the range and destructive force of the threats posed by the global trends that in the next fifty to 100 years are highly likely to alter fundamental dynamics of human settlement and stability (McMichael/Haines/Sloof/Klovats 1996; IPCC 2007a)⁵. These global trends, described at the outset of this chapter, will create sweeping hardship, dislocation, and risk to lives and livelihoods for many developed as well as developing societies. Furthermore, all populations, but particularly the most poor, will continue to suffer from the high human and social costs of war, internal conflict, pandemic disease, and major disaster. These crises may themselves increase in frequency and magnitude because of the global trends that exacerbate population pressure on resources and disrupt established weather and climate patterns.

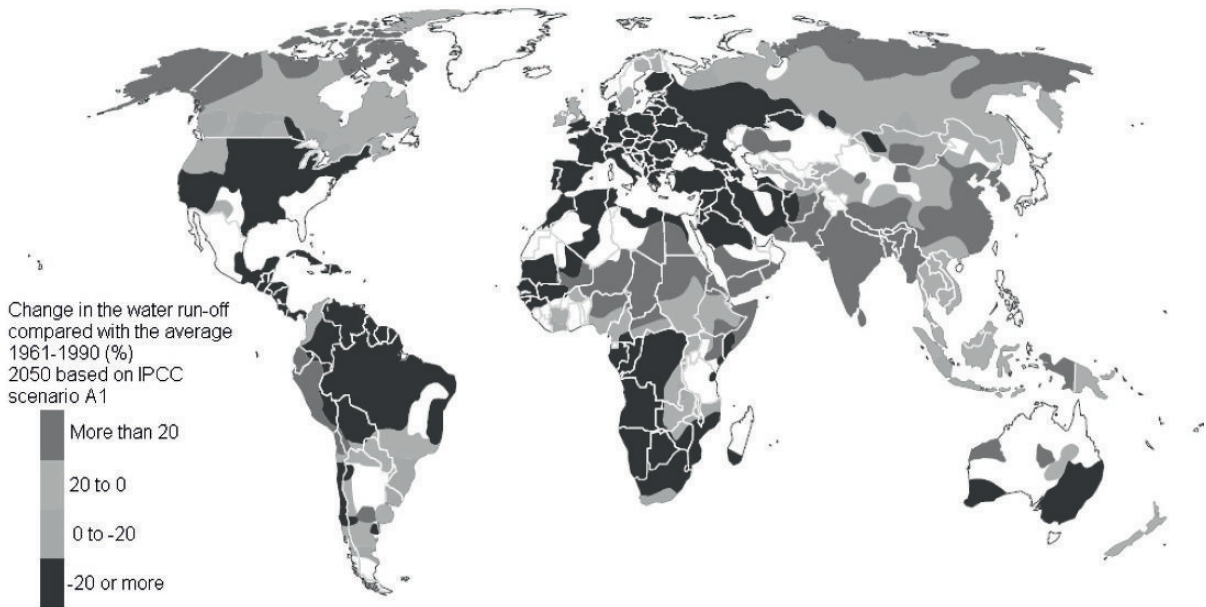

The impact of these trends on health and human security cannot be projected except in general terms, and even then much must remain speculative, given unknown interactions between and among predicted trends and social and political responses over the years ahead. A few major possible impacts merit brief mention here.

38.5.1 Accelerated Forced Migration

Several global trends, in particular climate change and population growth, will accelerate the frequency and magnitude of forced migration (Brauch 1997a, 1998, 2000/2001). When this migration occurs rapidly, as in natural disasters, or in great magnitude, as may be the case with population flight from sea-level rise, it

5 See for the debate and scientific assessments: IPCC 2007, 2007a, 2007b; McMichael/Haines/Sloof/Klovats 1996.

Figure 38.4: Change in water run-off compared with average 1961-1990 (%) for 2050 based on IPCC Scenario A1.
Source: UNDP (2006:162); at: <<http://www.hdr.undp.org>>.

can be expected to bring about significant increases in human morbidity and mortality (Reed/Keely 2001). Regional weather changes, such as increased heat waves, diminishing rainfall in drought-prone areas, and extreme wind and flood events will increase the numbers of people who episodically flee from disaster-stricken areas, will increase the annual death rate from such natural disasters, will expose increasing numbers of people to vector-borne disease threats, and will prompt longer-term migration away from terrain that can no longer support agriculture or animal husbandry (WHO 2007). This longer-term migration will undoubtedly arise only after more frequent and intense episodes of prolonged drought and famine for populations in these marginal zones.

Overall warming by the end of the century poses certain risks of rising sea levels that, depending upon the levels predicted, could jeopardize vast swathes of heavily populated areas on earth and cause forced migration from environmental threats on a scale never seen in recorded history. Hundreds of millions of people now living on low-lying Asian coastlines may be forced to move in relatively short time frames and may face very few options, given dense populations in their interior (Small/Gornitz/Cohen 2000). Entire Pacific island nations may be submerged, under projected levels of sea rise (chap. 7 by Kinnas).

38.5.2 Increased Potential for Armed Conflict

Contestation over dwindling shares of arable land and diminishing access to water sources may prove increasingly pivotal factors in promoting armed conflict, particularly in areas now already stressed by drought and over-population (figure 38.4).⁶ The number of people living below the water-stress threshold of 1,700 cubic meters per person per year, now 700 million world wide, is expected to grow to 3 billion over the next 20 years (UNDP 2006).

The literature on environmental causes of war suggests that usually good governance and economic development can mitigate potential struggle between groups over scarce water and land resources. However, this literature is based on historical examples and what lies ahead suggests on a global scale far more extreme conditions than populations have faced in the past. Current assessments suggest that regional and sub-regional conflict over water may pose a large threat in the Middle East and many parts of Asia, and that struggles for arable land and grazing rights will intensify across the Sahel and Horn of Africa (CNA 2007).

⁶ See the comprehensive debate with contributions by Homer-Dixon 1991, 1994, 1995b, 1996, 1999, 2000; Homer-Dixon/Blitt 1998; for recent reviews of the debate: Brauch 2003, 2005, 2009, 2008a; Dalby 2008.

Figure 38.5: International Tourist Arrivals (1950-2005). **Source:** Created by author based on data from: UNWTO (2006: Annex 3); at: <<http://www.worldtourism.org/facts/menu.html>>.

38.5.3 Greater Risk of Pandemic Disease

The number of people who travel each year as an underpinning of globalization also serves to transport and disseminate contagious disease on an ever increasing scale of risk (Wilson 1995: 39-46; figure 38.5).

Systems for tracking and containing disease transmission have developed rapidly since the SARS epidemic of 2003 but much still needs to be done to ensure that early warning and mitigating strategies are instituted in an effective time frame. Furthermore, projections of new disease entities, such as pandemic influenza or bird influenza, include the sobering recognition that no effective remedies now exist to prevent or treat these infections once they begin to move into human populations. Most analysts maintain that a major pandemic is very likely to occur in this century and are likely to have disproportionately heavy consequences for people in the developing world, who already suffer from malnutrition and lack access to minimum health care services (Murray/Lopez/Chin/Feehan/Hill 2007: 2211-2218). The health security apparatus that has been constructed, linking WHO and nations throughout the world, has the potential to institute the necessary systems for ascertainment but can only advise on how to organize the response at the national and sub-national level, relating to constraints on human behaviour, measures to contain spread through animal populations, and access to essential drugs and vaccines.

38.5.4 Greater Burden of Social Distress

Driven by global trends, these impacts of forced migration, war, and disease will only augment endemic levels of hunger, desperation, loneliness, and grief. The UN Human Development Index does not directly include these indicators of social distress but they are implied by the indices that are monitored, aimed to assess healthy lifespan, knowledge, and decent level of living. The distance between those countries on the upper end of the scale and those at the lower end is increasing each year. Predictors of health and human security for the 21st century would suggest that this disparity will become ever more extreme (Desjarlais/Eisenberg/Good/Kleinman 1995, UNDP 2006).

38.6 Response Strategies

A range of actors and institutions from the entire world community will need to engage in meeting these challenges and addressing their potential impacts. It is argued here that a broad approach based on shoring up human security, rather than the narrow one based on strengthening health security in either of its two meanings, is more likely to make headway against the global scale of what lies ahead. The increased threats of forced migration, war, and pandemic disease, arising against background projections of concerning trends in health and social disparities,

can only be dealt with through concerted and integrated efforts undertaken at the level of international institutions, national governments, and international and local civil society.

The approach begins by recognizing that the calamitous consequences of these 21st century trends will fall most disproportionately on the poorest sixth of the world's population. These people, approximately 1 billion in number, live in geographic regions that will be most prone to climate-driven forced migration, wars over scarce resources, and mass epidemic disease. The consequences of their misery will be felt by the rest of the world, in that people will flee to areas of relative prosperity, local wars may well become regional and spawn global instability, and disease reaches all societies, whether prepared or not. Responding to these terrible events will also incur financial and social costs that will be borne by the developed world, in terms of expanded humanitarian response.

The approach moves to the next step by acknowledging that these dire global trends may be interrupted or at least deflected or slowed by comprehensive and sustained strategies aimed at reducing poverty, improving food, water, and public health delivery to all people in grave need, and intervening at key nodal points in the predicted trends (population growth, energy use, local sources of instability and potential conflict). These strategies may be developed and funded at international levels of engagement but to be successful must translate into local priorities, at the national and sub-national level, for policy and implementation. It is suggested here that these priorities focus on strengthening the human security parameters of home, community, and sense of hope. Health, as a state of wellbeing, may be too much to ask for in the next 100 years. But measures taken against poverty and disease, interventions to protect against climate change and war and major disaster – if made priorities for international action – may allow us to hold on to the hard-earned and meagre gains achieved to date. If there is work, if the children live past five, if there is a school and a clinic within reach, if it seems as if the world cares, people will plan and make sense of their own futures.

39 AIDS – Challenge to Health Security in Africa: Politics in Africa and Case Study on Botswana

Fred Eboko and Tereza Nemeckova

39.1 Introduction

AIDS constitutes the most deadly pandemic in the history of mankind. This pandemic has challenged the world order and security. Since the year 2000, HIV/AIDS is no longer seen by international organizations solely as a public health problem but also as a threat to the national security for those states most affected by the epidemic, and also for states (mainly Western) which perceive this situation as an external threat to their own security. Its implication for the notion of security of African states and the question of a certain world order are addressed in the first part (39.2).

The dynamics of the expansion of AIDS, mainly in Sub-Saharan Africa, has produced and reinforced new dangers in international relations. These various international poles of what Marc Dixneuf (2003: 213–225) called the “world public health governance” (UN, UNAIDS, WHO, Security Council, etc.), which are illustrated in the fight against AIDS in particular for Africa, highlight the latter’s place in an abrupt perspective (39.3). The aim of this chapter is to show how ‘the security’ theme was developed in the domain of AIDS in Africa, the most HIV/AIDS affected region in the world (39.4 and 39.5). The example of Botswana, a relatively developed country in the region, yet one of the countries with the highest HIV/AIDS prevalence among its population, aims at presenting firstly that AIDS is not only a threat to the poorest countries in the world, and secondly, a sound national multi-sectoral approach to the national security threat is needed to combat the pandemic and save the nation (39.6). The case study also illustrates the evolution of an approach to the AIDS threat from a national perspective. The conclusions place the AIDS challenge into a broader global context (39.7).

39.2 HIV/AIDS in Africa

Since the outbreak of the AIDS pandemic in Africa, various attempts of political regulation were made from the international sphere down to local political and health arenas (Eboko/Chabrol 2005: 193–216). The global expansion of the AIDS pandemic during the past decades (1980–2000) was accompanied by evolutions which underscore the unity of a tragedy, the relative diversity of epidemiological dynamics and the variety of international and national responses. The first institutional response at international level was the creation of the *Global Programme on AIDS* (GPA) within the *World Health Organization* (WHO) in 1986, and in most states the creation of *National anti-AIDS Programmes* (NAP)/*National AIDS Committees* (NAC).

From 1986 to 1996, the key goal of international policy in the fight against AIDS was ‘prevention’ and security of blood transfusion. The problems of coordination of the activities of the various United Nations (UN) agencies involved in the management of the problem of AIDS and, especially, the obvious failure of ‘all prevention’ efforts, led to the abandonment of the GPA in 1996 and to the creation of the *UN Common Programme on AIDS* (UNAIDS) which brings together all major UN agencies and the World Bank

During the mid 1990’s other notable changes occurred at the international level, with the scientific validation and the publication of the effectiveness of antiretroviral drugs and tri-therapies at the international Conference on AIDS in Vancouver in 1996. While this major discovery provoked a significant drop in HIV/AIDS in the North (e.g. in a more than 80 per cent decline in deaths in Paris hospitals, after the tri-therapies since 1996), countries of the South and in particular of Sub-Saharan Africa, continued to pay the highest tribute. More than 22.5 million Africans presently live with HIV, and almost 61 per cent of adults living with HIV in 2007 were women (UN-

Table 39.1: HIV and AIDS statistics in Sub-Saharan Africa, 2001 and 2007. **Source:** UNAIDS (2007: 7).

	Adults and children living with HIV/AIDS	Adults and children newly infected with HIV	Adult prevalence (%)	Adult and children deaths due to AIDS
2007	22,5 million [20,9 - 24,3]	1,7 million [1,4 - 2,4]	5,0 % [4,6 - 5,5]	1,6 million [1,5 - 2,0]
2001	20,9 million [19,7 - 23,6]	2,2 million [1,7 - 2,7]	5,8 % [5,5 - 6,6]	1,4 million [1,3 - 1,9]

AIDS 2007: 6). Nowadays the prevalence in Africa for the 15–45 year old persons is 5.0 per cent (UNAIDS 2007: 8).

In Sub-Saharan Africa, adults (15–49 years) HIV prevalence declined from 5,8 % [5,5%–6,6%] in 2001 to 5,0% [4,6%–5,5%] in 2007. AIDS continues to be the single largest cause of mortality in Sub-Saharan. (WHO, 2003); of the global total of 2.1 million [1.9 million–2.4 million] adult and child deaths due to AIDS in 2007, 1.6 million [1.5 million–2.0 million] occurred in sub-Saharan (UNAIDS, 2007: 8).

In 2001, international agencies already estimated that close to 15 million Africans have died of AIDS since the beginning of the epidemic.¹ These figures indicate a gross reality: no war, no phenomenon, and no epidemic has killed as many people in Africa at any given period of its history. AIDS constitutes the most deadly pandemic in the history of mankind (Eboko 2003). This pandemic has already challenged ‘world order’ and security when the UN Security Council took up this issue in 2000.

Since early 2000, HIV/AIDS is no longer seen by international organizations solely as a public health problem but increasingly as a security challenge to the national security of those states most affected by this epidemic, and also for states (Western) which perceive this situation as an external threat to their own security and as more than a risk of contagion from one continent to the other, but as a risk of a profound destabilization of the states which is perceived as a security threat.

39.3 Securitization of HIV/AIDS

In January 2000, the international scope of HIV/AIDS and the perception of the epidemic have changed when the UN Security Council for the first time in history addressed the HIV/AIDS epidemic as the “the No. 1 security threat in Africa”. This meeting marks a turning point not only because it endorses a specific perception of HIV/AIDS, notably on the Af-

rican continent (as a security threat), but because it also opens the way for new developments in the international fight against AIDS (priorities in terms of prevention and treatment). It was followed by a special session of the UN General Assembly in June 2001 which led to a ‘Declaration of Engagement’ by all UN member states. During these deliberations, the states, notably in the North, promised to reinforce their financial contributions for the fight against AIDS by creating a *Global Fund against AIDS, tuberculosis and malaria*.²

HIV/AIDS and its scope in Africa also contributed to a widening of the notion of security in international relations, which has been underway (Brauch 2008, 2008a, 2008b, 2008c). The security concept in international relations has widened and deepened since the end of the Cold War, an evolution which is however always subject to discussions between proponents of the traditional approach and the promoters of a wider vision of security.³ The HIV/AIDS epidemic contributed to an evolution of the notion of security at the end of the 20th century, also as ‘human’ (see chap. 74 to 96 in part IX) and ‘health security’ (see chap. 37 by Rodier/Kindhauser and chap. 40 by Fischer/Salehin). The existence of threats which are not posed by states but that are equally dangerous and destabilizing included health threats as well as the various intra-state and transnational threats like terrorism. The HIV/AIDS epidemic has coincided with the emergence of the notion of ‘human security’ by UN Development Programme (UNDP 1994) that closely associates individual security with ‘health’, ‘food’, ‘environmental’, ‘economic’, and ‘social security’.

These conceptual innovations at the end of the 20th century were based on observations of the social

1 The number of deaths due to AIDS in Africa varies from 13,5 million to 17 million (UNAIDS 2001a, 2004; and the epidemiological synthesis by Delaporte/Laurent 2001).

2 This *Global Fund* has been operational since January 2002 (<<http://www.globalfund.org>>).

3 The traditional or narrow approach to security reflects the realist theory in international relations where the term ‘security’ refers to these two propositions: 1) the existence a threat to security coming from outside; and 2) a threat which is first of all military in nature (though not exclusively) and generally calls for a military response in order to preserve the security of the state in question (Graham/Poku 1998).

and political life which are presented here as characteristics of African states. Africa has been first of all the epicentre of the HIV/AIDS epidemic with more than 70 per cent of affected persons. Some states in southern Africa have alarming prevalence rates surpassing 30 per cent of the population (Botswana, Zimbabwe, Namibia). In the absence of large-scale treatment in most of these countries the demographic forecasts are alarming, especially regarding the drop in life expectancy (Ngoma/le Roux 2008: 815).

The relation between AIDS and security challenges enables some analysts to establish probabilities of new conflicts or the explosion of violence due to HIV/AIDS (chap. 17 by Benz). The phenomenon of AIDS orphans feeds these studies, as well as the question of war children who are regarded as future street children, with the risk of becoming new desperate slaves and taking up to gratuitous violence.

Looking at the manner in which AIDS embraces the new aspects of security, there is a correlation between the epidemic, the political system, and the peace or war situation in question. In many regards the relation between AIDS and security seems to be an African specificity. HIV/AIDS was primordially seen as an aggravating factor of numerous destabilizing elements already present in Africa which become a new dangerous security issue. The already precarious social and political equilibriums are seriously challenged in all scenarios making AIDS a 'national security' threat.

Given the many analyses on AIDS and security in Africa, it is necessary to critically reflect on the bases and implications of this reasoning. In the case of prospective analyses it is often a question of suppositions and projections. Sometimes a rhetorical constitution is based on subjective truths and not on objective realities. Numerous authors willingly acknowledge the shortcomings that exist at this level. To understand the effects of this security vision of the epidemic, from a pragmatic perspective, it seems appropriate to discuss these mechanisms used by those African states that are primarily concerned.

The 'securitization theory' (Wæver 2008, 2008a) developed during the 1990's by the Copenhagen School is of interest that addresses the importance of the dynamics and the process by which an object is transformed into a security stake (*securitization*), who the actors and what the rationales are (Buzan/Wæver/de Wilde 1998) for emphasizing the logic of security. These deliberations inspired this analysis. How did AIDS in Africa change from the 'African

tragedy' to a 'security' stake for the international community?

39.4 HIV/AIDS in Africa and International Security

On 10 January 2000, for the first time the problem of AIDS in Africa was put on the agenda of the UN Security Council as: "the situation in Africa: the impact of AIDS on peace and security in Africa" (Chabrol 2002: 129-136). This session launched a cycle of meetings and discussions, from Washington to Paris, on 'security' and AIDS in Africa. This link was then taken up by the US government and its then UN ambassador, Mr. Richard Holbrooke who formalized the scourge represented by the HIV/AIDS infection for African armed forces, and especially for peacekeeping forces in Africa. The AIDS prevalence rates of security forces are sometimes five times higher than the national average (Ngoma/Le Roux 2008: 815-816). Based on these facts, the American diplomat concluded that the conflicts, the displacements of populations, and their contacts with soldiers could provoke the collapse of the capacities of defence and peacekeeping in Africa.

In this context, Mr. Al Gore, the then US Vice-President in charge of international cooperation with countries of the south ('e-education', AIDS prevention, etc.) declared that AIDS was endangering international security. In April 2000, US President Bill Clinton argued that AIDS poses "a threat for American national security". Several dailies, among them *The Washington Post* and *Le Monde* (30 April 2000), reported on these discussions which thus became highly newsworthy. The 'African tragedy' thus changed its image at the international level. Did this justify the 'efforts' initiated by the American Executive in the fight against AIDS for poor countries to American public opinion and to Congress, with a potentially global nuisance of AIDS in Africa?

In the US, the Democrats thus extended the fight against AIDS in the Caribbean to Africa. When in 2000 the seroprevalence for North America was 0.5 per cent compared with 5.5 per cent for Haiti, the Governor of Florida, Mr. Jeff Bush, started a campaign of cooperation with Haiti to enhance the health 'security' of the American population in contact with migrants from Haiti. The Security Council thus became a catalyst for the reorientation of American policy by converting AIDS into a challenge for the international community, on the fringes of the responsible

UN agencies (UNAIDS, WHO). In July 2001 the Security Council adopted resolution 1308 that “aimed at intensifying prevention and the fight against AIDS amongst armed and peacekeeping forces” (Bonnet 2002 cited in Chabrol 2002: 132).

It is a ‘scourge’ if it is compared with other social effects of AIDS. So far no army has been completely decimated or numerically weakened due to AIDS. But it is already clearly established that AIDS already has a formal impact on the education system due to the deaths of teachers who are more difficult to train, recruit, and replace than soldiers; on agriculture in certain zones, such as on the Rakai agricultural region in Uganda in the late 1980’s due to the disappearance of young adults (men and women). It is appropriate to ask whether the ‘health’, ‘economic’, and ‘social security’ of Africans is less relevant than the perception of ‘national security threats’ of world powers at the international level.

Several developments preceded the turning point of the year 2000, in the international fight against AIDS, for poor countries and especially in Africa. In January 1996, the failure of the *Global Programme on AIDS* (GPA) led to the *UN Common Programme on AIDS* (UNAIDS). In April 2001, UN Secretary General Kofi Annan launched the *World Fund for the fight against AIDS, tuberculosis and malaria* as a sort of international subscription for rich countries and private donors to reduce the financial burdens of countries in the south due to the high prices for medicines fabricated by big laboratories. In June 2001 an extraordinary session of the UN General Assembly on AIDS that was initiated by Kofi Annan again referred to the ‘international security’ option, at the same time when the idea of the *Global Fund* was launched.

While the function, role, and mission of this Fund have been supported by the international community and activists, the financing by large states did not always conform with their previous promises, especially for the United States. Meanwhile the Fund is functioning and initiated several programmes in several countries which have been able to permit access to tri-therapies for thousands of patients. Mr. Annan’s Fund, mostly suffers from what is supposed to be its force and its vocation: the multilateral nature of international cooperation.

39.5 International Security between ‘Health Security’ in the South and ‘Economic Security’ in the North, or American Domination vs. Multilateralism

During the presidency of George W. Bush, in 2003 the US government set up a rival programme in 2003 to the *Global Fund* with the *President’s Emergency Plan for AIDS and Relief* (Pepfar) that allocated 15 billions US\$ to fifteen African, Caribbean, and Asian countries. It finances access to tri-therapy treatment programmes based on two key conditions: a) exclusive recourse to big pharmaceutical firms (no generic drugs); and b) prevention campaigns based on abstinence. This modality of the ‘abstinence’, ‘fidelity’ and ‘condom’ triptych has been denounced by NGOs for its moralist character. These organizations also regret the monopoly granted to ‘Big Pharma’ (the nickname representing the big pharmaceutical groups) to the detriment of generic drugs which would have permitted to take care of millions of additional patients.

Despite these legitimate criticisms, the *Pepfar* presents a major advantage due to its unipolar nature: rapidity of execution and therefore celerity in taking care of persons benefiting from the funded programmes. It seems to constitute an archetype of a co-operation policy whereby elected officials guarantee the economic interests of multinationals by entirely controlling the invested funds. *Pepfar* also strengthens the unilateral approach of the United States in the ‘new world order’, including the area of aid which appears as ‘humanitarian’, but is so only partially. Therefore, AIDS as a danger for ‘international security’ also concentrates its resources in the ‘financial security’ of economic allies of the United States. The idiom ‘abstinence’ may be counterproductive, if one takes the case of Botswana as an example.

The results in terms of prevention and the delays with which the civil society adheres to voluntary screening in these countries clearly translates the situation of a society that suffers from the cleavage between the elites and the rest of the population, despite the economic redistribution and the welfare state. With close to 38 per cent of seroprevalence rate among the sexually active population and 17 per cent of the general population, Botswana offers a tragic illustration of a fundamental contradiction between the economic integration and the separation of elites from subordinate social groups.

Population	1,8 million
GDP p.c. (PPP)	11,611 USD
Life expectancy	34.4 years
Illiteracy rate	18.8 per cent

39.6 Case study of Botswana

Botswana belongs to the top performing countries in Africa based on sound macroeconomic policies, good governance, reliable institutions, and political stability. The country has managed its diamond wealth efficiently. It has the reputation of being the least corrupt country in Africa and also carries the highest sover-

eign credit rating on the continent. Since the 1960's Botswana has transformed from a very poor agricultural country to a country ranking among the richest countries in Africa, with GDP per capita above US \$11,600 in 2007 (OECD 2005: 105).

For African standards, the achievements of Botswana in the human factor area are also admirable. Almost 100 per cent of children have access to free primary education, the literacy rate has risen above 80 per cent, nearly 90 per cent of the population is within the reach of state health facilities, and nearly all children enjoy basic immunization.

But these achievements are threatened as the country is devastated by the HIV/AIDS epidemic and faces its future national, regional, and international consequences.

39.6.1 Extent of the HIV/AIDS Pandemic

AIDS was first reported in Botswana in 1985. At that time AIDS was seen as a disease that affects mainly male homosexuals in the Western states. Almost 20 years later, in 2003, the National AIDS Coordinating Agency of Botswana released a survey on the HIV/AIDS surveillance of the population. Despite the macroeconomic success of the country, HIV/AIDS has spread throughout and affected 37.4 per cent of the sexually active population. The speed of the HIV/AIDS spread has been alarming - HIV/AIDS prevalence has more than doubled within only a decade (from 18.1 per cent in 1992). Eight of 25 districts in Botswana reached even higher than 40 per cent of HIV/AIDS prevalence, and other 8 districts ranked between 30-40 per cent. The worst hit districts lie in the north-west, where Selebi and Phikwe noted an AIDS prevalence of 52.2 per cent.⁴ However, almost 5 years after, latest data show a declining HIV prevalence in Botswana, which reached 'only' 24.7 per cent in 2007 (UNAIDS 2007: 11). It seems that the triple approach of prevention, care and treatment (see 40.6.2) has already begun to yield dividends.

As Botswana is a transport hub for Zimbabwe, South Africa, Namibia and Zambia, all of which share the high HIV prevalence rate, districts situated closely to these borders welcome thousands of work migrants who tend to have more free sexual behaviour. Therefore, demographic mobility presents a key factor of the high HIV prevalence in Botswana, or in se-

lected districts respectively (Government of Botswana 2003: 65).

Two relevant conclusions could be drawn from the survey. First, there is no marked difference in HIV prevalence between rural and urban areas (see table 39.3).

Table 39.3: HIV prevalence by residence and age (2003), in percentages. **Source:** AIDS surveillance 2003; at: <www.naca.gov.bw/documents/flyer_english_A4.pdf> (10 May 2006): 3.

Age	15-19	20-24	25-29	30-34	35-39	40-49
Rural	24,1	40,4	50,4	42,2	35,2	34,6
Urban	22,1	37,9	49,4	47,5	44,5	34,4

Secondly, the data show a significantly higher prevalence among young women (15-29 years) than among men of similar ages (see table 39.4). Similarly, men above 35 years show higher HIV prevalence than women.

Table 39.4: HIV prevalence among men and women aged 15-49 years (2003), in percentages. **Source:** AIDS surveillance 2003; at: <www.naca.gov.bw/documents/flyer_english_A4.pdf> (10 May 2006): 3.

Age	15-19	20-24	25-29	30-34	35-39	40-49
Women	15,4	29,7	54,1	61,5	55,9	45
Men	1,2	8,4	29,7	49,9	59,6	56,9

The reason for negligible differences between the rural and urban population could be found in the already mentioned demographic mobility. Rapid economic growth forces people to move from rural to urban areas. While urbanization rises there is a high number of people living in towns but still having strong rural roots to which they frequently return. Such an environment that leaves children often unattended when commuting between towns and fields, possibly increases the risk of infection.

The significantly higher prevalence among women and among older men respectively, could be explained by the socio-cultural determinants of HIV/AIDS. Subordination of women underlines many aspects of their vulnerability, especially their weak position in decisions about sex. This is highly important at the young age of a woman. Another key role play the multiple sexual relationships mostly by men (Government of Botswana 2003: 68). The above data stress the urgent need for appropriate measurements. Oth-

4 AIDS surveillance 2003, at: <www.naca.gov.bw/documents/flyer_english_A4.pdf> (10 May 2006): 2.

erwise the nation will pay a very high price for the epidemic.

39.6.2 Government Response to the Epidemic

The government of Botswana failed to realize the real extent of the HIV/AIDS threat in the early stages. Its response to the AIDS epidemic can be divided into three stages:

- The *early stage* (1987–1989) focused, according to international recommendations, mainly on the screening of blood to eliminate the risk of HIV transmission through blood transfusion. There was not much information provided either to the public or to the hospital staff.
- The *second stage* (1989–1997), and the first *Medium Term Plan* (MTP I), saw the introduction of information, education, and communication programmes focusing on AIDS as one of the diseases which have started to spread throughout all segments of society. But the public response was rather narrow. Therefore, in 1993 the Government of Botswana adopted the first *Botswana National Policy on AIDS* (Government of Botswana 1993), the first action plan to combat the spread of the HIV/AIDS epidemic throughout the country.
- The *third stage* (since 1997) marked a paradigm shift from tackling HIV/AIDS as a health issue to HIV/AIDS as a development issue that needed a multi-sectoral response. The *second Medium Term Plan* (MTP II) aimed to involve many stakeholders who had been previously excluded (e.g. teachers, employers or broad civil society), with the overall goal of not only to reduce the HIV/AIDS infection and transmission rates, but also to reduce the socio-economic, demographic or political consequences of the rapidly spreading HIV/AIDS epidemic. HIV/AIDS in Botswana has been lifted to the level of a security threat to the nation.

Due to the urgency of this threat the *National AIDS Coordinating Agency* (NACA) was formed in 1999 and given responsibility for mobilizing and coordinating a *multi-sectoral national response* to the epidemic. Key agencies in Botswana were assigned as follows:

- The *President* presents the political leadership for the national response and ensures that all sectors of society are mobilized;
- The *Ministry of Health* is responsible for the implementation of the health sector based on interventions regarding the prevention of sexual,

blood-borne, and vertical transmission of AIDS, for implementing and managing the antiretroviral therapy, epidemiological research, etc.;

- The *Ministry of Local Government* is responsible for providing care and support services to families affected by HIV/AIDS, including orphans and vulnerable children;
- The *Ministry of Education* will ensure that HIV/AIDS awareness is mainstreamed into all aspects of the educational system;
- The *Department on Information and Broadcasting* plays an active role in disseminating information on HIV/AIDS;
- The *Directorate of Public Service Management* develops a policy for managing HIV/AIDS in the public service and ensures that HIV/AIDS programmes are fully implemented;
- The *Ministry of Labour, Home Affairs and Social Welfare* is tasked to ensure that the rights of all HIV-infected people are protected;
- The *private sector* has been asked to develop HIV/AIDS programmes for their staff in line with national strategies, to mobilize resources, and to integrate HIV/AIDS awareness into their training programmes; and
- *Civil society* takes responsibility for advocacy and social mobilization, the design and implementation of innovative and prevention programmes, etc.

In 2003 Botswana completed its *National Strategic Framework* which offers a real strategy for combating the epidemic until 2009. The Framework stresses that HIV/AIDS poses a significant *threat to national security* in terms of loss of human resources and the ability to mobilize for the protection of national interests (Government of Botswana 2003: 65). The framework also stresses the need of an efficient HIV/AIDS *prevention and treatment*.

39.6.2.1 HIV/AIDS Prevention

The National Strategic Framework outlines several areas where HIV/AIDS prevention is needed:

Public awareness and education. Public awareness and education have previously been based on the ABC of AIDS: Abstain, Be faithful and, if you have sex use Condoms. Previously, Botswana has been flooded by safe-sex billboards and posters, but people did not pay much attention to them. As stated above, the reason for the public attitude can be found in the moralist character of the campaign, e.g. in pressure to change sexual behaviour, which has been regarded

mainly by the older generation as taboo. The new strategy has changed in a way. It targets the young people who are just about to start their sexual life and who are more willing to talk about issues. Several new initiatives appeared, e.g. the development of a radio drama, Makgabaneng that deals with culturally specific HIV/AIDS-related issues, or the Youth Health Organization (YOHU), a youth-run non-governmental organization (NGO) which conveys messages of safe sex through art festivals, dramas, and group discussions. The *Ministry of Education of Botswana* and UNDP, in collaboration with the Government of Brazil and with support from the *African Comprehensive HIV/AIDS Programme* (ACHAP), introduced a programme to improve primary and secondary teachers' knowledge in this area, in order to demystify and destigmatize HIV/AIDS, and to break down cultural beliefs about sex and sexuality.

Condom distribution and education. Condom use presents a crucial part in effective HIV/AIDS prevention. *Population Services International (PSI)* has helped to promote the 'Lovers Plus' condom since 1993 and the 'Care' female condom since 2002. One of the key strategies for marketing condoms in Botswana has been chosen peer education, conducted in a variety of settings such as fairs and festivals, shopping malls, at work places and bars. Besides, in 2003 the Government of Botswana, with funding and technical support from ACHAP, launched an extensive condom distribution and marketing campaign, providing for the installation of 10,500 condom dispensers in traditional and non-traditional outlets throughout the country. Millions of condoms have been procured for free distribution.⁵ Indeed, condom use has substantially increased. Condom use at last with non-marital or non-cohabiting partners reached 84 per cent by men and 77 per cent by women (aged 15–24).⁶

Improvement of blood safety. The Ministry of Health, the Safe Blood for Africa Foundation and other partners, with funding from ACHAP, have helped to improve the safety of blood transfusion in Botswana. The national supply of HIV-free blood doubled in size in two years up to September 2005. Over the same period, the amount of HIV-infected blood given by donors fell by half, largely due to better screening of donors and counselling. One of the

projects contributing to the improvement of blood safety is called 'Pledge 25'. This project recruits young people to become blood donors and teaches them how to prevent HIV infection.⁷ Botswana lacked for a long time an HIV/AIDS laboratory. All blood samples had to be sent to South Africa for testing. In 2002 a new laboratory was opened in Gaborone, funded by the Government of Botswana, Bristol-Myers Squibb and ACHAP, and it has been operating with technical assistance from the Botswana-Harvard AIDS Partnership.

Prevention of mother-to-child transmission of HIV. As was stated above, the prevalence rate among pregnant women in Botswana reaches 35.4 per cent. In the absence of any interventions, around a third of the babies born to HIV-positive mothers become infected during pregnancy and delivery or through breastfeeding. This rate could be substantially cut through the use of antiretroviral treatment and safer feeding practices. A prevention of mother-to-child transmission programme was the first programme in Botswana starting to distribute antiretroviral drugs for free. However, enrolment of women in such a programme is still disappointingly low (range of 11–20 per cent).⁸ One of the reasons could be a severe shortage of hospital staff and an inadequate infrastructure. The Government of Botswana has already responded with training and recruitment for new counsellors.

HIV testing. HIV testing plays a key role in HIV prevention and treatment. It is particularly important as a starting point for accessing other HIV/AIDS-related services. Since 2000, the Government of Botswana supported the Tebelopele network of voluntary testing centres providing immediate and confidential services for sexually active persons from Botswana aged 18–49. By October 2005, the network had provided free services to over 230,000 visitors. The Tebelopele centres have been supported by the "Know Your Status" and "Show You Care" campaigns, as part of the marketing strategy developed in collaboration with PSI. These campaigns do not pressurize on sexual behavioural change as before, but concentrate on prevention and on provoking an interest in HIV/AIDS affected people. Botswana became the first country in Africa having a national policy of routinely

offering HIV tests at medical clinics. Apart from that, HIV tests are required when applying for a new job, for studying at the university, etc. Health officials believe that such a broad testing is a good way to help prevention programmes and to access antiretroviral treatment at an earlier stage of the disease.

39.6.2.2 HIV/AIDS Treatment - MASA Programme

In 2000, the Government of Botswana declared AIDS as a 'national security' threat. The President declared his intention of making antiretroviral drugs⁹ available to every HIV-infected citizen in need. Already in 2002, Botswana became the first country in Africa offering antiretroviral drugs to HIV-infected citizens throughout the public health system *for free*. The national programme was called MASA.¹⁰

By the time of the start of MASA, there were already warnings about the financial sustainability of such a programme. It was estimated that it would cost US \$ 24.5 million to include 19,000 people in 2002 (or about US \$ 1,300 per patient), and an additional 20,000 people were projected for the subsequent year. Thus, expenditures on the health system have steadily been expanding. In 2003 all HIV-related government programmes amounted to 6 per cent of the total budget (OECD 2005: 112). Fortunately, MASA has been substantially supported from abroad – US \$ 3.3 million came from the *Global Fund* and US \$ 26 million from different NGOs, charities or foundations.

The initial proposal found 110,000 people eligible for the programme. MASA identified the following main target groups:

- pregnant women and their partners with less than 200 CD4¹¹;
- all infected children older than 6 months;
- all infected tuberculosis patients with less than 200 CD4;
- all adults infected with less than 200 CD4.

MASA was launched initially only in the four biggest cities of the country. By the end of 2002, the number of enrolled patients reached only 2,000. Records of these patients showed that the average CD4 count on registering with the programme was about 57, but for some patients even zero. This proves that people came to enrol only when they felt really sick.

By mid-year 2005 the number of enrolled patients reached already 54,000.¹² The introduction of free antiretroviral therapy requires a broadening of the infrastructure, including testing centres and skilled personnel in order to facilitate more patients. Within the last three years a significant change has been recorded, but it was obviously insufficient.

MASA's greatest challenge is a critical shortage of skilled personnel, mainly in hospitals. To be eligible to prescribe the antiretroviral drugs for the MASA programme, doctors must go through specialized training where they learn everything from virology and immunology to drug interactions and side-effects of the antiretrovirals. The Harvard AIDS Institute helps to organize such training for them. Another training programme sponsored by ACHAP tries to speed up the number of personnel understanding the illness and being able to counsel the people. HIV experts from renowned international institutions work with clinic staff mentoring them and giving them lectures. Unfortunately, the number of patients increases much faster than the number of skilled personnel.

39.6.2.3 Active Role of the Private Sector

As already mentioned, in the multi-sectored approach to the HIV/AIDS epidemic the private sector has been involved. The first pioneer in implementing HIV/AIDS programmes for employees was the Debswana Diamond Company,¹³ the biggest private employer in the country.

The first case of an HIV-infected employee appeared in 1987 in the Jwaneng Mine Hospital. As a consequence of that, in 1991, the company decided to

9 Antiretroviral drugs reduce the level of HIV in the body, so that the immune system is allowed to recover partially and further damage is slowed or prevented. But it does not cure HIV/AIDS.

10 In Setswana, meaning "new dawn".

11 HIV mainly infects cells in the immune system called CD4 cells, gradually destroying them and causing the number of CD4 to drop, so that the immune system is weakened.

12 "Merck Official Says Partnership in Botswana is Learning from Experience and Passing It On"; at: <http www. allafrica.com>: 1 (13 May 2005).

13 Debswana is owned in equal shares by the Government of Botswana and De Beers Centenary AG. The company mines diamonds at three operations in Botswana, namely the Orapa, Letlhakane and Jwaneng mines. Debswana has two fully-owned subsidiaries, the Botswana Diamond Valuing Company, which sorts and values diamonds, and the Teemane Manufacturing Company, which cuts and polishes diamonds. The total number of employees exceeds 6,000.

publish posters, pamphlets, and videos showing people with AIDS. Due to significant percentage increases in AIDS-related health retirements between 1996 and 1999 (75 per cent), the company conducted a survey on the HIV prevalence rate of its employees. This survey was made in May 1999 and it showed that 28.8 per cent of the employees of Debswana were HIV positive.

Thus, in May 2001 Debswana introduced its *Debswana HIV/AIDS Strategy*. The vision was to become a global benchmark company in fighting against HIV/AIDS at the workplace. The most visible part of it was the introduction of a new rule that every HIV-infected employee and his/her legally married spouse who is also HIV positive were offered to be paid 90 per cent of the antiretroviral therapy costs. Further measures have been undertaken, e.g. every new job candidate got HIV tested, plans of replacement for critical posts have been developed, the company strictly protects the rights of all their employees (regardless of their HIV status) etc. Debswana took a leading role in the Botswana private sector's contribution to the fight against AIDS. Other private companies started to follow.

39.7 Conclusion

In 2007, 22.5 million Africans lived with HIV/AIDS and, 61 per cent of them are women and 90 per cent of all HIV-positive children live in Sub-Saharan Africa (UNAIDS 2007: 9). These figures indicate a gross reality: no war, no phenomenon, and no epidemic has killed as many lives from Africa at any period in history. AIDS is the most deadly pandemic in the history of humankind.

At the turn of the third Millennium, the international scope of HIV/AIDS and the international perception of the epidemic have been changed by the UN Security Council. In January 2000 for the first time in its history, the Security Council referred to the HIV/AIDS epidemic as a threat to international security, and as "the No. 1 security threat in Africa".

The emergence of HIV/AIDS and its scope in Africa have also contributed to a widening of the notion of security in international relations. Since the end of the Cold War the security concept in international relations has also deepened. But this reconceptualization of security has been disputed between the proponents of the traditional narrow approach and the adherents of an enlarged and elaborated vision of security.

The existence of threats which are not necessarily posed by states but who are considered as equally dangerous and destabilizing has included health threats as well as various intra-state and transnational threats like terrorism. Particularly, the HIV/AIDS epidemic has coincided with the emergence of the notion of 'human security' developed by UNDP (1994) that has closely linked individual security to health, food, environmental, economic, and social security. In this sense, national authorities across Africa were asked to respond to this growing and rapidly spreading new security or health threat.

Botswana presents a relatively developed African country that has been severely devastated by the HIV/AIDS epidemic. Several attempts have been made to reverse it. In 2000, when the epidemic reached a catastrophic dimension, the Government of Botswana declared HIV/AIDS as a national security threat. Botswana representatives correctly realized that AIDS constitutes not only a security threat to the nation and region, but also a threat to humankind as life expectancy had dropped to 35 years.

The declaration of HIV/AIDS as a security threat has been important but not sufficient to reverse this epidemic. Several conclusions can be drawn from the Botswana experience.

- *First*, the HIV/AIDS epidemic is not solely related to the gap between prevention messages (abstinence, be faithful, use condom - "ABC"), AIDS policies and the reality of sexual behaviour which are very different to moralistic prevention messages.
- *Secondly*, massive national prevention programmes need to take the cultural and social differences into account, as well as the national treatment programmes and their financial sustainability.
- *Thirdly*, the impact of the HIV/AIDS epidemic should not be underestimated. Botswana has severe problems due to the shortage of skilled hospital personnel, who are also vulnerable to the virus. The increasing scarcity of skilled personnel is visible not only in hospitals, but also in schools, in other government institutions and in private sector, and has large economic consequences. Beside the impact on the decline in the productive workforce, the epidemic has an impact on increased poverty and human suffering, and last but not least, weakens the government's capacity to deliver essential services and sustain human development.

40 Health and Poverty as Challenges for Human Security: Two Case Studies on Northern Vietnam and Bangladesh

Isabel Fischer and Mohammad Musfequs Salehin

40.1 Introduction

About one fifth of the world population, that is 1.2 billion people, live in extreme income poverty with less than one US\$ a day. Another 1.6 billion have less than two US\$ a day (CHS 2003: 73). Most of the poor live in severe livelihood uncertainty and lack access to basic education and health services. The United Nations' *Millennium Development Goals* (MDGs) aim at cutting poverty in half by the year 2015. As health¹ is considered crucial for poverty reduction, three MDGs focus directly on health, covering maternal mortality, infant mortality, HIV/AIDS, malaria and tuberculosis. The MDGs 4-6 directly concern health issues, while other MDGs such as goal three ("Promote gender equality and empower women") and seven ("Ensure environmental sustainability") deal with nutrition, water and sanitation and thus impact on health² (see box 40.1).

The concept of 'human security' has emerged slowly but steadily over the 1990's -influenced by the end of the Cold War, the awareness of previously neglected insecurities and globalization- and the question was raised about the expected implications of this concept for health and human development (Chen/Narasimhan 2003a). There are various definitions³ of 'human security', which obviously "means different things to different people"⁴. This chapter applies the definition of the Commission on Human Security (CHS), that stated as the objective of human security "to protect the vital core of all human lives in ways that enhance human freedoms and human fulfilment" (CHS 2003: 4).

The emergence of the concept of 'human security' will be briefly reviewed (40.2), before focusing on human, livelihood and health security (40.2.1) including current debates of human and health security in South and Southeast Asia (40.2.2) as well as the linkages of poverty, health and human security (40.2.3). Empirical evidence will be presented based on two case studies (40.3) on Vietnam (40.3.1) and Bangladesh (40.3.2). Lessons learned (40.3.3) will be summarized, before turning to the conclusions (40.4).

The emergence of the concept of 'human security' will be briefly reviewed (40.2), before focusing on human, livelihood and health security (40.2.1) including current debates of human and health security in South and Southeast Asia (40.2.2) as well as the linkages of poverty, health and human security (40.2.3). Empirical evidence will be presented based on two case studies (40.3) on Vietnam (40.3.1) and Bangladesh (40.3.2). Lessons learned (40.3.3) will be summarized, before turning to the conclusions (40.4).

40.2 The Concept of Human Security

Today's idea of human security is generally thought to go back to the United Nations Development Program (UNDP) report of 1994 and Mahub ul Haq⁵. The UNDP Report stressed that "the concept of security must change - from an exclusive stress on national security to a much greater stress on people's security, from security through armaments to security through human development, from territorial security to food, employment and environmental security" (UNDP 1994: 2). The report calls for "faster economic development, greater social justice and more people's participation ... (for) the new concepts of human security" (UNDP 1994: 3). Human security was defined as "...safety from chronic threats as hunger, disease and

1 Health is defined by the Commission on Human Security (CHS 2003: 96) not just as the absence of disease, but as "a stage of complete physical, mental and social well-being".

Box 40.1: Millennium Development Goals on Health Issues. **Source:** United Nations Millennium Declaration, at: <<http://www.un.org/millennium/>>; UNDP (2000): Millennium Development Goals, at: <<http://www.undp.org/mdg/basics.shtml>> and at: <<http://www.undp.org/mdg/goallist.shtml>>. Text is in the public domain.

The Millennium Development Goals (MDGs) are eight goals to be achieved by 2015 that respond to the world's main development challenges. The MDGs are drawn from the actions and targets contained in the *Millennium Declaration* that was adopted by 189 nations and signed by 147 heads of state and governments during the UN Millennium Summit in September 2000.

The 8 MDGs break down into 18 quantifiable targets that are measured by 48 indicators.

- Goal 1: Eradicate extreme poverty and hunger
- Goal 2: Achieve universal primary education
- Goal 3: Promote gender equality and empower women
- Goal 4: Reduce child mortality
- Goal 5: Improve maternal health
- Goal 6: Combat HIV/AIDS, malaria and other diseases
- Goal 7: Ensure environmental sustainability
- Goal 8: Develop a Global Partnership for Development

The MDGs 4–6 and the targets 5–8, and indicators 13–24 are devoted to Health Issues

Goal 4: Reduce child mortality

Target 5: Reduce by two thirds the mortality rate among children under five

- 13. Under-Five Mortality Rate (UNICEF)
- 14. Infant Mortality Rate (UNICEF)
- 15. Proportion of 1 year-old Children Immunised Against Measles (UNICEF)

Goal 5: Improve maternal health

Target 6: Reduce by three quarters the maternal mortality ratio

- 16. Maternal Mortality Ratio (WHO)
- 17. Proportion of Births Attended by Skilled Health Personnel (UNICEF)

Goal 6: Combat HIV/AIDS, malaria and other diseases

Target 7: Halt and begin to reverse the spread of HIV/AIDS

- 18. HIV Prevalence Among 15–24 year-old Pregnant Women (UNAIDS)
- 19. Condom use rate of the contraceptive prevalence rate and Population aged 15–24 years with comprehensive correct knowledge of HIV/AIDS (UNAIDS, UNICEF, UN Population Division, WHO)
- 20. Ratio of school attendance of orphans to school attendance of non-orphans aged 10–14 years

Target 8: Halt and begin to reverse the incidence of malaria and other major diseases

- 21. Prevalence and Death Rates Associated with Malaria (WHO):
- 22. Proportion of Population in Malaria Risk Areas Using Effective Malaria Prevention and Treatment Measures (UNICEF):
- 23. Prevalence and Death Rates Associated with Tuberculosis (WHO):
- 24. Proportion of Tuberculosis Cases Detected and Cured Under Directly-Observed Treatment Short Courses (WHO)

Goal 7: Ensure environmental sustainability

Target 9: Integrate the principles of sustainable development into country policies and programmes; reverse loss of environmental resources

- 25. Forested land as percentage of land area (FAO)
- 26. Ratio of Area Protected to Maintain Biological Diversity to Surface Area (UNEP)
- 27. Energy supply (apparent consumption; Kg oil equivalent) per \$1,000 (PPP) GDP (World Bank)
- 28. Carbon Dioxide Emissions (per capita) and Consumption of Ozone-Depleting CFCs (ODP tons):

Target 10: Reduce by half the proportion of people without sustainable access to safe drinking water

- 30. Proportion of the Population with Sustainable Access to and Improved Water Source (WHO/UNICEF)

- 31. Proportion of the Population with Access to Improved Sanitation (WHO/UNICEF)

Target 11: Achieve significant improvement in lives of at least 100 million slum dwellers, by 2020

- 32. Slum population as percentage of urban population (secure tenure index) (UN-Habitat)

Implementation of the MDGs

In 2005, the Secretary-General prepared the first comprehensive five-yearly report on progress toward achieving the MDGs. The report reviews the implementation of decisions taken at the international conferences and special sessions on the least developed countries, progress on HIV/AIDS and financing for development and sustainable development.

repression...and protection from sudden and harmful disruptions in the pattern of daily life” (UNDP 1994: 24).⁶

In 2003, the CHS, supported by the Japanese government and co-chaired by Sadako Ogata and Amartya Sen, has released its version of the holistic approach. Overall, human security is a multi-faceted concept that articulates the following issues: human

rights, rule of law, democracy, accountability, participation, empowerment, diversity, conflict resolution, peace, income security, poverty, food security, health security, and sustainability.

These two policy reports, the different approaches of Canada (‘freedom from fear’; see Dedring 2008) and Japan (‘freedom from want’, see chap. 84 by Shinoda), as well as the policy agenda of the *Human Se-*

curity Network (HSN, see chap. 75 by Fuentes/Brauch) were accompanied by an intensive scientific discourse (Brauch 2003; 2005, 2005a, 2008, 2008a, 2008b) that gradually spread from the OECD world (North America, Europe, Asia Pacific) to the developing countries with a special interest in South and Southeast Asia (chap. 76 by Sabur). From this 'Southern' perspective, human security concerns were conceptually linked with other debates on livelihood (chap. 36 by Bohle) and health security (chap. 37 by Rodier/Kindhauser; chap. 38 by Leaning).

40.2.1 Human, Livelihood and Health Security

Following Chen/Narasimhan (2003) health and human security are tightly interlinked and several major policy papers on health and human security were produced. Poor health - illness, injury, disability, and death - are critical threats to human security. Figure 40.1 displays relevant linkages that occur due to (1) violence and conflict, (2) global infectious diseases and (3) poverty and inequity.

The recognition of the linkages between health and development has grown on the global political agenda (cf. UN's MDGs in box 40.1). According to Acharya (2000)⁷, however, the concept of human security, which has attracted much attention in the West, remains poorly understood and contested in Asia. The next part will briefly review current debates in Asia.

40.2.2 Conceptual and Empirical Debates on Human and Health Security in South and Southeast Asia

In contrast to the international appearance of the human security concept in the post-Cold War area, it's emerge in Asia can be linked to the Asian financial cri-

sis of 1997. Following Acharya (2000)⁷, ongoing debates over the exact definition and scope of human security persist in Asia, as elsewhere. Many definitions have adopted a holistic concept, tackling human rights, environmental degradation, poverty, crime, terrorism, gender and social biases, health and natural disasters⁸.

Japan and Thailand have most vigorously promoted the broader approach, which was favoured by several Asian intellectuals, among them Tadashi Yamamoto (Japan Center for International Exchange), some members of ASEAN and the Institute of Strategic and International Studies (ISIS) group, as well as Obuchi Keizo, Surin Pitsuwan, and Kim Dae-jung (Evans 2004). Despite varying conceptions, the key lesson of the Asian crises is that it would be counterproductive to pursue a notion of human security through economic growth and political stability alone - without regard to human rights and democratization.

Three case studies on health issues in Cambodia, Indonesia and the Philippines show how the concept of human security is translated into action in Southeast Asia.⁹ Human security has the potential to act as a viable policy framework in addressing urgent problems. Primary health care is such an issue. It is not yet considered a priority by most policymakers who often care more about jobs and inflation. A similar reasoning can be found in Gutlove/Thompson (2003). They argue that health is a crucial concern for human security. The concern for health provides a context for building partnerships across disciplines, sectors and agencies - offering the potential for discussing and acting upon shared interests and mutual vulnerabilities.

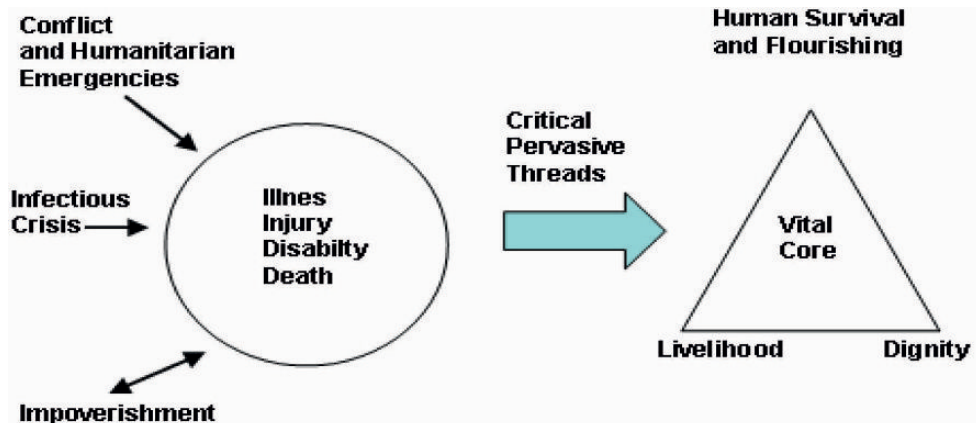

6 The UNDP report identified seven categories of human security: *economic security* (freedom from poverty), *food security* (access to food), *health security* (access to health care and protection from diseases), *environmental security* (protection from the danger of environmental pollution), *personal security* (survival of traditional cultures and ethnic groups), *community security* (physical protection against torture, war, criminal attacks, domestic violence) and *political security* (civil and political rights, freedom from political oppression).

7 Amitav Acharya, 2000: "Human Security in the Asia Pacific: Puzzle, Panacea or Peril?", posted on 24 October 2000; at: <<http://www.cpdindia.org/globalhumansecurity/puzzlepanacea.htm>>.

8 Many Asian scholars argue that the broad range of threats constituting the human security paradigm is a rehash of the old Asian notion of "competitive security" developed by Japan and the Association of Southeast Asian Nations (ASEAN) members - however the emphasis on human rights, which is missing in the competitive security approach, is crucial for a conceptual differentiation of both concepts. While some scholars regard human security in terms of its economic and social aspects (social safety nets, poverty alleviation) others stress its political dimension (e.g. human rights) (Acharya 2000, note 7 above).

9 Mely Caballero-Anthony, 2002: "Overview of Health and Human Security Case Studies", in: *Health and Human Security: Moving from Concept to Action - Fourth Intellectual Dialogue on Building Asia's Tomorrow*; at: <http://www.jcie.or.jp/thinknet/pdfs/health_overview.pdf>.

Figure 40.1: Human Security and its Relationship to Health. **Source:** Chen/Narasimhan (2003: 6).

Focusing on South Asia, Abdus Sabur (2003 and chap. 76) provides an overview on regional human security debates. In contrast to other regions, an overall emphasis on national security –against human security– has severely deteriorated the security situation (particularly in India and Pakistan) and significantly increased security concerns. Eventually, it has transformed South Asia into the poorest and most deprived region of the contemporary world. However, Najam (2003) shows that the South Asian experience can contribute to the larger literature on human security and sustainable development by arguing “that chronic and structural impoverishment – rather than resource scarcity alone – forges the connection between environmental degradation and conflict. It also states that poverty and weak institutions of governance are the more immediate triggers of environmental insecurity” (Najam 2003a: 59).

40.2.3 Poverty, Health and Human Security

The relationship between poverty, health and human security (cf. figure 40.2) was vividly revisited during the Asian financial crises, when millions of people were suddenly impoverished due to macroeconomic shocks¹⁰. Global infectious diseases, poverty-related threats, and violence and crisis are three health challenges that are closely linked to human security (chap. 17 by Benz).

According to the CHS (2003), poverty and disease produce a vicious spiral with negative economic and

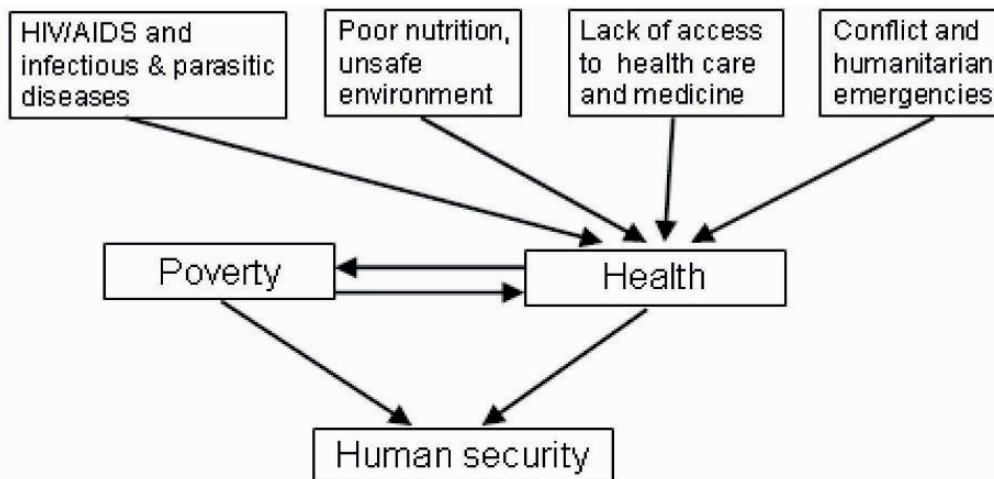

human consequences as not only is people’s health severely affected by poverty, but at the same time, ill health can lead to poverty. Lack of access to nutritious food, safe water and sanitation facilities, and poor or overcrowded housing make people vulnerable to illness which are caused by poverty. For the poor with a fragile livelihood, sickness may deprive the family of daily wages and compulsory health expenditures may put enormous pressures on their limited capital assets.

Poverty and infectious diseases are fellow travellers. The poor are at higher risk of infectious diseases, and sickness can deepen poverty, creating again a vicious cycle of illness and poverty. About 80 per cent of the total population is living in developing countries where 90 per cent of those with HIV/AIDS are living. In contrast to Eboko and Nemeckova (chap. 39) Fenton (2004) argues that there is a positive correlation between HIV prevalence and poverty whether it is measured in gross domestic product (GDP) per capita, income inequality or the *Human Poverty Index* (HPI)¹¹.

Furthermore, health issues are linked to *gender security* (Shepherd/Weldes 2008; chap. 89 by Serrano) and integrated into Human, Gender and Environmental Security (chap. 90 by Oswald and Oswald 2001). Worldwide, 70 per cent of the poorest people are women and children who suffer from malnutrition, illiteracy and severe health problems. Female education has a positive correlation with child health and child education. Gender inequality, female poverty and poor-health issues keep a part of the workforce away

¹⁰ The connections between poverty, health and insecurity were highlighted by the World Bank’s series of *Voices of the Poor studies* for its *World Development Report* 2000 (Washington, D.C.: World Bank, 1999).

¹¹ The HPI attempts to assess the percentage of the population suffering from a variety of basic deprivations, and which ranks 95 developing countries for which adequate data are available.

Figure 40.2: Health, poverty and human security interactions. **Source:** Salehin (2005: 10).

from participating in income generating activities (Derbyshire 2002 cited in Thomson 2004). Thiesmeyer (2005)¹² argues that for women in developing countries, the capabilities of education and health are less dependent on progressive national politics, but more on the availability of facilities in walking distance as women often lack time and transportation to reach existing facilities.

About 30 per cent of the world population lack access to essential medicine. This applies to over 50 per cent of the poorest parts in Africa and Asia (WHO 2004). Data on life expectancy at birth show that it ranges from 38 years in Sierra Leone to 82 years in Japan¹³. Clearly, this huge gap can be minimized if more efforts are undertaken to control major diseases, improve health systems and minimize the level of poverty (Marmot 2005). Two case studies on Bangladesh and Vietnam will discuss in detail the poverty and health links and their impacts for ‘human’ and ‘livelihood security’.

40.3 Case Studies on Northern Vietnam and Bangladesh

Two case studies were selected to explain why health and its link to poverty has become crucial for human

security. The first case on Northern Vietnam¹⁴ reviews health as a major human capital asset, and poverty in the livelihoods of ethnic minorities. The second case on Bangladesh¹⁵ focuses on the general health situation. Based on findings from both cases the results and their impact on human security will be discussed.

40.3.1 Case Study on Northern Vietnam

Despite the achievements of the ‘doi moi’ reform process¹⁶, which was launched in 1986, Vietnam is still one of the poorest countries in the world, with 28.9

13 WHO, 2005: *The World Health Report 2005 – Make Every Mother and Child Count* (Geneva: WHO); at: <<http://www.who.int/whr/2005/overview/en/index.html>>.

14 This case study is based on Fischer (2005). The research was carried out within the framework of the German-Thai-Vietnamese Collaborative Research Programme ‘Sustainable Land Use and Rural Development in Mountainous Regions of Southeast Asia’. Funding from the Deutsche Forschungsgemeinschaft (DFG) and co-funding from the Ministry of Science, Technology, and Environment of Vietnam is acknowledged.

15 This case study is based on Salehin (2005). The research was carried out at the Centre for Peace Studies, University of Tromsø, Norway.

16 Vietnam’s economy grew by 7.2 per cent in 2003 despite challenges from the Severe Acute Respiratory Syndrome (SARS) and a lacklustre global economy. In the first quarter of 2004, the economy faced the challenge posed by the Avian flu, which overall economic impact remains relatively negligible and disruptions to the general economy have been avoided. See: World Bank: “Vietnam Country Brief, 2005”; at: <<http://web.worldbank.org/WBSITE/EXTERNAL/COUNTRIES/EAST-ASIAPACIFICEXT/VIETNAMEXTN/0,menuPK:387575~pagePK:141132~piPK:141107~theSitePK:387565,00.html>>.

per cent (50.9 per cent in 2003) of the total population (85 million in 2004) living below the national poverty line¹⁷. Especially the mountainous, rural areas of Northern Vietnam are underdeveloped and the poverty rate in this region was still 68 per cent in 2002, which is the highest in Vietnam (World Bank 2003a). In the HDR 2007/2008 Vietnam is ranked 105 out of 177 countries with a HDI¹⁸ of 0.733 (table 40.1). This development reflects the country's successful attempts to reduce poverty. Nevertheless, vulnerable groups are still affected by poverty and insecurity. According to the Vietnamese *Ministry of Labour, Invalids and Social Affairs* (MOLISA), vulnerable groups are women, ethnic minorities, those with low education or illiterates, the disabled and the ill, families with many children, especially when they do not have enough labour and more generally the poor and hungry, but also those above or near the poverty line (Conway/Turk 2001).

The Vietnam's Health Sector Report (World Bank 2001a) states that many of the 'doi moi' reforms affected the health sector (e.g. the introduction of user fees for health services, legalization of private medical practice and the deregulation of the retail trade in drugs and medicines) and thus the household's health seeking behaviour. A study by Tuan (2004)¹⁹ provides insights into the provincial rural health system ten years after the health sector reform was launched.

Health insurance services offered by the Vietnamese government are still limited to some target groups, making up to 20 per cent of the labour force and a faction of students as well as about 20 per cent of the poor (ILO 2004). Other previously initiated transfer programmes (e.g. free basic healthcare under the Hunger Eradication and Poverty Reduction (HEPR) programme) only supported few people to escape poverty and protected even fewer from slipping into poverty (Van de Walle 2003). All remaining people, including most of the households in the

Northern Uplands, still have no access to formal insurance services and thus have to rely on their own risk management strategies²⁰ in case of a crisis.

Empirical evidence (Fischer 2005) shows that limited endowment with and access to capital assets and institutions, as well as human and economic risks are the main components affecting rural livelihoods²¹. The *Sustainable Livelihood Framework* (SLF) of the *Department for International Development* (DFID), UK, was applied for investigating the complex livelihoods of people in a given vulnerability²² context (Carney/Drinkwater/Rusinow/Neeffjes/Wanmali/Singh 1999), including the socio-economic structure of society at large and their formal and informal institutions. According to DFID's SLF approach, people have access to five forms of capital assets, i.e. natural, physical, human, social, and financial capital assets. Health, beside education, is one of the most important human capital assets, which helps the poor to increase their income and thus reduce vulnerability.

Decision-making is linked to the ownership of capital assets. Formally, ownership is mostly in the hands

17 UNDP, 2007: "HDR 2007/2008 - Country Data Sheet Viet Nam", at: <http://hdrstats.undp.org/countries/data_sheets/cty_ds_VNM.html>.

18 The HDI measures achievements in key areas of human development, such as standard of living, health and education. Vietnam's HDI has continued to steadily improve since the mid-1980s, from 0.590 in 1985 to 0.672 in 1995, 0.711 in 2000 and 0.733 more recently.

19 Tuan Tran: "Community-Based Evidence about the Health Care System in Rural Vietnam", University of Newcastle, 2004, in: Australian Digital Theses Program; at: <<http://www.newcastle.edu.au/service/library/adt/public/adt-NNCU20050806.101920/index.html>>.

20 While less vulnerable households often have access to so-called (ex-ante) adaptive risk management strategies (e.g. accumulation of savings in cash or kind), which keep the level of vulnerability lower, more vulnerable households have to rely preliminary on (ex-post) risk coping strategies (e.g. sale of livestock), which negatively affect its long-term development (Carney/Drinkwater/Rusinow/Neeffjes/Wanmali/Singh 1999).

21 Chambers and Conway (1992) were among the first to give a scholarly definition of livelihood, as comprising "the capabilities, assets (including both material and social resources) and activities required for a means of living. A livelihood is sustainable when it can cope with and recover from stresses and shocks and maintain or enhance its capabilities and assets both now and in the future, while not undermining the natural resource base" (Chambers/Conway 1992: 7-8).

22 Vulnerability refers to "the relationship between poverty, risk and efforts to manage risk" (Alwang/Siegel/Jorgenson, 2001: 1). Vulnerable households are characterized by the potential for well-being to change in a negative direction or by no change within an existing negative status i.e. remaining in poverty (Conway/Turk 2001). This research applies the definition of Dercon (2002) that "vulnerable households are those likely to fall under an agreed poverty line over time with a particular high probability". In 2001, one third of the Vietnamese population lived in poverty and many of those who were not poor lived close to the poverty line. This sums up to 45 per cent of the population, if 'the vulnerable' are defined as the poor population in 2001 plus those who were near-poor within a line of 10 per cent above the poverty line (Conway/Turk 2001).

of men. They possess all livestock as well as the land right certificates. The later is especially important as formal credit is given to those who possess land, thus it is difficult for a woman to obtain a credit from a bank²³. Population growth, intensified agricultural production, the strict implementation of forestry policies and individualized land use rights are main reasons for a dramatic reduction of grazing land in Northern Vietnam, which also affects directly health management (Hager/Fischer 2005). Diminishing or disappearing natural resources have a negative impact on poor rural household's risk management as it limits their livestock raising potentials. In the absence of cash savings, livestock is commonly used as in-kind savings to be divested when cash is needed.

Dealing with financial assets, research showed that credit and financial transfers from informal sources are crucial, as no credit lines are available for health care so far. Even if people possess health insurance cards, they usually face additional expenses including costs for transport, special treatment and medication. People staying in hospital must further cover the expenses for food or a second family member has to provide food for the hospitalized person. A complex administration system and language difficulties are further constraints that are particularly faced by members of ethnic minority groups - especially women.

As suitable and accessible formal insurance markets hardly exist in developing countries, informal risk-sharing arrangements, so-called social networks, are crucial for the survival of the poor. In Vietnam gender, marital status, kinship and wealth influence the formation and size of social networks and within these networks, self-interest is the main motivation for helping each other (Beuchelt 2004). Hence, mutuality is of utmost significance and when not guaranteed or anticipated, support is very limited, even within the own family. Due to limited resource endowment, the capacities of networks of poor people are exhausted earlier than those of richer households. These informal risk-sharing networks provide basic support, but are insufficient to entirely buffer severe crisis of vulnerable households, thus intervention by the state is needed.

40.3.2 Case Study Bangladesh

In 2005, the population of Bangladesh was more than 153 million people, of whom 49.8 per cent live below the national poverty line²⁴. Even though significant progress could be reached in income and poverty reduction, poverty is still wide spread. During the 1990's the proportion of people below the poverty line declined by one per cent per annum while income inequality worsened, increasing faster in urban than in rural areas. In the HDR 2007/2008, Bangladesh is ranked as 140 out of 177 countries and its HDI value is 0.547 (cf. table 40.1).

The poor in Bangladesh receive very inadequate governmentally subsidized health care. They must finance health expenses themselves or rely on self treatment in case of illness. In most cases, visiting a *kobiraj* (traditional healer) is used first and transfers to tertiary health care facilities occur at a very late stage. Especially in rural areas, most poor people are either unaware of these facilities or do not have access to formal health care at all. A union-level (lowest tier of government administration) health and family welfare centre, which is the nucleus of primary health care, usually provides the first contact between people and the health care system.

In 2006, less than 40 per cent of the population had access to modern primary health care services. If available at all, the quality of health care provided by the government and in private clinics is often very poor. Lack of appropriate diagnostic facilities, over prescription of antibiotics, post-operative infections, doctor absenteeism, inadequate nursing services, lack of attention for patients and lack of sensitivity to women patients are just some examples (GOB 2002). A discrimination against female children in the provision of food was noted (Chen/Huq/D'Souza 1981). Despite some progress regarding this sad issue, discrimination in health care for women and girls has persisted (Perry 2000).

The status of reproductive health is very unsatisfactory and in addition, HIV/AIDS is a severe threat. The reasons are poverty, lack of access to health care, illiteracy, social stigma and other factors, including micro-nutrient deficiency. Despite several improvements, the maternal mortality rate is still very high, with 3.2 to 4 maternal deaths per 1,000 live births, of which 25 per cent are associated with haem-

23 According to Thomson (2004), the encouragement of female farmers to participate in credit and extension projects has largely succeeded and positive correlations between female loan-taking and rise in the knowledge level in families have been shown.

24 UNDP, 2007a: "HDR 2007/2008 - Country Data Sheet Bangladesh", at: <http://hdrstats.undp.org/countries/data_sheets/cty_ds_BGD.html>.

orrhage and anaemia, due to iron deficiency²⁵. According to the World Health Report 2005²⁶ children spend nearly 75 per cent of their life in illness, mostly due to malnutrition related debility and infections. Poor nutrition affects physical, cognitive and mental development.

Poor people must bear many hidden costs to get access to health service. They are exploited by the government medical staff with bribery, overcharging, and delay in the treatment of poor patients (Narayan 2002). People who visit private doctors must pay for the service. This may force them to reduce their current and future consumption or tap into the existing social networks. To ensure a more equitable and appropriate access to health services, it is essential to take the needs of previously underserved minority groups into account (WHO 2000b).

While there has been substantial progress in disease prevention and control and a decline in childhood communicable diseases, new and old infectious diseases, such as malaria, tuberculosis (TB) and acquired HIV/AIDS are still important health threats (for more details see table 40.1). Malaria is a major public health problem in Bangladesh, where 13 out of 64 districts belong to the high-risk malaria zone, affecting 14.7 million people. TB is also a major public health problem and it is estimated that about 70,000 people die every year in Bangladesh.

According to UNAIDS estimates Bangladesh had about 18,000 adults and children living with HIV infection at the end of 2005. Significant underreporting of cases occurs because of the country's limited voluntary testing and counselling capacity and social stigma, which leads to the fear of being identified and detected as HIV positive. Risk factors include a large commercial sex industry and low consistent condom use, which also increase the already significant prevalence of *sexually transmitted diseases* (STDs) among sex workers in central Bangladesh, where about 43 per cent of female sex workers and 18.2 per cent of male sex workers have syphilis. The incidence of STDs and HIV/AIDS are closely associated with the level of poverty and the overall situation of the health status shows how and why health should be addressed as a human security issue in Bangladesh.

Poverty is also often associated with a lack of education and illiteracy. This indicates that the knowledge of the risks as well as the prevention of HIV/AIDS is inaccessible for the poor people. The Bangladesh Demographic and Health Survey (2001) shows that only 31 per cent of women and half of the men heard of HIV/AIDS. Among currently married men only 23.3 per cent with an education ever heard of HIV/AIDS, whereas 85.1 per cent having secondary education heard of HIV/AIDS. 76.7 per cent of respondents without education do not know how to avoid HIV/AIDS. For those with secondary education the percentage is 14.9 per cent. Poverty related lack of education reduces health and increase human insecurity. One could say that poverty often forces people to engage in 'high risk behaviour'. Poverty driven labour migration and commercial sex work are activities that increase and spread the HIV infections (Collins/Rau 2000).

40.3.3 Lessons Learned

In recent years the governments of Vietnam and Bangladesh attained several notable achievements, including good economic performance, income growth, improved nutrition, health and education levels as well as reduction of population growth and poverty (table 40.1). However, with about half of their population living below the national poverty line, poverty rates are remaining high and the access to basic human capital assets, e.g. education and health care facilities remains insufficient.

Concerning maternal-, infant- and under-five mortality rates, the situation in Vietnam is less severe than in Bangladesh, where it is about three times as high (table 40.1). This confirms statements of the HDR 2004²⁷ that stressed Vietnam's ability to translate income growth into human development. Nevertheless, both countries still face deficiencies in the quality of social services and the case studies stressed that despite existing improvements, there are still many constraints vulnerable persons have to overcome.

People's livelihoods and hence their human security are affected by various constraints related to poverty and health, e.g. lack of nutritious food, safe water and sanitation facilities, poor or overcrowded hous-

ing, lack of accessible public health care facilities and skilled personnel. Imperfect/non-existent insurance markets, gender inequality, political will and stigma worsen the situation. The 'freedom from preventable diseases', equitable access to health care services and prevention of STDs and HIV/AIDS combined with suitable poverty reduction strategies can help to ensure the freedom to survive.

Strategies and interim success stories of achieving the MDGs still vary in developing countries, including Bangladesh and Vietnam. Specific targets were devel-

oped for each country and preliminary results are published in various reports²⁸. The government's efforts to reach the MDGs mainly aim at supporting the country's sustainable development²⁹ and thus bear the

potential to improve human security. However, no literature could be found that discuss the application of a specific 'human security concept' for Vietnam or Bangladesh.

40.4 Conclusion and Recommendations

Two case studies on Vietnam and Bangladesh were selected to review the linkages of poverty, health and human security in developing countries. Based on current debates of the concept of human security, particularly in Asia, the country's achievements in terms of poverty alleviation and improvements in the health sector were analysed.

Empirical results, especially from Vietnam, showed that government's efforts to reach the MDGs can be considered as a first step to improve the country's overall development and thus the 'human security' of its people. Nevertheless, vulnerable groups are still considerably affected by poverty and health constraints. The situation in Bangladesh, one of the most hazard prone countries in the world, is even worse.

Poverty related lack of education reduces health and increase human insecurity. Spread of knowledge on basic health care and reproductive health, STD and HIV/AIDS, particularly among the vulnerable groups, is as important as the political will to change cultural bias which so-far avoids efficient prevention programmes. In general, it is crucial to ensure good governance in the whole public sector, not only in the health care sector. New projects should be developed for areas that are left behind. For example, (micro-) insurance schemes in combination with improved extension services and knowledge transfer for all people, especially women, could support a sustainable future development of poor households and therefore, in the long-run, lead to poverty alleviation.

The concept of human security is a reliable tool for facilitating academic and political discussions as well as research and development activities - particularly in combination with the MDGs. Nevertheless, a common definition is still not available for this holistic approach and governments seem not yet to integrate a specific concepts of 'human security' in their policies, as it can be found e.g. for concepts of 'sustainable development'.

41 Global Trade: Balancing Existing and Future Regional Water Resource Deficits

Tony Allan

41.1 Introduction: What is Water Security?

This chapter evaluates the extent to which the well-established international ‘virtual water’¹ trade will continue to mobilize the ‘soil water’ and freshwater in the global system to meet future local water needs. The chapter emphasizes the role of virtual water ‘trade’ but it also examines the contexts and driving forces that have and will determine whether peoples and nations enjoy water security. These contexts and driving forces are first, demography, secondly the extent to which returns to water can be increased in agriculture to meet future food and energy (bio-fuel) needs, thirdly, the extent to which water use efficiency can be improved in industry and services, and fourthly, the pace at which economies can lift themselves out of poverty. The discussion emphasizes the need to conceptualize water security by accounting for all the types of water that meet the gross water requirements of societies, economies and environments. The analysis ranges, therefore, beyond freshwater – that is, surface and ground waters.

Two types of water security are addressed in this chapter. The main focus is on the water security of communities, economies and regions. It will be shown that local water security can be achieved, even

when there is insufficient water locally, by ‘importing’ virtual water embedded in water intensive commodities. Since about 1970, all the Middle East and North African region has depended on such trade. Virtual water fills the gaps between the water actually needed by the local society, its economy and the environmental services provided by water and the smaller volumes of water actually available.

The second type of water security is water security at the global level. The present global population of 6.5 billion needs about 6.5 billion cubic metres of water per year; about 86 per cent for food, and the rest for drinking and domestic uses and for other jobs in industry and services. A balance has also to be struck vis-à-vis the needs of the environment. The volume needed by the future population of about nine billion will be 9000 billion cubic meters per year. The purpose of this chapter is to highlight the very successful achievement of local water security by those economies that diversify so that they can ‘import’ virtual water. Water surplus regions meet the needs of water deficit regions through trade in water intensive commodities. The extent to which the global system can provide water security for the overall water demands of future populations is also discussed. The main aim of this chapter is to establish the importance of economic processes beyond the water sector in the achievement of a form of water security by the water scarce. This form of water security is heavily dependent of orderly international relations. These last are beyond the scope of the analysis

Having established the role of virtual water and commodity trade in providing local water security in a world at peace it is possible to use the same political economy concept to define different levels of water scarcity. An economy which is not self-sufficient in food because it lacks water, or does not manage its water resources in agriculture efficiently, is water scarce. An economy that does not have sufficient water for food self-sufficiency almost always, however,

1 Virtual water is the water needed to produce a commodity. Water is embedded in the commodity in the sense that if the commodity were to be produced by an importing economy local water would have to be mobilized. It requires about 1,000 m³ (tonnes) of water to produce one tonne of wheat. It requires about 16,000 m³ to produce a ton of beef. For one cotton tea shirt it requires about two m³ of water; for one pair of leather shoes it requires eight m³ (Hoekstra/Chapagain 2007). The ‘virtual water’ and ‘virtual water trade’ concepts have been developed by: Allan (2001, 2003, 2003b); Chapagain/Hoekstra (2003, 2004a); Chapagain/Hoekstra/Savenije 2005; Hoekstra/Hung (2002, 2005).

has sufficient water to support a diverse and strong economy. More than half of the world's 200 economies are water scarce in the sense that they are not food self-sufficient. All the 22 economies of the Middle East and North Africa endure water scarcity as they are not food self-sufficient.

The chapter also emphasizes the different types of water that enable economies to be water secure or economically secure. Water in the soil profiles – normally ignored – is shown to be the major water resource for many economies and for the world's populations as a whole. Globally soil water is the major type of water that when embedded in agricultural and livestock products is 'conveyed' virtually to water and food deficit economies. It is this international trade that enables water scarce economies to be water and food secure. Water scarce economies avoid the economic and political stress of mobilizing and over-using scarce local water and further damaging their water environments by 'importing' water embedded in commodities – mainly in food.

Soil water is ignored by water resources professionals and by those making water policy. because it cannot be pumped or easily valued. As a consequence it has also escaped the attention of engineers and economists. Invisible soil water and the invisible 'trade' in virtual water have been securing economies facing water scarcity for millennia. The invisible remedy has been particularly important during the last quarter of the twentieth century when scores of economies encountered serious water deficits as their populations increased.

The national and regional water deficits that emerged across the world in the last quarter of the 20th century have stimulated a number of responses: *first* there is a range of technological measures to increase supply; *secondly*, technical, behavioural and institutional measures that have reduced demand, by increasing water use efficiency and sometimes by reclaiming the environmental services of water; *thirdly*, and most significant have been the adaptations made possible by the global trade in water intensive commodities.

The analysis emphasizes the rich explanation derived from a political economy approach. Social and economic development brings about diverse, strong and capable political economies that multiply the options for those facing water scarcity. The analysis will highlight the numerous options available to those consuming and managing resources in rich and diverse political economies. These economies have the capacity to adopt powerful and flexible economic proc-

esses. But it is political processes that are most important as they create the contexts that enable effective economies.

Politics also mediates the way economic solutions are perceived. For example solutions such as trade have worked miracles in ameliorating water scarcity but in the political domain they are subordinated to the interests of those leading and managing the economies. For the detached outside analyst, without political entanglements, the 'import' of virtual water in food commodities is an evident underlying positive fundamental. It explains the economic security of a national economy and of the global economy as a whole. For a water professional or prime minister of a food importing economy such imports are evidence of insecurity. If attention is drawn to such insecurity there could be very high political prices to pay. For example a president of a water short country enjoys the actual security brought by importing subsidized food commodities. But it is an imperative for them that they obscure the absence of self-sufficiency; this task is a small challenge for the experienced politician.

Those, such as the author and most readers of this chapter have a particular perspective [*positionality*]. They can identify the underlying fundamentals of getting high returns to water and protecting the environmental services of water. Their perspective is different from that of water users and politicians who have not, until recently, experienced water scarcity. Some regions and their water users have often enjoyed water surpluses for millennia. Outsiders are concerned with underlying fundamentals such as water economics and environmental sustainability. These outsiders are concerned with the concrete. Water users and politicians allocating resources, on the other hand, operate in an abstract world of constructed knowledge. Such knowledge is projected to re-assure water users and citizens so that those in power stay in power. As Marx pointed out 150 years ago, the abstract always overwhelms the concrete. A bad idea with power always overwhelms a good idea, such as water security via trade, without power. At least in the short and medium term a very prominent example of such a discourse is the current debate on climate change.

The purpose of this chapter is *first*, to provide a perspective on the status of global water resources (4I.2 and 4I.4). *Secondly*, to evaluate their capacity to meet the needs of current and future human populations and at the same time sustain the environmental services provided by water resources (4I.3). It is shown that 'soil water' plays a major role in securing water security for water deficit economies. It plays

this role when embedded in agricultural and livestock products. It is 'conveyed' virtually from water surplus economies to water and food deficit economies enabling them to be water and food secure. These water scarce economies then avoid the economic and political stress of mobilizing and over-using scarce water and further damaging their water environments.

Thirdly, this evaluation of global water security requires an analysis of the main driving forces that determine the changing nature of the water supply/water demand relationship (4I.5). The numerous factors affecting current and future water resources security can be summarized into five major driving forces and ameliorating processes. The four driving forces are: a) the future demands for water related to future demography; b) the capacity of the agricultural sector to increase returns to water; c) the capacity of other water using sectors to manage water demand to increase water use efficiency and at the same time protect the water environment; d) most important are the over-arching socio-economic processes that enable economies first, to lift themselves out of poverty and to engage in international trade to address, if necessary, their local water scarcity. It is poverty that determines water poverty. Water poverty does not determine poverty. e) The fifth factor affecting the water security of an economy is the ameliorating process of virtual water 'trade'. The process currently enables water surplus economies to meet the water needs of the water scarce (4I.6).

Currently it is this fifth, virtual water 'trade', factor that is meeting the water needs of water deficit economies such as those of the Middle East, Japan and Europe. In the long term, however, it has to be a combination of the management of all four driving forces and international trade that will address, or not, the challenge of providing secure water for all needs for all economies.

Fathoming the world's water futures is fraught with uncertainty. The uncertainties are socio-economic and relate to population trends, the capacity of water users to use water more efficiently in agriculture and industry, as well as the patterns of the future consumption of food and industrial commodities. Most important are the uncertainties deriving from political instability and armed conflict. Political instability determines whether the global trading processes that bring water security will operate or even exist. Most economies endure water deficits and their current water security depends on international political stability. Armed conflict and political instability currently are seriously impacting the capacity of some eco-

nomies - especially in Africa - to be water secure. Conflict impairs their access to local and international trading systems. A global conflict would reveal the extent of the dependence of water security - of almost all economies - on international commodity, mainly on food trade.

4I.2 Political Economy of Regional and Global Water Security

Evidence of water scarcity is normally evidence of the extent to which a political economy is well-functioning, but not of the status of its water resources. The chapter will take a political economy approach. Poorly governed economies tend to be poor. Poverty determines water poverty. Well functioning political economies have invested in effective water infrastructures. They have provided domestic, industrial and agricultural water services as well as water treatment to protect health and the environment. These well functioning political economies can also generate incomes and revenues with which to engage in international trade. Through international trade water and food scarce economies can access commodities that cannot be produced using the limited water resources available in the local economy.

People in poor non-diverse economies have poor water services and infrastructures and frequently cannot mobilize their local freshwater and soil water effectively to raise sufficient food. Nor can they generate the incomes to access water intensive commodities, for example food, on the global market. Evidence of water scarcity is normally evidence of the extent to which a political economy is well-functioning, not of the status of its water resources.

Strong and diverse economies do not have water problems. In rich economies in Europe and North America, poor households have water problems. They cannot pay for their water services. In poor and non-diverse economies in the South rich families also do not have water problems although they do not enjoy the reliability of water services as those who live in OECD countries. But vast numbers of households in these poor, non-diverse economies have serious and enduring water problems. *Water poverty does not determine poverty. Poverty determines water poverty.*

The analysis emphasizes the way economies have adapted to water scarcity rather than quantifying the water endowments of individual economies. It is also essential at the outset to conceptualize and understand the nature of water resources. Water resources

come in two main forms – freshwater and soil water. Our economic systems overall need water for drinking water, for domestic water, for water to provide food and for other agricultural products (for fibres), and for industry and the services sector. Our environments also need water to sustain the environmental services of water.

The water in the environment is found in a hydrological system of flows and storages. These flows and storages take place at the surface, in groundwater aquifers and in soil profiles. Freshwater in surface and groundwaters is special because it can be diverted, pumped and conveyed by users to new locations. It can also be drawn upon for all uses – domestic use, agricultural use, industrial use and services use. Soil water can only be used for crop and livestock production.

By the end of the 20th century 4.6 per cent of water was being used for domestic purposes, 9.6 per cent for industry and services and 86 per cent of the water used world-wide for agriculture. Freshwater from surface and ground waters accounted for 26 per cent of global water use. Soil water accounted for 74 per cent. It should be noted that freshwater, despite being only 12 per cent of the water devoted to agriculture, it accounted for over 40 per cent of the output.

Freshwater is very valuable, *first*, because its strategic role in food production. *Secondly*, it can enhance the value of soil water by supplementing water in the soil profile. *Thirdly*, it is valuable because it can be devoted to all economic sectors, some of which use water so effectively that they enable the development of diverse and strong economies. These strong economies secure the prosperity of even the extremely water scarce, such as Singapore. But freshwater is not the major volume of water used in our economic systems.

The major value of freshwater is its third value in underpinning a very high proportion of the jobs in diverse and strong economies. It makes possible more jobs per drop. There can also be more jobs per drop in agriculture if higher value crops are raised which need more labour inputs. Agriculture can be managed to increase the labour input two- or threefold. Although market forces and the mechanization and industrialization of agriculture tend to reduce farm labour, industry, by contrast, can increase jobs per drop a hundred fold. In service activities the contrast is even starker. In marketing, commerce, education, civil service administration, in some tourism, and in advertising and financial services the increase in jobs can be a thousand-fold that of agriculture. It is this economic diversification in water scarce economies that enables

them to be secure, *provided there is enough water in the global system* to meet the food needs of future populations. The task of this analysis is to estimate whether there will be enough water to meet the water demands of a diversified global economy.

41.3 Water Availability and Future Requirements

There is sufficient water to meet the needs of the world's currently configured economies. Fathoming the world's water futures, however, is fraught with many uncertainties. These uncertainties include *first*, population trends, *secondly*, the capacity of water users to use water more efficiently in agriculture and industry, *thirdly*, the patterns of future consumption of food and industrial commodities, and *fourthly*, the unfathomables of political stability and armed conflict that determine how economic processes and globalization play out.

Water professionals tend to assume that solutions to water scarcity will be found in the water sector. They have technologies that address rising water demand by supplying and treating more water. More recently the approaches of demand management have been adopted. These approaches also focus on the water within national watersheds. But effective water resources allocation and management within watersheds is just one of several inputs that lead to the creation of diverse and strong economies.

Where an economy cannot meet its water needs for domestic uses, for its food needs, and for the jobs in its industries and services it has to look beyond its own watersheds. A hydro-centric approach is a very narrow and dangerous analytical perspective (Brichieri-Colombi 2004). The second half of the 20th century has witnessed a little heralded adjustment. The peoples and economies of the world's 200 or so national economies have adapted to demographically driven increased water demands. These adaptations are discussed briefly here to provide a flavour of the uncertainties integral to understanding the future global and regional water security. The scale and pace of adaptation to water scarcity has been patchy.

The neo-liberal economies of North America and Europe in the temperate northern hemisphere have produced a surge in rainfed crop production in the second half of the 20th century. This surge came at a time when other economies were coping less successfully in terms of socio-economic transformation with increases in their populations and very sluggish eco-

conomic development. The major Asian economies did, however, also produce a surge in crop production and productivity in the same period. Africa meanwhile has rapidly rising populations and stagnant economies.

The late 20th century challenge of, and adaptation to, evidence of increasing water scarcity has fortunately occurred in a period when the neo-liberal industrialized economies in temperate North America and Europe put in place a remarkable experiment. They tested how much farmers would produce, especially on rainfed farms, if given strong incentives. The purpose of this agricultural experiment in these neo-liberal economies was in some cases to increase food self-sufficiency. For others it was judged necessary to secure rural livelihoods in rapidly mechanizing farming systems. Rural societies were in rapid and stressful transition to part-time farming. The outcome of this experiment in the new high input and high output farming in North America and Europe was to almost double by the 1990's the already high returns to soil water at mid-century. Populations also rose. But very little compared with the rates of the late 19th century and the first half of the 20th century. In some European economies populations fell below replacement rates by the 1990's.

Together the farmers of the European Community and North America achieved much higher returns to soil water between 1950 and 1990. The controversial subsidized systems of the EU and of the US Department of Agriculture created global market circumstances in which they competed down the world prices of staple grains. World prices were on occasions half the costs of production. For many economies world-wide this was good news. Many economies, in for example the Middle East and North Africa, encountered water scarcity for the first time after 1950. Even more did so after 1970. Where they could devote some of their national revenues to food imports – and they mainly could – the low price of grain was very good news. For many economies in Africa South of the Sahara, however, where yields were less than one tenth those on rainfed European farms the new circumstances were malign. These economies had neither the hard currency to afford the low world grain prices nor could they price their own agricultural commodities locally to match their farmer's costs of production. Languishing yields and poor performances of agricultural sectors are evidence that farmers lack the stimulus of fair commodity prices (Berkoff 2001). Underperforming but strategically important rural economies in turn slow down the development of the economies of which they are a part.

Diversification of the economy as a whole is also slowed down. The relevance here is that it is non-diversified economies that have water problems.

That the global market can secure economies, including their water security, is spectacularly evident in Europe. Some major European economies have been dependant on the global market for their water and food security for well over a century. This dependence on imported food was highlighted by the disruptions to trade of the 1939–1945 war. As a consequence a post-war experiment was launched to reduce this dependence on global trade. The experiment has had unintended global consequences – for example on world grain prices – and these consequences have been complicated by some other social challenges which had to be faced by the governments of both Europe and North America. They had to cope in the area of social policy with an unprecedented mid-twentieth century agricultural revolution. The revolution involved technologies transforming cultivation, nutrient management, weed and pest control, and harvesting. Most of these radically impacted agricultural productivity and/or rural employment. A new priority emerged. The support of farm incomes in rapidly expanding industrialized economies became salient. Rapid socio-economic development and rising incomes forced governments to address the social impacts. Production and trade subsidies were introduced to enable farmers and farming to survive. These subsidies have been stubbornly enduring and have severely tested European unity. The subsidies were high but generally acceptable for the strong and diverse North American and European political economies. By the second half of the 20th century the US and EU agricultural sectors were contributing progressively smaller proportions of national GDPs, in some countries only one per cent. The proportion was rarely over five per cent. The contribution of agriculture to most of these Northern economies was within the precision with which GDP can be estimated.

By the end of the century European economies had got used to agricultural sectors producing much less than five per cent of their GDPs with similar proportions of farmers in the employed population. Other economies with substantial agricultural economies and with surplus production to meet the needs of the water and food scarce, in for example the southern hemisphere – Argentina and those in Australasia – had to endure unreasonable international competition in the grain trade (ABARE 2000). Commodity surpluses and low world commodity prices

were the consequence of European and North American agriculture over-producing strategic food commodities and not reflecting the fiscal impacts of subsidies in their export prices. The subsidies secured the incomes of their farmers and funded some of the costs of alleviating the impacts of agricultural intensification on their natural environments. Strong and diverse economies have many options in an unregulated trading regime. This nexus of productivity and social policy have been associated in the agricultural sector with the use of soil water more productively but also with the abuse of the environment.

The reason why the North American and European experiment has been examined in a little detail is that the 'experiments' of the past half century have highlighted how a number of processes integral to the global economy play significant roles in enabling national water security. The impacts can be negative, however, at the global scale in worsening the options of some weak economies. At the same time the impacts can be positive by enabling - without either economic or political stress - the national water resource security of most of the water scarce economies of the world. Such economies may be poorly endowed with water - Japan and Singapore for example, or not sufficiently diversified to be economically secure - many Middle Eastern economies, or even economically dysfunctional - many Sub-Saharan economies.

41.4 Global Water Resources: A Summary

What are the water resources available for human users and the protection of environmental services? The water resources of the world are vast. But most are of an unusable quality - for example sea water - and most groundwaters as they are saline or currently too costly to develop.

The demands on the water environment have only increased in the relatively recent five millennia and mostly in the past century. Through several millions of years of evolution human individuals needed less than five litres of freshwater per day to survive for drinking. They did not need additional domestic water. Nor did they raise crops until relatively recently. It did not matter that the hydrological and ecological systems on which human societies and economies depended varied greatly spatially and seasonally. The demand for freshwater was trivial and the consumption of food derived from natural vegetation and animals also had negligible impact on the water environment

- whether soil water or fresh water. The five litres per day of easily available water has, unfortunately, been 'hard-wired' into the expectations of the human race. This unchallenging entitlement is a deep and dangerously embedded assumption as it is only about half a per cent of the water used by the world's inhabitants today.

Hoekstra and Chapagain (2004) estimate that 1,250 litres per day are needed by an individual to survive comfortably in an industrialized society in the early 21st century. They have shown that the levels of water use range from 2,500 litres per person per day (ppd) in the industrialized United States to about 700 litres/ppd in China. Most highly industrialized economies in the EU and Japan manage with between 1,100 and 1,500 litres/ppd. Human societies have, unfortunately, chosen very frequently to expand their numbers in places where the water resources are not available to meet the high water volumes needed by industrialized societies, e.g. in the arid and semi-arid regions of Asia, Africa and the Middle East.

Water resources that supply these water demands come in two main forms - freshwater and soil water. All the freshwater and soil water available for human and natural use is delivered originally by rainfall. Freshwater can be diverted and pumped from surface water - from rivers, lakes, and reservoirs - and from groundwater. Groundwater is the water lying some distance beneath ground level. It has percolated from the surface after precipitation. Soil water is located in the soil immediately below the surface and is used by natural vegetation and crops. They draw water from soil water in the soil profile as it is percolating downwards to the groundwater table. Soil water is not stored in the profile. It is accessed by the roots of vegetation and crops to enable plant development and growth and for transpiration. The water which is not intercepted by the roots of vegetation can continue on its way to recharge the groundwater reservoir.

Hoekstra and Chapagain (2004) have estimated that most of the water - 86 per cent - used in human economic systems derives from soil water (table 41.1). This is not the same thing as saying that most economic value derives from the use of soil water. Most soil water is used in agriculture and it produces a very low return to water in terms of value. These vast collective low returns are of great strategic importance, however, as they provide the majority of our agricultural commodities globally.

The message from table 41.1 is that the water security of the world is mainly provided by soil water, as 86 per cent of the world's water derives from soil pro-

Table 41.1: Estimates of global use of water and 'trade' in virtual water. **Source:** Hoekstra/Chapagain (2004) and author's estimates (*)

	Used in economies				Proportion of global food production	'Traded'

files. Unfortunately soil water is everywhere counted as a free good. Its value is indirectly reflected in the higher rental value of land that has moist soil profiles either seasonally or perennially. Calculations of productivity in relation to soil water are usually, and properly, made with reference to area rather than to water use. In semi-arid countries that have advanced industrialized economies, such as Australia and the United States, the returns to millimetres of rainfall in rainfed farming are often quoted. To compare the productivity of rainfed agriculture with the productivity of irrigated farming it is necessary to quote returns to a cubic metre of water use.

Crop yields in terms of area are much higher from irrigated farming. But the water inputs are roughly proportional in terms of output. As a consequence irrigated farms produce about 40 per cent of the world's agricultural production while only calling on 14 per cent of the water used in crop and livestock production. Freshwater in irrigation systems supports yields per hectare as much as four times those from rainfed farms.

The role of soil water is very significant in global trade. There is no researched figure for the proportion of virtual water derived from soil water but it can be approximated. All the major traded agricultural and livestock commodities - wheat and barley, tea and coffee, and most of the maize, soya, sugar, bananas, and almost all the livestock - are raised in rainfed systems. It is likely that over 80 per cent of these commodities in global trade are raised with soil water.

The significance of the proportion of soil water in global agricultural systems is important. This water has stabilized many of the world's economies during the first phase of water scarcity where some economies - such as those of Europe, Japan and Korea and

all the Middle Eastern economies - would have been seriously destabilized by their inadequate water resource endowments. Soil water is also of pivotal strategic significance as it is in rainfed farming that there is significant potential for increased productivity in for example Africa. The advances made in the industrialized economies over the past century show that it is possible to increase by many times the yields and the productivity of soil water used in crop land and pasture production. Effective agronomic practices and a diverse range of market and institutional arrangements were shown bring major advances in water productivity. It has taken centuries to mobilize effectively tens of inputs and countless institutional forms in advanced agricultural systems. The farming systems in many impoverished economies in sub-Saharan Africa have not yet mobilized these numerous farming practices and enabling institutions, including price incentives, which would bring about high returns to scarce water and especially scarce soil water.

These higher returns to water cannot be obtained in circumstances of poverty, civil insecurity, and the consequent absence of sustained market incentives. Yields of half a tonne a hectare were common in 18th century Europe when the rural economies were as insecure, unhealthy and afflicted by poverty as those of Africa are today. Africa's water problems will be substantially solved when poverty is eradicated and institutions and markets can operate effectively and safely. Increases in returns to water of ten times will not be necessary. Increased water productivity of only two to three times in crop and livestock production will be sufficient. Such improvements have been achieved in the industrialized economies that farm unpromising semi-arid tracts in Australia and North America (Chatterton/Chatterton 2006).

41.5 Driving Forces and Scenarios

In order to answer the questions associated with the challenges of achieving current and future water security it is necessary to cope with a number of uncertainties. The absence of a definitive understanding of current and future water security reflects these major uncertainties. In brief the uncertainties are:

- Demographic trends and the pace of the demographic transition;
- Water use efficiency in agriculture;
- Water use efficiency in industry and the services sector;
- The dynamics of food consumption patterns;
- The dynamics of consumption patterns of industrial commodities and services;
- The consideration given to the environmental services of water;
- The levels of diversification and strength achieved by the water using economies.

It is not possible to treat each of these issues exhaustively. Particular remedies such as desalination and water re-use will be of strategic significance for many economies, but they have not been discussed here. There will be an attempt to highlight the main features of the uncertain water futures to show how they are likely to figure as driving forces in the next half century and beyond. All the issues are associated with high levels of uncertainty. The combined uncertainties make the reliability of any predictions very low indeed.

41.5.1 Demographic Trends and Demographic Transition

What will be the impact of demographic dynamics on the global demand for water? There is a close relationship between the demands for domestic water together with the demand for water for food and the number of consumers.

The volume of *high quality* domestic water used by an individual is small – 10–50 m³ per person per year provided at a cost of about US\$ 1/m³. The volume of *low quality water* needed to meet the food needs and preferences of an individual is, however, large. It ranges from 500 to 1000 m³ per person per year. This water has to be provided at very low costs ranging from zero to US\$ 0.10 /m³. It has been calculated that the global average consumption of water per day by an individual is about 1,250 litres/p/d. In more developed economies with tendencies to high

consumption of all types of commodity – for example the United States – the levels of water use are higher at about 2,400 litres/p/d. China's consumption is much lower at about 900 litres/p/d.

An approximation of how future estimates of population will impact on the demand for water requires assumptions about:

- the pace of the demographic transition in the more and less developed economies, and
- the future levels of use of water by the more developed and the less developed economies.

The more developed – industrialized – countries have reached the final phase of the demographic transition where populations are at replacement levels or just below. The less developed countries have different demographics. China with 1.3 billion people has had a strong population policy for the last decades of the 20th century and is already approaching replacement. India with over one billion people is still expanding but is showing signs of reducing its rate of growth. The economies that have populations that could more than double by 2050, and even grow beyond mid-century are the least developed economies of Sub-Saharan Africa, such as Ethiopia.

An attempt has been made to summarize the nature of population in table 41.2 that shows estimates of the combined effects of demand for water driven by the median variant of the UN population projections, augmented by other estimates including some interpolations by the author.

Table 41.2: Population estimates for more and less developed economies – UN medium variant in millions. **Source:** UN (2004), Medium Variant, US Census Bureau, historic estimates and author's interpolations.

	1800	1850	1900	1950	2000	2050	2100
More developed regions	300	400	550	812	1193	1236	1100
Less developed regions	660	850	1100	1707	4892	7840	7500
Total	960	1250	1650	2519	6085	9076	8600

It is clear from the above data that the population driving force is extremely important. Whether one uses the low or the medium variant is also very significant. Estimating future populations has proved to be a very unreliable activity. On the basis of our past tendency to underestimate the rate of the demographic transition it is likely that future populations will be

Table 41.3: Water use estimates per head in litres per day assuming level use by less developed economies and a reduction by users in more developed economies. **Source:** Hoekstra/Chapagain (2004) and author's estimates.

	1800	1850	1900	1950	2000	2050	2100
More developed regions	950	1100	1200	1400	1700	1500	1400
Less developed regions	900	900	900	900	900	900	900

Table 41.4: Water use in more and less developed regions on the basis of population estimates [medium variant] and projected use in Laces same as in 2000. **Source:** Author's estimates.

	1800	1850	1900	1950	2000	2050	2100
More developed regions	285	440	660	1137	2028	1854	1540
Less developed regions	661	851	1101	1708	4893	7841	7501

nearer the low variant than the medium variant. The main challenge will be in the economies of Sub-Saharan Africa where population increases will drive up demand and current adaptive capacities are very limited.

41.5.2 Water Use Efficiency in Agriculture

The unprecedented population increase in the second half of the 20th century was fortunately matched by an unprecedented adaptation in the economies of the high income economies of North America, Europe and Oceania. The productivity of soil water doubled between 1950 and the 1990's. Even more important was the adaptation in China and South Asia. A combination of extensions of cultivated and irrigated area and the mobilization of more water – especially groundwater – enabled production of key grains such as wheat, maize and rice to increase by four and five times.

It is unlikely that the more developed economies will achieve further increases in water use efficiency. It is probable, however, that the Asian economies will achieve further water use efficiencies. In regions with rainfed farming low cost soil water is available in soil profiles. The costs of water services in irrigation systems are high. But they are frequently avoided by users as governments find it very difficult to charge the full economic costs of irrigation water. A very high proportion of irrigated crops are subsidized as a con-

sequence. The costs of irrigation water are frequently avoided by irrigators because, understandably, they do not want to pay for unreliable water and in addition their incomes are very low.

There has been a groundwater revolution in the last quarter of the 20th century (Llamas/ Martinez-Santos 2005; Llamas/Garrido 2006; Gordiano/Villholth 2006). The intensification of irrigated farming based on groundwater has been responsible for substantial increases in agricultural outputs associated with increased water productivity. Groundwater is much more easily controlled by the irrigator as the wells are usually on the land of the irrigator. Irrigators prefer reliable groundwater under their own control provided through their own investment and operating costs than unreliable water from a public system.

41.5.3 Water Use Efficiency in Industry and the Services Sector

Water users in industry and services in the industrialized countries have been very responsive to the calls to improve water productivity. Private sector companies have responded to the economic pricing of water and to the progressive increases in the regulation of water use and water quality. The research of Chapagain and Hoekstra (2004b) on virtual water and water footprints has been very useful in providing approximations of water use in the major sectors and in the different types of economy. Figure 41.1 shows that industrialized economies have a significant water footprint in consuming industrial goods. They also show that a significant proportion of the water in industrialized goods is associated with imported manufactures – often coming from water scarce economies in Asia.

41.5.4 The Dynamics of Food Consumption Patterns

Consumption preferences change with income. Unfortunately there is a tendency for people to consume more livestock products as their incomes improve. China is already demonstrating this trend and its imports of fodder are increasing steadily. Fortunately China's population is approaching replacement and as a consequence the increase in the consumption of livestock products is viable in terms of its capacity to purchase meat and fodder from abroad. India has a different culture. The majority of its population is vegetarian and therefore the 700 million extra consumers

Figure 41.1: The national water footprint per capita and the contribution of different consumption categories for some selected countries. **Source:** Hoekstra/Chapagain (2007: 44). Permission to reprint this figure has been granted.

by the end of the century will not have such a serious impact on its own and the world's water footprint.

41.5.5 The Dynamics of Consumption Patterns of Industrial Commodities and Services

41.5.5.1 The Experience of Industrialization and Post-industrialization

Estimates of water consumption by people living in pre-industrial, industrial and late industrialized political economies have not yet been adequately researched. The work of Hoekstra and Chapagain (2007) suggests that the consumption of water related to food consumption falls in a late industrial economy such as the US. However, these *late industrial* economies in the North do have a strong capacity to indulge in the consumption of non-agricultural goods (figure 41.1).

A number of trends will affect the future. The *industrialized* economies will tend to reduce both their consumption of agricultural and of non-agricultural goods. This reduction will be the consequence of the increased efficiency of water use and the impact of changed consumption patterns, partly associated with responses to awareness of climate related environmental change. Progressive regulatory regimes will reinforce these tendencies. The industrializing economies will at first increase their water use and some

time before mid-century it is likely that they will adopt the consumption patterns of the late industrialized economies.

Future trends in the non-industrialized economies in sub-Saharan Africa (SSA) are difficult to predict. They have been very slow to diversify and at the same time populations are rising rapidly. Many economies will experience a doubling of population with predictable doubling in food consumption. Africa is not everywhere short of water, however. The economies in SSA have had little investment in their freshwater resources to enhance storage and provide irrigation services. Their farmers, mainly living on rainfed tracts, are subject to serious variability in rainfall and the even more negative impact of low agricultural commodity prices. There is potential to match the increased demand for food with higher levels of water productivity from these underdeveloped rainfed tracts (FAO 2000e). This potential could be significantly augmented by the development of small and large scale irrigation (IWMI 2007).

41.5.5.2 Consideration of the Environmental Services of Water

The water requirements for the maintenance and/or recovery of sustainable environmental services of water is a complicated element of the water needs equation. The late industrialized economies have demon-

Table 41.5: Estimates of water use per head – more and less developed economies. **Source:** Chapagain/Hoekstra (2004b) and author's estimates.

	1800	1850	1900	1950	2000	2050	2100
More developed regions	950	1100	1200	1400	1700	1500	1400
Less developed regions	900	900	900	900	950	1500	1400

strated their capacity to put water back into the environment (Allan 2001). It will take some decades for the industrializing economies to adopt such policies but they are already attempting this approach in China and the other industrializing economies will adopt such measures in the coming decades.

During the period of writing and editing this analysis the world economy was very strongly impacted by the oil price spike after 2006. Oil prices reached US\$100 per barrel; equivalent in constant prices to the spike of 1979–1980.

One of the many consequences of the heightened awareness of energy scarcity was the reinforcement of investment in biofuel production. Brazil had responded to the earlier 1979–1980 price spike by establishing a viable biofuel production systems based mainly on sugar-cane. The post-2006 price spike has led to investment in biofuel in the highly developed economies of both the United States and in Europe, and to a lesser extent in the South Asia and Africa. The initiatives have proved to be very controversial for two reasons. First using land and water to produce energy instead of food has major implications vis-à-vis food availability and just as important for food prices. Secondly, clearing tropical forests to provide land and water for biofuel production has already had serious impacts on the environmental services and carbon sequestration capacities of these tracts.

In the space of only half a decade that which seemed to be a good approach in terms of energy security and environmental services by 2008 was heavily criticised. It now appears very unlikely that biofuel and biodiesel will play a significant role in achieving energy security

41.6 Conclusion: Will There be Enough Water?

The essential question in this analysis is – will there be enough water in the global hydrological system to meet the current needs of the world's peoples and

economies as well as for the demands of the environment? In the discussion so far it has been shown that the extent to which water managing technologies and trading capacities will evolve to meet future demands have also been shown to be very important but they are difficult to quantify.

Water demand will be driven by population and the future consumption patterns of the global society. Food production, the main user of water, will be required for a global population estimated by the United Nations (2004 - medium variant) as about nine billion by 2050.² The global water systems have enough water and food raising capacity to meet the needs of the current population of 6.5 billions. However, data on undernourished populations (FAO 2005) shows that despite the world's endowments of fresh and soil waters the least developed, non-industrialized economies have not yet been able to mobilize their endowments to meet their food needs.

It is the economies of sub-Saharan Africa that have least mobilized their water resources (FAO 2004b). These economies endure second-order scarcities. That is they lack social adaptive capacity and as a consequence they lack the capacity to install the technical and institutional water allocating and managing infrastructures. In addition, they cannot mobilize the necessary surpluses to import water intensive commodities from the world market.

What evidence do we use to establish the adequacy of the world's water resources? Do we assume that because there are some water resources crisis spots that society does not have the capacity to respond and adjust. Using evidence from water scarcity hotspots is not a safe approach. The scarcity hotspots exist because the political economies in those regions have not adapted to their water circumstances. It is the approach of the blind man and the elephant. Using evidence from touching the elephant in diverse places does not provide a useful version of the elephant when the analyst is blind to the whole creature.

In relation to global water resources there is strong evidence that there are some seriously water short basins or parts of basins. The Yellow River does not always reach the sea. The Nile discharges much

2 The United Nations' (2005a) world population prospects of 2004 suggest that a median population estimate would be 9.1 billion by 2050, with a low projection of 7.7 billion and a high projection of 10.6. By 2050 most of the regions will be converging on replacement level or lower. The populations of Africa and the Middle East will still be increasing but at a declining rate.

less than is environmentally sound into the Mediterranean Sea. The Central Asian surface water resources have been irreversibly damaged. These major, but second order regional rivers that have been very important in human history and economic development have been over-used. Most first order rivers - for example the exceptional Amazon with a 7,000 cubic kilometres annual flow, and the others that carry about 1,000 cubic kilometres annually - the Congo, the Mississippi, the Mekong and the Yangtze have been relatively lightly developed in terms of abstraction. Others such as the Ganges and Indus have been seriously developed for irrigation and hydropower with significant impairment. It is the third order rivers that have been most intensively developed and effectively 'closed' to further development. When closure is recognized as it has been in some basins in the Western United States and in the Murray River in Australia - both partly at least in semi-arid regions - it has been shown that policies can be put in place to reduce abstractions. The Colorado in the New World with a flow of 18 cubic kilometres annually is an overused relatively minor water resource. The Orange River at 11 cubic kilometres annual flow in southern Africa is another closed water resource where there is need to put water back into the environment rather than extract further water for irrigation and other uses.

Groundwater resources have also been seriously over-used in all the continents with the exception of Africa. But Africa is not well endowed with renewable groundwater although much research needs to be done to establish Africa's groundwater potential. Groundwater has proved to be a major element in meeting the increased water needs of the unprecedented population increases of the second half of the twentieth century. Groundwater is, however, a fatally attractive water resource for users (Allan 2006). Groundwater is usually high quality, it can be used at

will rather than when nature determines or the schedules of irrigation managers allow. Unfortunately ground waters are even more difficult to manage collectively than surface waters. And when an aquifer closes the tragedy of the commons is normally impossible to reverse at a pace which is relevant to the livelihoods of affected local communities (Handley 2001: 53). There is at the same time strong evidence that over-intensive use of groundwater has assisted rural communities to cope with a transition involving improved farm income, the education of a younger generation and the migration of most of the family to nearby cities. This process is evident in the Middle East where permanent shifts have occurred (Allan 2006), and in South Asia where there are flexible and diverse adaptive part-time modes of rural-urban interaction (Moench 2006). In both these cases the 'solution' of urbanization can only be effective if there are water resources in the global system to meet the needs of these expanding urban populations.

Relatively prosperous rural communities also face problems when aquifers close. The experience of the farmers and agricultural enterprises using the High Plains Aquifer in Nebraska, Kansas and Texas is one of expansion, retrenchment, litigation and ethical challenges (Peck 2006). This US case is also a good example of how solutions that served one generation apparently rather well until technological, economic and environmental circumstances change. Then water managing practices are neither economically efficient, environmentally sound nor ethically acceptable. Although they may be legal.

In the span of this chapter it has only been possible to pose the four most important questions on how local water security can be achieved. If they could be answered with high levels of precision the answers would provide useful estimates of future adequacy of water resources to meet future demands of

societies, economies and environments. The four questions addressed related to, a) demography; b) the efficiency of water use in agriculture and in the other economic sectors, c) the changing patterns of consumption of economies at different phases of development and d) the role of socio-economic development in bringing economies to the stage where their adaptive capacities enable them to solve their water problems outside the water sector.

The consideration of these factors has led to the conclusion that there will be enough soil water and freshwater in the global system to meet the needs of well adapted future populations and their environments. There will be regions which will face major water deficits. But the past half century, in fact the past three millennia, have shown that the water in the global system can be accessed by individual economies via 'trade' in virtual water. Table 41.6 shows how about twenty per cent of the virtual water related to crop and livestock production is moved between the world's economies. That this virtual water 'trade' is not increasing in some key staple food commodities such as wheat - despite increases in the human population - suggests that there are important water resource management efficiencies being achieved.

The future is complicated by many unknowns. The impact of bio-fuel production on the use of water is as yet unclear. Such production could reduce the availability of food commodities on the international market. This in turn could affect world food commodity prices. But stronger food staple prices are needed to provide the incentives for subsistence farmers, in for example sub-Saharan Africa, to increase their crop and livestock production.

What about the future? The world's political economies have coped with a threefold population increase since the mid-20th century. They will have to mobilize a further 2,500 km³ (billion m³) per year to secure a global population which will level off in the second half of the century. There have been spectacular advances in rainfed and irrigated agricultural productivity and it is argued here that these advances in late industrial economies will be emulated to some extent in as yet non-industrialized economies. Another unknown is the extent to which, and how quickly, the water needs of the environment will be addressed.

The pressures of water demand, the possibilities of further advances in water use efficiency in all productive sectors and the uncertainty of the pace of adaptive capacity of all the political economies, are impossible to predict with certainty. Nor is it possible

to predict the future stability of the world's political systems. It is this stability that will be crucial to the continued mobilization, and where necessary the expansion of virtual water 'trade'. Such 'trade' has been shown to have the capacity to meet the needs of the water scarce with products from economies that are water rich. It is important to grasp that it will be in the domain of politics that the water security of a particular region or of the whole global system will be determined. It is in stable politics that the remedies to water scarcity outlined in this chapter will be mobilized. Conflictual politics will prevent these remedies being combined effectively to bring water security to the water scarce.

42 Water Wars in India

Vandana Shiva

42.1 Introduction

Water has already become blue oil – commodified, dwindling, yet overused and abused. From a renewable resource, it is being converted into a non-renewable resource like fossil fuels – from a community resource it is being transferred into a privatized commodity – to be traded and sold. The transformation of water into a commodity to be traded for profit is also leading to its overexploitation and its long distance transport. Instead of following the laws of ecology and the hydrological cycle, water is being forced into markets. Instead of following the law of gravity – flowing downwards, it is flowing against – upwards to money. And as water is diverted, rerouted, mined and privatized, water conflicts and water wars are an inevitable result.

42.2 Large Dams and Water Conflicts

River valley projects are usually considered the solution for agricultural water needs, flood control, and drought mitigation. In the past three decades, India has seen the erection of some 1,554 large dams. Between 1951 and 1980, the government spent US\$ 1.5 billion on large or medium irrigation dams. Yet the return from this large investment has been far lower than anticipated. Where irrigated lands should have yielded at least five tons of grain per hectare, output has remained at 1.27 tons per hectare. The annual loss due to unexpected low water availability, heavy siltation, reduced storage capacity, water logging now amounts to US\$ 89 million.

The Kabini project in Karnataka is a perfect illustration of how water development projects can themselves disrupt the hydrological cycle and destroy water resources in basins. While the dam submerged 6,000 acres of land, relocating displaced villages required the cleaning of 30,000 acres of primeval forests. Local rainfall fell from 60 inches to 45 inches, and high siltation drastically reduced the life of the dam. Within

two years, water logging and salinity destroyed large areas of coconut and paddy fields nearby.

The damming of two of India's most sacred rivers, the Ganges and the Narmada has generated vehement protest from women, peasants, and tribals whose life-support systems have been disrupted and whose sacred sites have been threatened. The people of Narmada Valley are not merely resisting displacement due to the Sardar Sarovar and Narmada Sagar Dams; they are waging war against the destruction of entire civilizations. As the internationally acclaimed novelist Arundhati Roy puts it:

Big dams are to a Nation's development what nuclear bombs are to its military arsenal. They are both weapons of mass destruction. They are both weapons governments use to control their own people. Both Twentieth Century emblems that mark a point in time when human intelligence has outstripped its own instinct for survival. They are both malignant indications of civilization turning upon itself. They represent the severing of the link, not just the link – the understanding – between human beings and the planet they live on. They scramble the intelligence that connects eggs to hens, milk to cows, food to forests, water to rivers, air to life and the earth to human existence.

Over the past two decades, many men and women have dedicated their lives to the protest of the damming of Narmada Valley and the Ganges. Since the 1980's, two old men have been engaged in Satyagraha (Gandhian nonviolence) on the banks of the two rivers. Sunderlal Bahuguna has been living in a small hut at the Tehri Dam site on the Ganges to block the flooding of Tehri and stop the building of a dam on an earthquake fault. Baba Amte, who resisted dam building in Maharashtra, has been stationed on the banks of the Narmada for years. In 1984, Amte wrote a letter to the Prime Minister, in which he referred to the dams as genocide. Although bedridden due to a severe back problem, he still remains by the valley and says he will go with the river. Medha Patkar, a leading activist of the Narmada Bachao Andolan, and Arundhati Roy have also committed themselves to the fight

against the Narmada Dam Project – the world's largest water project.

The Narmada project consists of 30 large, 135 medium and 3000 minor dams on the Narmada River and its tributaries. It is expected to uproot one million people, submerge 350,000 hectares of forest, drown 200,000 hectares of cultivable lands, and cost US\$ 52.2 billion over the next twenty-five years. The Sardar Sarovar Dam, already under construction, is facing major opposition from human rights and environmental groups as well as tribals likely to be displaced. The dam threatens people in 234 villages. Next in line for construction is the Narmada Sagar project, which promises to submerge 91,348 hectares of land and displace people from 254 villages.

The Narmada Valley protest, which once was a fight for a just settlement of the displaced people, has rapidly evolved into a major environmental controversy, calling into question not only the method of compensation for the evictees but the logic of large dams altogether. The movement has taken inspiration from earlier successful struggles that led to the withdrawal of two major dam proposals – the Silent Valley and the Bodhghat Dam projects. Large coalitions of local communities, environmentalists, and scientists worked together in the 1980's to stop these dams. As dam tensions emerge and grow, they will not only address problems created upstream due to submergence they will also raise questions about problems created downstream due to water overuse and misuse by intensive irrigation.

The construction of the Ukai Dam across the Tapi River in Gujarat displaced 52,000 people. The farmers who once occupied fertile agricultural lands were forced to resettle in an area cleared of forests. Prior to their settlement in their new site, the government promised to level the land, clear the tree stumps, sink wells free of charge, and install power connections.

Once the farmers arrived, however, they found that most of the promises were not kept. The land was levelled with some assistance from the Government, but the farmers cleared the tree stumps themselves with great difficulty. Moreover, the clearing of the forest and the removal of the remaining tree stumps led to topsoil erosion and made farming impossible. The government reneged on the wells, saying it had promised to sink wells only for those who had wells in the old villages. However, most of the old villages were near the river, and not many farmers had needed to sink wells. With insufficient water, little food, and almost no work, the settlers soon be-

came migrant labourers in surrounding sugar cane fields.

The Pong Dam in Himachal Pradesh in the Himalayas displaced 16,000 families. The government then attempted to rehabilitate about half of them in the far-away deserts of Rajasthan, and each family was given 16 acres of land – the largest compensation in the country so far. Despite these efforts, the families were unable to adjust to the new climate, water, people and language, and most of them sold their lands and returned to their native place.

The Bhakra Dam was responsible for the displacement of 2,180 families of Bilaspur in Himachal Pradesh. The families, who were promised land in surrounding Haryana 25 years ago, have yet to be fully compensated; only 730 families (33 per cent) have been rehabilitated. Moreover, while the land taken from them between 1942 and 1947 was estimated at the prevailing rates during the time, the lands they actually received were appraised at rates prevailing between 1952 and 1957, leaving them with a mere one to five acres per family. Like the people displaced by the Pong Dam, they too fled their harsh new environment and returned to Himachal Pradesh.

Dam conflicts in the past revolved around displacement. Today, the ecological imperative for the protection of nature has added a new dimension to the struggle of displaced people. They are now fighting for their own survival as well as for the survival of their forests, rivers, and land. In East India, tribals of 121 villages, who faced eviction by the Koel-Karo project in Bihar, successfully stopped the construction work. Had the project been completed, it would have taken water from the Koel River at Basia and diverted it to another dam near Lohajamir village in Topra block, Ranchi district, and to the Karo River. It would also have submerged more than 50,000 acres of land, including 25,000 acres of forests under tribal control by customary law.

In postcolonial India, most large dams have been financed by the World Bank. I was personally involved in assessing the impact of the World Bank-financed dams on the Krishna, Kallada, Suvernakha, and Narmada Rivers. In each case, the ecological and social costs far surpassed the benefits. Typically, the benefits were grossly exaggerated in order to accommodate the World Bank's logic of returns on investment.

42.3 The River Linking Project: New Conflicts in the Making

Free-flowing rivers are free, in the sense that they do not need capital investment, they are not enclosed, and their waters are accessible to all. Water locked in dams and canals are captive waters. They can be privatized, commoditized, bought, sold, and controlled by the powerful. The massive US\$ 200 billion River Linking Project, supported in part by the World Bank, is a key to the privatization of water and the enclosure of India's water commons.

The River Linking Project is divided into two broad components: the Himalayan component and the Peninsular component. The Himalayan part consists of 14 river links with an estimated cost of 3,750 trillion rupees, and the peninsular component consists of 16 river links, estimated at 1.85 trillion rupees.

Even the minimum estimated cost of 5,600 trillion rupees equals one quarter of India's annual gross domestic product (GDP), two and a half times India's annual tax collection, and twice our present foreign exchange reserves. The cost of this project, according to the government's economic survey for 2001–2002, is higher than India's gross domestic savings and more than US\$ 12 billion higher than India's total outstanding external debt. Where is capital of this magnitude available?

The only option would be funds from international sources. Such funding would place a debt of about US\$ 112 on every Indian – 20 per cent of the av-

erage annual income. The annual interest would range between 200 and 300 trillion rupees. It also raises questions about how this loan would be repaid and what guarantees will be needed to secure it.

External borrowing on this scale would also make future governments more vulnerable to foreign financial pressures. The real threat is that after starting the project with much fanfare and investing thousands of crores into it, a future government would have to simply abandon the project as its financial implications become clear, leaving billions of cubic metres of earth dug up and the face of the country scarred for centuries. In that scenario the only alternative left would be to hand over the project – along with the country's entire water resources – to multinational corporations.

The Research Foundation has studied the first link – the Ken–Betwa link – which is being financed by the World Bank. The Ken–Betwa river linking project includes constructing a 73-metre-high dam on the Ken in Bundelkhand, on the border of the Chhattarpur and Panna districts, and a 231-kilometre-long canal which will connect the Ken and Betwa. Seventy-five per cent of the estimated 20 billion rupees will be extracted from the local peasants out of various taxes imposed over the next 25 years. That is why the government is proposing such crops, which are water intensive, leading to a hike in the water tax.

Fifty square kilometres of Panna Tiger National Park would be submerged by this interlinking project. This national park, through which the Ken flows, is a natural homeland of 10 endangered species listed un-

der Schedule 1 of the 1972 Wildlife Protection Act. This interlinking and transfer of water will affect not only these animal species but also the vegetation, as hundreds of thousands of trees would be cut down.

This project proposes five dams altogether, one on the Ken and four on the Betwa, which would displace around 18 villages. All five dams are proposed to be built in protected forest area. The four dams on the Betwa would submerge 800 hectares of forest. Besides creating conflicts with local people, the River Linking Project also threatens to generate water wars with India's neighbours, Nepal and Bangladesh, since diversion of water out of the Ganga basin will leave less water for sharing with neighbouring states.

42.4 Water Wars Due to Privatization

Water privatization transfers water from where it flows to where there is money – cities and industrial areas. Two examples of 'water wars' caused by privatization are the diversion of the Ganga waters to Delhi for privatization by Suez Degremont, and the diversion of the Baner River in Rajasthan to Ajmer and Jaipur.

For two years, from 2004 to 2006, the supply of water from the Ganga was held up due to water conflicts between the Government of Delhi and the Government of Uttar Pradesh whose farmers are to lose because they would have no irrigation water. Studies by the Research Foundation show that the losses of farmers amount to Rs. 70 billion because of this diversion.¹

The ADB gave a loan to Rajasthan to divert the Baner River water to Ajmer and Jaipur. As a result the fields and wells of farmers went dry. They protested on 26 August 2005 and five farmers were shot dead during a protest. The martyrdom of Prakash Mali, M.S. Gujar, Madan Lal Jat, Krishan Lal Chaudhry, and Ram Narayan Chaudhry is just one reminder that 'water wars' are not the issue of the future. They are already taking place.

43 Sustainability of Environmental Regimes: The Mekong River Commission

Bastien Affeltranger

43.1 Introduction

As a natural consequence to the increase in inter-governmental agreements on transboundary environmental issues or challenges, the evaluation of environmental regimes has become a topic of study by scholars in political science, International Relations, geography etc. Lindemann for instance, develops an analytical framework that explains the success of international water regimes “*with the complex interplay of problem factors; process factors; institutional factors; country-specific factors; and factors of political context*” (Lindemann, 2005). However, only few publications so far have focused on the management of technical data and information as a condition to the institutional effectiveness and sustainability of such regimes. Considering that access to data is critical for sound water-related decisions, this chapter advocates that the unavailability of water-related information deprives basin organizations from technical credibility and political legitimacy¹.

The *Mekong River Commission* (MRC) is an environmental regime and an attempt to establish a basin organization for the Lower Mekong. The MRC was created in 1995 by its member states: Lao PDR, the kingdoms of Thailand and Cambodia and the SR Vietnam,² under the auspices of the United Nations.³ Until now, the MRC has but shared the characteristics of the river itself: “a turbulent past and an uncertain future” (Osborne 2001). The MRC is actually still

fighting to be acknowledged as an institutional framework for assessing the state of the resource, and as a forum for making water-related decisions. Unsurprisingly, its member states remain reluctant to delegate pieces of the sovereignty to the Commission – the more developed these countries are, the more reluctant they are to co-operate with the MRC.

This chapter introduces the circulation and exchange patterns of environmental information as an analytical tool to understand and assess the day-to-day operation and effectiveness of an environmental regime such as the MRC. In particular, difficulties experienced in the sharing of water-related (hydrological/hydraulic) data and information help identify the players, issues and power relations of Mekong hydro-politics. A multi-scalar, institutional analysis guides the approach described below.

This chapter introduces flood and drought hazards in the Mekong river basin, and details related to data needs for forecasting activities (43.2); research results on the present status of the Mekong Commission are offered (43.3); the concept of the “value(s) of hydrological data” is introduced (43.4); and the conclusion comments on the recent (2004–2005) recruitment of a new *Chief Executive Officer* (CEO) at the MRC (43.5).

1 This chapter presents research results from a Ph.D. conducted at Laval University in Quebec, Canada (2003–2006). It also elaborates on consultancy (flood warning) for the MRC in 2002 (Affeltranger 2002). The views presented in this chapter do not reflect the opinion of any country, government, organization or individual, neither in the Mekong river basin nor elsewhere, nor does the text endorse any official boundary.

2 Countries are listed upstream to downstream.

3 See the: *United Nations Economic and Social Commission for Asia and the Pacific* (UN-ESCAP). For the full-text of the MRC Agreement, visit the *Water Page*: <http://www.africanwater.org/mekong_river.htm> (15 September 2006). For a historical review and analysis of the institutional processes that have shed the environmental regime of the Lower Mekong, see: Browder/Ortolano (2000).

43.2 From Water-related Hazards to Data Needs

Basic facts on the Mekong river basin are provided below:

- Basin size: 783,000 km² and river length: 4,200 km.
- Basin countries: China, Myanmar, Thailand, Laos, Cambodia and Vietnam.
- Basin population: 60 million (est. 2006). Per capita GDP: varied from US\$ 2,565 (Thailand) to US\$ 265 (Cambodia).
- Water uses: Irrigation, fisheries, power generation, transportation, industrial and domestic supply.

Respective contribution of each riparian state to the total annual discharge of the river is given in table 43.1.

Table 43.1: Mekong River Basin-Hydrological contributions from riparian countries **Source:** Wolf (1999a).

Country	Basin area (km ²)	Basin share (%)
Laos	198 400	25,42
Thailand	194 100	24,87
China (Yunnan Province)	168 400	21,58
Cambodia	157 000	20,11
Vietnam	35 000	4,49
Myanmar	27 500	3,53

Floods have always been a fact of life in the Mekong river basin, and since 2000, floods have caused annually between 300 to 800 victims, 100 to 400 million US\$ of damage, and 1 to 8 million people were affected each year. No wonder that flood mitigation remains high on the present institutional agenda of the Mekong Commission (MRC 2006). For instance, an estimation of the impacts caused by the 2005 flood season on Lower Mekong countries is given in table 43.2.⁴

It should be noted here that beyond their humanitarian and economic goals, flood mitigation and management activities have also a strong political dimension in the Mekong river countries. In short: by managing risk, authorities gain technical credibility

from the public which backs their political legitimacy to rule the nation.⁵

Flood mitigation has progressively been an objective of intergovernmental cooperation and institutional developments on the Lower Mekong. Major floods in 1966 triggered riparian countries of the lower basin to set up a flood forecasting system in January 1968, based on the *Streamflow Synthesis and Reservoir Regulation* (SSARR) model, developed by the U.S. Corps of Engineers (1966). After the 1978 and 1981 floods, the forecasting system was extended to the Mekong delta (DELTA Model developed with support from UNESCO) as well as to major tributaries.

More recently, the 1995 Agreement has confirmed that flood mitigation should be key objective and task of the *Mekong River Commission* (MRC). Consequently, the *Flood Management and Mitigation Strategy* (FMMS) has been established in 2001 to serve as a framework to MRC's policies and activities related to floods.⁶ In 2004–2005, the MRC established a regional centre for flood mitigation and management in Phnom Penh (Cambodia). Observers have interpreted this decision as a balance to the recent move (2004–2005) of the MRC Secretariat to Vientiane (Lao PDR). Despite a steady interest in flood mitigation (MRC 2006), other natural hazards, such as drought and salinization, have however started to rank higher on the political agenda of riparian governments. This was confirmed at the 3rd Annual Flood Forum, held in April 2005 in Vientiane, where strong requests from Member States were made that the MRC Secretariat should increasingly address these hazards (personal observation).

On the Mekong main stem, flood mitigation still heavily relies on short-term measures, such as emergency intervention and relief. To perform well, these activities need sufficient lead time over hazardous events. This can only be gained through appropriate forecasting – hence requesting fine hydrological knowledge, data and models. In particular, data must be sufficient both in quantity and quality, and provided timely to forecasting teams at the MRC Secretariat (Operational Hydrology Unit and the *Flood Forecasting Core Team* (FFCT)).

Similar to the situation in other large river basins throughout the world, floods on the Mekong's main

stem are actually *combined* hydrological and hydraulic events. These are formed on tributaries to the Mekong, with basins featuring both shorter and longer concentration times – and hence with both ‘flash flood’ and ‘slower flood’ characteristics. The very nature of the Mekong, a transboundary river, therefore requires technical co-operation of basin countries. In particular, sharing of technical data – in short, hydrological data – is key to improved flood forecasting and mitigation.

The next section does, however, explain why circulation of water-related data is difficult on the Mekong river basin – both among basin countries, and inside them. The process of *politization* of water-related data is explained, with the Mekong river basin and hydro-politics as a case study.

43.3 The Politics of Hydrological Data

Field observations show that access to, and quality of hydrological data remain a challenge in the Mekong river basin. Intra-national features, such as lack of technical and financial capacities for data collection and management often limit the possibility of international data exchange. The lack of political will or commitment also plays a role, both in terms of investment in data management and transboundary access to data produced. In short, control over hydrological data remain a political tool.

Key features explaining for the difficulty or absence of information circulation include:

- *At the national level:* data are utilized by civil servants as a currency to navigate (or survive) through power relations within and among organizations, institutions or administrations⁷. This is particularly the case in countries where state bureaucracies are confronting major changes. Such changes are usually a by-product of joining market economy or globalization, and / or a conditionality to loans granted by international financial institutions.
- *At the inter-national level:* non-disclosure of hydrological data deprives downstream countries from technical clues on upstream water withdrawals, hence protecting upstream governments from scientifically-based hydro-political claims.

The dynamics of these two key groups of features are detailed in the next sub-sections.

43.3.1 Institutional Instability

The Mekong river countries, including the PR China, have undergone major changes during the past 20 to 25 years. A key feature has been the transition from a command to a market economy. Thus, the role of the

⁷ This confirms, when applied to intra-national hydro-politics, findings in Sociology of Organizations made by Crozier (1964) and by Crozier/Friedberg (1977).

state is being redefined. In some cases, even its actual *capacity* is being discussed or challenged. The water management sector, including flood management and relief activities, has also been influenced by these changes.

The overall result of the process is an institutional instability of hydrological administration. State services in charge of water-related issues and tasks are confronted with major or repeated organizational changes. Consequently, power relations are jeopardized, allocation criteria for public spending are revised, the performance of civil servants is questioned and salaries are kept low – if not lowered. In this context, hydrological data appear as a key asset to navigate through these rough institutional waters.

43.3.2 Competition over Water in the Mekong River Basin

Contrary to public perceptions, at the basin level water is not yet under quantitative stress, but water availability faces a rising stress in some sub-regions, for instance in the Khorat Plateau in North-eastern Thailand (Affeltranger 2005). Besides, water is a matter of competition among users – at least for those players with a political and economic bargaining clout strong enough are in a position to voice out their views or concerns.

Due to water competition – for instance in relation to hydraulic or hydroelectric developments, both on the Mekong main stem and major tributaries – national authorities believe that sharing water-related information opens the door to a more transparent understanding of hydrological impacts caused by their projects. Thus, sharing data is perceived as a potential risk of later criticism from downstream stakeholders. Sharing data implies becoming accountable on the sub-regional hydropolitical scene.

43.3.3 Values of Hydrological Data

As a consequence of these two major features, the *value* of hydrological data rises as a social and political construct. There are as many facets to it as there are reasons (not) to share water-related information. Based on interviews conducted in Mekong basin countries, a typology of the *total value* of hydrological data is suggested below:

- *Operational value*: Data enable informed decision-making and help reduce negative externalities;
- *Economic value*: Data as a commodity help data owners make up for insufficient budget or salary. In some cases, data can be used to start an external business activity;
- *Organizational value*: Data help civil servants negotiate power deals through institutional instability. Data serve as currency in organizational and power transactions;
- *Financial value*: Exclusive access to data enable owners to report first to authorities allocating water resources development budget or post-disaster assistance;
- *Strategic value*: Non-transmission of data help planners conceal downstream environmental impacts of projects;
- *Political value*: Control over data helps authorities limit public scrutiny, stakeholders' protest and political controversy over water issues;
- *Cultural value*: Some data owners are not confident in data quality – or data simply do not exist. These actors are therefore reluctant to share data for fear of losing face, or being made responsible for data misuse, or unsuccessful projects. In addition, political heritage and culture has been found to play a role.

43.3.4 Consequences

In theory, *hydro-meteorological data* (HMD) are a key feature of water-related decision-making. By increasing the probability of negative externalities (ecologically, socially, economically), the lack of HMD usually jeopardizes the sustainability of decisions made. In practice, it is far from certain that all water-related decisions in the Mekong basin have been made only after careful scientific check and consideration of multiple scenarios. In addition, a lack of data also deprives parties of water-related debates or controversies to support their views and discourses with official figures and scientifically robust back-up. The parties involved can be riparian countries, donors, aid agencies, or non-governmental organizations (NGOs).

Basically, the actual patterns of HMD circulation on the Mekong basin reflect the geopolitical landscape of the subregion. Competition over data is tied to competition over water. However at this stage, it seems unrealistic to advocate for a 'de-politization' of water-related data.

Indeed: an inherent fear of governments in the Mekong basin is that they endanger themselves by providing water-related data. In particular, governments fear that sharing this knowledge will limit their

capability to conduct domestic policies and projects in the water sector. There are two kinds of players: upstream governments are reluctant to provide data to downstream countries, for these might complain of unfair basin-wide water allocation; then, environmental NGOs might mobilize public opinion (and donors) against potentially destructive (ecologically and socially) water resource development projects. Thus, the total value of water-related information reflects a variety of coexisting rationalities that must be reconciled.

As an environmental regime, the MRC process offers an opportunity for basin countries to introduce technical and political transparency in the management of water resources. A wider access to hydrological data also facilitates public scrutiny and environmental advocacy based on informed opinion and discourse. But is this in the interest of riparian governments? Next, key features influencing the institutional capacity, stability and sustainability of the Mekong River Commission are discussed.

43.4 Institutional Sustainability of the MRC

43.4.1 The Mekong Commission: Ten Years of Commitment

The governments of the lower Mekong basin have shown a high degree of resilience in developing institutional cooperation on water issues since the late 1950's.⁸ Despite years of political turmoil and manifold tensions, the process of shaping an institutional mechanism for transboundary cooperation has been maintained. Although extra-regional players have influenced this process, the repeated commitment of the lower Mekong governments must be acknowledged. Without such an involvement at the highest political level, cooperation on the Mekong would already have ceased to exist. This resilience of the 'Mekong Spirit' is also witnessed in the upper reaches of the basin. Cooperation with China should also be acknowledged, since hydrological data from two stations in Yunnan Province are now provided to the

MRC Secretariat on a daily basis during each flood season.

Thanks to these efforts and commitment, the MRC and its Secretariat have achieved numerous tangible results since 1995. These results go beyond mere theoretical research and studies. The MRC has developed as a political forum for lower Mekong countries to maintain a dialogue on basin issues, and to establish a link with upstream neighbours Myanmar and China. The MRC Secretariat has also matured into a well established organization that relies on a unique knowledge base, a multifaceted technical expertise and a broad spectrum of sectors and programmes. The contribution of the staff of the Secretariat and of national and international experts must also be acknowledged.

Despite these remarkable political and technical achievements however, hydropolitical clouds have formed over the river basin. The present situation is a mix of strengths, challenges, threats and opportunities for the future cooperation on the Mekong. This also applies to the MRC Secretariat as an organization. What tell us those voices foreseeing only a gloomy future for the Mekong River Commission?

43.4.2 The Mekong Commission: Ten Years of Tensions

Ever since the early 1950's, when the U.N. *Economic Commission for Asia and the Far-East* (ECAFE) and the U.S.A. supported efforts to set up a common future for countries of the lower Mekong basin, the related institutional efforts have always experienced numerous tensions among players from within and outside the region, including extra-regional organizations, entities or individuals. The Mekong basin is both a geopolitical space, where these players meet and interact, and a geopolitical object that is instrumental for their goals.

The tensions over the Mekong Commission boil down to the controversy, on what role water resources should play for the social and economic development of basin countries. An easy way to summarize this debate is to divide the political ecology landscape in terms of pro-dams and anti-dams groups. But the controversy is more complex and goes way beyond this divide. Rather, it questions what development models, or paradigms, should be used in the Mekong basin. An easy way to summarize these past decades is to oppose extra-regional donors (mostly Western and European) to governments of the Mekong countries. The former are often presented as ad-

8 The agreement setting up the *Committee for the Coordination of Investigations of the Lower Mekong Basin* was signed on 17 September 1957 by the governments of Cambodia, Laos, Thailand and Vietnam. For text details, visit Oregon State University's (OSU) database at: <<http://ocid.nacse.org/cgi-bin/qml/tfdd/treaties.qml>> (15 September 2006).

vocates of sustainable development, while the latter are said to be interested only in structural water resources development. Yet again, this simplified view does not adequately reflect reality. This can for instance be observed in the differentiated patterns of water resource development that upstream and downstream Mekong countries advocate for or against.

Neither on the Mekong nor elsewhere is the advocacy for, and the implementation of sustainable development policies a smooth process. Already early in the process of hydrological co-operation on the Mekong, most players have been aware of these tensions over choices for the basin future(s). These tensions have been accepted as a price to pay for the development process to continue and for related projects to be carried on. Despite these difficulties, players, especially western donors, to leave the region.

A recent illustration of these tensions is the debate that emerged when the present Chief Executive Officer (CEO) came into office (2004–2005). Based on interviews, conducted in 2004 and 2005 with staff of the MRC Secretariat, with donor governments and agencies, and with the CEO himself, it is reasonable to say that the apparently clear-cut discourse of the CEO (e.g. on dam building) has somehow made more tangible the disagreements or clashes on what should look like the economic, hydrological and environmental future(s) of the Mekong basin.

Ever since his arrival, the present CEO has stressed that he had been recruited by Mekong governments to implement their will in terms of basin development. This includes for instance supporting the development of hydraulic infrastructures (e.g. dams and reservoirs). The present CEO also initiated a communication strategy with China, and soon after his arrival he was invited by the authorities in Beijing.

These elements may be interpreted as an encouraging sign of a burgeoning MRC strategy closer to the expectations of its member states. In that respect, this discourse of the CEO – perceived by some as a hardliner – probably also serves the integration of riparian countries into a common vision for the basin's future. But to some observers this position of the CEO has been found as being too much 'pro-dam'. In particular, donor governments and aid agencies – mostly those from Northern Europe – have started to consider this approach as a direct threat to sustainable development in the Mekong basin.

43.4.3 Line Agencies: Last Frontier for Hydrological Cooperation?

Improving the technical efficiency of the MRC Secretariat cannot be achieved without a parallel improvement of the overall capacity of line agencies in MRC countries. Practice shows that a sustainable process of institutional cooperation can be obtained only if the players have an equitable, technical and organizational capacity to interact with each other. So far, this has not been the case as will be illustrated with these three examples:

- *Financial capacity.* The budget of hydrological or meteorological departments is usually very limited, e.g. an estimated annual budget of 15,000 US\$ for one of the visited meteorological departments. In many cases, salaries are extremely low and varied – ranging from a monthly average of 30 US\$ to more than 1000 US\$. Thus, staff members have no choice but to find other sources of income and look for additional jobs.⁹ This multitask occupational pattern has two major consequences. First, time actually spent in office can be reduced, as well as motivation to commit, thus jeopardizing official duties. Second, in some cases, conflicts of interest arise when the purpose of additional job selected contradicts the official duty (e.g. application of regulations).
- *Human resources.* Besides, human resources management in many line agencies is also problematic: technical skills are usually quite low¹⁰, and the capacity of using English as a professional language is also very limited if it exists at all. This last point is a clear limitation for the capacity of line agencies to engage in, and be accountable for cooperation with the English-speaking staff of the MRC Secretariat. In addition, in some cases, water-related line agencies have been created only recently – and for some, even after the creation of the MRC. This is one explanation for the relative lack of experience in engaging in transboundary or international cooperation – for instance with the MRC Secretariat. Besides, the political history and

9 These include: business, tourism, driver, engineering, consultancy, teaching, etc.

10 In some cases, the selection or appointment of head of department may not necessarily reflect professional excellence, but rather personal or political preferences. Although this may be an asset for legitimacy and team management, it is of little help in terms of transparency of the recruitment process.

tradition of some Mekong countries have influenced the professional culture of civil servants. This makes some staff of MRC line agencies not really keen on cooperating with partners from outside the country or the Mekong region.

- *Political capacity.* The political capacity of these agencies must also be discussed. More precisely, it appears that the *National Mekong Committees* (NMCs) are not necessarily staffed with delegates of the 'real' decision-making ministries in their country. According to a western diplomat: "depending on ministries and individuals, the readiness to cooperate, and the actual capacity to cooperate, varies a lot among Lower Mekong countries." For instance, ministries of transportation, economy, finance, army, etc. are traditionally not members of NMCs. Thus, these Committees only have a limited capacity to actually influence water-related policies and projects in their country. NMCs may not want to see the situation change drastically, as a privileged relation to the MRCS may also mean priority access to donors' funding and financially valuable positions at the MRCS. This may explain why these Committees are reluctant to share their power with other ministries in their country. Matters of sovereignty have probably limited the capacity of donors to voice their views (or concerns) in terms of how relevant the composition of NMCs might be in its present form.

These weaknesses of line agencies and water-related administrations in Mekong countries have a direct influence on the availability and circulation of hydrological data. Symptoms of these induced difficulties include:

- Data are simply not available in countries. When available, data series are not consistent, scientifically robust or have blanks. A resource-consuming (both time-wise and money-wise) process of data reconstruction is then needed at the MRCS.¹¹ In some cases, countries accept to provide data to the MRCS only if the Secretariat subscribes to a series of conditions describing data utilization and dissemination;
- Line agencies in MRC countries are often not capable of devoting sufficient resources (staff and fi-

nancial) to operation and maintenance costs of hydrometric networks – even when these networks have been installed with donors' assistance. Consequently, line agencies usually ask for additional agreements to be signed, so that they can be paid by the MRCS for providing data. This situation also mirrors that governments chose not to devote more resources to these line agencies.

- There has been a lack of public spending in hydromet data collection and management and a double inconsistency of riparian governments. High-level agreements are signed under the aegis of the MRC, whereby governments commit to data sharing or exchange. But MRC governments do not invest enough money for their line agencies to be capable of actually delivering the data promised under these agreements. Sometimes, the very political will of delivering available data is simply lacking. According to an ADB expert: "the national bureaucratic machineries are not keeping pace with the agreements signed by Mekong governments."

Thus, the lack of data is compensated by the development of parallel, often less rational processes of knowledge production. For instance, rumours often served as instrumental in filling knowledge gaps. In practice, when confronted with a lack of data, some segments of society develop their own information sources and explanatory patterns for understanding their social and technical environment – and for acting upon it. Again, the problem can be that this kind of knowledge is biased by value judgements or instrumental for specific purposes. According to a senior expert in hydraulic modelling "some day these parallel, unconfirmed and ideologically motivated descriptions of the river basin will have become *the* reference truth on the state of the Mekong river basin."

There might, however, be reasons for hope. Countries of the lower Mekong basin have started to implement international regulations and standards (e.g. of the World Meteorological Cooperation) in collecting and managing hydromet data. In this process, economically least advanced countries of the basin are much less advanced than stronger nations. Data users are also being progressively charged for access to data. However, pricing patterns remain unclear in many cases. Usually a 'data care' or 'data handling' fee is calculated and charged, although interpersonal connections appear to still play a role as a condition to access to data. Still, and despite some normative advances, existing regulations are usually not enforced by state agencies themselves in Mekong countries. A

¹¹ A senior expert even mentions rumors in a lower Mekong country providing the MRCS with biased data sets, with the only purpose to later make the MRCS have to pay for obtaining corrected data sets.

reason for it can be that these prescriptions are too vague to be operational – or too constraining – or simply because they are not known to the staff involved.

43.5 Do Mekong Countries Need the Mekong River Commission?

The Mekong River Commission is not, and has never been, the only catalyst for water-related cooperation in the (lower) Mekong basin. Since the late 1950's, and despite successive institutional frameworks until the creation of the MRC in 1995, governments of the basin have maintained bilateral patterns of cooperation with each other.¹² This represents multiple, co-existing tracks of hydro-diplomacy that may or may not run parallel to each other, and in some cases take opposite directions.

Observers of the Mekong region have witnessed that in several occasions, major water-related projects have in the recent past not been designed, nor implemented, through the MRC. These projects include: the Vietnam-Cambodia controversy on the Se San dam; the considered water transfers from a Mekong tributary into the Chao Phraya River in Thailand; the Nam Theun II dam in Lao; the Lao-Thai-Birmese-RP China cooperation on the navigability in the Upper Mekong. In none of these developments, the MRC nor the MRCS have been involved in the decision-making process – neither as a political facilitator, nor on technical aspects of this process.

The absence of the MRC/MRCS from several water-related debates or controversies on the Mekong is quite surprising. Current discourse of Western scholars on hydropolitics does advocate for environmental regimes to level out regional power differences on environmental issues. In the case of transboundary river basins for instance, river basin organizations are expected to help 'weak' countries to better negotiate with more powerful ones. However, in the case of the Mekong, it appears that Cambodia could not utilize the MRC to voice its concerns in the Se San debate. Or maybe it did not want to. Or maybe Vietnam would not accept the MRC to play such a role of 'neutral facilitator'. The same seems to have happened for water diversion schemes in Thailand.¹³

Another example is the Upper Mekong navigability projects. Neither Thailand nor Laos did request

the MRC to get involved in the signing of an agreement with Myanmar and China. The *Lao National Mekong Committee* (LNMC) had not even been involved in this process. In Laos for instance, only the Ministry of Transports did join the negotiation process with its Chinese ministerial counterpart. It was only when regional and international public opinion and NGOs voiced concerns on the potential ecological consequences of reef blasting (for clearing of navigation channel) that the LNMC was invited to join the discussion. "The MRC is shying away from any transboundary conflict", according to a western scholar who has been studying the basin for about a decade.

Does this mean that the MRC/MRCS is only here to serve as an 'environmental legitimization resource' for governments of the basin? Are these governments worrying that any involvement of the MRC would only end up in making water-related projects more complex to manage (ecological considerations; public scrutiny; etc.)? At this stage, the MRCS as an organization has no real capacity to influence water-related policies and projects in Mekong countries. Nor does the MRC have this capacity, although this is not surprising, as governments appoint members to the Council and Joint Committee of the MRC. For instance, the difference with the ADB reads in terms of bargaining clout. According to an Asian ADB expert: "the ADB is more a catalyst than the MRC, because it comes with money."

If MRC should be useless, should it disappear? "Not at all", according to a member of a National Mekong Committee, "we are too poor!" An easy interpretation of the situation would be to say that the MRC is considered by governments of the basin only as an instrument to channel donors' money in – and to increase environmental legitimacy and 'sustainable development' image of riparian countries.

43.6 Conclusion

Water remains a major resource in development plans for Mekong countries. As long as water is an important contributor to GDP formation, it will remain a resource for competition. In turn, and as long a competition over water is maintained, hydrological data will

12 Technical cooperation goes beyond mere hydrological issues, to include topics such as: meteorology; domestic security; border patrols; hydropower; etc.

13 Likewise, it is a fact that Mekong countries do not have similar capabilities in terms of economical, political and military bargaining clout for backing up their views or complains on water-related issues.

remain politicized information. So far, the race for water on the Mekong basin has only jeopardized the institutional sustainability of the Mekong River Commission. But the MRC and its Secretariat remain key assets for riparian states of the Mekong in the field of water-related information management.

This is of course mostly the case for the least developed countries of the basin. The contribution of the Mekong Commission in this field includes: upgrading the hydrological data collection; standardization of data and products; training line agencies of the MRC; wider access to environmental information; etc. However, a basin-wide accepted framework for data exchange was still in the making in mid-2005. Should hydrological administrations in MRC member states be considered as the 'last frontier' to hydrological co-operation on the basin?

Though this is likely to be the case, the burden of making this environmental regime a success should be shared with donors and other lending or aid agencies. Indeed, the hydropolitical challenge of this river basin depends today on the capacity of regional and extra-regional players to reach a consensus on what development pattern(s) should be opted for on the Mekong basin. As discussed above, the tensions generated by diverging, or opposed views of the future(s) of the river basin are a common thing on the Mekong. A renewed interest can however be found in recent developments that make these tensions more perceptible and visible than before. It is the opinion of the author that the recruitment of a new CEO at the MRC (2004-2005) has been a key feature of that shift. Considering that the head of the MRC Secretariat should carry on the task member states have recruited him for, the CEO has preached - at least until mid-2005 - a discourse overtly in favour of (structural) water resource development. Unsurprisingly, this policy has done nothing but comfort most of Mekong riparian countries - and upset those donors that are more accustomed to a pro-environment line.

Reaching a point where some European donors request external auditing of the MRC institution and performance (Hirsch 2006), it appears more critical than ever to involve riparian countries, donors and other stakeholders in a reconstruction of a negotiated, common representation of the Mekong's possible future(s).

44 Water Scarcity and Political Wrangling: Security in the Euphrates and Tigris Basin

Mustafa Aydin and Fulya Ereker

44.1 Introduction

Water scarcity as a security issue has been analysed with an increasing interest since the 1980's, mostly with an emphasis on the causal linkage between the shortages of water in a given locality and the possibility of conflict thereby (Gleick 1993; Westing 1986; Frey 1993). A majority of the case studies in this context have been concerned with the probability of conflicts over water sharing in the Middle East (Naff/Matson 1984; Starr/Stoll 1988; Starr 1991; Bershorner 1992; Lowi 1993; Libiszewski 1995). Similar focus on disputes over water can also be found in the analyses from environmental perspective (Homer-Dixon 1994). Following the widening and broadening of the security agenda, since the late 1980's (Buzan/Wæver/de Wilde 1998; Brauch 2003, 2008, 2008b, 2008b) the way in which environmental and thus water issues are analysed has included new concepts such as *global environmental security* and *human security*.¹ There are now studies on environmental and water problems ranging from critical (Smith 2001; Blatter/Ingram 2001) to Marxist analysis (Selby 2005 and chap. 46), with traditional approaches still dominating the scene (see chap. 41–58).

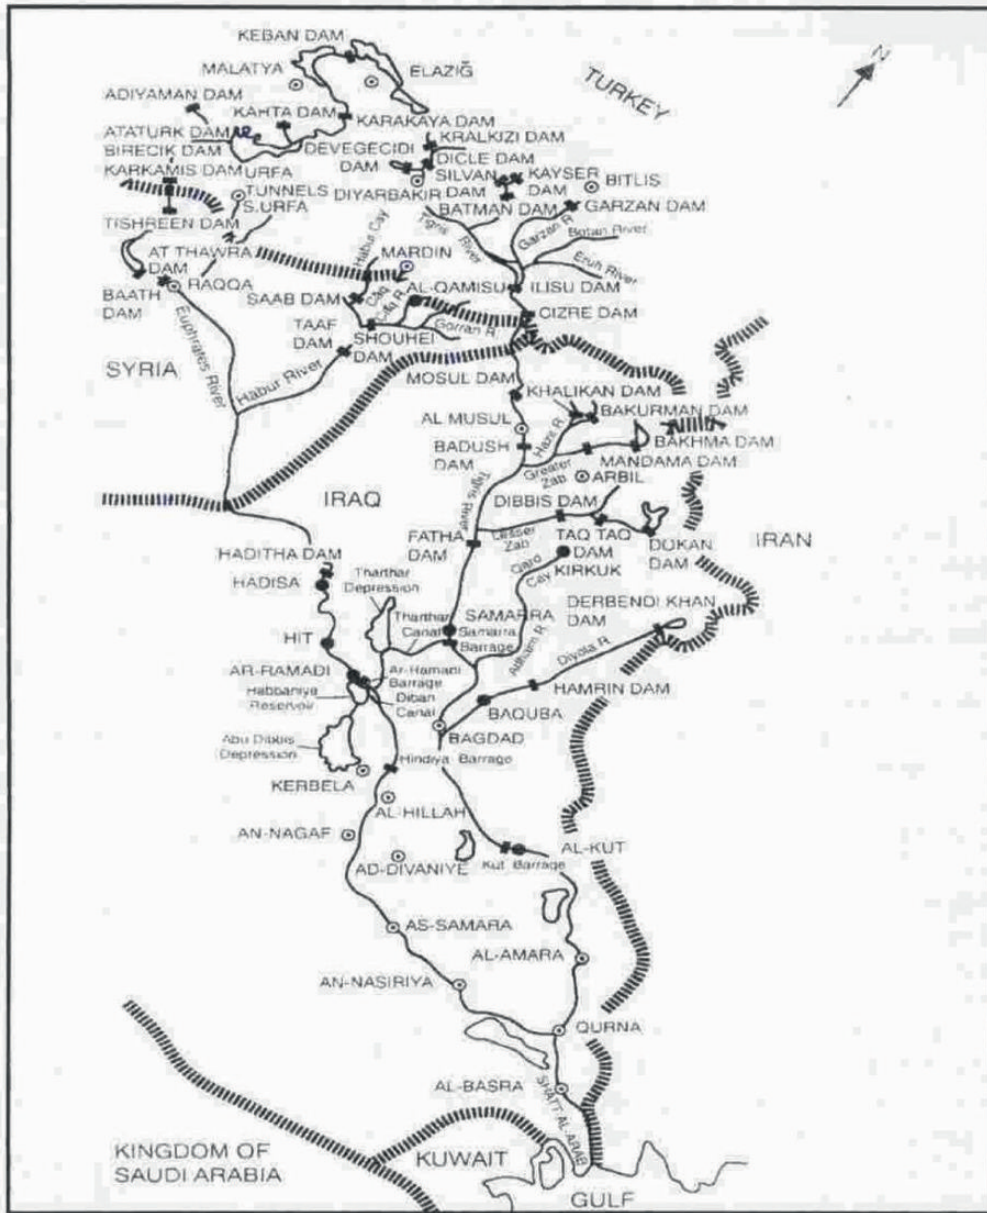

A glance at the literature on environmental issues clearly indicates the fact that outside the scholarly research and mainly the West, new understandings of the environment have not made much progress. The overwhelming tendency of the countries involved in

disputes with their neighbours is to use the traditional understanding of power politics as the main analytical tool. This is more evident in cases where official security conceptualization of the country is still dominated by traditional 'hard security' issues. With their traditional understanding, these countries approach water disputes as one of the threats to national security and find themselves in a zero-sum game in which effective cooperation can not be expected. Turkey, as the upstream country of the Euphrates-Tigris Basin, is an example of these countries though economic, cultural, environmental and humanitarian issues have started to factor in the analysis alongside traditional hard security conceptualization (Aydin 2003: 178). The other riparians of the Euphrates-Tigris basin (Syria and Iraq) also possesses similar views in their approach to the water issue. In this regard, it is hard to expect cooperative structures among them, though not impossible as will be shown below.

This chapter focuses on the discussion over the waters of the Euphrates-Tigris (*Fırat* and *Dicle* in Turkish) river basin, analyzing the tension between the three riparian states: Turkey, Syria and Iraq (45.2). The technical data about the available water resources, water use and demands of the riparian countries and the underlying reasons of the tension between them, as well as their conflicting arguments and initiatives for cooperation will be discussed. It will be argued that their dispute over water has a clear connection with the level of overall relationship between them. As the 'basins at risk' (BAR) project, a comprehensive quantitative global exploration of the relationship between water and conflict, demonstrates, the countries that cooperate with each other in general also cooperate over water issues and *vice versa* (BAR Project 2002). The chapter will also show that, although the current literature of the water sharing disputes is inclined to see the opportunity for cooperation solely in connection with the efforts of the powerful upstream riparian countries, for positive-

1 The *global environmental security* approach (part VIII, chap. 59 to 73) differs from traditional studies that focus on environmental problems as threats to national security, with its primary focus on threats to the environment itself. The *human security* approach (part IX, chap. 74–96) though also emphasizes the protection of the environment for the broader human security, avoid privileging any aspect of security, thus the environment (Sheehan 2005: 109–112).

Figure 44.1: General Layout of the Euphrates-Tigris Basin. Source: Altınbilek (2004: 17).

sum results the actions of the downstream states serve a critical function, where uncompromising and unreasoned rhetoric against the upstream states leaves no room for further steps towards an agreement (Williams 1997: 77).

44.2 The Euphrates-Tigris River Basin: Scarce Water and Unsatisfiable Demands

The Euphrates and Tigris rivers emerging from the highlands of Turkey are often considered as forming one basin (al-Qudsi 1995: 175; McCaffrey 1993: 93; figure 44.1). The River Euphrates (table 44.1) emerges where the Murat and Karasu rivers join each other in Keban, around the town of Elazığ and flow through Turkish, Syrian and Iraqi territories without enriched

Table 44.1: Potential Water Demands on the Euphrates (mcm). **Source:** Beaumont (1998: 179).

Country	Irrigation Water Use	Evaporation	Total
Turkey	10.830 - 13.000	1.100	12.000 - 14.000
Syria	4.750 - 12.500	630	5.400 - 12.600
Iraq	24.400 - 27.500	600	25.000 - 28.100
Total Demand			42.300 - 54.800
Available Water			31.800
Balance			-10.500 - -23.000

Table 44.2: Potential Water Demands on the Tigris (mcm). **Source:** Beaumont (1998: 182).

Country	Irrigation Water Use	Evaporation	Total
Turkey	5.600 - 6.700	630	6.200 - 7.300
Syria	0	0	0
Iraq	37.200 - 60.000	1.00	38.200 - 61.000
Total Demand			44.400 - 68.300
Available Water			52.700
Balance			+ 8.200 to 15.700

by any other stream in the latter. It merges with the River Tigris near the Gulf and becomes the Shatt al-Arab which flows into the Gulf. The entire length of the Euphrates is 2,780 kilometres. A total of 35 per cent of the river's basin is in Turkey, 22 per cent in Syria and the remaining 43 per cent in Iraq. The average annual discharge of the Euphrates is about 32 bcm (billion cubic meters) and Turkey contributes approximately 90 per cent of its waters, whereas Syria contributes the remaining 10 per cent and Iraq makes no contribution to the run-off (en 1999; Kibaroglu/Ünver 2003; MacQuarrie 2004).

The Tigris (table 44.2), originating from the eastern Anatolia's Hazar Baba Mountain range, is 1840 kilometres long and flows through Turkey for 532 kilometres, follows the Turkish-Syrian border for 30 kilometres and the Syrian-Iraqi border for eight kilometres, and enters the Iraqi territory reaching the Gulf after joining the Euphrates near Kurna. The average annual discharge of the Tigris is about 53 bcm and Turkey's contribution is 40 per cent of the total annual flow, whereas Iraq contributes 51 per cent. The remaining 9 per cent is contributed by waters from Iran; Syria has no contribution into the Tigris (en 1999; Kibaroglu/Ünver 2003; MacQuarrie 2004).

Although looking solely to the total amount of water carried by the Euphrates and Tigris, it can be argued that they should be sufficient to satisfy the demands of the three riparians, physical characteristics of the rivers and fluctuations coupled with the effects

of development projects reduces the available supply of the rivers, thus creating seasonal shortages for lower riparians. Though technical data on the available water and water demands are disputed among riparians (for national figures see for example: MFA 2005; DSI 2006a; Iraqi MoW 2007; AQUASTAT-FAO 2006), it is clear that the waters of the Euphrates and Tigris are scarce resources, especially problematic for satisfying irrigation demands. Water demands estimates for the Euphrates show that the potential water deficit might be as high as from 10,500 to 23,000 million cubic meters/year (mcm/y) whereas with minimum data estimates the waters of Tigris will be sufficient with a surplus of 8,000 mcm/y, but the maximum values shows a deficit of 15,700 mcm/y.

To draw a reliable conclusion on the adequateness of the amount of water, not only the total amount of available water but also the estimated annual volume of water available per capita should be taken into account. In this respect, the picture is not good even for Turkey which is generally counted as rich in terms of existing water potential. According to the *UN World Water Development Report* (2006: 133-135), the total amount of water resources of Iraq, Syria and Turkey are 75.42 bcm/y, 26.26 bcm/y and 229.30 bcm/y respectively, while the per capita annual water shares are 2.920 cubic meters (m³) for Iraq, 1.440 m³ for Syria and 2.950 m³ for Turkey.² These figures show that the three riparians have insufficient water resources and could be classified as 'water stressed countries'.³

Figure 44.2: Average Annual Flow Values for Euphrates-Tigris Rivers. **Source:** Altınbilek (2004: 19).

The irregularity of the flow both between years and within years of the Euphrates-Tigris river system is also a considerable factor affecting the availability of water for the riparians. There are vast differences between monthly flows (which is nearly 80-fold for the Tigris and 28-fold for the Euphrates) and this irregularity causes not only extensive flooding, but also losses of water required for irrigation and power generation purposes during the much-needed summer season. Annual flows of the rivers are also instable as shown in figure 44.2, making it harder to compromise over the amount of available water per country (Altınbilek 2004: 18–19).

Moreover, with the high population growth in these three countries, the amount of water available per person will shortly decline to serious low levels.

- 2 In Turkish official documents the total available amount of water for Turkey is indicated as 193 bcm, while the available annual volume of water per capita for the year 2000 is stated as 1500 bcm (DSİ 2006: 4–5).
- 3 Those countries that have less than 1000 cum annual water volume per capita are classified as *water poor*; while countries with less than 2000 cum/y water volume per capita are classified as *insufficient* or *water stressed*; and those that have an amount of water more than 8,000–10,000 cum as *water rich* countries.

According to the General Directorate of State Hydraulic Works, the annual available amount of water per capita in Turkey will be about 1,000 m³ by the year 2030 as a result of Turkish population reaching an estimated 100 million (DSİ 2006: 5). As for Syria it is forecasted to decline to 770 m³ per person by the year 2025 (UN Economic and Social Commission for Western Asia 2006: 7). The expected decrease of the available water rate is similar for Iraq while an increase of two-fold of the population is estimated (Zawahri 2006: 1045).

Furthermore, all three riparian countries have vast irrigation plans along the Euphrates-Tigris Basin. Syria aims to increase its irrigated area along the Euphrates from officially reported 863,300 hectares (ha) to 1.4 million (ha) (Kibaroglu 2002: 199). Iraq has already undertaken a number of water management schemes on the Euphrates to irrigate 1 million ha and the waters of the Tigris are used to irrigate 2.2 million ha, as well as the Shatt al-Arab is used to irrigate 105,000 ha, though the current picture is uncertain due to the economic disruption caused by wars (Olçay 2004: 389–90). Turkey plans with its Southeastern Anatolia Project (Turkish acronym GAP) to cover an irrigated area of 1.8 million ha. 65 per cent of the total amount will be irrigated using Euphrates and 35 per cent will

be irrigated through Tigris (DSİ 2006: 11). As⁴ a result of these plans, irrigation demands will increase and cannot be satisfied by the actual water volumes (see the chap. 35 by Kapur/Kapur/Akca/Eswaran/Aydin).

In addition to the population growth and irrigation demands, the inefficient use of water, especially in Syria and Iraq, is another cause of the stress over the water resources of the basin. The main problem is excessive use of water for irrigation as a result of outdated irrigation systems. According to a World Bank Report (2001b: XI, XIV), improvement in water use efficiency through both irrigation efficiency development and utilization of less water-intensive crops appear to be the primary avenue for increasing water availability for Syria in the short term, and in the longer term it needs a comprehensive structural reform in all its agricultural production system. However, the capacity of the government organization for support such a water management is limited as the report indicates.

Iraq faces similar problems because of an un-modernized irrigation system and thus excessive use of water. According to Sultan, Becker, Al-Dousari, Al-Ghabdan and Bufano (2003: 19), Iraq should immediately develop nationwide programmes to modernize water usage and alternative water resources (e.g. groundwater and non-conventional water resources) instead of exerting all its efforts to water allocation issues with its neighbours. On the other hand, the rate of the water consumption for irrigation in Turkey's total use of water is also remarkable with 74 per cent (industrial consumption is 11 per cent and water supply is 15 per cent) but its modernization programme is well-developed compared with Syria and Iraq.

The current conditions of the Syrian and Iraqi agricultural and irrigation systems indicate that they are far from carrying out their vast irrigation plans in the near future and therefore their demands based on an estimated future irrigational water use seems exaggerated.

44.3 The Euphrates-Tigris Dispute: From National Development to National Security

Until 1960's the main user of these two rivers was Iraq. Turkey had focused on Western Anatolia for water resource development until the late 1960's (Rob-

erts 1991: 157), when the Euphrates and Tigris attracted energy-hungry Turkey's interest for their potential in producing hydro-electric energy for industrial development as rapidly as possible (Kolars 1986: 62). Syrian and Iraqi interests in harnessing the waters of the Euphrates, on the other hand, are closely associated with their agricultural productions. These demands exacerbated by requirements of national economic developments of the riparian countries turned the water issue into a serious concern over national security and even survival. Over the years, the issue of water security has been intertwined more and more with hard security issues, and it became difficult to discern the genuine causes of disputes and to make a judgement whether the essential cause of the conflicts between the riparians is water or another aspect of their relationship. However, a detailed analysis of the riparian relations will show that the water issue is deeply connected to the overall relations of the three countries and that a rapprochement between the riparians in other areas of cooperation could induce a cooperative structure regarding the water issue.

44.3.1 Historical Background

It was not before 1970's that the use of the water of the Euphrates-Tigris Basin has become an inducement of major disagreements between the three riparian countries. However, regulations over water have been a subject in the relationship between these countries since the 1920's. First regulations were made in 1921 with the Ankara Treaty between Turkey and France (the then mandatory power in Syria) that included an article over the equitable use of the Koveik Water (flows from Turkey to Syria) to ensure water supply to Aleppo, and in 1923, article 109 of the Lausanne Treaty pointed out that issues over transboundary waters should be dealt with separately and in a way of mutual respect (Kut 1994: 225). There was also an agreement between Syria and Turkey signed in 1939 regarding the equal share of the water of the Orontes (Asi) River. The first regulation related to the Euphrates-Tigris rivers were made in 1926, an agreement over the Turkish-Syrian frontier which stipulated commitments of joint usage of the Euphrates (MacQuarrie 2004: 61). Another and more known agreement of the Euphrates-Tigris is the Friendship and Good Neighbourliness Treaty signed in 1946 between Turkey and Iraq, which committed Turkey to inform Iraq of its plans for construction works on the rivers.

Like the regulations, the first dispute over water between the three countries was not about the

4 Currently the area that are in operation is 213,924 ha; under construction 160,260 ha and planned 1,351,471 ha.

Euphrates-Tigris waters, but the Orontes (Asi) River when Syria attempted to initiate the Ghab Valley project in 1950 (Kut 1993: 4). Turkey as a downstream riparian of that river felt uneasy with this project fearing that Syria would decrease the flow of water. Half a century later, it became clear that Turkey's fears were not without grounds as Syria, notwithstanding its commitment to the 1939 arrangement of equal share of the water, leaves generally very few and depending on the seasonal variation nearly no water flows into the Turkish province Hatay (Picard 1994: 217). Due to Syria's refusal of negotiation on the Orontes (Asi) River, this issue has been left unresolved.

After establishing the General Directorate of State Hydraulic Works (Turkish acronym DSI) in 1954, Turkey entered incrementally the phase of planning to develop the Euphrates' waters. Syrian plans on the Euphrates and Iraqi plans on the Tigris also began simultaneously. The activities of Syria and Turkey in ambitious development plans on the Euphrates-Tigris Rivers for irrigation and energy increased during the early 1960's. Although Iraq also announced new projects for irrigation, its efforts remained modest compared with Syria and Turkey.

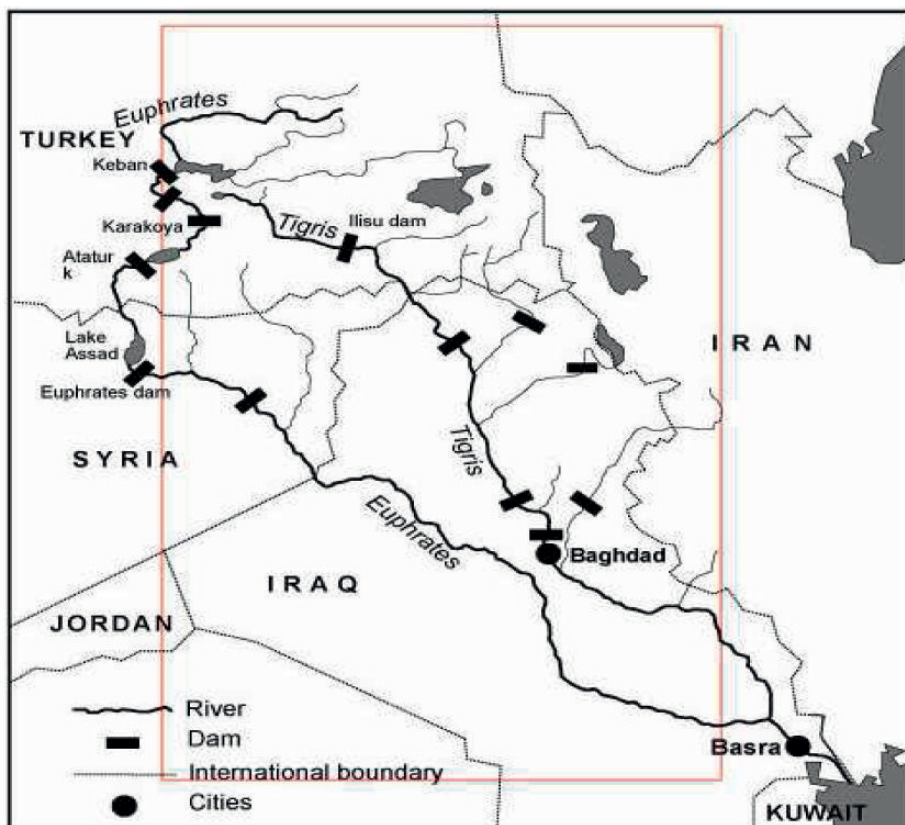

Turkey put into practice its first project with the construction of the Keban Dam in 1965 on the Euphrates, which moved the relationship between the three riparian states into a new phase over water development. Iraq and Syria as downstream riparians began to express their demands for guaranteed flows of 350 cubic meters/second (m^3/sec) at a minimum during the impounding period. Turkish and Iraqi experts held a meeting in 1964 on this issue and although Turkey stated that a final formula for the flow of water could not be reached before the impounding of the dam. Turkey guaranteed the release of $350 m^3/sec$ as minimum after the negotiations. However, this unilateral guarantee was prompted by the conditions of an agreement reached between Turkey and U.S. Agency for International Development (USAID) on financing the construction of the Keban Dam than by the demands of Syria and Iraq (Kut 1993: 4). Nevertheless, the idea of establishing a Joint Technical Committee (JTC) between the three riparians was raised for the first time during this meeting held with Iraq in connection with a proposal by Turkey to establish a regular technical body between riparian countries (Kibaroglu/Unver 2003: 4). After another bilateral meeting held between Syria and Turkey in 1964 during which information of the two countries' dam construction projects (Turkey's Keban Dam and Syria's

Tabqa Dam) were exchanged, the first trilateral meeting was held in 1965 in Baghdad. Besides the exchange of technical information on the Keban, Tabqa and Haditha (Iraq) dams, the negotiations were concentrated on the draft agreement submitted by the Iraqi delegation to establish a permanent *Joint Technical Committee* (JTC). However, Turkey strongly refused the status of the JTC with powers to supervise a water sharing agreement as proposed in the Iraqi draft. In the meantime, the Syrian suggestion to divert the waters of the Tigris to the Euphrates to compensate water shortages in Iraq faced strong opposition from Iraq. Although no agreement was achieved, technical meetings continued to be held between the three riparians.

This relative cooperative scene was changed when the Keban and Tabqa dams became operational a year apart, and the first major crisis between the riparians erupted in 1975. During the impounding of the Tabqa and Keban dams in 1974 and 1975, Iraq accused Syria of reducing the water flow to an intolerable level. Syria on the other hand refused to take the blame, and in turn accused Turkey of reducing its water flows. While Iraq was not satisfied with this response, the tension increased to a level which brought both countries to the brink of an armed conflict that was averted due to intense mediation efforts of Saudi Arabia (Naff/Matson 1984: 93-95).⁵ Iraqi accusations of Syria regarding the amount of the flow of water repeated on several occasions.

In the mean time, Turkey's second major step in its plan for developing the Euphrates was initiated the same year when the construction of the Karakaya Dam started. Iraq reacted to this by cutting its oil exports to Turkey in 1977 and called for an immediate debt repayment. Iraq resumed its oil supplies in 1978, when Turkey agreed to a $500 m^3/sec$ flow during the impounding of the dam (Scheumann 2003: 748). In any case, both the Karakaya and Keban dams were designed solely for hydroelectric power generation and therefore did not require any water consumption. In fact, instead of causing harm, these two dam's impact on downstream users was beneficial as they regulated the river discharge (Roberts 1991: 158). But, the worst crisis erupted when Turkey decided to proceed with

5 As a result of Syria's unilateral decision at this time to release an additional amount of water from Tabqa Dam, Iraq came to regard this decision as an unwritten agreement about apportion of the Euphrates waters for 40 per cent to Syria and 60 per cent to Iraq (Naff/Matson 1984: 94).

Figure 44.3: Dams in the Euphrates-Tigris Basin. **Source:** Allan (2002, Annexes).

its comprehensive *Güneydoğu Anadolu Projesi* [Southeastern Anatolia] (GAP) Project that prompted fierce opposition from both downstream countries due to their fear of a reduction of the water flows and subsequent possible harm to their own agricultural and energy projects.

44.3.2 The Development of GAP and Worsened Relations

The GAP was initially undertaken as a programme to develop water and land resources of the south-eastern Turkey and planned as a package comprising 13 projects envisaging irrigation schemes and hydraulic power plants in the Turkish part of the Euphrates and Tigris basin. As a whole, the package included 22 dams, 19 hydraulic power plants and irrigation of 1.8 million hectares of land. It is expected that upon the completion of the project, energy production in the region would reach 27 billion kWh, per capita income will rise 209 per cent and about 3.8 million people would be provided employment opportunities (GAP RDA 2006: 2; see the chap. 35 by Kapur/Kapur/Akca/Eswaran/Aydin).

Table 44.3: GAP Land and Water Resources Development Projects. **Source:** GAP Regional Development Administration (2006: 2).

EUPHRATES	TIGRIS
Karakaya Dam/HPP	Kralkızı Dam/HPP
Atatürk Dam and Şanlıurfa Tunnels	Batman Dam
Border Euphrates (inc. two dams/HPP)	Batman-Silvan (two dams)
Suruç-Baziki (irrigation projects)	Garzan Dam and irrigation projects
Adıyaman-Kahta (two dams)	Ilisu Dam
Adıyaman-Göksu-Araban (irrigation projects)	Cizre (dams/HPP and irrigation projects)
Gaziantep (irrigation projects)	

As the technical information shows, the GAP is above all a domestic project to develop a very poor region of Turkey. It is expected to affect the entire structure of the region in its economic, social and cultural dimensions through a process of transformation to be trig-

gered by agricultural modernization (Bağış 1994: 18). Yet the main problem that prompted the strong opposition from both downstream countries lays actually in this fact. With the GAP, Turkey shifted its emphasis from its mainly hydroelectric use of water to an integrated project, including broad irrigation schemes (Çarkoğlu/Eder 2001: 59). Because irrigation meant that Turkey would increase its water consumption with a possibility of reduced water flows, Syria and Iraq reacted anxiously with an effort to hinder the development of the project. The first considerable attack towards the GAP came when Turkey sought for additional international funding. Syria and Iraq succeeded through their ability in mobilizing the entire Arab world to thwart the World Bank funding for the GAP. Since donors demanded a comprehensive agreement between the riparian countries, Turkey approached Syria and Iraq to negotiate an agreement but was rejected by them (Zawahri 2006: 1046). While Turkey eventually decided to finance the GAP through its own means, this caused both a slow down of the GAP project, and the decline of Turkey's economic rationale for seeking downstream riparian countries' approval for its project (Williams 1997: 74).

Although Iraq was more active in the above mentioned incident, during the 1980's the water issue was not the main problem on its agenda because of the Iran-Iraq war. When Syria in 1982 shut down the pipelines transporting Iraqi oil to the Mediterranean through Syria, Iraq's dependence on Turkey increased since the only outlet for Iraqi oil was through Turkey (Çarkoğlu/Eder 2001: 59). Syria on the contrary began to play the terror card against the GAP. Damascus was providing the PKK (Kurdistan Workers' Party) forces with training and equipment and was also a major patron of the ASALA (Armenian Secret Army for the Liberation of Armenia) which conducted terror attacks on Turkish representatives abroad, killing over 40 Turkish diplomats and citizens between 1973-1983. In this context the water issue and Syrian support for terrorist organizations acting against Turkish interests were linked and the dispute of water became a national security concern for Turkey with strong ties to territorial integrity.

44.3.3 The JTC: Cooperation in a Hostile Environment

Through the worsening of the relations in the early 1980's, the *Joint Technical Commission* (JTC) that has been under discussion since the 1960's was established and many meetings were held until 1993 when

it was discontinued. The formation of the JTC was agreed in a meeting of the Turkish-Iraqi Joint Economic Commission in 1980 and held its first meeting in 1982. Syria joined the JTC in 1983 and up to 1993 sixteen meetings were held. The 17th meeting that was scheduled for 1993 was cancelled by Syria's decision not to attend along with strongly worded accusations against Turkey in December 1992. Syria accused Turkey of "intransigence, violation of international law, usurpation of rights, misuse of right, lack of desire to improve atmosphere of relations, imposing conditions and resorting to procrastination to delay final agreement on sharing Tigris and Euphrates waters" (TFDD 2003). Since then no JTC meeting has been held. The mandate given to the JTC was defined as to "determine the methods and procedures which would lead to a definition of the reasonable and appropriate amount of water that each country would need from both rivers" (Kibaroglu/Unver 2003: 6).

The JTC failed in performing its goal and except the exchange of technical data no progress was made on water allocation. Among others, the most important reason for the failure was that all three countries differed in their approaches on the description of both rivers. While Syria and Iraq claimed that the rivers are *international watercourses* which can be classified as *shared resources*, Turkey argued that since both rivers emerged and gathered their waters in one country (Turkey) and then cross international borders, the rivers are *transboundary waters*, as opposed to *international rivers*. Reaching an agreement about the rivers proved impossible when the riparians disagreed on their classification. The difference in definition emerges from different interpretations by riparian countries on international law on water resources, and remains the main source of the dispute. Accepting the Euphrates and Tigris as international waters would require an *equal share* of the water, as Syria and Iraq have claimed. On the other hand the transboundary waters in Turkey's approach implies that Turkey has sovereign rights over the use of these waters and they are not subject to sharing but only to *equitable and reasonable use* without prejudice to sovereign rights by states' obligation *not to cause appreciable harm* to others. In other words, Syrian and Iraqi interpretations stressed the principle of sharing waters to the fore while Turkey's perspective emphasized the principle of optimal and rational utilization of waters.

In addition to the disagreement over the classification, the three riparian countries could not agree on which waters to negotiate. Turkey claims that for an

efficient allocation, they should not only negotiate on the Euphrates and Tigris rivers, but on all the waters that contribute to the riparians' total water amount. However, Syria and Iraq wish to abstain from including the waters of Orontes (Asi) and the waters flowing to Iraq from Iran into the negotiations. Turkey has also argued that both rivers should be seen as a *single water system* since both join before reaching the Gulf, while Syria and Iraq have objected to this interpretation, arguing instead that each river should be discussed separately (Çarkoğlu/Eder 2001: 58).

During the period when the JTC was active, major crises occurred between Syria and Turkey. First, in 1983 Syria blamed Turkey for the water shortage in the Lake Assad. Then in 1984 Turkey submitted a *three-stage plan* to the JTC. Although it was meant as a step towards an agreement, it became another obstacle to an efficient cooperation. The plan rested on two principles; the first is that the Euphrates and the Tigris make up a single *transboundary river system*, and secondly that the three countries need to work together on preparing and assessing a common inventory of water and land resources in the basin. To reach the most efficient allocation of the available water resources, the Turkish proposal suggested to proceed in three stages: In stage one, an inventory of water resources would be made, in the second stage the inventory would be made of land resources and in the third and last stage in light of the outcomes put forward by the inventories, the most efficient methods of irrigation would be established (MFA 2005: 1). The plan suggested the application of appropriate technologies in order to minimize water requirements for agriculture and proposed to allocate resources 'equitably', according to the needs of the riparian states and benefits they would get using their allocated amounts (Kibaroglu 2002: 256).

It was rejected by Iraq and Syria mostly because it appeared that the results would have favoured Turkey (Zawahri 2006: 1047). Instead, they proposed an arithmetic formula, whereby the waters would be shared 'equally' but not 'equitably' as the new formula did not consider the discrepancies between the riparian states' actual needs for water (Kibaroglu 2002: 256). While discussions in the JTC meetings on the plan were continuing another tension arose between Syria and Turkey during the filling of the Karakaya Dam in 1986. Syria again raised its voice claiming reductions of the water flows and Turkey responded by ordering higher water releases for the downstream countries (Scheumann 1998: 121).

This was followed by a signing of two protocols between Turkey and Syria in 1987. The first one was an economic cooperation agreement but at the same time it included an article that contained a unilateral commitment by Turkey to "release a minimum annual average of 500 cum/sec from the Euphrates until the ultimate allocation of the river's waters between the three countries", thus making this protocol the first bilateral agreement which dealt with water sharing. The second protocol was a security cooperation agreement and it was related to Turkey's pressure on Syria for ending its support to PKK terrorism (Kut 1993: 8). This is a clear indicator of Turkey's approach in that security and water issues are intertwined. However, Turkey saw immediately after the signing of the protocols that its expectations were not met by Syria when the dramatic increase in the activities of the PKK occurred in 1988. Thereupon, Turkish governmental circles discussed playing the water card in response to Syria's play with the Kurdish card, but did not put them into practice (Scheumann 1998: 121).

Turkey developed another initiative in 1988 regarding water sharing in the Middle East. It proposed to establish two parallel pipelines carrying fresh water supplies from the Turkish rivers of Seyhan and Ceyhan to Syria, Jordan, Israel, Palestine, Saudi Arabia and the Gulf States. Named appropriately as the *Peace Pipeline Project*, it was rejected by the Arab countries due to a fear of dependency on Turkey and the involvement of Israel as well as the high cost estimates (Martin 2000: 91).

The 1990's started with major tensions between the three riparians. In January 1990, Turkey began to divert water from Euphrates in order to fill the Atatürk Dam reservoir. Although Turkey had notified its downstream neighbours and released twice the usual amount for two months prior to the impoundment (Kibaroglu/Ünver 2003: 6), Syrian and Iraqi protests could not be stopped. Turkey also sent delegations to other Arab countries to prevent the perception that this cut-off was a political manoeuvre to oppress its neighbours (Bağış 1994: 20). Nevertheless, Turkey was unable to prevent a pan-Arabic outcry against Turkey and the incident triggered an Iraqi-Syrian rapprochement in joint opposition to Turkey over the water issue. The two longstanding rivals signed an agreement for sharing the waters of the Euphrates under which Syria would receive 42 per cent and Iraq 58 per cent of the flow reaching their territory from Turkey. This rapprochement since then, except the rift during the Gulf War due to the Syrian participation in

the U.S.-led coalition forces, has continued (Berman 2002: 44).

On the other hand Iraq indicated its dissatisfaction with Turkey in 1990, by refusing to renew the security protocol signed in 1984 under which Turkey had the right to follow Kurdish terrorists into the Iraqi territory. Turkey's support to the coalition forces during the Gulf War worsened the relations and Iraq declared after the war that, if normal relations between Turkey and Iraq were to continue, the final arrangement of the water issue was essential (Bölükbaşı 1999: 29). During the Gulf War, although there were behind the scene suggestions to Turkey to cut-off of the Iraqi water supply in response to its invasion of Kuwait, Turkey declined to do so (Gleick 1993: 89; Aydin 2002: 59).

Another phase of Iraqi and Syrian protest over the water issue came in 1996 when Turkey started the construction of the Birecik Dam. Even though this dam was designed only to regularize the water level and therefore was not consumptive, both Syria and Iraq opposed its construction by sending official notes to Turkey (Kıbaroğlu/Ünver 2003: 7). In the same year, Syria made a diplomatic bid to acquire more water from Turkey during the Syrian-Israeli peace negotiations. Syria tried to persuade both the United States and Israel to exert pressure on Turkey to supply it with more water, to compensate it for the loss of Golan Heights' water resources. Turkey rejected the Syrian effort to make the availability of the waters of the Euphrates a precondition for the Middle East peace negotiations (Sever 2001: 91). Syria repeated this move in 2000 when Syrian-Israeli negotiations over the Golan Heights restarted but Turkey successfully stopped such a deal at its expense with strong protests (Çarkoğlu/Eder 2001: 62).

The tension between Syria and Turkey escalated in 1998 when Turkey issued an ultimatum that it was ready to resort to military means if Syria continued to support the PKK and to host its leader in Damascus. In response to Turkey's massing of troops along its border, Syria expelled Abdullah Öcalan, the leader of the PKK, from its territory and the two countries signed the Adana Accords in 1999 where Syria agreed to stop its support for the PKK (Altunışık 2004: 367). This eased up Turkish-Syrian relations in general, having also a positive effect on the water dispute between the two countries, though not yet to the level that they were finally able to shelf the problem once and for all.

44.3.4 Opportunities, Expectations and Steps for a New Phase of Cooperation

The 2000's witnessed an increasing rapprochement between Iraq and Syria, as well as a gradual warming up of the relationship between both countries and Turkey, including the water issue. Here the first step was the opening of the Iraqi and Syrian talks on the sharing of the Euphrates waters in 2001: While Turkey was uninterested in tripartite negotiations on water sharing despite Syria's call⁶ to Turkey to join such negotiations, unexpectedly Turkey signed a Memorandum of Understanding (MoU) with Syria in August 2001 promising further cooperation on agricultural water research and training. During a visit to Syria in 2002 by the Turkish Minister of Irrigation, it is agreed to implement the 2001 MoU,⁷ though no substantial progress has been achieved yet. Since then Syria and Iraq had repeatedly announced their wish and the need to restart the JTC meetings. Although no trilateral meetings were held until end of 2006, the growing number of bilateral meetings mainly on exchanging technical information has created a noteworthy climate of cooperation.

Turkish policy towards the war on Iraq had another improving effect on its relationship with Iraq and Syria as well. After the rejection of the Turkish Parliament of the deal that would have allowed U.S. troops to pass through Turkish territory to open a northern front in the war, although the situation in Iraq has still punctuated with uncertainties (particularly the future of the Iraq as a unitary state has been a concern for Turkey), the atmosphere between Turkey and Syria raised hopes for an effective cooperation between them over the water issue. For example, during the visit of Bashar Asad to Turkey in January 2004, there was an extra positive mood especially in Turkey as if all its problems between both countries were about to be solved.⁸ It was mainly as Asad said in an interview to the Turkish CNN Türk TV that "...when we improve the relations more, we will see

6 "Damascus Hopes of Turkish participation at negotiations about the Tigris", in: *Arabic News Online* (26 March 2001).

7 "Syrian Turkish Water Coordination", in: *Arabic News Online* (23 August 2002).

8 While some parts of the Turkish media support this view (i.e. Mehmet Ali Birand in an article in a Turkish daily newspaper *Milliyet* on 7 January 2004), some were critical about turning a deaf ear to the real problems (i.e., Serpil Yılmaz in the same newspaper on the same date).

that our interest are the same, even on the issue of water.” This statement clearly indicated that water has become a problem among the riparian states in connection to their overall relations. On the other hand, it would be a mistake to overemphasize the current positive climate since no tripartite meeting on the water issue has yet taken place and the approaches of the three countries still diverge.

In late 2006, Iraq has tried to mobilize a diplomatic campaign against Turkey’s decision to start the building of the Ilisu Dam on the Tigris River. Iraq asserted that the irrigation projects of Turkey on the Tigris, and especially on the Ilisu Dam, will deprive thousands of hectares of Iraqi lands of water and that all irrigation projects Turkey intended to construct on the Tigris River will cause a reduction of about more than half of the water quantities (estimated about 11 billion m³/year) currently reaching Iraq (MoW: 2006).

While the positions of the riparian governments has not made enough progress towards an effective cooperation, track-two efforts for cooperation have produced a result: The Euphrates Tigris Initiative of Cooperation (ETIC) was established in 2005 with the initiatives of scholars from the three riparians and the USA. It aims to provide opportunities for dialogue among the riparians; develop project concepts that will be attractive to decision makers and implementers in the region; create sub-networks by bringing together different private stakeholder groups including farmers, community-based organizations, NGOs, business and professional societies; provide a venue for public officials and professionals to address common problems; implement joint pilot projects that benefit all riparians; increase public awareness regarding the issues in the Euphrates Tigris region; facilitate education and capacity building to ensure sustainability for cooperation and development (ETIC 2007: 3). Although ETIC is an important step towards creating cooperative structures among the riparians, the history of the relationship between the riparians clearly indicates that, in order to get desired results, it is imperative to engage the states.

44.4 Conclusions

Water is first of all a vital resource for human security, as well as for the socio-economic development of states. Thus, water scarcity makes it instantly a ‘national security’ issue, as in the case of Euphrates-Tigris Basin. In one respect, the ongoing dispute over the

water issue between Turkey, Syria and Iraq is an outcome of the inter-state relations but it can also be argued that the water issue is mainly related to the development plans of the riparians. The situation is so complex that it has political, economic, social, and ethnic dimensions and comprises terror and conflict along with cooperation. Even the classical idea to use water as a weapon has a place in this case, as it was discussed during the Gulf War.

In this complex web of relations where non-water issues are as important as they are, the way for an effective solution seems hard to find. The best option for a peaceful resolution may be based on international law, but the law on the shared water resources is still emerging. The *1997 Convention on the Law of the Non-Navigational Uses of International Watercourses* is the most important international instrument that specifically focuses on shared water resources but it is not yet in force. Only 12 countries have ratified the Convention that requires 35 ratifications to enter into force. However, it is increasingly used as a framework, at least for the analysis of water sharing issues. But even if it will be implemented, a problem on the Euphrates-Tigris Basin would remain as Turkey was one of three states (besides Burundi and China) who opposed the Convention in the UN General Assembly. Iraq did not vote whereas Syria voted for the Convention and has already ratified it in 2000 (Allan 2001: 302–3). Moreover, Turkey’s opposition was strong and it asserted that “...the draft convention goes far beyond the scope of a framework convention and in contradiction to its intent and nature establishes a mechanism ... [which] creates an obvious inequality between states...” (UN General Assembly 1997: 4–5). This is not surprising since Turkey’s approach towards transboundary waters has been that the originating country has sovereign rights over the waters until they left its borders.

In this context, the improvement of the overall relationship and an effective cooperation between Turkey, Iraq and Syria to a level to conclude a comprehensive agreement would be the most appropriate expectation to solve the water-related disputes among the three countries. The idea that the best solution is “sharing the benefits not the water” (Kibaroglu/Ünver 2003: 1) can be fulfilled with such a cooperative relationship. The continuing rapprochement among the three riparians has been encouraging. However, if and how this level of cooperation could be intensified has remained uncertain due to the ambiguity on Iraq’s future as well as the continuing zero-sum perception of the countries vis-à-vis their water rights.

45 Water Resources in the Arab World: A Case Study on Jordan

Bassam Ossama Hayek

45.1 Introduction

Water is vital to sustain lives of the people of the planet earth. Water resources available for use are only three per cent of the total available water. Due to the uneven distribution of the usable water, some nations are deprived from the minimum amount, while other nations receive too much water and in some areas floods cause disasters. People living in areas of scarce water resources became increasingly vulnerable due to increasing water demand from a growing population and the associated needs for development and food security. In water scarce areas, water is a very valuable commodity and water saving is essential. Many people in the Middle East have experienced water scarcity in their daily life.

In Jordan availability of water is a top priority. For his Majesty King Abdullah II water in Jordan is a strategic challenge that cannot be ignored, and that a balance among the drinking, industrial, and agricultural needs must be achieved, while drinking water remains the main and the most important subject.¹ The per capita share of renewable fresh water resources declined from 905 m³/year in 1955 to 327 m³/year in 1990 and is expected to decline to 121 m³/year in 2025 (Royal Scientific Society 2000).

Most Arab countries are located in the arid and semi arid area, thus water availability is a major challenge due to population growth and development needs. According to the *World Resources Institute* (WRI) with regard to fresh water availability, most Arab countries suffer from severe water shortage (figure 46.1). Abdin Salih (1995) claimed that in 1990 the per capita water resources in the Arab world were 1490 m³/year, which are projected to decline to around 440 m³/year in 2030 assuming a three per cent population growth. This illustrates the degree of water insecurity the Arab region is facing. Since the

year 2000 water scarcity started when the available water per capita started to fall below the bench mark of 1000 m³/capita/year (Salih 1995: 53). Due to the continuous increase in urbanization and industrialization the water competition will be at the expense of the agricultural sector what affects the culture and security of local communities.

The availability of food is also a major concern in arid and semiarid regions. With the shortage of water resources, people suffer from securing the amount of food needed for a healthy diet. Due to high population growth 'food security' and 'water security' may become a major cause for crises.

This chapter analyses the case of Jordan's water and food (45.2). A background of its water status is given linked to demographic change, present water uses and future needs (45.3). Then current official plans for meeting the future water demand based on comprehensive studies are summarized (45.4). The key question is how Jordan will be able to adjust its economic practices to cope with this challenge, what the role of policy-makers will be, and which contributions will be needed from the international community (45.5). This analysis is based on available data and scenarios. It compares present water uses with future water needs and the projected supply, taking current and future national plans, the role of institutions and the international community into consideration.

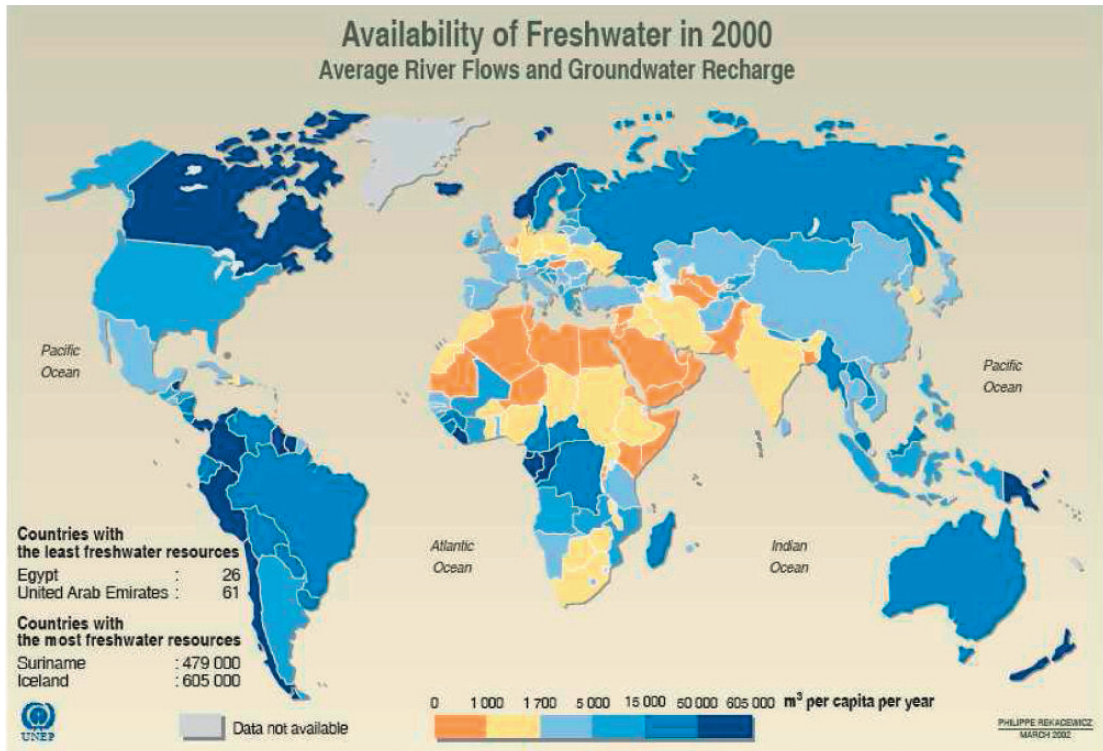

45.2 Jordan

Jordan – in the eastern Mediterranean – has an area of about 90,000 km² and a semi arid to arid climate, where temperature ranges from -3°C to 45°C. More than 70 per cent is covered by desert (figure 45.2). Precipitation ranges from less than 50 mm in the Badia to about 650 mm in the highlands, but only about four per cent of Jordan receives more than 300 mm of rain.

Jordan's population has significantly increased during the past five decades, and reached 5.6 millions

1 His Majesty King Abdullah II introduction on water; at: <<http://www.mwi.gov.jo/>>.

Figure 45.1: Availability of Freshwater in 2000. Average River Flows and Groundwater Recharge. **Source:** Designed by Philippe Rekacewicz, UNEP/GRID-Arendal (2000); in: World Resources Institute: *World Resources 2000-2001, 'People and Ecosystems: the Fraying Web of Life'* (Washington, D.C.: WRI); at: <<http://maps.grida.no/go/graphic/freshwater-availability-groundwater-and-river-flow>>. in 2004 (national census of 2004) compared with less than 0.5 million in the 1940's. The population growth, however, has greatly been affected by the in-flow of immigrants, refugees, and returnees due to the conflicts in the region (in 1948, 1967, 1991, and in 2003). At present the population growth rate is (3 per cent), which is also being controlled and expected to decline to 2.5 per cent.²

In addition to water, sources of energy are very limited and only minor quantities of oil and gas were found in the eastern part of Jordan. Phosphate, potash, limestone, oil shale, in addition to the Dead Sea minerals are the key natural resources and thus comprise the major industries.

45.3 Water Resources in Jordan

The scarce water resources are the major constraint for the development of Jordan. At present, the per capita consumption is around 160 m³ per year, why Jordan is one of the most water stressed countries what has also challenged different economic sectors.

Jordan's renewable water resources available for use are estimated at 780 MCM/Y, including ground and surface water. The safe yield from ground water amounts to 275 MCM/Y, while the maximum amount of useable surface water is 505 MCM/Y. In addition, fossil water is being made available (143 MCM/Y) together with the use of brackish water (50 MCM/Y). Reclaimed or treated wastewater has also become an additional resource that is estimated at 80 MCM/Y. Thus, the total water that can be made available in the short term is about 1053 MCM/Y.

45.3.1 Water Demand

The water demand increases due to population growth, agriculture and a better quality of life. In Jor-

Figure 45.2: Map of Jordan. **Source:** University of Texas at Austin, Perry-Castañeda Library Map Collection; at: < http://www.lib.utexas.edu/maps/middle_east_and_asia/jordan_rel_2004.jpg>. This map is in the public domain.

dan there have been sharp increases in demand due to the sudden waves of immigrants, refugees, and returnees in the recent past. With the natural growth in demand this has severely reduced the available water from 3,600 m³/capita/year in 1946 to 906 m³/capita/year in 1955 (a scare water situation), to an absolute scarcity by 1990 (327 m³/capita/year) and to a much worse situation thereafter (150 m³/capita/year in 2004).³ To respond to this immediate water demand in the past few years, the ground water was over

pumped to a percentage reaching to 185 per cent of the safe yield. In parallel, in an effort to respond to the severe shortage during the very drought years, e.g. from 1998 to 2002, water consumption in agriculture was reduced to 68 per cent (of the annual water budget) as opposed to 75 per cent in the 1990 (Ministry of Water and Irrigation 2002: 6, 2002a, 2002b).

3 Al Rai Newspaper, 12 September 2005, issue: 12775; at: <<http://www.alrai.com/>>.

Based on the ‘water strategy’ of the Ministry of Water and Irrigation (2002: 9), the projected water demand is presented in table 45.1. It is estimated that in 2020 the population would reach 9.2 million and the total demand for water will be 1,647 MCM assuming that population growth will decline from 3.1 per cent in 2005 to 2.7 per cent by 2015. The then available resources are estimated at about 1,300 MCM, thus a deficit of about 347 MCM will still be experienced. Thus, water will be a prevailing problem and integration of efforts in the region is required to meet this challenge.

Table 45.1: Projected water demand per sector (million cubic metres, MCM). **Source:** Ministry of Water and Irrigation (2002: 9).

Use	2005	2010	2020
Municipal	382	434	611
Industrial	81	99	146
Agriculture	858	904	890
Total	1321	1436	1647

At present water is allocated in an asymmetric way with agriculture taking the largest portion (67 per cent). The contribution of this sector to the GDP is the lowest. The ‘National Agricultural Strategy’ has triggered plans to improve the productivity and water management in agriculture (Ministry of Agriculture 2002: III: 2). This strategy includes plans to enhance on-farm efficient water use and irrigation schemes, re-use of reclaimed water of safe quality, to plant low water intensive plants, investigate the saline water agriculture scheme where the brackish water can be a good option, to enhance water harvesting, concentrate on the high value products and on increasing the added value (figure 45.3).

On the other hand, this strategy also confirmed the role of the agricultural sector in the socio-economical dimension, as agriculture employs a large number of people in the Jordan Valley, in the western mountain range and in some areas of the eastern parts of Jordan. Land ownership and agriculture are generally seen as part of the cultural heritage and tradition. The local social dimension must be considered as an aspect of the culture and as a ‘soft security’ issue in local communities.

On ‘food security’ a survey by the *Islamic Network on Water Resources Development and Management* (INWRDAM) that was conducted in 21 Arab

Figure 45.3: Water use distribution among sectors (million cubic meters supplied), in 2000. **Source:** Ministry of Water and Irrigation (2002: 9).

countries found that 1205 m³/cap/year are needed for food production and domestic water consumption (Islamic Academy of Science 1995). If Jordan would be self-sufficient in food production and domestic water consumption, about 6.7 BCM of water would be needed annually. Jordan depends on food imports (‘virtual water’) to satisfy its needs. Al Nasser (2002: 8) estimated that Jordan annually imports about 6 BCM of virtual water as food. This amounts to approximately seven times of the annual Jordanian water budget, and about 10 times of the renewable resources. Certainly 100 per cent self-sufficiency in food is impossible in a water scarce country; but this figure demonstrates the level of vulnerability Jordanians may experience during food crises or due to the negative impacts of global environmental change. Together with the trend in the declining per capita water supply over the years this indicates social and economic threats Jordan may face and they require comprehensive remediation plans.

With global environmental change (due to climate change), food production may very well be negatively impacted by the rise in temperature. According to reports by UN organizations (UNFCCC 2003; IPCC 2007, 2007a, 2007b; Brauch 2007i, 2009; WBGU 2008), climate change may result in reducing food production efficiency by 1/3, and arid and semi arid areas would be the most sensitive areas to impacts of climate change. Being the largest water intensive sector and yet the lowest contributing to the GDP, the agricultural sector may thus become the most vulnerable sector and issues of ‘food security’ as well as ‘social security’ will become a greater concern than it is already today. How Jordan can cope with this challenge? Would it be more feasible to switch the amount of water used in agriculture to other sectors? How should Jordan respond?

45.4 Current Plans and Initiatives

Responding to the projected water shortage, since 1997 Jordan has formulated and implemented a comprehensive 'water strategy' at the national level that tackles several issues facing the water sector mainly in the following areas:

- Water resources development;
- Water resources management;
- Legislation and institutional set-up;
- Shared water resources;
- Public awareness;
- Performance efficiency;
- Public sector participation.

Based on the strategy several actions are successfully being implemented in the areas above. In the following, the attempt is to summarize key planned projects that concerns directly the water supply and use issues. This is intended to visualize the level of investment and work required to try to provide as much water as possible to reduce the gap between the supply and demand.

45.4.1 Water Supply

Several projects are being considered to enhance the water supply of Jordan during the coming decades: a) the *Disi water conveyance project* (46.4.1.1); b) the *Red Sea - Dead Sea Conduit* (46.4.1.2); and c) the *Wehdah or 'unity dam'* (46.4.1.3).

45.4.1.1 Disi Water Conveyance Project

It aims at supplying potable water to the Greater Amman to satisfy the growing demand. The project includes building a conveyor system to pump and transfer water (100 MCM/Y) from the Disi - Muddawwara area in the south of Jordan to the greater Amman (the capital), over a distance of about 325 km. The water is of a high quality non-renewable ground water (Disi Aquifer), and it is a shared aquifer with Saudi Arabia. Some quantities are presently being extracted to provide Aqaba, the major tourist, commercial and industrial city in the south of Jordan, and some private agricultural projects with water. In Saudi Arabia, relatively large quantities are also being extracted. The current use does not reflect the value of the resource, thus it is seen that the future use as potable water is a much more valid and sound option. The project is in the final tendering process, the implementation will start in 2008. The estimated capital cost of the project amounts to about 600 million US \$.

45.4.1.2 The Red Sea - Dead Sea Conduit

This project aims primarily to solve an environmental problem by reclaiming the level of the Dead Sea to its position in 1950 as well as providing desalinated water. The project, when implemented, can be regarded as one of the fruits of peace in the Middle East, as Jordan, Palestine and Israel will benefit from the project not only with regard to the supply of water, but as equally important in saving the Dead Sea, which is regarded as a historical and cultural treasure. Concerning the benefits in supplying water, the project will result in supplying about 600 MCM of fresh water for the three parties engaged in the activity, about 350 MCM will be the share of Jordan, and this will augment the future supply plans and efforts. The project is undergoing detailed feasibility studies in 2007–2008. The estimated cost for the feasibility and environmental studies is 15 million US \$. The initial estimates for the project cost would be in the order of 8 billion US \$.

45.4.1.3 The Wehdah (Unity Dam)

The project comprises the construction of a major dam structure on the Yarmouk River on the Jordanian border with Syria. Construction work has started. The project will be storing about 225 MCM per year from the flow of Yarmouk River with incremental yield of 108 MCM per year. The dam will contribute to supply water for municipal and agricultural demands and to produce electricity. The total cost of the project is estimated at about 200 million US \$.

In addition to the above three key investment projects, a number of water harvesting projects, brackish water desalination and conveyance, reclaiming water projects, refurbishment of the water supply network in different cities are either underway or in the process. Many of these projects are supported and financed by international institutions. The development of the sector is also supported by a number of programmes and initiatives for enhancing awareness and education on water management issues.

45.5 Discussion and Further Actions

Water and food are major challenges for Jordan's development. The government together with non-governmental and international organizations have been putting much effort in meeting this challenge by developing plans and executing large projects to augment the water supply and to satisfy the needs of the economic sectors including agriculture, industry and

tourism, as well as the domestic use. In terms of supply, it is evident that all efforts (national and international) should be joined to help in easing the problem of supply, this can be achieved by directing and fostering the financial aid programmes to Jordan to be able to implement high investment projects such as the *Red Sea - Dead Sea Conduit* and the *Disi - Amman Water Conveyance* projects.

On the demand side, as far as the agricultural sector is concerned (which has been the largest water consumer), it is seen that more efforts are needed to manage, administer and market the production of high value products. The farmers still lack the contacts, links and tools to market their products at a better price. This issue is crucial as selling agricultural products implies selling water ('virtual water'). Thus, the value of the precious water of Jordan should somehow be reflected in the price of the agricultural product. In addition, a continued effort in water efficiency management in the agricultural sector is also necessary.

This leads to an important topic of its relevance for the sustainability of the economic sectors and the environment, to environmental economics. It is vital to include both the cost of natural resources and the cost of environmental damages caused by the economic sectors. For agriculture the cost of water used in planting certain crops should be accounted and given its economic value; building awareness in this regard may enhance a shift to plant high value products for external markets. Moreover, if we consider the cost of the environmental damage, then the cost of reclaiming the land due to the use of chemicals, increasing soil salinity (due to fertilizers and if brackish water is used), plastic wastes and others must be accounted for to determine the eco-efficiency and feasibility of this sector. Although this is rather difficult or could be complex, however, it is essential to introduce certain acceptable assumptions to get a clear picture on the long term feasibility of the sector to strengthen the plans for sustainable practices. The social dimension is also a part of the equation; however, moving to a more sustainable practice implies a more productive sector in the long term, better local economies and thus a better quality of life and a more secure society.

Stressing the environmental economy of a sector should also to be accompanied by better water and product management. The introduction of environmental economics into planning for the agricultural sector could be most effective when it is accompanied by a well managed institutional structure and programmes to help farmers produce more valuable

products and yet use less water. The institutions should also assist in determining the environmental cost of the activities; the cost of the resources (water and land being utilized and in advancing the awareness among farmers and all concerned parties. For the agricultural sector to be economically viable, the net revenue taking into account the cost of water or price of water, cost of utilization of land and any associated impact costs should be positive; and this cannot be achieved unless farmers ration the use of water, introduce water management schemes, adopt planting high value products, apply appropriate practices for pesticides and chemicals, and have a suitable and adequate market chain and the natural resources are priced properly. Thus, here comes a call for international assistance to vitalize the agricultural sector and to make it valuable and economically and environmentally efficient.

The same argument applies to a certain extent also to the other sectors, for example to the industrial sector, where the intention is to advance this sector by promoting industrial investments in different parts of Jordan. So far, the cost of the natural resources and the environmental damage costs were not yet properly taken into account. Therefore, a major issue is to ensure that industrial enterprises are optimizing the use of natural resources and that the cost of the resources and of any associated environmental impacts cost on the environment are also covered by the price of the product. In this regard, it is required to have more intensive programmes to help industrial enterprises in minimizing the use of water; this can be achieved through a focussed programme for cleaner production and by helping industries to be more eco-efficient. One aspect of the eco-efficiency of the enterprises is the amount of water used per mass of product. It is so important for the industries and governmental institutions in Jordan to check the benchmarks for water consumption noting that a number of options or means of minimizing water consumption could be identified by undertaking an audit or cleaner production assessment, where the water balance can be revised and the real demand for water in certain industry can be determined and then optimal measures can be implemented.

If a complete cleaner production assessment is carried out, that covers the whole issues of materials and resources, the effluent quality of water discharges from the enterprises will also be improved by minimizing and avoiding sources of pollution. This will also influence efforts to preserve the quality of the resources. Less pollution in the industrial water efflu-

ents means less stress on the quality of the resources, and thus reduced costs of environmental damages. The textile production sector is a good case study, where garments are produced in Jordan and sold internationally. This process is very water intensive and thus wastewater is also a concern. Selling the garments means also selling water and the impacts on the environment. Thus, a proper pricing of the natural resources would be a good means to foster sustainable production (Pillet 2005).

A few additional important actions are considered as being necessary:

1. In vitalizing the agricultural sector and at the same time reducing its allocation of water, development of technology and know-how are key elements. Efforts are required to create the know-how and to implement programmes to produce high nutritional value products and yet at the optimum amount of water needed. International efforts should be directed at such programmes. This has become more and more urgent as the future allocation for the agricultural sector will remain steady at about 900 MCM (table 45.1). Vitalizing the agricultural sector will also respond to a social and cultural aspect, as many communities depend on agriculture for their living and the ownership of this way of living is appreciated. It is also noted that the agricultural sector employs about 9 per cent of the workforce in Jordan.
2. As the trade and services sector are the major contributor to the GDP in Jordan, it is wise to continue fostering efforts to promote Jordan as a country of business and services and in parallel to improve the level and quality of these services. This activity will earn the foreign currency to support the needed imports of fuel, food and other products.
3. Enhancing industrial development will only improve the value of the currency if and the exports are improved. Therefore, marketing Jordanian products globally is required. However, it is also important to ensure the long term sustainability of this sector by taking environmental economics into account.
4. Finally, there is a need for a maximum cooperation within the region and with international organization to help solving the water issue that is also a security issue that challenges the continued development and sustainability taking the growing population and the needs of the society for a better life into account. The water stress may also be more and even more urgent if the growing impact

of climate change is taken into account, which for Jordan implies higher temperature, even less precipitation, and lower food yields (Brauch 2007i, 2007j). International conventions that were adopted to respond to global environmental change should focus more on the most highly affected and thus most vulnerable countries like Jordan.

46 'New Security Thinking' in Israeli-Palestinian Water Relations

Jan Selby

46.1 Introduction

The post-Cold War era has witnessed a great deal of rethinking of the notion of security (Brauch/Oswald Spring/Mesjasz/Grin/Dunay/Behera Chadha/Chourou/Kameri-Mbote/Liotta 2007). This applies both to the objects of security (i.e. the goods that are to be secured, e.g. through 'energy security', 'food security', 'environmental security', etc.) as well as to the subjects for whom these objects are so desired (i.e. the individuals or groups who are claimed to be included in 'national security', 'human security', 'collective security', etc.). The extent and creativity of these numerous re-conceptualizations is beyond doubt. What is less certain, however, and is far from clear, is the extent to which these re-conceptualizations have impacted upon the actual practices of global politics. It is this more complex issue which the present chapter attempts to address, by focusing on one specific site of environmental conflict and insecurity - that of Israeli-Palestinian water issues.

In analyzing the impacts of new security thinking on Israeli-Palestinian water politics, two discrete sub-issues demand attention: firstly, the impacts of post-Cold War re-conceptualizations on the two main parties' approaches to water issues during the course of their peace process (46.3); and secondly, the impacts of these re-conceptualizations on external actors' approaches to and involvement in these water issues (46.4). This chapter considers these two issues in turn, in each case attempting to weigh up the extent and form of the influence, and to evaluate whether this influence has been largely positive or negative. Prior to that, however, the chapter considers the impacts of new security thinking within Israeli-Palestinian relations at large, this providing necessary context for analyzing the specificities of their water relations (46.2).

Theoretically, the chapter is informed by political Marxism (Wood 1981; Halliday 1994; Rosenberg 1994), and by historical materialist scholarship on the Middle East (Bromley 1994; Owen 2004; Shafir/Peled

2002). It thus assumes that material conflicts and compromises over production and distribution (rather than ideational or discursive variables) are the principal determinants of social structures and social change; that history is made by social structures and collectives, especially classes (rather than by individuals); that individual societies are shaped through their own unique histories of socio-economic struggle and accommodation, within the context of an uneven and expanding global capitalist system; that state forms, projects and interests are products of (even if they are not wholly reducible to) their social bases; and that new concepts, discourses and ideologies can only change the world when there exist material social structures and actors to nurture and promote them. While these assumptions are not developed to any great extent herein, they do provide a theoretical backdrop to the analysis.

By 'new security thinking', I refer to all those re-conceptualizations of and arguments surrounding security which do not rest upon traditionally 'realist' assumptions. In traditional security studies, the subject of security is the nation-state; the principal aim of security is to ensure the territorial integrity of that nation-state; and the main tool at that nation-state's disposal is military power - the threat of violence, and its use when necessary. In new security thinking, by contrast, the relevant subjects of security lie either above ('collective security') or below ('human security') the level of the state; the purpose of security ranges well beyond territorial integrity to include 'economic security', 'water security' and so on; and the tools of security range from economic development to international cooperation. 'New security thinking' varies widely from one field and one institution to the next. In the water arena, for instance, it includes and ranges between liberal functionalist, neo-Malthusian and neo-liberal perspectives, these being united as 'new security thinking' less by what they share than by their collective theoretical antithesis - traditionally state-centric security discourse. The key question with

which this chapter is concerned is whether, within the specific context of Israeli-Palestinian water relations, new security thinking has managed to challenge traditionally state-centric and militarist approaches to security, transforming the actual practices of inter-state politics.

The chapter's core contention is that the practical influence of new security thinking on Israeli-Palestinian relations and their water politics has been at best negligible, at worst politically regressive. In the case of Israel, the military establishment with its narrowly realist understanding of security has continued to dominate policy (including water policy) towards the Palestinians, while new security thinking has functioned above all as an ideological accessory to political realism and state power. In the case of the Palestinians, the struggle for national self-determination and statehood has stifled debate on non-traditional security issues, while security in the traditional sense has remained the preserve of Israelis only. Finally, in the case of the 'international community', the major impact of new security thinking has been to legitimize a politically insidious international aid programme that has done little to either combat the injustices of the peace process, or promote sustainable development. It is these arguments that are developed at greater length below.

46.2 New Security Thinking in the Oslo Process

Israeli-Palestinian relations over recent years have been dominated, indeed over-burdened, by the language and pursuit of security. The 1993 Oslo agreement between Israel and the Palestine Liberation Organization was above all a security accord, whereby Yasser Arafat's PLO-in-exile took over responsibility for policing and administering the Palestinian population of the Israeli-occupied West Bank and Gaza in return for a vague promise of negotiations on all major issues separating the two parties at some point in the future. Arafat returned from Tunis with his phalanx of Fatah cadres and Palestine Liberation Army officers, becoming responsible for governing and securing first most of Gaza, and later the major Palestinian population centres of the West Bank. As mandated by the terms of the agreements with Israel, the Palestinian Authority became 'Israel's enforcer' in the West Bank and Gaza (Said 1995: 10). It established a 'strong police force', such that the PA areas had the highest proportion of police in relation to population in the

world (Usher 1996: 34). It established, besides its regular civil police force, fourteen shadowy intelligence and security organizations.¹ And it developed a deplorable record of human rights violations that outdid Israel's (Amnesty International 2000). Israel for the most part raised few objections to these excesses.² To the contrary, Israel gave the PA unofficial licence to operate against the Palestinian opposition right across the West Bank and Gaza - even in areas that were officially under Israeli security control (Usher 1996: 27-28). There was extensive security coordination between the PA's security services and the Israeli Defence Forces and its internal intelligence agency, the Shabak; after 1998, there was also extensive coordination with the CIA.³

At the centre of these arrangements was the relationship between the Israeli state and Yasser Arafat; as Noam Chomsky has appropriately labelled it, Oslo was an "Israel-Arafat agreement" (Chomsky 1999). Israel and Israeli businesses pumped billions of shekels that were meant to be transferred to official PA coffers directly into personal bank accounts held by Arafat, in a bid to strengthen his powers of patronage and control amongst the local Palestinian population, whilst keeping his client administration in a situation of economic dependency.⁴ PA authority was heavily constrained by this economic and in turn political dependency, as well as by Israeli military orders and by a matrix of joint committees which effectively ensured that Israel maintained veto powers over many areas of government. Of course, following the renewal of Israeli-Palestinian violence in September 2000 this patron-client relationship was terminated. Arafat was no longer able or willing to do Israel's security bidding for it in the West Bank and Gaza, and it was for this reason that Arafat was declared 'irrelevant', first by Ariel Sharon and later by the Bush administration. Such, in a nutshell, was the security-insecurity structure of the now-collapsed Oslo 'peace process'.

1 Danny Rubinstein: "Protection-racket, PA-style", in: *Ha'aretz* (3 November 1999).

2 Yitzhak Rabin and Shimon Peres were particularly unconcerned about them; it was only under Binyamin Netanyahu that objections began to be raised, in a tactical attempt to stave off international criticism.

3 The CIA's role is set out in: Israel; PLO, *Wye River Memorandum* (23 October 1998).

4 See e.g. R. Bergman: "Israel deposited NIS1.5b' in Arafat's personal account", in: *Ha'aretz* (8 October 1999); Amira Hass: "Chairman Arafat straightens out his financial accounts", in: *Ha'aretz* (13 January 2000).

What were the aims and ambitions, and the concepts of security, that underlay these political arrangements? On the Israeli side - which, given its dominant position, was and still is by far the most important - two different security logics stood out. On the one hand was the security doctrine espoused by Prime Minister Yitzhak Rabin, a traditional Labour Zionist 'security hawk', and backed by Israel's socially hegemonic security establishment, which saw the Oslo process in traditional 'national security' terms. Rabin himself was candid about this security logic, noting that the

Palestinians will be better at it [enforcing order] than we were because they will allow no appeals to the Supreme Court and will prevent the Israeli Association of Civil Rights from criticizing the conditions there by denying it access to the area. They will rule by their own methods, freeing, and this is most important, the Israeli army soldiers from having to do what they will do.⁵

The subjects of Rabin's very traditional conception of security were (Jewish) Israelis and the Israeli state. The main objects to be secured were freedom from Palestinian resistance or 'terror' (alongside ongoing Israeli control and colonization of the territory and resources of the West Bank and Gaza). And the means by which these goods were to be secured consisted essentially of what the Israeli sociologist Baruch Kimmerling has termed a "subcontracting of occupation" (Kimmerling 2001).

Alongside though subordinate to this vision of Rabin's was a second and very different logic, associated above all with Foreign Minister Shimon Peres. In Peres' more radical vision, what was needed to consolidate regional peace was the general transformation of Middle Eastern political, economic and social structures. In publications such as *The New Middle East*, he envisioned a virtuous circle of democratization, domestic political stability, regional security structures and regional free trade eventually effecting regional integration and stability, much as has happened (at least according to mainstream liberal accounts) in post-war Western Europe (Peres 1993). In keeping with this liberal functionalist vision, Peres and the Ministry of Foreign Affairs promoted a welter of multilateral regional development projects: the construction of regional energy and transport infrastructures, regional projects for optimal water management, schemes for the integrated development of the Jordan Rift Valley, and so on. These proposals built

upon a very different conception of security from that espoused by Rabin and the IDF. Here, the subjects and objects as well as the means of engendering security were much more akin to those of new security thinking, than were those of the traditional national security establishment. The subjects were not simply Israelis, but the people of the Middle East as a whole; the purposes of security were not simply territory, nation and state, but in addition the positive provision of economic, social and political goods such as energy, water and freedom; and these goods were to be achieved not simply through the most cynical political realism, but instead through multilateral initiatives. Such was the Peres-led vision of the new Middle East: a Middle East rebuilt on the basis of new security thinking, even if this order was also one in which the Israeli economy and polity would be decisively at the helm.

These intellectually incommensurable strands of Israeli security discourse represented different (though in practice overlapping) structural tendencies within Israeli society. The national security establishment viewed the Oslo process in narrowly traditional terms as a security arrangement, in which its success or failure would be judged by the PA's success in 'fighting terror'. The liberalizing middle class and business class, by contrast (or in addition), saw Oslo as a route towards the construction of a new Middle East, and towards the normalization and globalization of Israel's economy and society (Shafir/Peled 2002; Nitzan/Bichler 2002). Within the Israeli society of the early 1990s, the two images co-existed in uneasy alliance - as evidenced, most obviously, by the fractious relations between 'Rabin people' and 'Peres people' within the then-Labour led administration. But, owing to the military's hegemonic position within Israeli society, and to the acceptance and indeed complicity of the middle class and business class in that military hegemony, it was Rabin's security logic which prevailed, and which above all structured Israel's relations with the Palestinians and the Arab world during the 1990s (Ben-Eliezer 1998; Peled 2004: 47-70). Thus, whereas the initial 1993 Oslo agreement represented a compromise between the two groupings, thereafter Peres and his team were relegated to the relatively insignificant multilateral negotiations, with Rabin and the Ministry of Defence taking charge of all further bilateral talks. And it was this latter grouping, with its traditionally militarist conception of security, that henceforth directed and determined the course of the 'subcontracting of occupation'.

5 See in: *Ha'aretz* (7 September 1993); quoted in Usher (1999: 74).

Given the prevailing international balance of forces, Palestinian security discourse and concerns were inevitably subordinate to these debates and differences internal to Israel. Arafat and his Tunis-based PLO had entered Oslo in a position of extreme political and financial weakness, in relation both to Israel and to Palestinian factions centred inside the Occupied Territories; and Israel had looked to Arafat for precisely this reason.⁶ Arafat well understood his allotted role, giving Palestinian negotiators, as Israeli negotiator Uri Savir recalls, specific instructions to accommodate the Israelis on 'every aspect' relating to security (Savir 1998: 14). 'Security', it appeared, remained the demand and expected preserve of Israelis only (Khalidi 1995: 1-18). Palestinian political discourse, by contrast, became and remained centred on ethical-political appeals to those national and indeed human 'rights' denied Palestinians by their uprooting and subsequent occupation. It should be of little surprise, given this, that when the Oslo accords were translated from abstract ideas to material practice, their operationalization of security ideas inevitably reflected Israeli priorities. As Shimon Peres tellingly observed just prior to the onset of the 1995 Oslo II negotiations, "in some ways we are negotiating with ourselves".⁷

Internally, the political omnipresence of the Israeli occupation and peace process had the additional effect of stifling debate on non-traditional security issues. Arafat's priorities during the peace process were to maximize the territory under the control of the PA, and to consolidate the PA's political, economic and coercive resources vis a vis Palestinian society. In the first case, the result was that issues such as health, water and even economic development were demoted down the Palestinians' agenda during negotiations with Israel. In the second case, meanwhile, the pressures of state formation and patronage-building within the context of a deeply iniquitous peace process led to growing corruption and lawlessness, while simultaneously repressing debate on these key 'human security' issues (Khan 2004). As Palestinian critics of the such as Haider Abdul Shafi and Edward Said rightly complained, the Oslo process was disastrous

for Palestinian society; while as radical political economists like Adel Samara have pointed out, debates on issues such as globalization have largely bi-passed Palestinian intellectual and policy circles (Samara 2000, 2001). Until recently, the demands of occupation and the peace process were such that there was little space for intra-Palestinian discussion of such non-traditional security issues.

46.3 New Security Thinking in Israeli-Palestinian Water Relations

It is within these quite specific and deeply unequal 'high political' contexts that Israeli and Palestinian water security and insecurity since Oslo need to be understood. Israeli society and the Israeli state have traditionally viewed water issues through a straightforwardly national security lens. From this perspective, predominant from the pre-state days onwards, the absolute scarcity of water in the Middle East was such that Israel would have to maximize its control over regional water resources. This was the view of Chaim Weizmann and the Zionist leadership as far back as 1919 - it is "of vital importance not only to secure all water resources feeding the country, but also to conserve and control them at their sources", Weizmann observed at the Paris peace conference - and it continued to be the predominant view until well into the 1990s (quoted in: Hurewitz 1956: 28).

Israel as a result has historically been very activist in exerting and extending control over regional water resources: by resorting to force to prevent the Arab League's attempted diversion of the Jordan River in the mid-1960s; by invading and settling the water-rich Golan Heights and West Bank, in part for hydro-political reasons; and by minimizing the Palestinians' consumption of water resources, both within 1948 Israel, and, after 1967, within the occupied West Bank, to name but the most conspicuous examples. Water policy was led by the Ministry of Agriculture, which, due to its ideological proximity to the kibbutz movement and agriculture's crucial role in extending Jewish territorial presence across the land of Palestine, very much reflected the views of the Labour Zionist national security establishment (Rouyer 2000; Selby 2003, chap. 2). The subjects of this traditional water security thinking were the Jewish citizens of Israel. Its object, water, was conceived in essentially zero-sum terms, as a scarce and finite good that would be securely in Israel's hands only to the extent that it wasn't controlled by Arabs. And the threat and use of force were the

6 Peres was "convinced that if Arafat was allowed to return and rule in Gaza and Jericho ... he would yield, for the time being, on virtually everything else". quoted in Connie Bruck: "The wounds of peace", in: *New Yorker* (14 October 1996).

7 See, in: *Ha'aretz* (14 November 1994); quoted in Murphy (1995: 36).

primary means by which this zero-sum good was to be secured.

If this was how water was traditionally viewed by Israel's national security establishment, however, from the early 1990s attitudes started to change. The liberalization, globalization and deepening commodification of both the Israeli and the global political economy led more and more Israeli experts and policy-makers to argue that water should be viewed as an essentially economic rather than national security good, one potential effect of this being that the water issue could thus be 'desecuritized' and the primacy of the logic of force reduced.

For many Israeli water experts, commentators and policy makers, it became obvious that in strictly economic terms water is simply not that valuable in the contemporary Middle East - in at least two different respects. In the first place, some of a liberal functionalist persuasion argued that economic and technological developments now made it possible to overcome the zero-sum logic of traditional water security thinking, for instance through the construction of desalination plants or through regional multilateral projects such as a peace canal from Turkey, both of which could, it was claimed, provide water for household consumption at readily affordable prices. Shimon Peres and the Israeli Ministry of Foreign Affairs were clearly of this view (Peres 1993). In addition, others of more neo-liberal views argued that, even within the current water budget, huge savings could be made if only water were consumed more efficiently and rationally. These neo-liberal commentators pointed out, for instance, that most of Israel's water was allocated at heavily subsidized prices to the economically insignificant agricultural sector (which accounted during the 1990s for only 3-4 per cent of GDP), arguing that, given the globalization of the trade in foodstuffs, such subsidization and over-allocation of water to agriculture was no longer defensible. As one Israeli commentator put it, "Israel can import oranges from Europe for less money than it costs to farm them here" if the farmers had to pay the real price for water (Baskin 1992: 9). The combined impact of these arguments was a significant softening of Israel's traditionally zero-sum water security thinking.

What is more, these discursive changes found clear reflection in the institutional make-up of the Israeli water sector. As the Israeli economy expanded and liberalized, and the economic significance of the agricultural sector dwindled, so the predominance of the Ministry of Agriculture in water policy making itself came under threat. For the first time in 1990 a Water

Commissioner was appointed who was not from the agricultural establishment (Feitelson 2002: 305). In 1996, the Water Commission itself was transferred from the Ministry of Agriculture into a new Ministry of National Infrastructure. Israel's major para-statal water institutions have been liberalized, with the Mekorot water supply company becoming an autonomous cost-centre operating without government subsidies, and Tahal, formerly responsible for water planning, having been completely privatized (Rouyer 2000: 150-151). Israeli water policy has moved from being dominated by agricultural and 'national security' thinking, to being strongly informed by economic thinking, and by neo-liberal doctrine in particular.

The policy results have been clear. Water tariffs have increased, especially in the agricultural sector; and Israel has commenced construction of a raft of desalination plants which will soon be supplying 400 million cubic metres of water per year, not far off what it currently takes from West Bank aquifers shared with the Palestinians.⁸ With regard to relations with the Palestinians, water was intentionally relegated within the framework of the Oslo peace process to one of the "other areas of common interest" to be resolved during permanent status negotiations, secondary to the more pressing subjects of "Jerusalem, refugees, settlements, security arrangements, borders, relations and cooperation with other neighbours".⁹ Within the final status talks conducted in 2000 and 2001 at Camp David and Taba, water was barely touched on at all, while in the negotiations for the track two Geneva Initiative during 2002-2003, water was deliberately not discussed, it being generally accepted that it was simply a "technical issue".¹⁰ To a large extent, water has effectively been both economized and downgraded within Israeli security thinking and policy-making. As in the Israeli economy and

8 Amiran Cohen: "Work commences on desalination plant", in: *Ha'aretz* (12 August 2003); Sharon Kedmi: "Ashkelon desalination plant finally opens for business", in: *Ha'aretz* (5 August 2005).

9 See: Israel and the PLO: *Declaration of Principles on Interim Self-Government Arrangements* (13 September 1993), article 5.

10 While there were final status talks on water issues during this period (interview with Shaddad Attili, PA Negotiations Affairs Department, 2 June 2002), these were not significant enough to merit inclusion in the 'Moratinos Document' (in: *Ha'aretz*, 14 February 2002), which is generally taken as an accurate account of the Taba negotiations. On the Geneva Initiative, I benefited from an interview with Yossi Beilin (1 September 2005).

society more broadly, there has been a clear link between liberalization and the potential for water peacemaking (Feitelson 2002).

And yet, this *potential* for water peacemaking with the Palestinians has not so far been translated into *actualities*, for, as in the high politics of the peace process, so too the water negotiations have continued to be dominated by Israel's national security establishment. Within the 1993 Oslo agreement, Peres' liberal-civilian team had implicitly recognized Palestinian water rights - this being to the consternation of Defence Ministry officials, who believed that this would but create problems for future negotiations. Yet come the more substantive negotiations that followed, Peres' men had been sidelined into the multilateral arena, with the bilateral water negotiations with the Palestinians being led by Noah Kinnarty of the Ministry of Defence, a hawkish military man in the style of Rabin.¹¹

The water provisions of the 1995 Oslo II agreement clearly reflected this change of personnel. For despite Israel's increasing wealth and economic capacity to produce and manage water effectively, and its consequent potential to treat water as other than a zero-sum security good, its concessions to the Palestinians were negligible. Under the terms of the deal, a mere additional 3.1 million cubic metres (mcm) of water per year were made available by Israel to West Bank Palestinians (compare this with the estimated yield of the West Bank aquifers, 679 mcm, and Palestinian West Bank consumption in 1995, 118 mcm).¹² Israel retained an effective decision-making veto over the management of West Bank water resources, infrastructure systems and supplies. And the only 'new resource' that was made available to the Palestinians was largely imagined into existence by Israeli negotiators (Selby 2003: chap. 5). The Oslo II water agreement - constituting the high point of Israeli-Palestinian water diplomacy - involved little more than a repackaging of ongoing Israeli control and domination under the banner of peace and cooperation (Selby 2003a: 21-38, 2003: chap. 4).

How profound has been the impact of new security thinking on Israeli and Palestinian bilateral water

relations? Our answer has to be: not particularly. Whatever the extent of new thinking about water issues in general within its NGOs, universities and ministries, Palestinian discourse on water relations with Israel is understandably dominated by a concern with the attainment of legitimate 'water rights' to the use of Jordan River and West Bank waters, leaving little space, or indeed desire, for discussions of 'water security'; 'security', as noted previously, seems to be the demand and terrain of Israelis only.

In any case, Israel has so dominated Israeli-Palestinian water relations since the onset of the peace process - the text of the 1995 Oslo II water agreements were largely presented to the Palestinians as a *fait accompli* - that it is really on Israeli policy that we must focus if we want to assess the impact of new security thinking on the Israeli-Palestinian water arena (Selby 2003, chap. 6). And what we find there is that, irrespective of Israel's economic liberalization and the consequent liberalization of Israeli water policy, the country's military-led national security establishment has continued to call the shots in water relations with the Palestinians, insisting on maximizing its control of regional resources, and on making as few compromises as possible with Palestinian demands. If anything, the liberalizers' calls for efficient management and the creation of new water supplies have primarily served as rhetorical cover for the pursuit of narrowly-conceived national water interests, and for the furtherance of Israeli water security at the Palestinians' expense. And as in the peace process more broadly, Israel's liberalizing but far from progressive elites and middle classes have been largely happy to accept the enduring hegemony of military institutions and thinking, and the ongoing oppression of the Palestinians.

46.4 New Security Thinking on Israeli-Palestinian Water Issues Amongst External Actors

Just as Israeli security (and water security) discourse during recent years has been characterized by the unequal juxtaposition of conflicting liberalizing and nationalist tendencies, so something similar can be discerned in the international water arena. During the last twenty years, water issues have attained a much higher profile within international and global policy fora than they generally enjoyed hitherto, this being on the back of the mainstreaming of environmental concerns within the global North, and also within the context of the post-Cold War coalescence of inter-

11 Interviews with Noah Kinnarty, Ministry of Defence, Israel, and Oslo II lead negotiator (28 July 1998); and Moshe Yizraeli, Consultant to the Water Commission (21 July 1998).

12 Figures from (or extrapolated from): Israel and the PLO: *Interim Agreement on the West Bank and Gaza Strip* (28 September 1995), Annex III, Article 40; and Annex III, Appendix 1, Schedule 10.

national 'security' and 'development' agendas (Duffield 2001). This heightened profile of global water issues has been prompted, at least at a rhetorical level, by a new wave of neo-Malthusian thinking about the global environment. With its modern roots above all in the Club of Rome's 1972 report - which evinced an inevitable clash between economic development and environmental sustainability - this thinking has seen a flowering of international programmes, institutions, networks and agreements committed to raising awareness of, and combating, one of the main crises of our age (Meadows/Meadows/Randers/Behrens 1972). And this pessimistic neo-Malthusian thinking has been translated directly into the discourse on Israeli-Palestinian and Middle Eastern water issues, with countless commentators - journalists and experts alike - forecasting increasing competition over scarce, finite water resources, with violent inter-state 'water wars' as the result (Starr/Stoll 1988; Bulloch/Darwish 1993; Selby 2005). As one leading commentator, Thomas Stauffer, bluntly stated it, 'the Malthusian spectre is real in the Middle East'.¹³

Though dominant within media and public discourse, this neo-Malthusianism has in practice been subordinate to a second tendency within recent global environmental and water discourse, that of neo-liberalism. For while the former has raised the clarion cry of ecological crisis - alarming publics and politicians to the cause - it is the latter which has most structured global discussion and decision-making about how to respond. Accordingly, the policies promoted by the World Bank, USAID, and epistemic communities of water experts such as the World Water Council have emphasized above all the importance of valuing water as an economic commodity; of ending subsidies; of allocating water between sectors in accordance with economic logic (and in the Middle East, of reducing allocations to the agricultural sector); of improving institutional efficiency; and of making increased use of the private sector through privatization or public-private partnerships. Curiously, while one face of the new thinking, neo-Malthusianism, has sought to 'securitize' water as an emerging threat to international security, neo-liberals have argued the exact reverse - that by commodifying and economizing water, it can be effectively negated as an object of inter-state conflict.

As discussed above, the impact of neo-liberal ideas on Israeli-Palestinian bilateral relations has been negli-

gible, despite the significant internal liberalization of Israel's economy, society and water policy. Beyond the two central parties to the conflict, however, there are three major impacts (or non-impacts) of this new neo-Malthusian and neo-liberal security thinking that demand attention.

Firstly, for all the increased attention on international environmental issues over the past twenty years, this has not led to significant international political interventions to resolve the Israeli-Palestinian water dispute. Bilateral Middle East negotiations have been accompanied by multilateral talks, which during the early- and mid-1990s brought together regional governments, outside powers and international organizations to discuss regional water issues. But the focus of these multilateral talks was technical rather than political, and in the water arena they made no progress of any consequence (Peters 1996). In terms of actual conflict resolution, the role of outside powers has been minimal. During the 1950s, the Eisenhower administration devoted considerable effort to prompting the Jordan basin riparians to agree a water sharing plan which, though it was eventually rejected at a high political level, has nonetheless remained a continual reference point in discussions and negotiations on regional water issues (Lowi 1995). By contrast, the Clinton Administration - supposedly devoted to addressing post-Cold war challenges such as environmental insecurity - made no such ambitious attempt to address, let alone resolve, the Middle East's inter-state water problems. No doubt this difference has a great deal to do with the fact that Israel and the U.S. are today much more closely aligned than they were during the 1950s. But it is also clear testimony to the limited impact of new security thinking on external official political intervention in the Israeli-Palestinian water conflict.

By contrast with this, secondly, the newfound recognition of the social, economic and political importance of water has generated a tremendous level of international support for the reconstruction and development of the Palestinian water sector. The World Bank and USAID both defined water as one of their three top priority funding areas in the West Bank and Gaza, and led by these two donors, over 10 per cent of all aid money to the Palestinians between 1993 and the collapse of the peace process in 2000 went to water and wastewater projects (Rouyer 2000: 229; Selby 2003: 4-5). This aid has funded the establishment of autonomous Palestinian water institutions, the construction of new water and wastewater infrastructures, and the rehabilitation of local networks

13 Quoted in S. Peterson: "What could float - or sink - peacemaking", in: *Christian Science Monitor* (14 July 1999).

long run down through Israeli under-investment. It led to marked improvements in the water supply situation in many Palestinian communities, at least up to the collapse of the peace process in 2000 (though these improvements were extremely uneven, centring on high profile urban centres such as Ramallah and Bethlehem, at the expense of rural areas). By stimulating such high investment in the Palestinian water sector, new security thinking did have a limited beneficial impact on Palestinian water security.

However, these positives also need to be considered within their broader political and economic contexts. The main purpose of the aid programme to the Palestinians since 1993 has been to support a deeply unequal and unjust 'peace process'. In the water sector, as elsewhere, the post-Oslo development effort was premised upon a transfer of the burdens and responsibilities of managing the Palestinian population from Israel to the international community. This transfer of burdens was initiated at a time when Israeli leaders remained set against Palestinian statehood, when they remained committed to the ongoing colonization of the West Bank through settlement building, and when they retained the right to enforce security closures around (and within) the Palestinian territories, with disastrous effects upon the Palestinian economy and society. This transfer of burdens remained in effect despite Israel's re-occupation of much of the West Bank and Gaza between 2000 and 2002, and still remains in effect despite Israel's new policy of 'unilateralism', and its consequent refusal to re-open political negotiations with the Palestinians. In the water arena, as in all others, the international aid programme has worked within, been dependent upon, and thus been complicit in the vagaries of a deeply unequal macro-political context, whilst maintaining the fiction of being "non-political" (Selby 2003: chap. 7).

As this illustrates, thirdly, new security thinking on water issues has been thoroughly insensitive to questions of politics, power, poverty and inequalities. Whether in its neo-liberal or neo-Malthusian variants, the new mainstream environmental discourse has been blind to these questions, the former viewing environmental problems as caused by economic and technical inefficiencies, and the latter seeing them as caused by over-population and the over-consumption of limited natural resources – with neither of them allowing much space for discussion of structures of power and inequality. Intellectually as well as in practice, international environmental agendas have as a result usually operated within the context of, and have

implicitly accepted, confirmed and even exacerbated, enduring political economic structures. In keeping with this, international expert discourse on the Israeli-Palestinian water conflict has consistently understated the extent of ongoing Israeli control of the Palestinian water sector, and consistently overstated the changes wrought by the Oslo 'peace process' (Selby 2003a).

Likewise, international expert discourse has had very little to say about the 'internal' dimensions of water security within Palestinian society – about internal water inequalities in water supply between Palestinian towns and villages; about the small-scale local violence that often accompanies these inequalities; about the local black markets in water; about the marginalization of rural Palestine within international donor programmes; or about the impacts of the internal political economy of water on Palestinian livelihoods, gender relations and poverty.

The impacts of these intellectual lacunae on aid policy to Palestine are too nebulous to be stated with any great precision. But what can be stated is that within a political configuration where the ultimate purpose of aid programmes has been to support the high politics of the peace process, expert discourse on Middle Eastern water issues has done little to direct attention either towards the inequities of that 'peace process', or towards combating poverty, promoting sustainable economic development, or furthering 'human security'.

46.5 Conclusions

From a historical materialist perspective, using new words is easy, but transforming material structures and practices very difficult. The last twenty years have witnessed a flourishing of new discursive formulations of 'security', most of which have sought to take the concept out of the hands of the nation and state, to make it instead the possession of human individuals across the world, and to focus attention on issues other than military capabilities. Certainly, this new thinking has had effects within international institutions and NGOs, within some middle class thinking, and where it has provided fresh opportunities for the aid and development industry. But in deeply contested geopolitical contexts such as that shared by Israel and the Palestinians, traditional security logics have continued to predominate.

The reasons for this are various, and are country-specific. In Israel, the longstanding political hegemony of the military and the existential insecurity of the

Zionist project, combined with the complicity of Israeli middle and capitalist classes in the occupation of the West Bank and Gaza, and in Israel's 'war economy', have effectively neutered challenges to traditional military-led national security thinking (Nitzan/Bichler 2002; Selby 2006).

Amongst the Palestinians, the Fatah leadership's central preoccupation with maximizing territorial gains and consolidating internal power, combined with the dependence of large sections of the Palestinian middle class on the peace process, and on the donor funds and NGO jobs that it generated (Hanafi/Tabar 2005), has resulted in a stifling of debate on internal social, political and economic insecurities (incidentally, these internal insecurities were the primary reason for Hamas' victory in the January 2006 Palestinian legislative elections).

Within the US, the power of the right-wing Israel lobby, and US big business' economic interests in the continuation of war and conflict in the Middle East, have resulted in the administration doing little to promote sustainable regional economic development or human security (Mearsheimer/Walt 2006; Nitzan/Bichler 2002). Finally amongst international donors, the apolitical discourse of development (Ferguson 1990) is such that donors have largely accepted - and thus been practically complicit in - the overall framework of a 'peace process' that has done little to advance either peace or development.

There is 'no more dangerous enemy', asserted Marx and Engels at the beginning of *The Holy Family*, 'than *spiritualism* or *speculative idealism* which substitutes "*self-consciousness*" or the "*spirit*" for the *real individual man*' (1956: 15). Rephrased in more contemporary and rather less bombastic terms, it can be said that the belief that individual consciousness and socio-political realities can be transformed by inventing new concepts and discourses, is not just mistaken but also potentially dangerous. No matter how imaginatively the concept of 'security' is re-thought and re-used, socio-political realities such as the Israeli-Palestinian conflict and the Palestinian water crisis will not be overcome unless there exist structural, material bases for so doing. In the absence of material change, 'new security thinking' can come to serve primarily as a rhetorical cover for enduring inequities and interests. The real challenge is not to re-imagine security, but to support and hopefully embolden actual social movements struggling for social transformation.

47 Functional Water Cooperation in the Jordan River Basin: Spillover or Spillback for Political Security?

Anders Jägerskog¹

47.1 Introduction

Ever increasing attention is given to the importance of the world's water resources and aquatic systems. The rising demand for water is due to a variety of factors, such as population growth and urbanization. The sustainable management of water resources is extremely important in the developing world, which is continually faced with a lack of the financial resources, infrastructure, and human resources needed to improve water management. Today, more than 45% of the world's population lives in internationally shared river basins. The increasing pressure on the limited freshwater resources in places such as the Jordan River Basin makes greater and deeper knowledge of how to manage trans-boundary waters essential.

In spite of fears of water-related violence and conflict, Israelis, Jordanians, and Palestinians have maintained a basic level of cooperation over their shared waters.² Even during the *Intifada* that started in September 2000 this is true. Between Israel and Jordan low-level cooperation dates back to the 1950's when, under the auspices of the UN, they collectively have chosen to co-ordinate water activities related to the Jordan River. The cooperation was later formalized as part of the Israeli-Jordanian Peace Agreement of 1994 that has created a Joint Water Committee. The Israeli-Palestinian water relations are regulated in a 1995 interim agreement. This is not a full agreement but covers only part of the water issues between the par-

ties, such as protection of water and sewage systems. A Joint Water Committee is also in place between Israelis and Palestinians. Given the political stalemate and ongoing violence, substantial negotiations on water or other matters are not likely to take place soon. Still, Israelis and Palestinians agree that cooperation on their shared water is indispensable.

The hydrological interdependence, i.e. the transnational nature of international river basins provides a rationale for cooperation (Elhance 1999). Indeed, an awareness of the positive prospects of basin-wide cooperation through the development of a water regime might spur an increased hydro solidarity and cooperation. A database compiled by Aaron Wolf's institution at Oregon State University, comprising all the water agreements on international watercourses (<http://www.transboundarywaters.orst.edu/>), shows that states tend to find ways to reach agreement rather than to engage in conflict over shared water resources. There is still a need, however, to understand *why* and under *what conditions* such cooperation occurs. In addition, it is of interest to analyse the *quality* of that cooperation. A key question in this chapter is if and if so how, the existing cooperation over transboundary waters can be used to promote cooperation in others spheres, thereby potentially functioning as a conflict prevention mechanism.³ Increased understanding of the relationship between the technical level (where most of the actual water coordination and cooperation takes place) and the political level needs to be analysed. Some questions that will be dwelled upon are; Is it reasonable to argue that there are, or can be, cooperative spillover ef-

1 This chapter is partly based on Jägerskog 2003.

2 For examples of the water war thesis see e.g. Starr 1991 and Bulloch/Darwish, 1993. These sources should, however, rather be seen as examples of how knowledge can be very misleadingly constructed. For example, they ignore the mitigating role that international food trade has had on the water conflict in the region and the fact that water has been more of a source of cooperation and coordination in the region than of conflict.

3 Conflicts can in this context mean, for example, conflicts with regard to a shared natural resource, a potentially violent conflict with roots in for example diverging political interests, dispute over land or borders etc.

fects as a result of the existing water cooperation on other political questions and issue-areas in the region? Can the existing cooperation over transboundary water in the Jordan River Basin be used to promote cooperation in other spheres between the parties? Is it indeed feasible to think that water may be a catalyst for increased security and eventually peace?

Among other things the chapter aims to analyse prospects and potential avenues for increased coherence between different issues, in this case predominantly between conflict prevention and security issues and the sustainable use of natural resources. In the wider perspective (benefit sharing perspective) it will also contribute to our understanding of the importance of water for the economy, trade, regional integration etc.

47.2 Theoretical Dimensions

In an effort to utilize cooperation between riparians over transboundary waters it has been argued that the states (or entities) engaged in the cooperation must be able to *perceive* the potential for a range of benefits that are not only to do with water management *per se*. Sadoff and Grey argue that there are four basic cooperative benefits. The first is *benefits to the river*, which entails a better management of the ecosystems. The second is *benefits from the river* such as increased food and energy production. The third is the *benefit of reduction costs because of the river* since the tensions between riparian states that inevitably will exist over a shared river will be lowered by cooperation in the management thereof. The reduction of tensions will also result in a reduction of costs. The fourth example are the *benefits beyond the river* which cover the positive results that cooperation over a shared river can have in terms of spillover effects such as increased economic integration between two or more countries. Seemingly the cooperation between states sharing a river is in some cases vast, while in other cases not so significant. The perception of potential benefits as well as the materialization of those from water cooperation seem in any case imperative to a better management of the world's rivers as well as to relations among the riparians sharing a watercourse (Sadoff/Grey 2002).

The economic framework developed by Sadoff and Grey for understanding cooperation and benefit sharing ought to be complemented by an account of the political aspects involved in the joint management of international rivers. Many international relations

scholars try to understand why international cooperation occurs in spite of the presumed anarchic nature of the international system. Some try to explain the cooperation through regime or institutional theory.⁴

These regimes or institutions are considered to exist in areas such as international trade, monetary policy, security and arms control, and the use of natural resources. Regimes may function as a vehicle for international learning and the converging of states' policies (Haas 1994). The social interaction, which takes place in a regime, fosters a convergence in value orientation and thereby creates incentives for a further institutionalization of cooperation (Mayer/Rittberger/Zürn 1993). Wendt has clarified the institutionalization of cooperation in the international arena. He argues that: "The process by which egoists learn to cooperate is at the same time a process of reconstructing their interests in terms of shared commitments to social norms. Over time, this will tend to transform a positive interdependence of outcomes into a positive interdependence of utilities or collective interest organized around the norm in question" (Wendt 1994: 87).

The regime approach, which is an inherently constructivist way of analysing the institutionalization of cooperation, focuses on how the expectations that are produced by behaviour affect interests and identities.⁵ This process of institutionalization is one in which actors internalize new understandings of self and other and, furthermore, move towards increasingly shared commitments to the norms of the regime. Whereas an international treaty is a legal document stipulating rights and obligations, a regime is a social institution in which the behaviour of its actors constitutes the regime or institution (List/Rittberger 1992).

Evidently, there are some contained mechanisms that guide the actions of the parties in a river basin. In the international relations literature these mechanisms are referred to as regimes or institutions. Within the literature that deals with international waters a concept that is receiving increased attention is that of *water regimes*. Waterbury argues that "the process of regime formation itself – legislating, data

4 Economists tend to use the term institutional theory while political scientists and international relations scholars use the term regime theory more often.

5 The regime theory approach stems from the functionalist approach within international relations, see: Groom (1975: 93-III) and Mitraný (1975: 53-78), have usefully discussed both the tenets of functionalism and spillover and spillback concepts.

gathering, formal institution-building, and negotiating – can provide momentum, the creation of new institutional interests and expertise, and, occasionally, ‘tipping’ moments that lead to formal cooperation” (Waterbury 2002: 35).

The majority of the studies that deal with international relations tend to treat every state or nation as an unproblematic singular unit. This is also the case in most analyses of water relations between states. However, this approach is a gross simplification. In order to understand why nations choose the policies they pursue in the international arena one needs to study thoroughly the domestic political context, since the policies pursued internationally are likely to be a reflection of the domestic discourse. Thus, the need for governments to be in line with their respective domestic discourses in their pursuit of international policies is key to understanding foreign policy. In the words of Stein, “analyses that ignore the context in which negotiations take place, ... the impact of cultural, social, institutional, political and psychological factors or processes of communication and choice, are inadequate as explanations of international negotiations” (Stein 1988: 230). Obviously this either creates room for cooperation and possibilities for spillover effects or effectively limits this possibility.

Discourses become either accepted or “sanctioned” or not accepted within a society. The sanctioned discourse sets limits within which policies have to be pursued, that is, it indicates what avenues may be politically feasible (Allan 2001). It represents what may be said, who may say it, and also how it is to be interpreted. It is helpful in explaining why people who are confronted with the same scenarios or events nevertheless describe their experience in quite different ways. The rationale for explaining events in one way or another is often a result of the surrounding social context and the particular discourse that has been sanctioned. In a related line of thinking, the sociologist Pierre Bourdieu argues that the dominant knowledge or view in a society is dominant not because it represents a “higher level” of knowledge but because it is formulated from a position of greater power in the social hierarchy. This position depends on economic, social, and cultural capital (Bourdieu 1986).

In the creation of the sanctioned discourse, various “discursive actors” have special interests or stakes. However, interests and power positions will determine the outcome of this “discursive battle”. While politicians, in both democratic and non-democratic regimes, are in a position to influence the dis-

course, they are not able to exercise full control over it. Discourse analysis is useful in explaining why they sometimes choose not to implement the water policies, which would seem to be the most rational from a scientific perspective. Allan argues that the role of politicians is mainly to legitimize “that which is determined by the discourse” (Allan 2001, 2003). While that is true it can be added that politicians have a stake in the discursive battle, as they possess certain economic, social, and cultural capital. A useful distinction when analysing how discourse affects policy is the one made by Hajer, who argues that actors in a given area (such as the water sector) create coalitions that subscribe to the same narratives. He calls these “discourse coalitions”. It is not necessary that these actors strategically choose the narratives they do in order to create a coalition. The coalitions need not be formalized but may be a result of various story lines made up by actors from a sometimes different logic but with a conclusion that are supportive of the conclusion of the other actor(s). These coalitions can consist of government officials, water professionals, journalists, and so on (Hajer 1995).

47.3 The Importance of Politics: The Role of Discourses

In this section the importance of politics in the creation of water policy is scrutinized. This is key to our understanding of the possibilities for spillover effects to other political issue areas. By analysing the discourse within the respective states or societies it is evident that other considerations than purely related to water play a pivotal role in determining water management decisions and also the potential effect that those might have on other areas. Strategic concerns and security considerations are key ingredients of this mixture. Since control over and access to fresh water in a river basin with limited supply is of strategic importance, states are likely to develop a *hydraulic mission*, which feeds in to a hydro-political ideology.⁶ Below follows an analysis of the various features of the sanctioned discourse or hydro-political ideology among the parties in the Jordan River Basin.⁷

6 Anthony Turton, 2002: “The political dynamics of institutional development in the water sector: South Africa and its international river basins” (unpublished).

7 When referring to the parties in the Jordan River Basin, Syria and Lebanon are not considered since they have not been part of the research for this chapter, although they are formal parts of the Jordan River Basin.

In Israel the discourse on water was largely determined by ideology (i.e. predominantly Zionism) from the 1940's up until the 1970's, which implies a strong emphasis on water allocations to agriculture since it represents a central feature in Zionism (Feitelson 2002). Even though there has been a shift in the discourse towards more economic reasoning, the ideological preference for farming is still reflected in the disproportionate political power the agricultural sector enjoys in Israel: the agricultural sector possesses the cultural capital needed to deploy that political power.

From a military angle it is perceived that giving up farming in the remote areas of Israel would constitute a strategic risk. Keeping agricultural settlements in the remote areas is important since they are seen as a "buffer zone" against potential enemies. However, there are arguments for saying that the policy of using agricultural settlements as a tool in the strategic defence of the state has proved counterproductive. The inadequacy of buffer zones was also effectively shown during the Gulf War in 1991 when Iraq sent missiles directly into the heart of Israel. It was also evident in earlier wars. In the 1973 war many Israeli soldiers were occupied evacuating agricultural settlers in the Golan Heights rather than fighting the Syrians. Hence, the policy of keeping agricultural settlements in strategic areas of the state seems to be based on a misguided perception of their strategic importance and is perhaps better explained by other political reasoning. First, Israel's (misguided) policy of keeping agricultural settlements in strategic areas has to be explained by other reasons than their true strategic importance. Its policy suits the argument of the farming community and there seems to exist a farming-military *discourse coalition* (Hajer 1995). This discourse coalition represents the dominant discourse on water in Israel. Second, Israel's main interest in the negotiations, from a water perspective, is to maintain the high levels of allocation since a negotiation will most likely be based on some measure of current use. Third, it is also possible to trace the root of the arguments of the farming community and the strategic establishment in the domestic structures of the state and Zionism. Fourth, this perspective does not exclude cooperation on water issues in the region, but it limits the room for compromise solutions. In the case of Israel it seems as though the potential for positive spillover effects from water coordination and cooperation to other political sectors is limited. Rather, water is used as a political tool in other spheres.

However, today it is possible to find challenges to the sanctioned discourse in Israel. It can be described as a "discursive battle".⁸ In this sense there is a *differentiation* between various experts and water professionals in Israel (as well as in Palestine). On the Israeli-Palestinian water issue, besides the military-farming coalition, there is also a strong group of Israelis (and Palestinians as well) who argue for extended joint management of the shared aquifers (Had-dad/ Feitelson/Arlosoroff/Nassereddin 1999). This group emphasizes the risk aspect when they argue that joint management is the only way to counter the risk of non-reversible decline in the water quality of the shared aquifers. The current Water Commissioner of Israel, Shimon Tal, argues along similar lines and advocates cuts in allocations to agriculture as a means of countering the water crisis.⁹ Furthermore, in a subgroup under the Multilateral Working Group on Water Resources a group, named Executive Action Team (EXACT) involving Israelis, Palestinians and Jordanians, has met to discuss common water challenges under U.S. auspices without interruption since 1992. This group has, by and large, focused on technical matters of importance for all parties and has refrained from discussing political issues. This has contributed to the building of trust between the parties.¹⁰ What we can see when analysing how Israel views positive impacts coming from water cooperation, which goes beyond the actual cooperation, the main positive result is mainly *benefits to the river* which entails an increased protection of the ecosystems.¹¹ Potential *benefits from the river* are also on the table, predominantly through the work of EXACT.

The Palestinians, on the other hand, seem to be somewhat stuck in the prevailing discourse that the starting point of any negotiation ought to be their water rights. Haddad (1997) points to the fact that the Palestinians have long been denied self-rule and the right to develop and manage their natural resources. One water negotiator, Amjad Aliewi, argues that it is possible to discuss other issues, such as pol-

8 An elaborate discussion on the various competing Israeli discourses can be found in Feitelson (2002).

9 Shimon Tal, 2001: "Water Commissioner Shimon Tal briefs foreign press", Israeli Ministry for Foreign Affairs, <<http://www.mfa.gov.il/mfa/go.asp?MFAH0k8s0>>, accessed on 28 February 2005; and Zafir Rinat: "Watered-down advice", *Ha'aretz*, English edition, 24 June 2001.

10 For more see: <http://exact-me.org/>

11 The protection that is happening could of course be extended much further.

lution, only after the water rights of the Palestinians have been clearly established.¹² This is iterated by another Palestinian water negotiator, Shaddad Attili, who maintains that the core of the Palestinian negotiating position has to do with securing water rights.¹³ The history of the conflict, in which the Palestinians have been subject to inequality and repression, and the strong tradition of farming among the Palestinians are integral parts of the domestic structure in Palestine. Hence the idea that water rights ought to be *the* starting point in any negotiation is deeply rooted in the history of the conflict. This very strong paradigm effectively sets the boundaries for what is feasible. Needless to say there are various discursive actors who reinforce this view and thus bolster the sanctioned discourse.

Inevitably, a negotiation in which water rights are discussed as a main principle must be based on figures of current allocation and use. Today the difference between the allocations to Israel and those to the Palestinian areas is considerable. Thus the water rights that the Palestinians may obtain in a negotiation runs the risk of being far too limited. A shift on the part of the Palestinians towards the principle of equitable utilization is likely to produce a better outcome.¹⁴ But this is not part of the dominant Palestinian water discourse and consequently not on the table, in spite of international advisers pushing for it. It may well be that the power of the sanctioned discourse prevents the Palestinians from obtaining the best agreement possible. However, the Palestinian position on this issue is also beginning to change. The Negotiation Support Unit under the PLO is increasingly emphasizing that the permanent status negotiations should seek to allocate water on an equal *per capita* basis in Palestine and Israel. This argument is based on the principle of equitable utilization (Phillips/Shaddad/Mc Caffrey/Murray 2004). Another dominant feature in the Palestinian discourse is their insistence that the Palestinians' water problems are almost exclusively the fault of Israel (Trottier 1999). This rhetoric is found among academics, water professionals, and in the media, as well as from government officials. This is, of course, also

a result of the Palestinians having been deprived of their rights and self-rule by Israel.

In Jordan, the argument is emphasized that the water scarcity in the country is man-made. It is estimated that the Hashemite Kingdom absorbed around 450,000 Palestinians after 1948. Irrigation was a crucial factor in accommodating them, thus putting pressure on Jordan's limited water resources (Haddadin 2000). Thus, Jordanians argue that Israel is partly responsible for Jordan's water shortage. Dureid Mahasneh, a former Jordanian negotiator, also argues that it is not fair that Palestinian refugees from the West Bank should get Jordanian water while the occupant (Israel) is getting their water.¹⁵ The dominant view among the discursive elite in Jordan was that peace would be beneficial since it would bring U.S. economic and military aid (Ryan 1998).

As in Israel and the Palestinian areas, the advocates of "virtual water" are not strong in Jordan. The commercial sectors involved in agro-business as well as the farming community in Jordan are not positive to further increase import of foodstuff from the international market since it threatens their interests. In particular if this would take the shape of government policy. This is, however, to be expected since Jordan, like the other entities, has a strong tradition of farming, even though the agricultural sector today contributes a fairly small part (3-5%) of gross domestic product (GDP). In addition, the food self-sufficiency argument, emphasizing a strong domestic base and subsequently not an emphasis on the importation of food, is strong in the Jordanian discourse.¹⁶

47.4 Regime Theory Considerations

A central question of this chapter is why and under what conditions cooperation has occurred between the parties in the Jordan River Basin. A way to investigate this is to analyse the actual implementation of the agreements (both final and interim) between the parties in the Jordan River Basin. The case of Israel and the Palestinians is different from the Israeli-Jordanian case in that the agreement to be implemented is an interim one, while Israel and Jordan are working with the implementation of a final agreement (Dombrowsky 2003).

12 Amjad Aliawi, personal communication, Amman, Jordan, 9 March 2002.

13 Shaddad Attili, personal communication, Amman, Jordan, 9 March 2002.

14 Tony Allan, personal communication, London, UK, 23 October 2001.

15 Dureid Mahasneh, personal communication, Amman, Jordan, 9 March 2002.

16 Hazim el-Nazer, personal communication, Amman, Jordan, 11 March 2002.

With regard to the actual implementation of the various parts of the agreements it is concluded that they are often being implemented somewhat painfully. It is also evident that in the Israeli-Palestinian case many parts of the interim agreement awaiting implementation are being delayed despite a general understanding on part of the professionals (among experts) that implementation should be carried out.¹⁷ Although various problems have hampered the implementation of the agreement, both parties acknowledge the importance of it being in place. Indeed, even in the midst of the latest tensions during the current Intifada, the work of the JWC continues. A joint statement of 31 January 2001 from the Israeli and the Palestinian heads of the JWC reaffirmed their commitment to continue their cooperation. In the declaration the head of the PWA, Nabil el-Sharif, and the head of the Israeli delegation to the JWC, Noach Kinarty, promised to take all necessary steps to keep water out of the conflict, and also appealed to their respective constituencies to refrain from damaging water infrastructure¹⁸ (Schiff 2001). Arguably this might be referred to as a “tipping moment” (at least on the technical side) between the parties in favour of cooperation.

It is clear that while the ambiguities that exist in the agreements are useful when trying to reach an agreement, they work as obstacles in the post-agreement phase when they are to be implemented. For example, the lack of provision for drought in the Israeli-Jordanian agreements has served to create tension between the parties and has thus tested the robustness of the agreement. It is concluded that the power asymmetry between the parties, which is particularly evident in the case of Israel and the Palestinians, effectively gives Israel the upper hand in the decisions with regard to the implementation of the agreements. An example that illustrates this is the work within the Israeli-Palestinian Joint Water Committee (JWC). According to the Palestinians taking part in the JWC and its subcommittees,¹⁹ there have been delays in decisions with regard to permits to drill wells, and so on.²⁰ While the Palestinians attribute many problems and delays in decisions regard-

ing Palestinian projects to Israeli unwillingness, the Israelis maintain that they have hydrological reasons for turning down Palestinian proposals.²¹ However, well-informed sources admit that Israel's refusals to agree on project proposals with the Palestinians are sometimes due to political rather than technical reasons.

Furthermore, it is noted that, in comparison, the Israeli-Jordanian cooperation and implementation of the agreement can be described as fairly smooth, while the Israeli-Palestinian cooperation and implementation of the Interim Agreement have encountered obstacles. These obstacles cannot be attributed to problems of cooperation on a professional level. They are rather the result of the surrounding political circumstances which are much more sensitive and problematic in the case of Israel and the Palestinians than in the case of Israel and Jordan. In that sense the possibilities for an extension of the water cooperation to other political sectors is confined.

Despite the problems in implementation there exists a kind of contained mechanism that guides the action of the parties. This can be called a water regime. While this does not imply that there are no problems in the sector, it is concluded that the evolving principles, norms, rules, and decision-making procedures resemble a water regime. In addition, during times of pressure on the regime, such as the drought in 1999, which resulted in strained relations between Israel and Jordan, or the Intifada between Israel and the Palestinians that started in September 2000, the water regime has showed robustness and resilience, as referred to above, although its effectiveness has been hampered.

In the work of the EXACT group referred to above (which consists of Israel, the Palestinians and Jordan) it is evident that a sense of shared commitments to shared norms of how to handle their shared waters has grown. Since the early 1990's, their work has led to an institutionalization of cooperation. The interaction that takes place between the parties in this setting shows that a shared vision is developing

17 Politically sensitive issues, such as the locations for the drilling of Palestinian wells in the West Bank, are generally blocked by Israel for hydrological reasons, but it seems that there are often political reasons for those decisions. This is also unofficially acknowledged by Israeli officials.

18 Zeev Schiff: “Unlikely cooperation”, in: *Ha'aretz* (English version), 13 February 2001.

19 The JWC has the right to form various subcommittees, which it has done, in order to work with specific issues such as technical matters. The decisions in these subcommittees are subject to approval of the JWC.

21 Shmuel Cantour, Personal communication, Tel Aviv, Israel, 30 April 2001.

for how to manage their shared problems. Hence it is concluded that the international water regimes that exist might be seen as a conflict-mitigating factor since they promote basin-wide interstate cooperation and thereby increase water security. The analysis of the water cooperation in the Jordan River Basin through the prism of regime theory is helpful in explaining why cooperation has occurred in spite of the significant political conflict. When a convergence of values has occurred within a regime and the cooperation has been institutionalized, it is more difficult than one might think to reverse or end this cooperation. However, whether this will have the possibility to extend beyond the water cooperation is largely determined by other political considerations that are largely outside the water management arena. Nevertheless, it is clear that the cooperation that has been institutionalized contributes to an increased water security for the parties in the Jordan River Basin in that the benefits to the river are more evident and possible to have a reasonable account of. Increased coordination and notification between the parties makes it possible to avoid sub-optimal decisions. On the other hand, the possibility to avoid sub-optimal outcomes does not always mean that the necessary decisions for avoidance of sub-optimal outcomes are taken. It is also important to bear in mind that the benefits are not always evident for the people in the region. This is in particular the case for the Palestinians in the West Bank or Gaza whose daily water situation is also negatively affected by the Israeli occupation of those areas.

47.5 Benefits Beyond the River: The Case for Spill(-)over Effects of Water Cooperation in the Jordan River Basin – Wishful Thinking or Tangible Reality?

While regime theory contributes to our understanding of why cooperation on water *per se* is taking place and a system of more or less formal and informal norms, rules, and procedures has evolved over time between the parties in the Jordan River Basin, it is not very helpful when analysing the potentials for positive spillover effects. The regime approach leads us to think (correctly) that the parties are able to avoid sub-optimal outcomes in terms of the management of the resource itself and that this is enough for bringing about cooperation. For the analysis of the potentials for positive spillover effects of this cooper-

ation we need to reach for a combination of economic and sociological (in particular theories on discourses) theoretical tools. As outlined by Sadoff and Grey there are four major “benefits” that could be derived from cooperation over a shared watercourse. These are benefits: a) *to* the river, b) *from* the river, c) *as a reduction of costs* resulting from river cooperation and d) benefits that go *beyond* the river (Sadoff/Grey 2002). Are those benefits possible to discern in the case of Israel, and the Palestinians and Israel, and Jordan and Israel? And does it matter *who* sees the benefits?

In terms of benefits to the river it is argued that there are tangible benefits to the parties in terms of a better management of the river system. For example, the canal for storage of Yarmuk water from Jordan in Lake Tiberias that was built after the peace agreement between Israel and Jordan has led to a more sensible (although by no means perfect) way of utilizing the water of the Jordan. In the case of Israel and the Palestinians an example of cooperation with benefits *to* the river is the local cross-border cooperation that takes place between the Israeli city Emeq Hefer and Tulkarem on water, in spite of being separated by the “green line”. The cities have an ambitious programme to manage their shared water resources.²² In terms of benefits stemming *from* the river the result is more mixed. There are plans between the parties for increased energy production but not much has happened. While the Israeli-Jordanian arrangements for storing part of the Jordanian share of the River Jordan in the Israeli Lake Tiberias during wintertime and the subsequent release of the water to Jordan in summer time when they need it more is a benefit to the river, it could also be seen as a benefit from the river. As a result the Jordan is able to optimize the water allocation to its farmers and to its cities. In terms of *reduction of costs* and the related reduction of tension as an outcome of the cooperation the result is mixed. While in the case of Israel and Jordan the relations are relatively smooth, it is highly doubtful whether this has to any large extent to do with the functional water cooperation. Rather, there are strong political factors (such as U.S. pressure, Israeli interest of keeping good relations with Jordan, etc) acting as strong forces reinforcing this cooperation. In the case of Israel and the Palestinians it is not apparent that the basic cooperation that is taking

22 Nahum Itzkovitz, personal communication, Antalya, Turkey, 2 November 2002; Eran Feitelson, personal communication, Jerusalem, 24 May 2001.

place between the water professionals is resulting in cooperation in other political areas. In terms of benefits *beyond* the river (for example economic integration) it is not apparent yet. In the case of Israel and the Palestinians there is on the contrary a sort of disintegration that is taking place.

While visionary leaders such as Shimon Peres in his book *The New Middle East* (Peres 1993) pointed to a possible future of further economic integration and cross-border business parks in the Jordan Valley, this has not happened yet. If an economic integration should eventually take place it is furthermore not reasonable to argue that this would to any significant extent be a result of technical water cooperation between the parties, although it should not be neglected as a confidence building measure. Indeed, the confidence building has meant that there is a professional understanding across the borders, which have increased water security since the professional people involved have generally been helpful in providing assistance for reparation of water infrastructure even during the latest Intifada. In terms of donor thinking around the issue of potential spillover effects that goes beyond the river much analysis is still needed. Reasonable questions to be asked are: would increased conditionality (demanding or at least linking water cooperation projects to cooperative measures in other political spheres) from the donor side facilitate increased spillover effects?

For a further understanding of why spillover effects of cooperative behaviour are hard to find in this case it is indeed useful to draw on discourse theory. In order for benefits to be tangible and gain momentum to stir further cooperation in other areas the benefits must be apparent to a broader public. Otherwise it is hard for the policy-makers to take the necessary steps to capitalize on the cooperation that is tak-

ing place. While the water professionals and practitioners in the field see the potential benefits in all of the above-mentioned areas, their respective superior political system is not so attuned to that (and indeed have many other interests to weigh in against the water question). And the broader public is even less aware of the cooperation that is taking place and naturally neither aware of its actual and potential benefits. Thus the strong public discourses discussed above largely determine what spill(-)over of cooperative behaviour is possible.

47.6 Conclusion

The main focus of this chapter has been on analysing whether the actual water cooperation and co(-)ordination that takes place within the water sector (primarily on a technical level) could be further utilized as a conflict prevention and cooperation enhancement mechanism in other sectors. Drawing on functionalist theories the reasonable conclusion would be that it is possible for cooperation on water issues between the parties in the Jordan River Basin to also co(-)operate on issues "beyond the river" as a result stemming from the water cooperation.

While functionalism provides a sensible way of viewing the world it is still largely questionable if cooperation on water resources in the Jordan River Basin provides reason enough for increased cooperation in other spheres in this conflict-ridden region. While the cooperation on water is rather strong and robust it has not been shown to promote cooperation in other political sectors. Ending on a slightly negative note it is at the same time acknowledged that the cooperation that is taking place is an important process.

48 Water and Food Security in the River Nile Basin: Perspectives of the Government and NGOs in Egypt

Emad Adly and Tarek Ahmed

48.1 Introduction

Water is a scarce resource that should be equitably utilized and sustainably allocated and should take into account the social, economic and environmental conditions. Egypt, like any other arid country, faces the pressing challenge of closing the gap between its limited water resources and the increasing water demand. Egypt considers the River Nile its 'vein of life', being the sole source that covers nearly 95 per cent of the population requirements. The dependence of the other nine riparian countries (figure 48.1); Burundi, Democratic Republic of Congo, Eritrea, Ethiopia, Kenya, Rwanda, Sudan, Tanzania, and Uganda, on the Nile water varies according to each country's precipitation and water use patterns. These countries, being mostly humid and/or less populated than Egypt, are less vulnerable to fluctuations of the Nile flows.¹

Despite the fact that declining Nile water availability with respect to growing populations and increasing requirements for development is an alarming issue, Egypt has not yet reached the stage of a crisis. Rigorous efforts by both the government and the civil society are carried out to avoid an unbalanced offer/demand ratio. Exploring and exploiting existing available resources will only balance the water demand and supply in the short-term. Demand-driven and participatory oriented solutions and remedies constitute the basis for longer-term solutions.

This chapter discusses the views in Egypt, the major downstream country, on water and food security challenges from both governmental and non-governmental perspectives. It presents their visions and plans for the future, analyses their strategies and policies and attempts to find means of reconciling traditionally opposed and diverging approaches. Prospects for collaboration and complementarity should shift from the traditional unilateral supply-driven centralized approach to more effective participatory, demand-driven and consultative policies and action in the framework of a continued regional dialogue. This complex and challenging relationship should be extended from the national to the regional level, allowing countries of the Nile Basin to share their concerns, responsibilities and visions.

48.2 Nile Basin Population Growth and Increasing Water Demands

The population in the Nile basin countries is characterized by high population growth rates (table 48.1). Estimations of the UN World Population Prospects - the 2006 Revision (2007) and the Population Reference Bureau (2005) up to 2050 highlight the increasing future water needs for all Nile Basin countries.

This rapid population increase, adding from 2005 to 2050 about 518 million 'consumers' to the current population of the Nile Basin, imposes a human pressure on water demand and underlines the necessity of rationalizing water use. It also emphasizes the importance of tapping the potential for exploiting non-conventional sources, such as desalinated brackish/sea water.

It is noted that Egypt's population grows each year by approximately 1.5 million people. The United Nations projections indicate that its population will grow from 62.3 million in 1995 to 95.6 million by

1 For detailed information on the River Nile see: Fahmi (1986); Evans (1990); Whittington/Mc Clelland (1992, 1992a); Saeed (1992); Said (1993); Al-Mahdi (2002); AOYE (2003); FAO (1997); Howell/Allan (1994); Shady/Adam/Mohamed (1994); Shady/Grover (1996); Hvidt (1997); World Bank/UNDP/CIDA 1998: Waterbury (1987, 2002); Allan (2001, 2003); ESCWA (2002); Peichert (2003); for a comprehensive bibliography, see at: <http://www.nilebasindiscourse.net/biblio_EN.php>.

Figure 48.1: The Nile River Basin. **Source:** NBI (2005). This map is in the public domain (<<http://www.nilebasin.org>>).

2025 and will reach 114.8 million before it stabilizes by the year 2065.

The anticipated per capita water consumption for Egypt in 2025 and 2050 is projected to continually decline from 936 m³/year in 1995 to 607 m³/year and 503 m³/year respectively. Table 48.2 shows the per capita share of water consumption in the Nile basin in 1995 and the anticipated consumptions in 2025 and 2050. The data shown reveal that some Nile basin countries have been below the water poverty line of

1000 m³/year since 1995, implying a disastrous impact on food production in the region.

48.3 Aspiration to Food Security in the Nile Basin

Securing the food supply is one of the key challenges in all Nile Basin countries. Food security exists when all people, at all times, have physical and economic access to sufficient, safe and nutritious food to meet

Table 48.1: Population Growth in the Nile Basin Countries. **Sources:** Data for 1950 and 2000 and projections for 2025 and 2050: UN (2007); at: <<http://esa.un.org/unpp>>. Compiled by H.G. Brauch, 23 January 2008; previous compilation: Brauch (2002).

their dietary needs and food preferences for an active and healthy life (chap. 33 by Oswald and chap. 34 by Salih). The major challenge for a sustainable use of water resources in agriculture is to manage community expectations to meet social and environmental aspirations, while ensuring that food and fibre are produced competitively and profitably. Water is seen as a major element in food security programmes as

the water, food and trade nexus is increasingly figuring in the consciousness of decision makers in the region. The necessity of securing one thousand tonnes of water [1000 cubic meters] to obtain one tonne of wheat is a simple example of how food production is extensively water consuming. For most Nile Basin countries, agriculture is the major consumer of water resources. On the other hand, the presence of water embedded in food crops ('virtual water', Allan 2003, 2003c) emphasizes the role trade can play in securing the food supply within a broader policy framework that encompasses both food production and trade.

Because of the limited opportunities to rely on increased and regularized precipitation, irrigation is seen as the main alternative to provide the bulk of the additional food needed in the decades ahead for the increasing population of the Nile Basin. Reliance on irrigation, however, depends mainly on the ability to store water, promoting its availability to meet the anticipated increase in food requirements. Just as land productivity became the frontier to exploit during the second half of the twentieth century, water productivity - getting more crops per drop - is considered the new frontier for the twenty-first century.

This new challenge requires creative strategies that would mix food production and trade, making securing the food supply less resource-intensive and more information- and participation-intensive. Rising to the challenge, the Nile Basin countries aim, in planning and/or implementing I&D projects, to bridge the gap between population growth and urban over-population on one hand, and food production

and rural development on the other hand. Efforts carried out in this direction go hand in hand with determined attempts to ensure sufficient water supplies while protecting the environment and ensuring economic and financial support, which are all necessary elements for maintaining agricultural sustainability.

The above-described procedure implies an evident application of integrated water resources management. This is encompassed by complementary measures that include institutional strengthening, raising awareness and development of information systems, participation of concerned stakeholders, working with other countries or regions to successfully manage internationally shared resources, etc. However, since each Nile Basin country has a set of unique legal, institutional, economic, social, physical, and environmental conditions that influence its water management policies and strategies, the application of integrated water management depend on many factors, such as the size and political organization of the country, its hydrological conditions, its regional milieu, and the diversity of stakeholders.

48.4 The Water Situation in Egypt with Respect to that in the Upper Nile Countries

The Nile River originates from the Ethiopian Highlands and the Equatorial Plateau, both located in humid areas representing the origins of the Blue and White Nile respectively (figure 48.2). On a national basis, Rwanda and Burundi and most of the Tanzanian part of the basin receive an average of 800 to 1000 mm of precipitation (figure 48.3). The eastern portion of the basin in Tanzania is dryer, with only 600 to 800 mm. Kenya, Uganda and the Democratic Republic of Congo fragment of the basin are quite well watered, with an average annual precipitation of 1200 to 1600 mm. Ethiopia has high rainfall, as the Blue Nile Basin includes a large area where the rainfall is over 1200 mm; but the Atbara Basin headwaters receive only 600 to 800 mm. The arid region starts in Sudan, which can be divided into three rainfall zones: the extreme south where rainfall ranges from 1200 to 1500 mm per year; the fertile clay plains where 400 to 800 mm of rain falls annually; and the desert northern third of the country where rainfall averages only 20 mm per year. Further north, in Egypt, precipitation falls to less than 20 mm per year.

The Nile and Lake Nasser are the only renewable sources of water supply for surface water in Egypt.

Most of Egypt's terrain is desert, divided into two unequal parts by the Nile River. Less than one-tenth of the land area of Egypt is settled or under cultivation. This territory consists of the valley and delta of the Nile, a number of desert oases, and lands along the Suez Canal, which connects the Mediterranean with the Gulf of Suez, an arm of the Red Sea. While more than 90 per cent of the country consists of desert areas, the Nile enters Egypt from Sudan and flows north for 1,545 km to the Mediterranean Sea, forming a narrow green valley lined by extended yellow cliffs.

48.5 The Challenges Egypt Faces with Regard to Water, Agricultural Development and Food Security

The principal water management challenges in Egypt stem from the nature and quality of supply and demand management responses to water shortage. Table 48.3 shows the water demand in Egypt in 1997

Figure 48.3: Rainfall Patterns in the Nile Basin. **Source:** SPIDER International Ltd., 1994, 1997: *Water Resources Atlas of the River Nile Basin* (Ottawa: Canadian International Development Agency). This map is in the public domain.

and that projected for 2017, demonstrating how these requirements will be met through tapping non-conventional water resources, including water savings and possibilities of reuse.

Water conditions are, however, likely to straighten despite the giant water storage reservoir in Lake Nasser created after the construction of the High Aswan Dam in 1964. This is due to climatic fluctuations,

accelerating development activities, and high price of untraditional water abstractions. The role of the High Aswan Dam in reducing Egypt's vulnerability to the fluctuations of external and shared resources originating from upstream countries cannot, nonetheless, be denied.

Table 48.3: Estimated Water Balance of Egypt in 1997 and 2017 (in km³/year). **Source:** Egypt, Ministry of Water Resources and Irrigation (2002). This table is in the public domain.

	1997	2017
Water Resources:		
From Lake Nasser through High Aswan Dam	55.5	55.5
Rainfall	1.3	1.3
Shallow Groundwater	6.1	8.4
Drainage Reuse	7.5	11.4
Wastewater Reuse	1.4	2.4
Total	71.8	79.0
Industrial water flushed back to system	6.8	17.8
Agricultural water flushed back to system (Not including Reuse)	4.9	1.9
Domestic water flushed back to system (Not including Reuse)	2.4	2.6
Fishery water flushed back to system	0.9	0.4
Total Water Resources	86.8	101.7
Water Demand:		
Agriculture	57.8	63.6
Domestic	4.7	6.6
Industry	7.5	18.7
Navigation	0.2	0.2
Evaporation	2.4	2.5
Fishery	1.3	0.6
Total	73.9	92.2
Drainage to Sea	12.9	9.5
Total Water Demand	86.8	101.7

As use mounts, environmental problems emerge, including deterioration of water quality, salinization, and reduction of the yield of heavily exploited aquifers. The decline in water quality has in part been caused by problems related to the fast growth of cities: inefficient wastewater treatment, poor or non-existent solid waste management, and weak pollution control and abatement programmes. In addition, the truth that 'somebody has to pay for the quality water

services' has often been overlooked. Institutional structures have paid too little attention to the imperatives of financial sustainability. Both in irrigation and in water supply and sanitation, the quality of service delivery has too often been undermined by inadequate budgets, themselves in part resulting from inadequate cost recovery.

Increased urbanization, less homogeneous societies which reduce the effectiveness of traditional water management institutions, high levels of unemployment leading to reluctance to reduce water diverted to irrigated agriculture on which the poor often depend, increased climate variability, and increased pressure on agriculture from imports, are additional challenges that would reduce water availability. As a result, more than 50 per cent of the population food requirements are currently imported from abroad as reflected by the indicators on the state of food security shown in table 48.4. Available water resources can do little to close this 'food gap' – self sufficiency in food would require an extra quantity of water that amounts to more than the entire current water use. There is, however, scope for improving returns to water through greater use efficiency and through a move to higher value crops.

48.6 Governmental Efforts to Secure the Food Supply

The Government of Egypt recognizes the significant role of the agricultural sector, contributing to the food needs of the country and providing the domestic industry with agricultural raw materials. This sector also accounts for about 20 per cent of GDP and total exports, and about 34 per cent of total employment. It promotes industrial development through expanding the market for industrial goods such as pesticides, fertilizers, equipment and machines. Moreover, agriculture helps finance economic and social development through the net capital outflow from agriculture to other sectors of the economy. To meet the different water requirements, most importantly those of the agricultural sector, the Government of Egypt has adopted a strategy based on three main pillars:

1. Using the available water resources appropriately;
2. Protecting the water quality and combating pollution; and
3. Identifying new water resources in consultation and cooperation with Nile basin countries.

Table 48.4: Indicators Used to Report on the State of Food Security in Egypt. **Source:** Egypt, Ministry of Water Resources and Irrigation (2003). This table is in the public domain.

Indicator	Year of Evaluation	Indicator Value	Remarks
Net cereal imports and food aid as a per cent of total consumption	1998-2000	33.7%	
Food aid as a per cent of total imports	1998-2000	0.3%	
Average daily per capita calorie supply	1999	3323 kcal	compared to the global norm of 2808 kcal
Average daily per capita calories from animal products	1999	241 kcal	compared to the global norm of 460 kcal

This strategy has been put into action by the Ministry of Water Resources and Irrigation (MWRI 1997), the responsible body for appropriating and distributing water in Egypt, at three main levels. At the first level, water scarcity has been felt, but *supply side solutions* exist and scarcity has typically been addressed through supply management and engineering interventions to divert more water or reduce conveyance losses.

At the second level, where classic supply side solutions are no longer practical, investments have more focused on *non-conventional supply solutions* like wastewater recycling, and have begun to make water use more efficient through user *demand management interventions*. Demand side approaches have proven challenging as they rely on the development of appropriate instruments and institutions to ensure sustainable and high quality water services to farmers and the population, as the counterpart to managing demand to maximize income and growth.

At the third level, where institutional reforms have led to enhanced water management within each sub-sector, demand and the needs of a modern economy continue to press on scarce resources, necessitating improvements in *overall sector governance*. Typically, this stage includes integrated water resources management, decentralization of water service management to locally accountable institutions, and the involvement of users and of civil society in governance structures. Difficult political tradeoffs and institutional accountability are involved to achieve more value per each drop of water. However, experience has shown that overall integrated management can be achieved, provided that political will is backed up by effective capacity building programmes, awareness campaigns, applied research, and adoption of innovative technologies.

Virtual water and agricultural product trade add another dimension to the question of securing the food supply. Under the GATT '94/WTO multilateral agreements and the free trade agreements, the obliga-

tions of Egypt are an important determining factor for food security. The Government of Egypt has steadfastly maintained that it will comply with all obligations and commitments under the framework of rules and procedures of global trade. The most relevant and significant provisions of the agriculture agreement relate to market access, domestic support and export subsidies. However, developing countries are not obliged to reduce domestic support measures which are 'an integral part of their development programmes'. While Egypt operates under these obligations and shares the burden of implementing them, it strives to achieve domestic economic growth, jobs and an enhanced living standard through increased exports.

In the same context, the Association Agreement between the European Union and Egypt, within the Barcelona process, is to establish an appropriate framework for cooperation and partnership, which is to contribute to the economic and social development in Egypt.² The establishment of a bi-lateral Free Trade Agreement is based on reciprocal tariff liberalization for both agriculture and agro-industry. The EU has increased the tariff quotas granted for Egypt's main exports. Egypt equally reduces tariff duties for several agricultural imports from EU countries. Processed agricultural products equally enjoy reciprocal concessions, thereby improving market access for both parties. In the light of all these measures, Egypt plans to increase its agricultural exports to a level of US\$ 1 billion annually (<www.agri.gov.eg/future.htm>).

48.7 Role of Civil Society and NGOs in Water Security

Non-governmental organizations may enhance transparency in presenting the facts on water issues. They may increase awareness on new techniques aiming to rationalize water use, whether for irrigation or drinking purposes, maintain water supply and combat pollution. They may expand the dialogue among different segments of society and involve more people with the executive officials to discuss water issues and forward constructive proposals. They may handle water issues in a comprehensive way, economically, socially, environmentally, legislatively, and geographically. They may also address the links between health problems of local communities with wrong attitudes and practices of citizens towards water streams. They may enhance the full cooperation of various activities of ministries concerned with water use in the active implementation of the Law on the Environment (Law No. 4 of 1994). Finally, NGOs may raise the awareness on water issues and promote national values and traditions that call for preserving water through various methods of regular and irregular education and various media channels.

NGOs operating in developing countries face, however, many obstacles and constraints that sometimes jeopardize their efforts, often due to a lack of recognition from various bodies of the government, and sometimes even from the society itself. In some other cases the reasons might be attributed to a lack of funding or capacities within the NGO itself. Some other reasons are more sector specific, i.e. related to the field in which the NGO is active. For example, there are only few NGOs working in the field of food security, many of which lack the necessary professional and technical capabilities. There is also a clear lack of interest in scientific research and a lack of data and information on voluntary-based activities dealing with food security. On the financial side and even on the technical one, the support of donors and the private sector is limited. Many NGOs depend on scattered and unsustainable financial sources, often leading to a discontinuity of their activities.

To overcome these problems, several actions and measures are proposed. The first involves organizing NGOs working on food security, and uniting them in a network of associations, unions, and institutions dealing with food security issues. Second, the integrated roles between government, civil society, academia and the private sector should be stressed. The NGOs should, thirdly, expand their capacities in

human resource development, knowledge and information, fundraising and strengthening of their structures. By highlighting success stories of NGOs working on food security, the media can also play an important role in combating hunger in Nile Basin countries. Expertise should finally be exchanged within the framework of international bodies working in related fields.

48.8 Successful Initiatives of NGOs in the Water Sector

48.8.1 Egyptian Water Partnership

The *Egyptian Water Partnership* (EWP) is an informal platform to discuss water issues and policies, exchange information and start joint activities among different stakeholders and water players. Its mission includes “promoting sustainable management of water resources at national and local levels, through partnerships.” Its objective is to identify critical water issues of local and national importance based on ongoing assessments of the state of water; disseminating information and facilitating sharing experience among users, policy makers, and planners on new developments, good practices and research findings and familiarize different water stakeholders with each others programmes. To achieve this objective, the EWP strategy is to coordinate the efforts of various water stakeholders to maximize the benefit from water; economically and socially without compromising the sustainability of water and its quality.

The partnership aims also to ensure a broader outreach and to co-operate with global and regional programmes and initiatives, and establish links with regional and international organizations such as GWP, GWP-Med, WWC, UNDP, CEDARE, UNESCO, etc. The EWP serves as a public instrument to solicit public opinion on water related projects at the local and national levels, to provide a platform for practical action by creating support for promising initiatives in the field of IWRM or lobbying for changes in water management practices.

The EWP will serve as an independent stakeholder platform, a vehicle to promote IWRM principles, build the capacity and raise awareness on IWRM in Egypt. The EWP will achieve this in a multi-disciplinary approach by bringing together organizations from many backgrounds to share knowledge and develop a common vision for facing water problems in a participatory approach. The EWP makes

water everybody's business in Egypt. The EWP work plan identified among its priorities the relevance of water security for Egypt's obligations towards the international and local community. The EWP has addressed Egypt's water scarcity as well as water rights and equity. The EWP is a strong advocate in supporting the government and society in Egypt to realize its Millennium Development Goals (MDG) for water.

48.8.2 The National Nile Basin Discourse Forum

The *Nile Basin Initiative* (NBI) emphasized the role of civil society in achieving its ultimate goal of co-operative development on the Nile and the need to engage the society to better represent the interests of the poor (Peichert 2003). This led to the Nile Basin Discourse (NBD) "to promote dialogue on sustainable and equitable development, peace and mutual understanding within the Nile River Basin"³, and to the establishment of National Civil Society Forums (NDFs) in each country in October 2003. The National Forum in Egypt (EgNDF) reflects the demographic distribution and selection of a representative sample of the Governorates overlooking the Nile in Upper Egypt and in the Delta. These national consultations resulted in many recommendations to raise the awareness of the general public, on the role of specialists (civil engineers, agronomists, medical doctors, media), on the need to enforce the regulation on Nile Protection and the Environment and to reconsider the traditional agricultural system to the economic value of water.⁴

These consultations resulted in a Declaration in which the members of the National Forum pledged to establish a democratic dialogue among all stakeholders at the national and regional levels on the shared responsibility of management and preservation of water resources. It also recommended to all concerned national, regional and international organizations, to civil society, the governments, academia and research centres to operationalize the recommendations of the Forum as a step to achieve the sustainable development goal for the River Nile.

48.9 Conclusions

This brief overview of the challenges facing Egypt with reference to water and food security, the development plans of the government, its implication for Egyptian civil society and non-governmental organizations offered a snapshot. The challenges facing all stakeholders led to recommendations based on manifold expertise and a willingness to start where others have ended. The cooperation within the Nile Basin Initiative offers a platform for partnership and a shared vision. There is a need to develop national integrated programmes for water resources management. Most Nile countries suffer food shortage and this needs more investments in new appropriate technologies to increase the crop productivity, and the promotion and wider use of such technologies. Financial sustainability can only be achieved if the private sector is attracted to water and food security projects.

Last but not least, the civil society has an important role to play especially in the areas of water conservation and sustainable livelihoods through food security. And it would be appropriate in this context to recall the goal of the Nile Basin Discourse "to promote dialogue on sustainable and equitable development, peace and mutual understanding within the Nile River Basin".

These data point out the need for coordination and effort unification among all Nile basin countries to reach unconventional solutions in facing the problem of the declining individual share of water supply, including improved water conservation, waste minimization and reuse of treated sewage water, besides a rationalization of the water demand.

49 Water and Food Security in the Nile River Basin: Perspectives of Governments and NGOs of Upstream Countries

Patricia Kameri-Mbote and Kithure Kindiki

49.1 Introduction

Water is an important resource for sustaining life. The uses of water are manifold, and include domestic uses, industrial uses such as the production of hydro-electricity, irrigation and animal husbandry (Godana 1985: 1). Moving and stagnant water – such as rivers and lakes – serve as reservoirs for waste disposal (Okidi 1996: 1). Water and food security around the world continue to be threatened by population explosion and the rising standards of living, confirming that water is finite and cannot withstand all pressures to its quality, quantity and life-giving purposes. With the increasing demand on water and pressure on national water resources, states are increasingly turning to international watercourses.

This chapter is concerned with the perspectives of governments and NGOs of upstream countries regarding the consumptive utilization of the Nile River resources in the pursuit for water and food security within the basin states (49.2). It reviews the debate on the relationship between water scarcity in the Nile basin and inter-state armed conflict (Starr 1991, Wolf/Yoffe/Giordano 2003; 49.3); and on the status in international law of the bilateral treaties (49.4) on the consumptive uses of the Nile entered between Egypt, Britain and other powers before and during the colonial period (Garretson 1960; Teclaff 1967; Okidi 1982, 1994; Carrol 1999; Okoth Owiro 2004: 50).

The chapter argues that even if water and food security may not necessarily lead to violent inter-state conflict (Wolf 1998), water and food scarcity in the basin has, however, nurtured political tensions among basin states thus retarding the efforts towards sustainable development (49.5). Food security is used here to mean food production and availability at the macro level as well as access and distribution of available food. Since our aim is to look at the situation of upper riparian countries, we do not explore discourses concerning meeting food security needs through dis-

tribution of food produced in one part of the basin to all basin countries (figure 49.1).

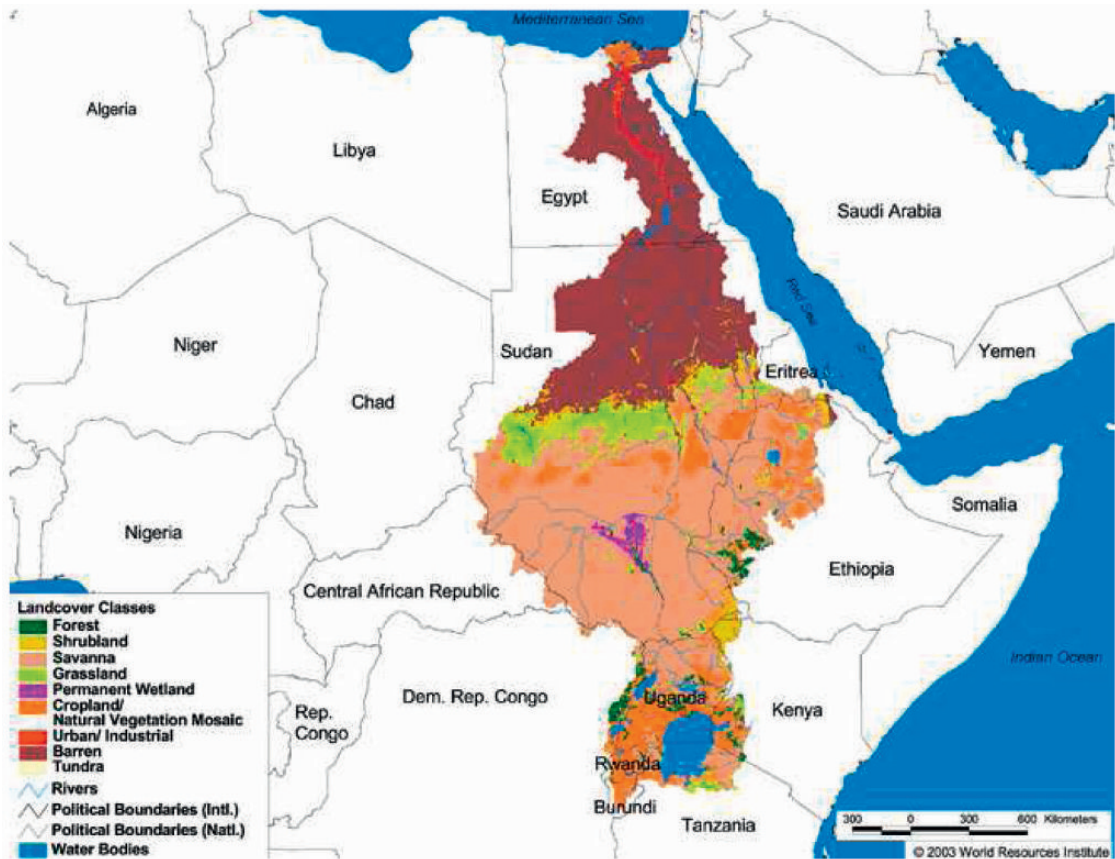

Further, it is contended that the current state of affairs whereby riparian states' interests in the Nile basin are diametrically opposed, coupled with the strong foundation in international law for the claims of upstream states, suggests that the traditional political methods of settling disputes like negotiation or conciliation are unlikely to yield results in the foreseeable future (49.6).

As a result, downstream states, notably Egypt, will continue to delay or complicate political dispute settlement mechanisms. The chapter recommends a change in diplomacy by upstream states to one of convincing downstream states to submit the Nile question to some international judicial process. This contribution is premised on the assumption that with the dilemma posed by water and food insecurity in the Nile basin, governments will choose to co-operate in the development of joint water management schemes for the benefit of all, based on the principle of equitable utilization of shared resources, rather than go to war as the finite limits of available water supplies are reached (49.7)

49.2 Reappraising the Hydrology of the Nile: Water and Food Security in the Basin

The Nile River, which is inextricably linked to Lake Victoria, as the only drainage outlet from the Lake is the second longest river in the world. Its length together with its tributaries is 3,030,300 kilometres (Kasimbazi 1998: 18). The entire Nile-Victoria basin is estimated at 2.9 million square kilometres, representing roughly one tenth of the African continent (Okidi 1994: 321). The Nile basin covers ten states, namely: Kenya, Uganda, Tanzania, Rwanda, Burundi, the

Figure 49.1: Landcover Classes in the Nile Basin. **Source:** IUCN: Water Resources E Atlas. Watersheds of the World; at: <http://www.iucn.org/themes/wani/eatlas/html/af15.html>; © World Resources Institute 2003. Permission has been obtained from the copyright holder.

Democratic Republic of Congo (DRC), Ethiopia, Eritrea, Sudan and Egypt (figure 48.1, table 48.1).

The Nile is made up of three main tributaries. These are the White Nile, the Blue Nile and the Atbara. The White Nile rises from its source in the highlands of Rwanda and Burundi and flows into Lake Victoria leaving its Northern shore near the town of Jinja, and heading north towards Lake Albert that receives much water from the Semliki River, which has its source in the DRC and empties first into Lake Edward, where it receives additional water from the tributaries coming from the Rwenzori Mountains in Uganda on its way to Lake Albert. From here, the White Nile flows into Sudan (Kasimbazi 1998).

Lakes Victoria, Edward and Albert are the natural reservoirs (figure 49.2), which collect and store great quantities of water from the high rainfall regions of Eastern Equatorial Africa and maintain a permanent flow down the White Nile with relatively small seasonal fluctuations (Beadle 1974: 124). In Sudan, near Khartoum, the White Nile meets the Blue Nile, which

drains Lake Tsana in the Ethiopian highlands. The two flow together to just north of Khartoum where some 108 kilometres downstream, they are joined by the Atbara, whose source is in Eritrea. The River then flows north through Lake Nasser and the Aswan High Dam before splitting into the Rosetta and Damietta distributaries just before flowing into the Mediterranean Sea (Okidi 1982).

The linkage between water and food security in the Nile basin is obvious, as water scarcity impacts negatively on agriculture and, therefore, on food security. Water scarcity is probably the single biggest threat to food security anywhere in the world. Water and food security in the Nile basin remains fragile. For instance, Egypt continues to strenuously defend its nearly 100 per cent dependence on the Nile waters to secure the livelihood of its ever-increasing population (figure 49.3; see chap. 48 by Adly/Ahmed; table 48.1). The situation in arid Sudan is no better. Ethiopia remains a country of perennial droughts and famine, despite the country contributing a substantial vol-

Figure 49.2: The Upper Nile Basin and Lake Victoria. **Source:** USDA, Production Estimates and Crop Assessment Division Foreign Agricultural Service: at: <http://www.fas.usda.gov/pecad/highlights/2005/09/uganda_26sep2005/images/nile_basin.htm>. Permission was obtained from the copyright holder.

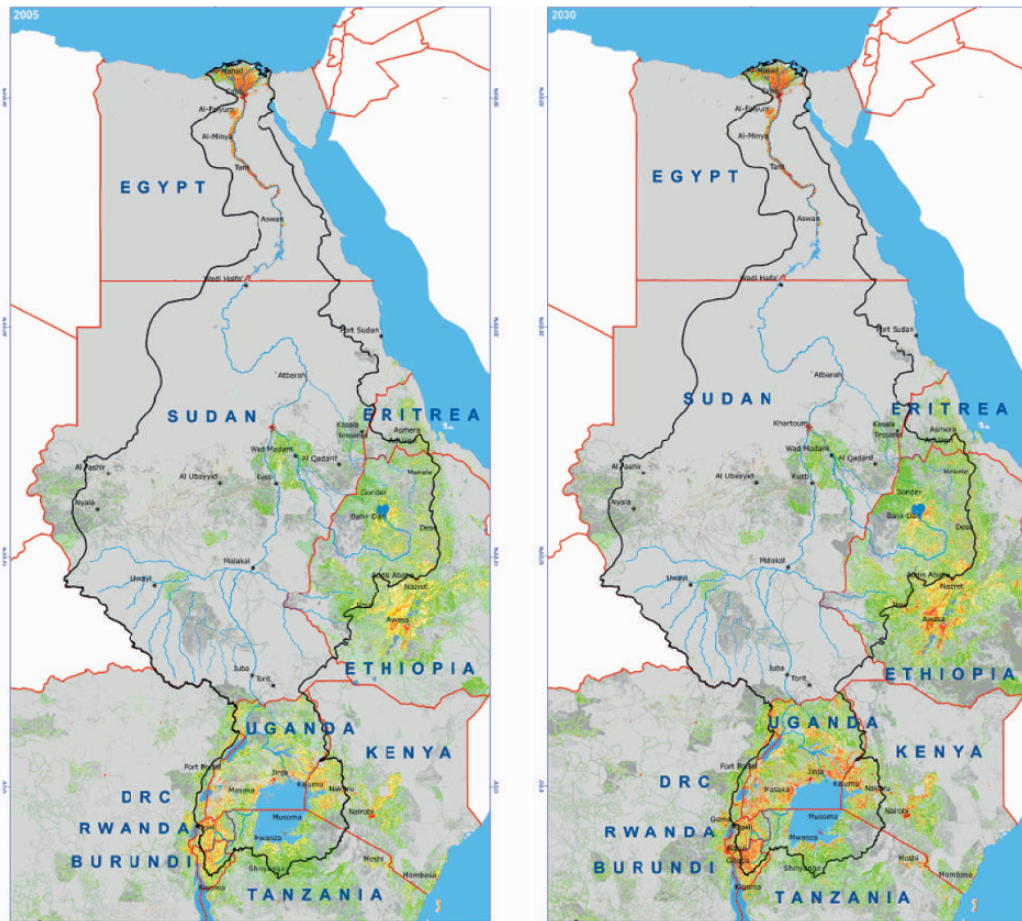

ume. Okidi (1982: 321) has explained the reason for this state of affairs as being the uneven monthly and geographical distribution of the Ethiopian rain.

Similarly in Kenya, another substantial contributor of water through six major rivers flowing into Lake Victoria, two thirds of the entire territory is classified as arid or semi-arid, where water and food remain scarce resources. Kenya has established the Lake Basin Development Authority to develop a master plan for the consumptive uses of its water for agricultural development, to the chagrin of Egypt. Tanzania, a contributor of approximately 25 per cent of the waters flowing into Lake Victoria, is grappling with its water and food scarcity by ambitious irrigation works under the aegis of the Kagera Basin Organization, despite Egyptian opposition to these works.

It is noted that one distracting factor in the quest for a basin-wide consensus on equitable utilization of the Nile waters emphasizes that upstream states contribute only 15 per cent of the water flowing into Egypt. According to Bard (1959), Godana (1985) and Okidi (1994), the average annual flow of the Nile measured at Aswan is 84 billion cubic metres. Of this total about 85 per cent originate from the Ethiopian plateau, whereas only 15 per cent come from sources in East Africa. However, these estimates over-simplify the statistics of the Nile which are complex (Garretson 1967; Godana 1985; Okidi 1994; Okoth Owiro 2004). At least three reasons debunk the claims based on these figures.

First, the flow of the White Nile is relatively regular throughout, while the Blue Nile-Atbara sub-system

Figure 49.3: Population Distribution on the Nile Basin in 2005 and 2030. **Source:** FAO < <http://www.fao.org/images/PopulationDistribution29Nov.png>>.

fluctuates seasonally. According to Godana (1985: 81) the Blue Nile swells to an enormous torrential flow and accounts for some 90 per cent of the water passing through Khartoum. But by April the water from both sources dwindles to one-fortieth of the flood discharge, to account for no more than 20 per cent of the water passing through Khartoum. This tallies with statistics by Garretson (1967), who argues that the Blue Nile alone supplies 90 per cent of the water passing through Khartoum during the high season from April to September; but this contribution reduces to 20 per cent during the low season from January – April.

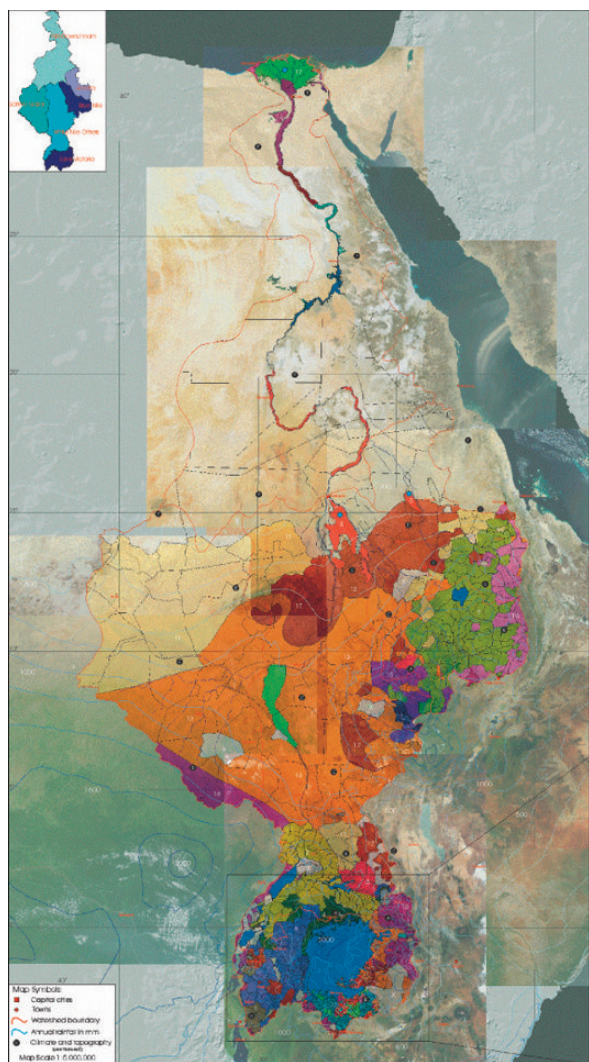

Second, it is incorrect to measure the flow of the Nile from Khartoum. A more realistic estimate of the White Nile's contribution could be obtained by measuring the amount of water leaving the Lake plateau of East Africa because of the estimated 24 billion cubic metres of water from the White Nile, half is lost

through intense evaporation and soakage in the Sod (Godana 1985: 83).

Third, estimating the flow of the Nile on the basis of how much water reaches the Sudan or Egypt appear to assume that the purpose of the Nile is to feed these two countries with water; thus only the water reaching its destination is worth accounting for (Okoth Owiro 2004: 3).

The worsening of water and food security in the Nile basin should enhance the need to comprehensively deal with the management of the quality and quantity of its water. The rapid population increase calls for equitable uses of the River to enhance basin-wide as opposed to single riparian food security (table 48.1; figure 49.4). By the year 2000, 280–300 million people lived in the ten basin countries. Of these, about 160 million depend on the Nile River and its tributaries (Kameri-Mbote 2004: 11). Within the next 25 years, the basin population may double to 594 million by 2025 (table 48.1), increasing the water demand

Figure 49.4: Dominant Crops in the Nile Basin Farming System. **Source:** FAONile; at: <<http://www.fao.org/images/dorminantcrops.png>>.

for agriculture and industry (table 48.2) with a possible increase in drought and famine (figure 48.3). There may be more erosion, soil degradation, pollution from chemical run-off from industry and agriculture and more water-borne diseases.

49.3 Riparian Interests

The economy of the entire Nile Basin heavily depends on agriculture. The water resources of the Nile are utilized for irrigation, hydroelectric production and fishing. The river is a source of water for domestic use and is also important for biodiversity and climate modulation as well as for tourism (Kasimbazi 1998:

19). To achieve these purposes, dams have been constructed by downstream and upstream states.

Egypt entirely depends on the Nile for its water needs (chap. 48 by Adly/Ahmed). In 1978, Egyptian President Anwar Sadat threatened to go to war were any country to tamper with the river's flow: "We depend upon the Nile 100 per cent in our life, so if any one, at any moment thinks of depriving us of our life, we shall never hesitate to go to war" (Kukk/Deese 1996: 46).

Egypt has never carried out this threat, despite the increasing interest in and in some cases abstraction of the water of the Nile Basin for various irrigation and other development projects. Egypt still holds the view that existing Nile Treaties are binding in perpetuity, and that the treaties grant Egypt natural and historic rights over the Nile (49.4).

Other co-riparians have expressed different views. Ethiopia adheres to the Harmon doctrine (49.4), arguing that it can do whatever it pleases with the waters in its territory despite any ramifications on co-riparian states (Kukk/Deese 1996). This position is similar to that of Tanzania, which does not recognize the Nile Agreements. Although Kenya does support the Egyptian position and opposes the Nile Agreements, its view is somewhat moderate, urging for a more equitable utilization of the water of the Nile and Victoria Basin in accordance with the principles of the United Nations Charter, and the modern principles of international watercourses law (Okoth Owiro 2004: 38-41). The position of Uganda, Burundi and Rwanda is the same, while the DRC has never stated its position (Okoth Owiro 2004: 41).

As a result of the positions taken by downstream states, in opposition to the radical Egyptian view, upstream states have increasingly viewed the Nile as a principal feature of their economies. Tanzania hopes to implement a plan to abstract the waters of Lake Victoria to irrigate the relatively low and dry steppes on central Tanzania. Kenya has begun treating more seriously the waters of Lake Victoria with the establishment of the Lake Basin Development Authority.

49.4 The Legal and Institutional Context

The Nile is an internationally shared river. With Lake Victoria the Nile forms an "international watercourse", defined in the UN Convention on the Non-navigational Uses of International Water (1997) as a

“watercourse, parts of which are situated in different states”.

According to Article 38 of the Statute of the International Court of Justice (ICJ) the basic sources of international law are treaties, customary international law and general legal principles, as well as judicial decisions and scholarly writings “as a subsidiary means for the determination of the rules of law” (Brownlie 1990: 10). While the Nile may be governed by the principles of both treaty and customary international fluvial law, the only treaty principles governing its water use are the bilateral treaties between Egypt, Britain and other powers between 1885 and 1959. Under these treaties upstream states committed themselves to Egypt and Britain that they would respect prior rights to and especially claims to natural and historic rights to the Nile waters, which Egypt asserted (Okoth Owiro 2004: 1).

All these treaties, except the 1959 Agreement, were adopted when all co-riparians of the Nile (except Ethiopia) were ruled by foreign colonial powers. After the independence of the states in the basin, the legal issue has remained whether or not the treaty commitments made by the predecessor states binds post-colonial states (O’Connell 1956: 16). As the lack of agreement on this question is responsible for the divergent positions adopted by upstream and downstream states, the legal status of these treaties is briefly discussed, before looking at the current general norms of international law on shared water resources such as the Nile.

49.4.1 The Legal Status of the Nile Treaties

Is the international legal regime established over the Nile through treaties concluded between Great Britain with other powers still operational or binding on the Nile Basin states? The answer to this question is fundamental to the issue of upstream and downstream riparian rights and obligations over the Nile water. If these treaties are valid and binding, they legitimize the legal order of the colonial period that gave Egypt pre-eminence in the control of the Nile and unimpeded use of the Nile for national development. This would pose a severe constraint on development efforts and opportunities of upper riparian states.

But if the Nile Agreements are not binding, then the control and utilization of its water are regulated by the general norms of international law discussed below (50.4.2). It would imply that the Nile needs a new legal regime in the form of a basin-wide treaty. This

would not only provide room for fresh negotiations amongst all basin states, but could also help develop a utilization regime that is more sustainable and equitable.

49.4.2 General Norms on International Watercourses

There are at least six principles of contemporary international law on the consumptive uses of international watercourses. Each of these, as well as their level of acceptance, is discussed from the perspective of upstream states. It will be seen that the first three principles are outdated while the last three seem fairly anchored in law.

The first one is the doctrine of absolute territorial sovereignty. In its absolute form, this doctrine, posits that states have absolute sovereignty over all water in their territory and may use it as they please including extracting as much of it as possible or altering its quality regardless of the consequences of the use on the supply of water on downstream or contiguous states (Birnie/Boyle 1992: 218).

This doctrine of absolute territorial sovereignty appears founded on the basic international law principle that there is absolute sovereignty for every nation as against all others within its territory (Kasimbazi 1998: 20). It is favoured by upstream states, as it is an extreme theory that completely ignores the rights of downstream states. However, the doctrine has remained unpopular, with the great majority of writers emphatically rejecting the doctrine (Godana 1985: 36). Even the U.S. itself quickly retracted from the full Harmon doctrine in subsequent treaties with Mexico and Canada.

Even if the Harmon doctrine were to be accepted by writers, it fails to appreciate that under international law, states not only have territorial sovereignty but ‘territorial duties’ as well. One such duty is encapsulated in the customary international law maxim *sic utere tuo ut alienam ad laedas* that creates an obligation for states not to conduct or permit activities within their territory that may be harmful to the territories of other states (Birnie/Boyle: 1992: 89). Reiterating this customary principle, the arbitral tribunal in the well-known *Trial Smelter Arbitration* (1938–1941) that involved transboundary pollution ruled that: No state has a right to use or permit the use of its territory in such a manner as to cause injury by fumes in or to the territory of another or to the properties or persons therein.

The second theory is that of absolute territorial integrity. It espouses an old common law of water rights whereby a lower riparian state has the right to the full and uninterrupted flow of water of natural quality. The upper riparian may not interfere with the natural flow without the consent of downstream states. This principle, which is favoured by downstream states and has been the basis of the 1929 and 1959 Nile treaties, is curiously also based on the 'good neighbourliness' doctrine espoused in the *sic utere tuo* maxim.

A major criticism to the absolute territorial integrity theory is that just as its absolute sovereignty counterpart, it is an extreme doctrine that creates something akin to veto rights in favour of downstream states against upstream states (Biswas 1993: 172). Current law on international watercourses, as espoused in the 1997 UN Convention, reject the radical approach and endorses a legal scheme that balances between rights and duties for both upstream and downstream states. According to Godana (1985: 39), the theory of absolute territorial integrity may also be considered as discarded.

The third principle is that of prior appropriation rights or to use the words used in the Nile Treaties, 'natural and historic rights' to internationally shared rivers. The principle allows any riparian that puts the water of an internationally shared river to use first to establish prior and incontestable rights over the particular use. Although in theory this principle favours neither upstream nor downstream states and therefore appears equitable *prima facie*, it is restrictive and unworkable (Kasimbazi 1998: 21). The theory's weakness is to allow the state that puts the waters of an internationally shared river into use first, enjoys veto rights over others, an undesirable scenario that seems unsupported by the 1997 UN Convention and other sources of international fluvial law.

The fourth is the principle of limited territorial sovereignty and integrity (Kasimbazi 1998: 22). The theory advances qualified sovereign and territorial claims over international watercourses. By it, co-riparian states have reciprocal rights and duties in the use of the waters of a transboundary water river.

Fifth is the principle of equitable utilization, already hallowed in treaty and customary international law. It is the most widely endorsed theory that treats international watercourses as shared resources subject to equitable utilization by all riparian states (Birne/Boyle 1992: 219). The doctrine rests on the foundation of equality of rights and relative sovereignty but should not be confused with equal division.

It calls for accommodation of the interests of all riparian states.

Equitable utilization as a principle of international law has found support from case law, state practice, treaties and other codifications. In the *River Order Case* the Permanent International Court of Justice (PCIJ), which is the progenitor of the ICJ invoked the exigencies of justice and considerations of utility, favouring "a community of interest" in the utilization of an internationally shared river by all riparians based on equality of rights on the whole of the navigable part of the River Order. Although this case involved navigation, the same principle is applicable to the consumptive, non-navigational uses of international watercourses.

While the precise meaning of the term 'equitable utilization' is the subject of future judicial or arbitral interpretation, guidance may be sought from the Helsinki Rules as well as the codification of the International Law Commission (ILC) in its report to the UN General Assembly I 1994 during the drafting of the 1997 UN Convention. According to the Helsinki Rules, 'equitable utilization' is to be determined in all the relevant factors, which include geography, climate, hydrology, prior utilization of the waters, economic and social needs of each state, the availability of other resources, avoidance of waste in the utilization of the water, and the practicability of compensation to one or more riparian states as a means of adjusting conflicts among the needs and uses of each riparian state.

Sixthly and finally is the principle of common basin-wide management of international watercourses. Also well-grounded in international law, this theory presupposes that internationally shared rivers and lakes are most efficiently managed as an integral unit. The theory stems from the consideration that international watercourses do not respect national frontiers across which they flow. Thus, proponents of this doctrine insist on a community approach management that downplays political boundaries and one that regards an international watercourse as a single economic and geographic unit.

Treaties in which the common management doctrine has been incorporated include the *Agreement on the Action Plan for the Environmentally Sound Management of the Common Zambezi River System* (1988: 28 ILM 1109), the *Treaty on River Plate and its Maritime Limits* (1973: 13 ILM 242), and the *Treaty for Amazonian Cooperation* (1978: UNTS). Other international codifications that endorse the common management theory include the 1972 *Stockholm Dec-*

laration on the Human Environment (article 2(5)(a), and the 1977 *UN Mar del Plata Water Action Plan*. The principle forms article 24(1) of the 1997 UN Convention providing that:

Watercourse states shall ... enter into consultations concerning the management of an international watercourse, which may include the establishment of a joint management mechanism.

It is worth emphasizing that the rather omnibus common management doctrine generates an array of other more specific principles. These include the general duty for each state to cooperate with co-riparians, and the procedural requirements of prior notification of intended projects involving the water resources of an international watercourse, as well as the duty to consult other riparians and negotiate with them where objections to the intended utilization arises.

49.4.3 The Institutional Set-up for Cooperation on the Nile

Although this chapter is not concerned with appraising the existing cooperative framework regarding the Nile Basin, a brief mentioning of two initiatives is appropriate: the *Nile Basin Initiative* (NBI) and the *Nile Basin Discourse* (NBD). The NBI, involving all basin countries except Ethiopia, has the ambitious goal of establishing regional cooperation and mutually beneficial relationship between the basin states. The initiative, therefore, is to achieve sustainable socio-economic development through equitable utilization of, and benefit from, the common Nile Basin water resources.

On its part, the NBD was conceived to respond to the challenges of involving civil society within the NBI so as to bring in the voices of stakeholders other than government in the furtherance of the ideals of the NBI. To achieve this purpose, the NBD promotes dialogue and sharing of ideas with the aim of eradicating poverty, promoting sustainable and equitable development and ensuring peace and mutual understanding in the Nile Basin.

49.5 Unlocking the Impasse: New Solution to an Old Problem?

From the foregoing discussion neither the unilateral claims of Egypt on maintaining the *status quo* on the Nile, nor the threat by upstream states like Tanzania, Uganda and Kenya to abstract the waters of the Nile-Victoria system is supportable in law. The question

still remains what needs to be done to move the Nile debate forward.

Although the threat by Egyptian President Anwar Sadat was made nearly three decades ago, Egypt's hard-line stance has not changed much. The potential for conflict over the Nile has long been identified, yet as the clock ticks away no practical solution seems to be forthcoming. Instead, scholars, diplomats, politicians, civil society, the international community and other stakeholders continue to either recommend more cooperative arrangements or simply to downplay the potential conflict over the Nile. For instance, Wolf, Yoffe and Giordano (2003) believe that violent conflicts over the use of scarce water resources are more likely to be found on the sub-national rather than the international level.

Even if the 'water war' hypothesis should be considered as wrong, water and food scarcity in the Nile Basin may be a politically destabilizing factor that may impair not only sustainable development in the basin states, but also intra-African cooperation in other areas such as regional integration for trade. While the ongoing negotiations and cooperative initiatives remain key in addressing the water and food security question in the Nile Basin, an exit route out of the Nile impasse must be found. This chapter recommends two approaches that upstream states need to initiate as a matter of priority either simultaneously or one after the other: the negotiation and adoption of a new treaty binding all riparian states and the reference of the issue of the legality of the Nile treaties to a judicial or arbitral forum.

The first recommendation - negotiating a new treaty - seems to be in agreement with what happens around the world to give effect to the evolving international water law. Basin states are coming together to agree by treaty on how best to achieve equitable utilization of transboundary rivers and lakes, taking into consideration the concept of sustainable development as the bedrock on which international environmental law and policy is based (WCED 1987: 43). Given the history of the Nile where Egypt has remained hostile to any attempts to re-negotiate the treaty arrangements over the Nile water, it is unlikely that a new treaty will be successfully negotiated in good faith in the foreseeable future. That makes the second option - reference of the matter to an international judicial or arbitral tribunal probably the more viable option.

The current state of affairs whereby riparian interests in the Nile Basin are diametrically opposed, coupled with the strong foundation in international law for the claims by upstream states as against those by

Egypt, suggests that the traditional political methods of settling disputes like negotiation or conciliation are unlikely to yield results in the foreseeable future. Downstream states (notably Egypt) will continue to delay or complicate the political dispute settlement mechanisms. It is therefore recommended that upstream states should change their diplomacy, from convincing Egypt to relent on its position, to convincing both Egypt and other basin states to submit the Nile question to an international judicial process.

The ICJ currently enjoys a high degree of acceptability by African states as a forum of settling their disputes. The historical suspicions relating to the attitude of the Court toward the developing countries appear to be addressed over the years. The Court has been able to resolve some of the most protracted territorial and frontier as well as maritime delimitation disputes involving African disputes, recent examples being the *Land and Maritime Boundary Between Nigeria and Cameroon* relating to the question of sovereignty over the Bakassi Peninsula and the dispute between Botswana and Namibia over the Kasikili/Sedudu Island in River Cunene, and the legal status of the island.

The Nile issue could also be referred to an international arbitration tribunal. This may be more likely to achieve since arbitration allows parties some leeway in determining the principles on which the dispute is to be settled. Arbitrations may lead to building the necessary consensus for 'resolving' the dispute by producing a win-win situation, as opposed to judicial tribunals that end up 'settling' a dispute by producing a win-lose outcome.

49.6 The Role of Civil Society

The continuing dialogue on the Nile cannot be fully participatory without civil society involvement. While this has been agreed upon, there have been concerns that a few NGOs currently engaged do not fully represent the diversity of civil society (Kameri-Mbote 2004: 21–22). Given the open nature of the dialogue under the auspices of the existing cooperative arrangements, the challenge of meaningfully putting in place an agenda that is not captured by the interests of powerful groups remains.

Moreover, providing adequate resources for the dialogue continues to be a challenge. The initial phase of funding provided by CIDA and the NBD is currently struggling to survive. It is unlikely that governments will provide resources for the dialogue of civil society given the suspicion with which they have

viewed civil society engagement and the broader resource constraints facing most governments. Non-involvement of civil society actors threatens the sustainability of the collaborative management initiatives and makes it expensive for state actors to bring in these actors at a latter stage. Without NGO participation, the NBI will never fully realize its goals of a shared vision or regional cooperation. While projects may be initiated and completed, they will fail to fully disentangle the problems surrounding equitable consumptive utilization of the Nile among the basin states while causing political tensions that may weaken the state and frustrate sustainable development in the basin.

49.7 Conclusion

Emile Lodwig, the famous German historian and geographer, made the following remarks on the Nile when he visited Egypt and the Sudan in 1937: "every time I have written the history of man, there hovered before my minds eye the image of a river, but only once have I beheld in a river the image of man and his fate" (Mageed 1994: 156). He made these remarks during a global confrontation, on the eve of the Second World War, which brought the threat of war to the Nile Basin after Italian occupation of Ethiopia. At that time, the whole basin was under the domination and influence of European powers.

Today, the situation is equally uncertain not only in terms of possible future conflicts but also of other complexities of unprecedented dimensions. The population of the countries of the basin is expected to rise from the current 370,000 million (2005) to 890,000 million by the middle of the twenty-first century (table 48.1), while scientific speculations exist that the basin is among the areas most threatened by global warming and sea level rise, where one fifth of Egypt's most populated and productive lands may be subjected to flooding (Mageed 1994: 156).

The ecological integrity of the Nile Basin (and therefore the water and food security in the basin) is hinged on a new framework of co-operation espoused in a new treaty. If this cannot be negotiated in good faith, then the legal option left is to refer the dispute over the Nile on the Nile Agreements to an international judicial and arbitral tribunal. Governments, civil society, the international community and other stakeholders have a joint role to promote such approaches.

50 Water and Security in Sub-Saharan Africa: Emerging Concepts and their Implications for Effective Water Resource Management in the Southern African Region

Peter Ashton and Anthony Turton

50.1 Introduction

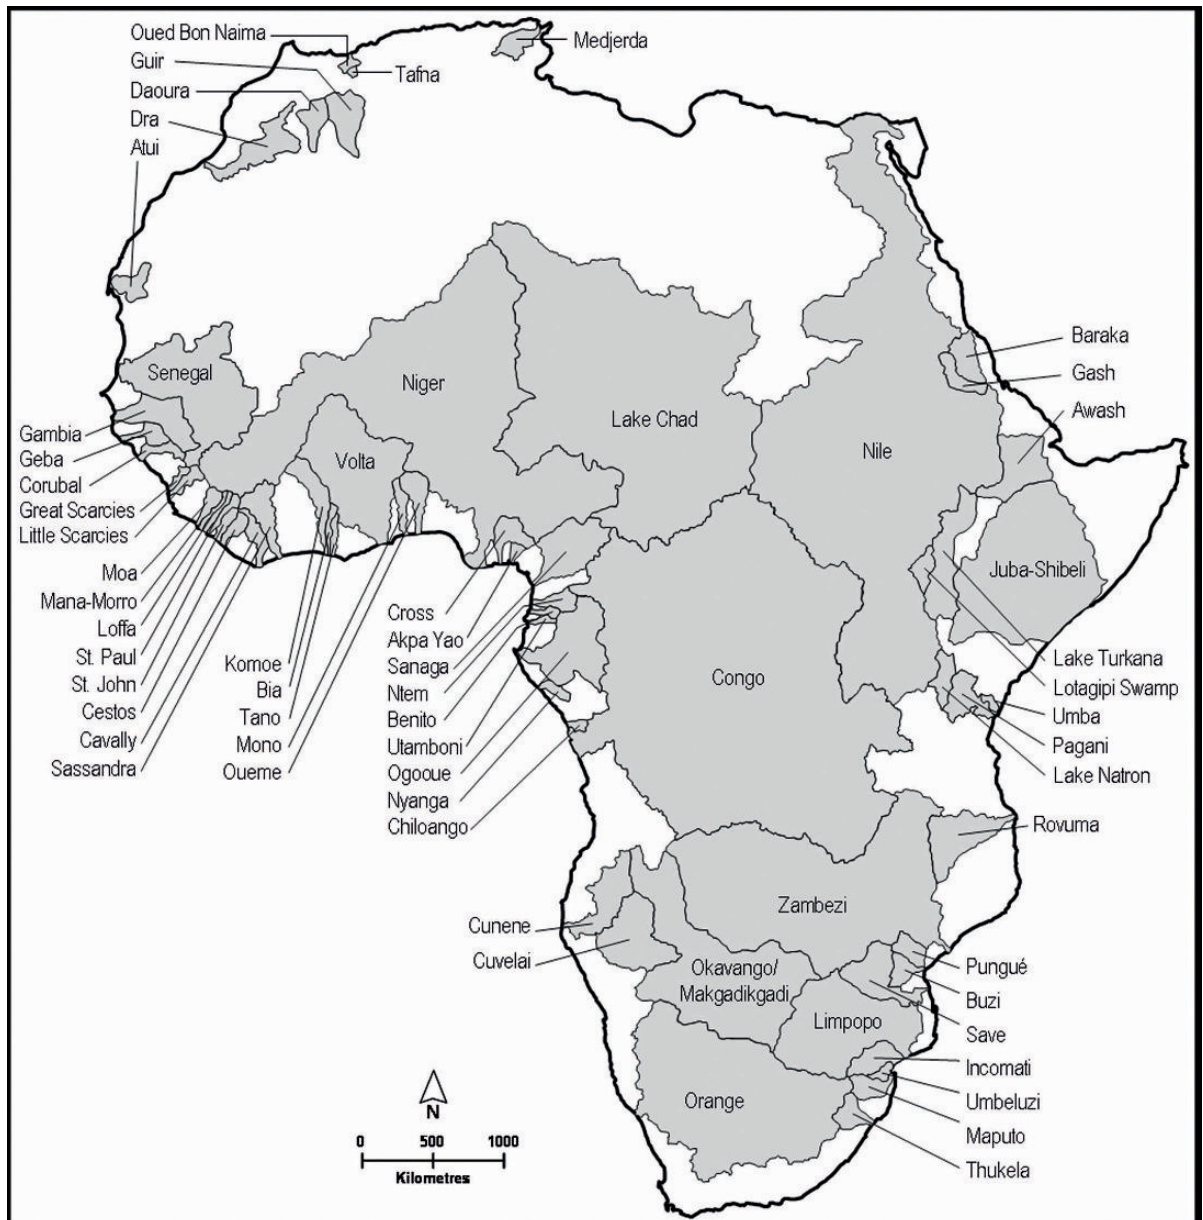

Africa has 63 river basins that cross the international political borders demarcating the 48 countries making up the African continent (Pakenham 1991: 15). Each of these river basins is shared by between two and ten states and this feature poses several strategic implications for the future economic development aspirations of the countries concerned. Significantly, large areas of Africa are arid or water scarce, where the spatial and temporal distribution of surface water is tightly controlled by the interplay between sparse and erratic rainfall and high evaporation rates. In these areas, the availability of surface water seldom matches the water needs of the respective countries and greater reliance is placed on water drawn from underground aquifers for domestic, agricultural, and industrial use (UNESCO-ISARM 2004: 4). In the extremely dry areas of North Africa, every country relies heavily on water drawn from the large shared aquifer systems that characterize this region. Here, the “Great Man-Made River Project” in Libya provides a classical example of this dependence, where the large volumes of water drawn from the Nubian Sandstone Aquifer (shared by Chad, Egypt, Libya, and Sudan) contribute over 90% of Libya’s national water budget (Kuwaiti 2004: 8).

The dilemma posed by the erratic availability of water in many African countries has prompted researchers to pose two inter-related questions. First, will governments go to war over scarce water resources as the finite limits of available supplies are approached? Or will they choose instead to cooperate in the development of joint water management schemes in order to optimize benefits to all? In the context of post Cold War Sub-Saharan Africa, more and more countries are engaging with their neighbours to share their common water resources (Tur-

ton 2003a: 32). Increasingly, this process is taking place through sets of negotiated water-sharing regimes that are most easily understood within the framework of a *Hydropolitical Complex*. The best example of this in sub-Saharan Africa is the Southern African Hydropolitical Complex, where water-sharing agreements between states are now a prominent feature of the international relations of the Southern African Development Community (SADC) region. Indeed, such is the importance of these agreements that water resource management is now widely considered as a driver of regional cooperation in its own right (Heyns 2002: 158, 176; Ramoeli 2002: 107; Turton 2003b: 281).

In this chapter, we argue that the answer to the dilemma posed above requires an understanding of two critical elements relating to the strategic access to water in the context of water and security in sub-Saharan Africa. The first element concerns security of supply (of water), with the hydraulic mission of the state being aimed at achieving this fundamental development objective as a foundation for economic growth, social wellbeing and political stability. The second element relates to the need for each state to choose an appropriate strategy or mix of strategies that will achieve and sustain a high level of security of supply. In our analysis, we explore the relevance of the Southern African Hydropolitical Complex, both as an analytical concept and as a possible mechanism for building and sustaining inter-state cooperation, and thereby avoiding possible conflicts over water.

50.2 Water Dependencies and Interstate Behaviour: The Basis for Cooperation or Conflict

Africa's shared river basins (figure 54.1) cover approximately 63% of the surface area of the continent, contain 78% of the human population and, more significantly, hold over 90% of the continent's surface water resources (Ashton/Turton 2004: 5). While far

less information is available on the water contained in shared aquifer systems (figure 54.2), or the precise extent to which countries in the more arid regions of Africa rely on these systems, they represent critically important sources of water for the countries located in Africa's desert and semi-desert areas (Kuwairi 2004: 2). Similarly, many major cities and towns across Africa rely heavily on groundwater resources to meet the needs of domestic and industrial water users (UNESCO-ISARM 2004: 5). Clearly, a full un-

Figure 50.2: Map of Southern Africa, showing the international (shared) aquifer systems used by the SADC states. derstanding of the strategic nexus between water and security in sub-Saharan Africa requires a sound knowledge of the role of international river basins and shared aquifers in the current and future development plans of each country.

Several recent social and economic studies (Gleick 1998b: 45; Hirji/Johnson/Maro/Chiuta 2002:

45; Hoekstra 2004: 66; Ohlsson 1999: 250) have highlighted the pervasive poverty and low human development index (HDI) values of many countries in sub-Saharan Africa. In these countries, problems caused by a shortage of ‘first-order resources’ (water) are accentuated by the shortage of ‘second-order resources’ (infrastructure, institutions, money, and skills; Ohls-

Figure 50.4: Map of the Southern African Hydropolitical Complex, showing the locations of three pivotal basins (Orange, Limpopo, and Incomati) and two impacted basins (Umbeluzi and Maputo), together with the main centres of economic activity and/or capital cities of the four pivotal states (Botswana, Namibia, South Africa, and Zimbabwe), and the positions of major inter-basin water transfer schemes.

states can more easily deploy a wide variety of resources to resolve their water supply problems (Ashton 2004: 163; Ashton/Turton 2004: 9).

Given the extent and importance of shared water resources in Africa, purely inward-looking strategies offer few dependable prospects of long-term national water security and several countries would likely suffer considerable hardship were they to adopt such strategies (Ashton 2002: 240; 2004: 170). This is clearly illustrated by South Africa and Zimbabwe, where efforts were concentrated on national rather than regional priorities and supply-side options were used to meet the growing demands for water. The outcome of the so-called “hydraulic mission” of these states (Waterbury 1979: 270; Allan 2000: 28) is clearly visible in the numbers of large-scale water storage reservoirs and inter-basin transfer schemes (figures 50.3 and 50.4). Whilst these schemes provide sufficient water to meet national needs, they increase the pressure on shared water resources and emphasize disparities with neighbouring countries that cannot afford such options (Pallett 1997: 59; Ashton 2004: 167).

The extent to which African countries rely on shared surface and groundwater resources heightens the need for states to look beyond purely national priorities and harness the region’s collective social, economic, and technological resources to attain a common goal, that of assuring long-term water security. In strategic terms, this challenge presents African countries with the opportunity to shape and secure a variety of shared benefits with implications far beyond those of national and regional water security. Most notable amongst these are the promotion of political and economic stability across the continent (Ashton/Turton 2004: 16).

Earlier studies (UNEP 2002: 14; Wolf/Yoffe/Giordano 2003: 29) evaluated the number and types of agreements between countries that shared transboundary water resources. These authors concluded that the available evidence indicated low levels of inter-state collaboration and that this represented a potential “risk” of future conflict between the states concerned. However, more recent studies (Heyns 2002: 158; Ramoeli 2002: 105; Turton 2003a: 302–304; Tur-

ton and Ashton 2004: 16) have revealed a widespread preference amongst Southern African states to cooperate in the management of their shared water resources. This view has been strengthened by the interim results of a study on the scope and intent of international agreements that South Africa has entered into with its neighbours. This study revealed that South Africa has entered into 59 international water-related agreements with neighbouring (SADC) states and the international community (Ashton/Earle/Malzbender/Moloi/Patrick/Turton 2005: 14).

50.3 Emerging Concepts: The Southern African Hydropolitical Complex

The collapse of the bipolarity associated with the Cold War prompted considerable speculation that there would be widespread worsening of the international relations between states. However, with few exceptions, this rather pessimistic view was not realised and scholars were prompted to seek reasons to account for the relative absence of widespread conflict. An important outcome of this was the development of a new concept, the regional security complex, and several examples were cited for the developing world (Buzan/Rizvi 1986: 1; Buzan 1988: 16; 1991: 187; 1994: 1; Buzan/Wæver/de Wilde 1998: 201). A regional security complex has been defined as a group of states whose primary security concerns link together sufficiently closely that their national securities cannot realistically be considered apart from one another (Buzan 1991: 190). Typically, a security complex occurs where a set of security relationships stands out from the general background by virtue of its relatively strong, inward-looking character, as well as by its relatively weak outward security interactions with its neighbours. Significantly, the boundaries between regional security complexes are defined by relative indifference towards security perceptions and interactions (Buzan 1991: 193).

In southern Africa, a regional security complex comprising ten of the mainland SADC states – Angola, Botswana, Lesotho, Malawi, Mozambique, Namibia, South Africa, Swaziland, Zambia, and Zimbabwe – has been identified (Buzan 1991: 210). In this context, the term “security complex” emphasizes the interdependence of both shared and competing interests, and incorporates the shifting patterns of cooperation and competition over time (Buzan 1991: 190). But what of transboundary water resources as a stra-

tegic security interest for states in semi-arid areas, specifically where water scarcity constraints can undermine the future economic viability of the state? In this regard an important concept in security complex theory is that of a referent object, which has been defined as “things that are seen to be existentially threatened and that have a legitimate claim to survival such as state sovereignty, national identity, the environment and the economic stability of the state” (Buzan/Wæver/de Wilde 1998: 36). In the context of water, the economic viability of the state becomes the main referent object, because future economic growth plans cannot be implemented in the absence of a high level of assurance of water supply.

Where African states have a relatively low level of socio-political cohesion, it is difficult for an effective central authority to emerge over time and enforce statehood (Oyebande/Amani/Mahe/Niang-Diop 2002: 35). In such situations, challenges to the central authority erode the state from within, making it impossible to enforce laws and guarantee personal security. This factor is critical to an understanding of water and security in sub-Saharan Africa because the hydraulic mission of the state is a necessary (but insufficient) condition for the foundation of an economically viable state. Significantly, most of the politically unstable states in sub-Saharan Africa have yet to embark on the hydraulic mission phase of their national development, and appear unable to secure a high assurance of water supply through infrastructural development.

Schulz (1995: 97) extended the security complex theory of Buzan (1991: 190) and developed the concept of a “hydropolitical security complex” as a distinct form of regional security complex, which he defined as “... including those states that are geographically part ‘owners’ and technically ‘users’ of the [shared] rivers and, as a consequence, consider rivers as a major national security issue.” Importantly, Schulz’s work illustrates what can happen in the field of hydropolitics when water resource management becomes linked to national security concerns, or to other issues of a high politics nature (Turton 2003a: 86; Ashton/Turton 2004: 4).

Given that national security is a relational issue that is mitigated by geographic proximity, the role of international river basins provides an interesting, and largely unexplored, analytical variable. Within the twelve mainland SADC countries, a total of 15 river systems are shared by two or more SADC states, with two major river systems (the Nile and Congo rivers) also being shared with other states to the north (table 50.1). In addition, Tanzania shares three smaller

Table 50.1: Countries sharing the international river basins found in the SADC region (figure 50.1). The Nile and Congo River systems are also shared with countries to the north of the SADC region, while the Pagani, Umba, and Lake Natron basins are shared by Kenya and Tanzania.

River Basin	Riparian States	Basin Classification
Buzi	Mozambique, Zimbabwe.	Impacted Basin
Congo	Angola, Burundi, Cameroon, Central African Republic, Congo, Democratic Republic of Congo (formerly Zaire), Rwanda, Tanzania, Zambia	Impacted Basin (though SADC countries have relatively little impact)
Cuvelai	Angola, Namibia	Impacted Basin
Incomati	Mozambique, South Africa, Swaziland	Pivotal Basin
Cunene	Angola, Namibia	Impacted Basin
Lake Natron	Kenya, Tanzania	Impacted Basin
Limpopo	Botswana, Mozambique, South Africa, Zimbabwe	Pivotal Basin
Maputo	Mozambique, South Africa, Swaziland	Impacted Basin
Nile	Burundi, Democratic Republic of Congo, Egypt, Eritrea, Ethiopia, Kenya, Rwanda, Sudan, Tanzania, Uganda,	Pivotal and Impacted Basin (though SADC countries have relatively little impact)
Okavango / Makgadikgadi	Angola, Botswana, Namibia (Zimbabwe, shares the Nata River sub-basin and is a riparian state of the Makgadikgadi basin, though not the Okavango sub-basin)	Impacted Basin
Orange	Botswana, Lesotho, Namibia, South Africa	Pivotal Basin
Pagani	Kenya, Tanzania	Impacted Basin
Pungué	Mozambique, Zimbabwe	Impacted Basin
Rovuma	Malawi, Mozambique, Tanzania	Impacted Basin
Save-Runde	Mozambique, Zimbabwe	Impacted Basin
Thukela	Lesotho, South Africa	Impacted Basin
Umba	Kenya, Tanzania	Impacted Basin
Umbeluzi	Mozambique, Swaziland	Impacted Basin
Zambezi	Angola, Botswana, Malawi, Mozambique, Namibia, Tanzania, Zambia, Zimbabwe	Impacted Basin

basins (the Pagani, Umba and Lake Natron basins) with Kenya to the north (figure 50.1). Clearly, sovereign control over these shared river basins has to be shared between the riparian states when a given basin is managed as a hydrological unit in keeping with the norms of Integrated Water Resource Management (IWRM).

Potential threats to economic security often become a national security issue because relative economic growth is a major determinant of the power of states in a given system (Buzan 1991: 127). Here, the perception of threat drives decision-making, thereby becoming an independent variable in the international relations of a water scarce state (Turton 2003: 89). This issue is particularly pertinent to international river basins that are approaching the point of closure, where the available supplies of water have

largely been exploited or allocated. When a shared river approaches closure, competition for water intensifies, with a concomitant increase in the potential for conflict between riparian states. This can become an issue of high politics when looming water scarcity is perceived to pose the threat of reduced economic growth potential (Turton 2003a: 86; 2003d: 78; 2003e: 85), and hence a threat to the economic viability and sovereign integrity of the state.

Because the availability of water supplies at a high level of assurance is a fundamental determinant of the economic growth potential of all states, reliable and sustained access to water supplies is a strategic issue for developing countries situated in arid and semi-arid regions (Ashton/Turton 2004: 2). The significant role played by water in Southern Africa is illustrated by the fact that the first cooperation proto-

col that was signed within the SADC region was the Protocol on Shared Watercourse Systems (Ramoeli 2002: 105). Heyns (2002: 158) notes that one of the major development challenges facing the SADC region in the near future is the need to implement large, regional water-sharing and transfer schemes that can alleviate the economic limitations imposed by looming water scarcity in some countries. This represents a strong call to launch a substantial regional hydraulic mission that will develop the infrastructure needed to provide a high assurance of supply on which future economic growth can be planned with confidence.

Whilst the SADC region contains a large number of international river basins, four of the economically most developed states in the region – Botswana, Namibia, South Africa, and Zimbabwe – are water scarce. These four states are approaching the limits of their readily available surface water resources and looming water scarcity is likely to impose limitations to their economic growth potential in the near future (Ashton/Turton, 2004: 4). This could become particularly acute if the dire predictions of global climate change result in a decrease in the quantity of water available. Significantly, these four states are also linked together through their co-riparian status in the transboundary Orange and Limpopo basins.

Using the work of Buzan (1991: 1; 1994: 1), Buzan/Wæver/de Wilde (1998: 1), and Schulz (1995: 91), Turton (2003a: 294) developed a conceptual model that factors in the hydropolitical dimension of international relations within the SADC region where water scarcity has not yet been intimately linked to national survival. The rationale for this is based on the fact that co-riparian status on the region's many international rivers (table 50.1) provides permanent linkages between different states within the Southern African security complex as originally defined by Buzan (1991: 187), but has not yet become a driver of securitization in its own right. The original typology proposed by Turton (2003a: 293) and refined here, distinguishes two types of riparian state (pivotal state and impacted state), and two categories of international river basin (pivotal basin and impacted basin). Each of these concepts is defined below.

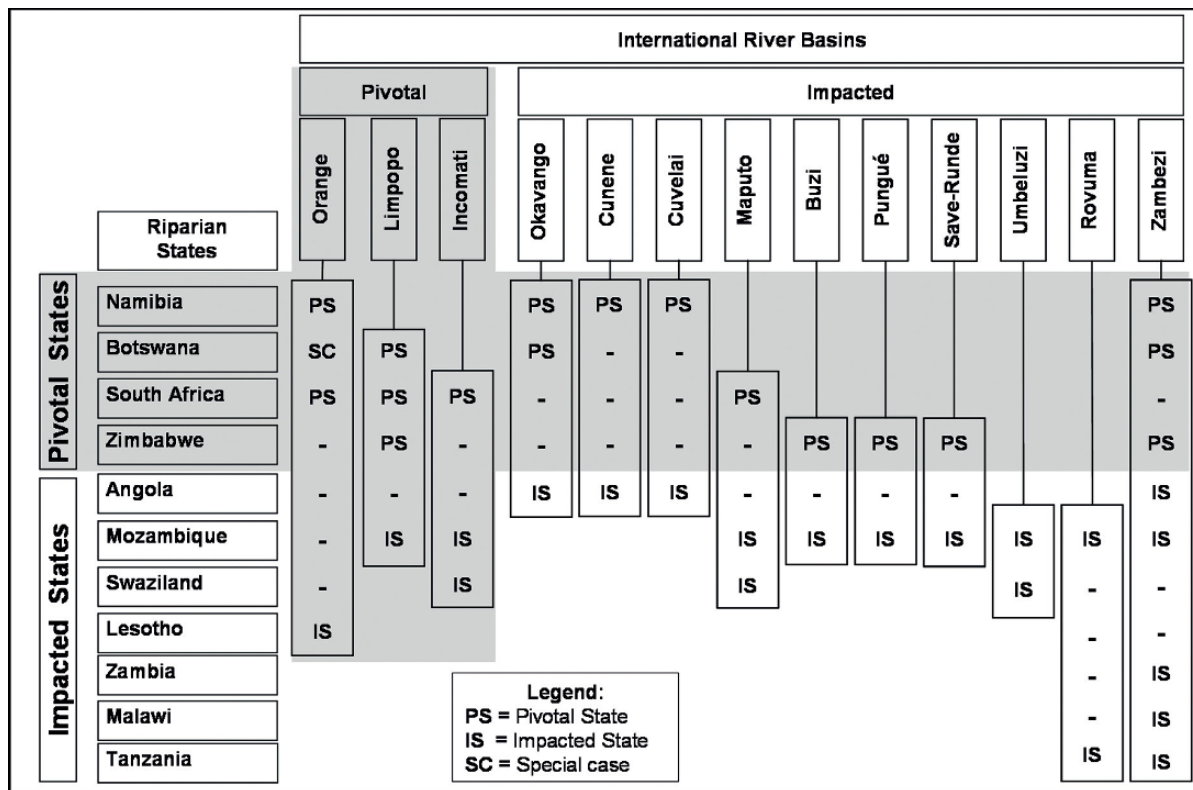

- *Pivotal States* are riparian states with a high level of economic development and a high degree of reliance on shared river basins for strategic sources of water supply. Four Southern African

states are in this category, namely: Botswana, Namibia, South Africa, and Zimbabwe.

- *Impacted States* are riparian states that have a critical need for access to water from an international river basin that they share with a pivotal state, but appear to be unable to negotiate what they consider to be an equitable allocation of water. As a consequence, their future developmental aspirations are impeded by their asymmetric power relations with the pivotal states to which they are co-riparian. In Southern Africa, seven states are seen to be in this category: Angola, Lesotho, Malawi, Mozambique, Swaziland, Tanzania, and Zambia.
- *Pivotal Basins* are international river basins that face closure, but are also strategically important to any one (or all) of the pivotal states by virtue of the range and magnitude of economic activity that they support. In Southern Africa, three basins are regarded as being pivotal basins (Orange, Incomati, and Limpopo).
- *Impacted Basins* are those international river basins that are not yet approaching a point of closure, and which are strategically important for at least one of the riparian states. An impacted basin has at least one of the pivotal states as riparian, so that there appears to be less freedom of choice for an impacted (riparian) state to develop its water resources in a manner that it deems to be fair and equitable. Often, this would appear to be due to perceptions about the asymmetric power relations that exist between the riparian states, where the pivotal state may view any unallocated water as a strategic reserve. Seven impacted basins occur in Southern Africa: Cunene, Maputo, Okavango, Cuvelai, Pungué, Save-Runde, and Zambezi.

Based on these concepts, Turton's original conceptual model (Turton 2003a: 294) has been expanded to display the patterns of cooperation and competition within international river basins (figure 50.5), as a critical component of the Southern African Regional Security Complex defined by Buzan (1991: 210). The Southern African Hydropolitical Complex can thus be understood as being a set of political interactions nested within the Southern African Regional Security Complex, across various levels and between different units, centred on patterns of amity and enmity in the broadest sense, but amplified specifically with respect to water resource management in transboundary river basins. It differs from the Hydropolitical Security Complex defined by Schultz (1995: 97), because water has not yet been elevated to

Figure 50.5: Schematic diagram illustrating the relationships between shared river basins within the SADC region and countries comprising the Southern African Hydropolitical Complex; pivotal basins and pivotal states are shaded. **Source:** Amended and redrawn from Turton (2003a: 294); Ashton/Turton (2004: 7).

become a major driver of threat perception in Southern Africa, or to the extent that national survival might be equated with direct control over the resource by military means. Within the SADC region, water has a long history of politicization (rather than securitization), having played a prominent but subtle role during the liberation conflict years of the last three decades (Turton 2003a: 203; Turton/Earle 2005: 155). The overt nature of Southern African water politics has changed somewhat in the post-Apartheid era, but the underlying drivers remain largely unchanged. The four economically most developed states in the region are also those facing the greatest scarcity of water; they all share international river basins with other states; and they all face significant limitations to their future economic growth prospects as a result of looming water shortages (table 50.2).

The population statistics shown in table 50.2 reveal two important points. Firstly, three SADC countries (Botswana, Lesotho, and Swaziland) are expected to have negative population growth rates during the period 2000 to 2025, with South Africa being expected to show a very modest increase in population numbers (UNPD 2005). This can be as-

cribed to the devastating effects of the HIV/AIDS pandemic in Southern Africa, with these four countries having the highest adult prevalence of HIV/AIDS of any African country (Ashton/Ramasar 2002: 219). Secondly, the other SADC countries are expected to have relatively high population growth rates of between 14.6% and 106.2% for the same period. Similar high population growth rates are also expected to occur in the other sub-Saharan countries, while slightly lower growth rates are anticipated in North Africa (UN 2005; table 50.2). Clearly, population growth rates of the magnitude shown in table 50.2 will exacerbate the existing problems associated with water shortages in these countries, making it even more difficult for the respective governments and water resource management authorities to provide their citizens with appropriate services.

Clearly not all international river basins are equal in strategic importance or in terms of their inherent conflict potential. The Orange, Limpopo, and Incomati basins in the SADC region have been classified as pivotal basins, based on three critical criteria: a significant portion of the basin falls within one or more of the pivotal states; at least one of those piv-

Table 50.2: Projected Population Growth in SADC Countries, (2000 – 2025 – medium estimate), Compared With Other African Regions.

Country	2000 Population (m.)	2025 Population (m.)	Increase (2000 – 2025)	
			(m.)	(%)

- Southern Africa = Angola, Botswana, Lesotho, Malawi, Mozambique, Namibia, South Africa, Swaziland, Zambia, Zimbabwe.
- Central Africa = Cameroon, Central African Republic, Republic of Congo, Democratic Republic of Congo (DRC), Equatorial Guinea, Gabon.
- East Africa = Burundi, Djibouti, Eritrea, Ethiopia, Kenya, Rwanda, Somalia, Sudan, Tanzania, Uganda.
- West Africa = Benin, Burkina Faso, Chad, Cte d'Ivoire, Gambia, Ghana, Guinea, Guinea Bissau, Liberia, Mali, Mauritania, Niger, Nigeria, Senegal, Sierra Leone, Togo.
- North Africa = Algeria, Egypt, Libya, Morocco, Tunisia, Western Sahara.
- Sub-Saharan Africa = Southern Africa + Central Africa + East Africa + West Africa (as listed above).
- Africa = Southern Africa + Central Africa + East Africa + West Africa + North Africa (as listed above).

otal states has a high reliance on the water from these basins; and each basin is approaching the point of closure. A deeper analysis of these three pivotal basins raises a number of subtle but important facts that are not immediately visible. For example, the Orange River is the largest of the three basins in terms of its volume of flow (Basson/van Niekerk/van Rooyen 1997: 44; Turton 2003c: 137) and it is arguably the most strategically important river to which South Africa has access. Whilst Botswana is a co-riparian state, the portion of the basin within the boundaries of Botswana is part of the Kalahari Desert, containing ephemeral watercourses that contribute no stream flow to the main channel of the river. Botswana is therefore listed as being a special case, because it occupies its position as co-riparian in all deliberations over the Orange River, but currently makes no use of the surface water in the basin (although it does use water from the transboundary Kalahari Aquifer).

50.4 Implications

While Africa's many states display varying levels of socio-political cohesion and different levels of economic development, their prospects for future development are linked to three key features: (1) the spatial and temporal variability of water across the continent; (2) the degree to which available water resources are shared by different states; and (3) the highly uneven levels of access to water supply infrastructure. Many of the less developed countries in Africa have low levels of water supply infrastructure and concomitant low assurance of water supply; this contrasts with regional hegemonic states that generally display a higher level of infrastructural development and enjoy a greater assurance of water supply.

The Southern African Hydropolitical Complex provides a potentially useful analytical tool with which to consider the water and security nexus in Southern Africa (Ashton/Turton 2004: 6). This approach offers a more nuanced understanding of two specific aspects – issues that are pertinent to the security of water supply, and issues that are important for the selection of a national strategy to achieve higher assurance of supply levels. Both are explored below.

50.4.1 Security of Supply

Assurance of supply lies at the heart of economic growth and development, because sustainable social

and economic development is impossible where a low assurance of supply prevails (Postel 1999: 25). In essence, a country is only able to develop once appropriate hydraulic (and other) infrastructure is in place and the quest to achieve a high assurance of supply - the so-called "hydraulic mission" (Waterbury 1979: 270; Allan 2000: 28) - has been initiated.

To date, the hydraulic mission of the Southern African Hydropolitical Complex can be segmented into two distinct phases, with a probable third phase that will likely occur in the future. The first phase saw South Africa as the regional hegemon develop massive hydraulic infrastructure, and lay the foundation for rapid and sustained economic growth centred on the mining sector and irrigated agriculture (Turton/Meissner/Mampane/Seremo 2004: 398). Simultaneously, a comparable sequence of events occurred in Namibia (which was being run as a *de facto* province of South Africa), whilst Zimbabwe initiated a strong hydraulic mission centred on the development of the Kariba Dam and numerous widespread irrigated agriculture systems. The start of the second phase occurred when the other pivotal states (Botswana, Namibia, and Zimbabwe) attained independence and launched their own hydraulic mission to underpin their economic growth. It is anticipated that the third (future) phase will begin when the other impacted states in the region launch their own hydraulic missions in pursuit of social development objectives consistent with the Millennium Development Goals (MDGs), and which will enable their economies to engage more fully with the globalization trend. Based on current trends of increasing inter-state cooperation in Southern Africa, this third phase is likely to be characterized by cooperative partnerships between the underdeveloped states and their more technologically advanced neighbours, the pivotal states.

Present water use patterns in the pivotal states are characterized by constraints found in two distinct categories. First-order, or hydrological, constraints are represented by the regional patterns of rainfall and runoff, with each of the four pivotal states generally receiving far lower rainfalls than they require to meet their development objectives (Pallett 1997: 14). Second-order, or infrastructural, constraints are represented by dams and inter-basin transfer schemes that capture and store the runoff and channel it to where it is required for use. Significantly, each of the four pivotal states in Southern Africa has amongst the lowest ratios of mean annual rainfall to runoff in the world, averaging less than 8% (O'Keeffe/Uys/Bruton 1992: 281). In South Africa, over 60% of the total an-

nual runoff is captured and stored in dams - this large fraction appears to be close to the limits of economic viability and sustainable ecological integrity (Rabie/Day 1992: 647). Significantly, both South Africa (ranked 11) and Zimbabwe (ranked 20) have been singled out amongst African states by virtue of the number of large dams that have been built in these countries (figure 50.3; WCD 2000: 370).

Another important characteristic of the Southern African Hydropolitical Complex is the high degree of dependence of the four pivotal states on flows in shared rivers that arise beyond their borders. In this regard, approximately 90% of the surface water within Botswana is derived from upstream countries, with Namibia (76%), Zimbabwe (58%) and South Africa (12%) also relying on inflows from neighbouring states (FAO 2004c: 2). This feature makes the pivotal states particularly vulnerable to the actions of other states, and requires them to cooperate with neighbouring countries to solve their assurance of supply problems. Compounding this problem is the fact that the centres of major economic development in each of the four pivotal states lie on or close to major watersheds (figure 50.4). The implications of this are that each country has a high degree of reliance on inter-basin transfers and major hydraulic infrastructure, and these infrastructure elements will always be a strategic feature of the economic and political vulnerability of the SADC region.

The countries comprising the Southern African Hydropolitical Complex share a total of eighteen transboundary aquifer systems (13 shared within the SADC countries, and a further five with countries to the north; figure 50.2; UNESCO-ISARM 2005: 7). Extensive exploitation of an aquifer in one country could lower the regional water table and exert adverse effects on the communities in neighbouring states who also depend on the system. Consequently, joint management of these groundwater resources is essential to ensure that the strategic interests of each state are not adversely affected.

One of the major implications of pervasive water scarcity for the future economic growth potential of the SADC region lies in the need to develop inter-basin transfer schemes (Heyns 2002: 176). Given the asymmetric distribution of rainfall patterns and river flows, many of the planned transfer schemes will have to cross international borders. This will require close cooperation between states and each pipeline or canal that crosses a border will entrench the co-dependency of the respective states on their shared water resources. The most developed state in the South-

ern African Hydropolitical Complex (South Africa) is already deeply dependent on inter-basin transfer schemes. For example, eight of the nine provinces in South Africa are already dependent for more than 50% of their gross geographic product (GGP) on water provided from outside their borders, with six of these provinces having a dependency in excess of 70% (Basson/van Niekerk/van Rooyen 1997: 55). Gauteng Province, the economic heartland of South Africa, generating 10% of the economic output of the entire African continent, is already totally dependent on inter-basin transfer schemes for its survival (Turton 2004: 12).

50.4.2 Strategies to Achieve Higher Assurance of Supply Levels

Since regional water scarcity has the potential to limit the future economic growth and prosperity of states in the SADC region, and every state also relies to varying degrees on transboundary surface and groundwater resources, it is important to understand the implications of possible cooperative strategies that could improve assurance of water supply throughout the region. In this regard, significant advances have been made to establish a body of international law and regimes for the management of transboundary river systems. Here, three elements are particularly important.

Firstly, the body of international water law codified in the *Helsinki Rules on the Uses of the Waters of International Rivers* and the *United Nations Convention on the Law of the Non-Navigational Uses of International Watercourses* has been supported by every state in the Southern African Hydropolitical Complex. Key elements from both of these international legal instruments have been incorporated into the *SADC Protocol on Shared Watercourse Systems* and its 2000 Amendment, the *Revised SADC Protocol on Shared Watercourses*, which form the legal and institutional foundation for the management of transboundary rivers in all SADC Member States (Ramoeli 2002: 106). This is highly significant, because there is no correlation between the ratification of these two pieces of international law by the respective riparian states, and their actual use of the principles embodied therein (Eckstein 2002: 88; Boisson de Shazournes 2003: 217). Therefore, even if an individual SADC state has not ratified the two international conventions described above, it is still bound by the core principles enshrined in them by virtue of their ratification of the *SADC Water Protocol* and

the 2000 revision. Further evidence for increasing cooperation is the emergence of a trend that shows African governments to be spearheading the notion of an ecosystem approach to the development of international environmental law (McIntyre 2004).

Secondly, contrary to earlier assertions (UNEP 2002: 14; Wolf/Yoffe/Giordano 2003: 29), there is increasing evidence for a high level of sophistication to the development of international water-sharing and cooperation agreements between riparian states in sub-Saharan Africa. A recent study (Ashton/Earle/Malzbender/Moloi/Patrick/Turton 2005: 14) indicates that South Africa alone is a signatory to 59 water-related agreements, and there is sufficient evidence to show that the corpus of international water agreements to which South Africa is a signatory, is more robust than originally shown by Turton/Meissner/Mampane/Seremo (2004: 392).

Thirdly, evidence has been presented to show that even during the height of the Cold War, when many of the local wars of liberation in Africa were being fought as proxy wars for the respective Superpowers (Turner 1998), water resource managers were able to negotiate peaceful water-sharing agreements (often between belligerent powers) (Turton 2003a: 300; Turton/Meissner/Mampane/Seremo 2004: 392; Turton/Ashton 2004: 13; Turton/Earle 2005: 162). These agreements demonstrate that shared concerns over scarce water resources provide a strong reason for countries to collaborate with each other for mutual benefit. In addition, these agreements provide strong support for regional economic integration efforts that accompany reconstruction and peace building in Southern Africa.

50.5 Conclusions

In answer to the worrisome question about the best options available to African states confronted by water scarcity limitations to their future economic growth potential, the balance of evidence suggests that cooperation will be favoured rather than conflict. In this regard, the African continent has seen the development of many water-sharing agreements for the management of its transboundary river basins. In sub-Saharan Africa, the best example of this can be found in the Southern African Hydropolitical Complex. Clustered on the strategic water needs of the four most economically developed states in the SADC region (Botswana, Namibia, South Africa, and Zimbabwe), the Southern African Hydropolitical

Complex shows that a variety of linkages exist between the sovereign states of the Southern African Regional Security Complex originally defined by Buzan (1991: 210).

In this regard, the referent object is the economic stability of the country, and consequently the sovereign integrity of the state in question, making water scarcity a strategic concern. Given the high reliance on transboundary rivers, combined with the historic evidence of cooperation in the development and utilization of those resources, the Southern African Hydropolitical Complex is unlike the Hydropolitical Security Complex mooted by Schultz (1995: 97) to exist in

the Tigris and Euphrates case. As such the Southern African Hydropolitical Complex is not a security complex in its own right, but rather a distinct component of the Southern African Regional Security Complex defined by Buzan (1991: 210). The implications of these conclusions are that, in terms of water security in sub-Saharan Africa, the future trajectory of the various states in the Southern African Hydropolitical Complex will most likely be based on mutual cooperation, where the management of transboundary water resources will become a driver of regional integration in its own right.

Box 50.1: "Protocol on Shared Watercourses in the Southern African Development Community (SADC)" signed in 2000. This text is in the public domain.

(Two key Articles have been taken from this important regional treaty. Article 2 describes the objectives of the revised Protocol while Article 3 list the details of the General Principles embodied in the revised Protocol. Together, these two articles convey both the spirit and intent of the Protocol and therefore provide a useful overview of the main features of this agreement).

Article 2

Objective

The overall objective of this Protocol is to foster closer cooperation for judicious, sustainable and co-ordinated management, protection and utilization of shared watercourses and advance the SADC agenda of regional integration and poverty alleviation. In order to achieve this objective, this Protocol seeks to:

- a.) Promote and facilitate the establishment of shared watercourse agreements and Shared Watercourse Institutions for the management of shared watercourses;
- b.) Advance the sustainable, equitable and reasonable utilization of the shared watercourses;
- c.) Promote a co-ordinated and integrated environmentally sound development and management of shared watercourses;
- d.) Promote the harmonization and monitoring of legislation and policies for planning, development, conservation, protection of shared watercourses, and allocation of the resources thereof; and
- e.) Promote research and technology development, information exchange, capacity building, and the application of appropriate technologies in shared watercourses management."

Article 3

General Principles

For the purposes of this Protocol the following general principles shall apply:

1. The State Parties recognize the principle of the unity and coherence of each shared watercourse and in accordance with this principle, undertake to harmonize the water uses in the shared watercourses and to ensure that all necessary interventions are consistent with the sustainable development of all Watercourse States and observe the objectives of regional integration and harmonization of their socio-economic policies and plans.
2. The utilization of shared watercourses within the SADC Region shall be open to each Watercourse State, in respect of the watercourses within its territory and without prejudice to its sovereign rights, in accordance with the principles contained in this Protocol. The utilization of the resources of the watercourses shall include agricultural, domestic, industrial, navigational and environmental uses.
3. State Parties undertake to respect the existing rules of customary or general international law relating to the utilization and management of the resources of shared watercourses.
4. State Parties shall maintain a proper balance between resource development for a higher standard of living for their people and conservation and enhancement of the environment to promote sustainable development.
5. State Parties undertake to pursue and establish close co-operation with regard to the study and execution

- of all projects likely to have an effect on the regime of the shared watercourse.
6. State Parties shall exchange available information and data regarding the hydrological, hydro geological, water quality, meteorological and environmental condition of shared watercourses.
 7. a.) Watercourse States shall in their respective territories utilize a shared watercourse in an equitable and reasonable manner. In particular, a shared watercourse shall be used and developed by Watercourse States with a view to attain optimal and sustainable utilization thereof and benefits therefrom, taking into account the interests of the Watercourse States concerned, consistent with adequate protection of the watercourse for the benefit of current and future generations.
 - b.) Watercourse States shall participate in the use, development and protection of a shared watercourse in an equitable and reasonable manner. Such participation includes both the right to utilize the watercourse and the duty to co-operate in the protection and development thereof, as provided in this Protocol.
 8. a.) Utilization of a shared watercourse in an equitable and reasonable manner within the meaning of Article 7 (a) and (b) requires taking into account all relevant factors and circumstances including:
 - (i) geographical, hydrographical, hydrological, climatic, ecological and other factors of a natural character;
 - (ii) the social, economic and environmental needs of the Watercourse States concerned;
 - (iii) the population dependent on the shared watercourse in each Watercourse State;
 - (iv) the effects of the use or uses of a shared watercourse in one Watercourse State on other Watercourse States;
 - (v) existing and potential uses of the watercourse;
 - (vi) conservation, protection, development and economy of use of the water resources of the shared watercourse and the costs of measures taken to that effect; and
 - (vii) the availability of alternatives, of comparable value, to a particular planned or existing use.
 - b.) The weight to be given to each factor is to be determined by its importance in comparison with that of other relevant factors. In determining what is an equitable and reasonable use, all relevant factors are to be considered together and a conclusion reached on the basis of the whole.
 9. State Parties shall deal with planned measures in conformity with the procedure set out in Article 4 (1).
 10. a.) State Parties shall, in utilizing a shared watercourse in their territories, take all appropriate measures to prevent the causing of significant harm to other Watercourse States.
 - b.) Where significant harm is nevertheless caused to another Watercourse State, the State whose use causes such harm shall, in the absence of agreement to such use, take all appropriate measures, having due regard for the provisions of paragraph (a) above in consultation with the affected States, to eliminate or mitigate such harm and, where appropriate, to discuss the question of compensation.
 - c.) Unless the Watercourse States concerned have agreed otherwise for the protection of the interests of persons, natural or juridical, who have suffered or are under a serious threat of suffering significant transboundary harm as a result of activities related to a shared watercourse, a Watercourse State shall not discriminate on the basis of nationality or residence or place where the injury occurred, in granting to such persons, in accordance with its legal system, access to judicial or other procedures, or a right to claim compensation or other relief in respect of significant harm caused by such activities carried on in its territory.

Signed at Windhoek, Namibia, on the 7th of August 2000 in three original texts in the English, French and Portuguese languages, all texts being equally authentic.

(The Protocol was signed by Angola, Botswana, Lesotho, Malawi, Mauritius, Mozambique, Namibia, Seychelles, South Africa, Swaziland, Tanzania, Zambia and Zimbabwe; not signed by DR Congo.)

51 Water Security in the Senegal River Basin: Water Cooperation and Water Conflicts

Martin Kipping

51.1 Introduction: Water War and Water Peace

The English noun ‘rival’ derives from the Latin ‘rivalis’, which in turn comes from ‘rivus’, i.e. river, stream (Onions 1966: 769). Sharing the same source of water thus seems to have been a sensitive issue already in ancient times. However, it is only after the end of the Cold War that ‘water conflicts’ have gained prominence within the social sciences in general and International Relations in particular. Demography, increased water consumption due to economic growth, worrying scenarios of climate change, and the growing ecological consciousness have contributed to this development. While the social and economic consequences of water scarcity and pollution have been discussed under the label of ‘environmental security’ (Brauch 2003; Kahl 2003; Dalby 2008), research on ‘environmental conflicts’ (Diehl/Gleditsch 2001; Gleditsch 2003) has investigated armed violence induced by water conflicts.

Three schools of thought can be distinguished in relation to ‘water security’, understood as security from water-related violence:¹ the Neo-Malthusian, the Cornucopian and the political approach (Gleditsch 2003; Selby 2003). The *Neo-Malthusian approach* derives its name from Thomas Malthus’s *Essay on the Principle of Population* (1798), which drew a gloomy picture of demography-induced resource scarcity, necessarily leading to either famine or war. With regard to water conflicts, Neo-Malthusians point out the conflictive consequences of growing water stress, defined as a shortage of renewable water resources per capita (Falkenmark 1989).

1 Although it does not deny the implications of water availability for human security, this chapter focuses on more conventional security aspects. In the present context, “water security” means the absence of violence induced by competition over freshwater.

Cornucopians, in contrast, adopt a more optimistic perspective: They underline the potentials of technical progress, market mechanisms, trade, and substitutes to avoid conflict-generating resource scarcities (Gleditsch 2001, 2003). Normative, sometimes technocratic concepts of rational water management, such as ‘Integrated Water Resources Management’ (IWRM), or the mathematical modelling of basin management are usually inspired by Cornucopian thoughts.

The *political approach* is more pessimist vis-à-vis these technical solutions, emphasizing distributional problems related to international watercourses. Transboundary rivers² cause upstream-downstream conflicts that cannot be solved within the established political institutions of individual riparian states. Instead, the opportunity for upstream countries to externalize the negative consequences of their water use (such as polluted or decreased water flow) creates constellations where ‘beggar your neighbour’ policies seem to pay off.

These insights, in combination with the dominant Neo-Malthusian discourse, have led to a kind of ‘water war hype’ in the 1990’s, when water was sometimes conceived as the renewable resource most likely to cause international wars.³ These propositions have somehow been muted, however, by the results of Aaron Wolf’s quantitative research, which found that no undoubted water war has ever been fought in modern times.⁴ Thus, attention has progressively shifted towards inter-state water *cooperation*, which

2 There are more than 260 international river basins worldwide.

3 A representative, and possibly the most cited article of the water war type is Starr 1991.

4 The last clear inter-state war over water occurred between the Mesopotamian city-states of Lagash and Umma around 2,500 B.C. (Wolf/Yoffe/Giordano 2003: 30).

has reached impressive levels in the industrialized world. Nevertheless, water is still discussed as a cause of *intra-state* resource conflicts: Indeed, it seems that “geographic scale and intensity of conflict are inversely related” (Wolf 1998: 6). Research programmes led by Thomas Homer-Dixon (University of Toronto) and Günther Baechler (ENCOP: University of Zurich and Swisspeace) have investigated these intra-state water conflicts from a Neo-Malthusian perspective, scrutinizing how and under which conditions different forms of resource scarcity may cause violent conflicts.⁵

Despite this intensive research on water conflicts and water cooperation, methodological shortcomings raise some scepticism vis-à-vis its results: Studies on intra-state water conflicts have suffered from biased case selection, favouring cases where both water scarcity and violent conflicts occurred. In addition, research on international water cooperation has focused on the industrialized world, not allowing generalizations for developing regions, where water problems are most acute. Finally, the Neo-Malthusian perspective appears to be overly pessimistic and one-sided, since it is as justified to expect reactions to common problems of resource scarcity to be cooperative as to suppose them to be confrontational.

The present chapter aims at refining the debate on water conflicts and water cooperation by investigating a case that constitutes a puzzle for the Neo-Malthusian discourse: the Senegal River in West Africa.⁶ Thereby, it intends to identify causal mechanisms that will help generating better hypotheses for future comparative analyses and large-N studies.

51.2 Case Selection: Why the Senegal River?

The Senegal River (figure 51.1) is an ideal object for a case study on water cooperation and water conflicts for two reasons: First, both cooperation and conflict over water have been extreme in the Senegal Basin. On the one hand, the three downstream states Senegal, Mauritania, and Mali have reached an extraordinary degree of integration in managing their shared river (Andersen/Rangeley 1993: 144; Rangeley/Thiam/Andersen/Lyle 1994: 33; Tangara 1998: 553;

GWP 2000: 17; GCI 2000: 37; Dombrowsky/Grey 2002: 91; WWAP 2003: 313).

Within the *Organisation pour la Mise en Valeur du Fleuve Sénégal* (OMVS or Organization for the Development of the Senegal River), they realized an ambitious infrastructure programme for irrigation, power-generation, and navigation purposes, including the construction of two major dams in common property. On the other hand, one of the most violent conflicts over water occurred in the Mauritanian part of the Senegal Valley in 1989/90, when the Moorish elite expelled the non-Moorish, ‘black’ farmers of the valley in order to gain control over their irrigated land (Magistro 1993: 203; Baechler 1999a: 94). The bloody deportation resulted in more than 200 dead and 70,000 refugees (Libiszewski 1999: 136).

Second, in addition to the occurrence of these extreme events, which permit the investigation of both cooperation and conflict over water, their correlation with the overall water availability in the Senegal Basin is of utmost interest, as it is decisively ‘Anti-Malthusian’. The decisions on the joint infrastructure programme were taken at the beginning of the 1970’s (Reichhold 1978: 148–159; Maiga 1995: 80–81; Meublat/Ingles 1997: 182–183). Thus, they coincided with the first devastating Sahelian drought, which started in 1968. The Mauritanian ‘events’⁷, in contrast, occurred after water availability in the Senegal Valley had risen, thanks to the dams constructed within the infrastructure programme. This means that, in the Senegal Basin, growing water scarcity correlated with more intense cooperation between riparian states, less water scarcity with a violent conflict within one of these states.

For these two reasons, it can be expected that the Senegal case provides interesting insights on causal mechanisms of water cooperation and water conflict that have not received adequate attention up to now.

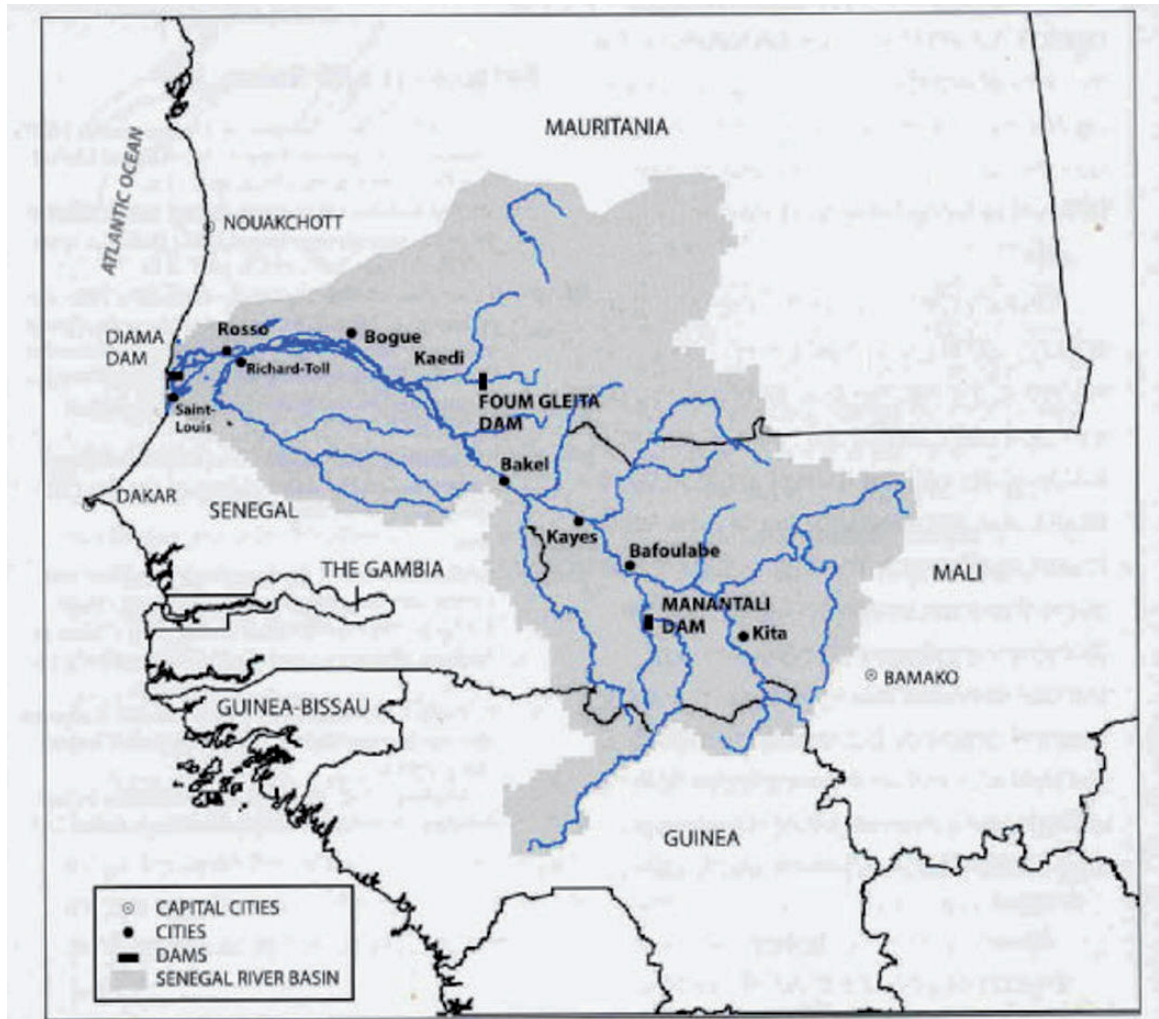

51.3 Hypotheses for the Puzzle of ‘Anti-Malthusian’ Correlation

How could the ‘Anti-Malthusian’ conjuncture of cooperation and conflict over the Senegal River be explained? In order to assure the case study’s connectedness to the theoretical debate, hypotheses on scarcity-driven water cooperation will be derived from the classic schools of International Relations

5 Homer-Dixon has objected to be classified as a Neo-Malthusian, see Brauch 2003: 75; Homer-Dixon 1999.

6 The chapter is a summary of an in-depth study written in 2004 (Kipping 2005).

7 In the region, the violence is euphemistically referred to as ‘les Événements’.

(Realism, Institutionalism, Liberalism), while the debate on resource conflicts will provide possible explanations of the Mauritanian events.

51.3.1 Intensified International Cooperation in Times of Growing Water Scarcity

A priori, international cooperation is an anomaly for *Realism*, as the latter conceives anarchy and survival as the key determinants of the international system. This is even more the case for water cooperation in times of water scarcity, as realist approaches to ‘hydropolitics’ (Elhance 2000) normally adopt a Neo-Malthusian perspective. Nevertheless, the concept of ‘hegemonic stability’ can account for ‘untrue’ cooperation in cases where a dominant power coerces dependent states into agreements which are tailored to the hegemonic state’s advantage. Quantitative re-

search provides some support for this concept with regard to international water cooperation. Bertram Spector, for instance, finds that disparities between riparian states in the share of water used for industrial purposes, in access to safe drinking water, in the Human Development Index (HDI) and in economic power correlate positively with water cooperation. He concludes that “in the inequality among riparians, the seeds for cooperation may be found” (Spector 2000: 233).⁸ Miriam Lowi also employs the concept of hegemonic stability in her research on the Jordan Basin: “[I]f the dominant power in the basin will benefit from regional cooperation in water utilization, it will take the lead in creating and maintaining a re-

⁸ A book example for such an agreement is the 1944 Water Convention between Mexico and the United States (personal communication from Ursula Oswald).

gime, and will enforce compliance with its rules” (Lowi 1993: 10). Under this perspective, water cooperation can only be expected if the hegemonic state is located downstream, whereas upstream states will not voluntarily enter into water-sharing agreements that tend to limit their freedom of action.

How can the concept of hegemonic stability explain intensified water cooperation in times of growing water scarcity? The dominant power might get interested in assuring that upstream states refrain from increasing their water abstraction or in redistributing the river’s water to its own favour in order to offset the negative climatic impact. Due to growing problem pressure, the dominant state’s interest in jointly developing the shared river could increase as well.

In contrast to Realism, where cooperation is dictated by the dominant power, *Institutionalism* perceives cooperation as the product of a shared demand. Collective problems – such as floods or the underdevelopment of common watercourses – are best for the prospect of water cooperation (Marty 2001: 38). Asymmetries of interest, reflected in upstream-downstream ‘Rambo’ situations (Haftendorn 2000: 64–65),⁹ in contrast, need to be balanced by additional, external incentives provided by packet deals or development assistance, for instance. The latter may also be needed to enable poor countries to implement agreed-upon cooperation projects (Marty 2001: 345). In addition to a common demand for cooperation, the transaction costs for reaching an agreement need to be sufficiently low. They can be minimized by a high degree of regional integration (Durth 1996) and by the institutionalization of water cooperation (Wolf 2001: 10).

How can growing water scarcity influence these factors? First, a drought is likely to increase riparians’ interest in developing their watercourse in order to alleviate problems of water supply (Sadoff/Grey 2002: 402).¹⁰ Second, a drought might induce international donors to provide additional incentives and means to realize transboundary water projects in the affected regions.

9 Game theory defines ‘Rambo’ situations as conflicts where one party completely lacks incentives for reaching an agreement with the other(s), as it can only lose out from a consensual settlement of the conflict. This distinguishes a ‘Rambo’ situation from a dilemma situation, where all parties may – theoretically – gain from an agreement if they succeed in overcoming the barriers to cooperation, such as lacking transparency, distrust or missing compensation mechanisms.

In contrast to Realism and Institutionalism, which perceive states as black boxes, *Liberalism* focuses on the domestic factors of foreign policy and international relations. Two strands of Liberalism are of particular relevance in relation to hydropolitics: First, polity features influence decisions on water cooperation. Notably in political systems characterized by “belly politics” (Bayart 1989), rent-seeking opportunities associated with water projects are extremely important: “[T]he main beneficiaries of dams are construction companies, consulting engineers, corrupt politicians and government officials, who work in tandem to promote them” (Biswas 2004: 4). Economic and other interest groups like agribusiness, consumers of hydro-energy or indigenous groups might also influence decisions on water cooperation. Second, ideational factors may play key roles for water policies, since national water resources and large infrastructure projects tend to be highly symbolic.¹¹

While water scarcity does not affect rent-seeking opportunities, it can boost influential pressure groups’ interest in international water cooperation. In addition, the symbolic value of cooperation projects is likely to rise, thus increasing the riparian states’ incentives to enter into such agreements.

51.3.2 Intra-State Violent Conflict in Times of Growing Water Availability

Whereas classic International Relations theory does not offer hypotheses for explaining the inner-Mauritanian conflict, the recent debate on natural resources as a cause of civil war suggests some promising arguments. This debate, however, rather dichotomously conceives either the *abundance* of *non-renewable* resources (diamonds, oil, coltan, etc.) or the *scarcity* of *renewable* resources (fertile land, vegetation, water, etc.) as causes of conflict. Most interesting about the Mauritanian case is that it combines a *renewable* re-

10 “The increasing scarcity of fresh water in the developing countries may by itself now encourage the basin countries to cooperate to achieve optimal benefits” (Swain 1997: 414). “[I]f all countries involved perceive a shortage, the stakes for developing the common resource by co-operation become very high” (Ohlsson 1995a: 24).

11 “[D]am construction projects are frequently prestige projects, symbolic for national development aspirations” (Libiszewski 1999: 123). “Water resources and projects are frequently highly symbolic to policy makers and publics both within the nation and outside” (Frey 1993: 64). See also Okidi (1988).

source (water) and its dam-induced *abundance* as a possible reason for the events of 1989 and 1990. Thus, both lines of argument might provide hypotheses for explaining this case.

The ‘resource curse’ argument is based on the ‘structural transformation of war’ observed during the 1990’s. According to this reasoning, globalization and the end of the Cold War have caused the progressive commercialization of war, leading to ‘war economies’ where rebel and governmental troops – which are increasingly difficult to distinguish – compete for the access to and the exploitation of highly valued non-renewable resources. Lacking economic alternatives for young men make countries particularly vulnerable to ‘greed’-driven rebellions (Collier/Hoeffler 1998).

Yet, for several reasons, this line of thought is difficult to adapt to the Mauritanian context. First, the economic outputs of freshwater use (cash crops, hydro-energy, etc.), unlike alluvial diamonds or gold, can hardly be produced and sold under conditions of civil war: “Water is not a lootable resource” (Gleditsch 2004). Second, the prices for these products are rarely high enough to finance war economies or to provide sufficient incentives for going to war. Third, the abundance argument is static in essence: There *is* too much gold for peace to be maintained. What is needed for the Mauritanian case, however, is a hypothesis that links the *increase* of resource availability to the outbreak of conflict.

Better fitting hypotheses might however be derived from the debate on scarcity conflicts, which is heavily influenced by Homer-Dixon’s and ENCOP’s research. Homer-Dixon has developed a full-fledged causal model of scarcity conflicts. According to this model, demand-induced, supply-induced, and structural (i.e. distribution-induced) scarcity can indirectly cause intra-state violent conflict via decreased agricultural productivity, economic decline, a sharper segmentation of society, migration movements, and the weakening of institutions like the state. Demand-induced, supply-induced, and structural scarcity reinforce each other in processes of *ecological marginalization*, where weaker groups of society move to ecologically fragile areas, and *resource capture*, where powerful groups modify resource distribution in their favour (Homer-Dixon 1999: 73–79).

Resource capture appears to be of particular interest for the Mauritanian events, since Homer-Dixon makes explicit use of the latter in order to exemplify his concept (Homer-Dixon 1994: 11–13, 1999: 76–77). Labelling the Mauritanian events “resource capture”,

Homer-Dixon however confounds his model’s independent and dependent variables, since the concept of resource capture only refers to factors of resource scarcity that may ultimately lead to the outbreak of violence, not to the violence itself. Thus, this concept is not well suited for explaining the Mauritanian conflict.

In contrast to Homer-Dixon, ENCOP considers intra-state violent conflict also as a *direct* result of resource scarcity (Baechler/Böge/Klötzli/Libiszewski/Spillmann 1996: 318–321). Most interesting is ENCOP’s concept of *socioecological heterogeneity*, inspired by structuralist development theory. According to this concept, discrepancies in the endowments of renewable resources, reinforced by inequality in economic and political power, motivate underprivileged groups to rise up (Baechler/Böge/Klötzli/Libiszewski/Spillmann 1996: 37, 308). This focus on discrepancies, as opposed to scarcity as such, makes ENCOP’s approach useful for the Mauritanian case. While ENCOP conceives the congruence of resource discrepancies with power discrepancies as conflict-generating, it however seems to be equally justified to suppose the *incongruence* of both as a cause of violent conflict: In societies where renewable natural resources constitute the main economic assets, politically dominant groups might resort to violence in order to assure control over these resources, if the distribution of the latter does not already correspond to the distribution of power in society. This mechanism could explain the Mauritanian events, since it was precisely the Mauritanian elite that initiated the expulsions of 1989 and 1990.

51.4 Process-Tracing: Causal Mechanisms of Cooperation and Conflict on the Senegal River

The hypotheses generated in the last section will now be used for tracing the processes of 1) the decisions on the OMVS infrastructure programme and 2) the violent conflict in Mauritania. Testing the *realist*, *institutionalist* and *liberal* hypotheses for the international cooperation, on the one hand, and the hypothesis of a conflict-generating incongruence of resource and power distribution for the intra-state conflict, on the other hand, will reveal in how far the ‘Anti-Malthusian’ correlation of water availability and conflict or cooperation in the Senegal Basin is backed by causal linkages.

51.4.1 Intense Cooperation: Infrastructure Projects of the Organization for the Development of the Senegal River (OMVS)

Plans for the development of the Senegal River date back to colonial times. In 1822, the French Government established a first experimental plantation in the lower Senegal Valley (Reichhold 1978: 110–119; Tangara 1998: 110–128). With increasing technological capacities, projects for the regulation of the Senegal River for irrigation, navigation, and hydropower purposes surfaced in the 1920's, and numerous studies on development options were commissioned by the French administration. However, due to the shift of colonial interest from the Senegal Valley towards the Senegalese Peanut Basin and the projects' doubtful economic profitability, none of these plans was realized under French rule (Maïga 1995: 18–21).

At the beginning of the 1960's, the newly independent riparian states took up the colonial plans. With the help of the United Nations, the preparatory work continued, and a first inter-governmental organization for the development of the Senegal River, the *Comité Inter-Etats*, (CIE), was founded in 1963. In 1968, the CIE was superseded by the *Organisation des Etats Riverains du fleuve Sénégal* (OERS), which aimed at the political and economic integration of the riparian states beyond the mere development of their common river. Due to political frictions between Léopold Sédar Senghor's pro-French Senegal and Sekou Touré's decisively anti-colonial Guinea, the three downstream states replaced the OERS with the OMVS in 1972 in order to pursue the agreed-upon development projects without Guinea (Maïga 1995: 63–76).

In 1974, the three OMVS member states adopted a *schéma directeur* for their infrastructure programme, encompassing a main regulatory reservoir in the upstream Malian part of the river, and a downstream anti-salt barrier to prevent the intrusion of marine water during the annual low-water period. The upstream Manantali dam was designed to guarantee a minimum water flow for the all-year irrigation of 255,000 ha in the middle and lower valley as well as uninterrupted navigation between the Atlantic Ocean and the Malian town of Kayes. In addition, the Manantali dam was supposed to be equipped with a hydropower station, producing 800 GWh annually (Reichhold 1978: 148–159; Maïga 1995: 80–81; Meublât/Ingles 1997: 182–183).

While the main pillars of this infrastructure scheme had already been conceived by the French, the internationalization of the river due to decolonization led to the disappearance of their sovereign, unitary control over the whole river basin. According to the *realist* hypothesis, Senegal – as the basin's most advanced and most powerful state¹² – could have taken over the colonial heritage and pushed forward the infrastructure programme. Indeed, it seems that Senegal was particularly active in this regard (LeMarquand 1982: 234–235, 1986: 14–15). However, the potential successor of the French did not really act like a hegemonic power. During the negotiations on the infrastructure programme, Senegal adopted a more than benevolent attitude towards its neighbours, eager to satisfy their demands. In addition, the two leading positions of the OMVS – the posts of its Secretary General and High Commissioner – were reserved for Mauritania and Mali (Tangara 1998: 138). Finally, Senegal proved to be unable to integrate Guinea, although the latter's upstream position makes it strategically important (Kane 1994: 174).¹³ Thus, the *realist* hypothesis of a hegemonic power unilaterally pushing through the water cooperation over the Senegal River can be rejected.

This is even more true, as the *institutionalist* perspective reveals that there was not even a need for a hegemonic power that would have forced its neighbours to cooperate: “The Senegal River is a case in which there is not only a common interest among the three lower riparian countries, but, in addition, the interest is complementary” (Fox/LeMarquand 1979: 16). Where did this “rare harmony of objectives among the participating States” (Godana 1985: 230) come from? Senegal and Mauritania were mainly interested in expanding irrigated agriculture in the Senegal Valley, necessitating the regulation of the river through an upstream reservoir. Mali, in contrast, was in desperate need of a direct connection to the sea to alleviate its land-locked situation. In addition, cheap hydro-energy was supposed to boost its industrial development (Niasse 2004: 8). Manantali thus constituted a “win-win-win” project, as this “key component” (Platon 1981: 1084) of the infrastructure pro-

12 At least for the first 20 years after independence, Mali and Mauritania nearly completely depended on Senegalese infrastructure for access to the sea (Stewart 1989: 163).

13 Due to the political frictions mentioned above, Guinea even threatened Senegal with diverting the river with Chinese assistance (Tangara 1998: 135, footnote 22).

gramme – accounting for ¾ of the investment costs – was designed as a multipurpose dam, satisfying all three objectives of irrigation, navigation and energy generation. In order to account for differences in benefit, the contribution of each participating state to the costs of the infrastructure programme was calculated according to a complicated formula, based on econometric estimates of the relative gains (Godana 1985: 224–228).

In addition to this win-win-win constellation, the cooperation between Mali, Mauritania and Senegal was eased by relatively low transaction costs. The three OMVS member states share the same official language, their juridical and political systems are similar, and the common colonial history and religion (Islam) act as unifying factors. Furthermore, the considerable amount of data on the Senegal Basin collected by the French and the institutionalization of the cooperation within the CIE and the OERS certainly facilitated agreements.

If the *institutionalist* explanation of the cooperation over the Senegal River thus appears to be plausible, what role did growing water scarcity play for the realization of the common infrastructure programme? Although the riparian states' interest in jointly developing their river was already substantial, the onset of the severe Sahelian drought of 1968–1973 made it even more pressing. Food deficits and food imports sky-rocked, increasing dependence on external aid and undermining development plans (LeMarquand 1982: 53, 1986: 8–9). Thus, Senegal and Mauritania in particular accelerated their efforts to realize the agricultural potential of the Senegal Valley, which offered good conditions for the cultivation of rice, the basic food crop of urban inhabitants (White 2000: 50; Park 1993: XV; Seck 1991a: 17).

While the interest in the infrastructure programme was already there before the drought, the financial means to realize it, however, were not. The investment costs had to be almost completely¹⁴ borne by international donors. Arab oil states, the Federal Republic of Germany, and the French Government together provided the lion's share of funds (Maïga 1995: 91). Although these donors had their specific interests in supporting the OMVS plans as well,¹⁵ their final consent cannot be understood without the context of the Sahelian drought. The resulting famine with approximately 100,000 dead caused growing awareness of the region's poverty and a real "donors' run" on the Sahel (Brantly/Ramsey 1998: 108; GWP

2000: 4). The OMVS member states succeeded in exploiting this increased openness to support Sahelian countries. With continued reference to the drought (Reichhold 1978: 291, 300, 307), the national leaders were able to convince the donors to support the OMVS programme with sums that were far above normal country quotas¹⁶ – despite growing doubts regarding the economic profitability of the planned infrastructure (LeMarquand 1982: 75–80, 214–216; 1990: 227). This is why the growing water scarcity after 1968 clearly was a necessary condition for the intensified water cooperation in the Senegal Basin.

Although the water cooperation within the OMVS can satisfactorily be explained by the *institutionalist* approach, the *Liberal* hypotheses might still provide some refinements. Both domestic politics and the discourse on the infrastructure programme are relevant in this regard. In addition to the agribusiness in the Senegal Valley and to urban consumers of electricity and rice, the interest groups that benefited most from the infrastructure programme were the bureaucracies of the public extension services operating in the Senegal Valley. The drought provided the Senegalese SAED (*Société nationale d'Aménagement et d'Exploitation des terres du Delta du fleuve Sénégal et des vallées du fleuve Sénégal et de la Falémé*) and the Mauritanian SONADER (*Société nationale pour le développement rural*) with strong arguments for the continued modernization of farming practices: It "offered new opportunities for development planners, allowing them to suggest with some plausibility that the farming and livestock-rearing systems by which [sic!] the Valley's inhabitants lived, belonged to the past, and that the future lay with irrigated farming alone" (Adams undated: 1). Nevertheless, it seems that the riparian states' leaders acted rather independently from such particularistic interests, but in

15 The Arab oil states aimed at increasing their influence in Muslim Sub-Saharan Africa, the French had economic interests in the Senegal delta, and the German Government seems to have been interested in opening up iron ore reserves in the upper parts of the river. In addition, most tenders – and thus Arab funds – went to construction firms from the European donor countries (LeMarquand 1986: 43; 1990: 226).

16 Cf.: "In general the OMVS plans to 'push back the desert' struck the right political chord with western and Arab sources of finance" (LeMarquand 1982: 175; 1986: 31). "Politically, the major selling points of the plan [of the OMVS, MK] were that it would lessen the impact of future droughts and help close the food gap that was emerging" (Brantly/Ramsey 1998: 109).

14 At 96% (Tangara 1998: 511).

what they perceived as the “national interest” (Le-Marquand 1982: 134–135, 253). Their perception, however, was heavily influenced by the symbolic significance of the large-scale infrastructure programme. In fact, the OMVS disposed of a considerable “‘modernist’ legitimacy” (Meublat 2001: 444), which was further boosted by the hope of a “‘re-greening’ of the Sahel” (Meublat/Ingles 1997: 163) since the beginning of the drought.

51.4.2 Violent Conflict: The Mauritanian “Events” of 1989/1990

While the degree of water cooperation between the OMVS member states was extraordinary high, the expulsion of non-Moorish farmers from the Mauritanian part of the Senegal Valley was exceptionally violent. It occurred as the third in a row of three violent conflicts (Wegemund 1991: 90–101; Leservoiser 1994: 219–221): First, a deadly struggle between Senegalese farmers and Mauritanian herders near the Senegalese village of Diawara in the upper Senegal Valley led to mutual pogroms in Mauritanian and Senegalese towns against the (alleged) citizens of the other state in April 1989. Second, these pogroms, which motivated an airlift to exchange populations between Nouakchott and Dakar, caused inter-state tensions between Mauritania and Senegal, which deployed military forces on the common border along the Senegal River and occasionally exchanged fire. Third, in the context of these Mauritanian-Senegalese tensions, Mauritanian security forces and state-supported militia systematically deported about 70,000 non-Moorish inhabitants of the Mauritanian part of the river valley in two campaigns in the summer of 1989 and the spring of 1990 (Amnesty International 1990; Magistro 1993: 203–204). While only these last events are the object of our case study, they need to be analysed in relation to the preceding developments.

The media and some analysts have called the events “ethnic riots” or “ethnic cleansing” (Leservoiser 1994: 234, Wegemund 1996: 284, Libiszewski 1999: 137). Although this study intends to assess the role of growing water availability for the expulsion, it is unquestioned that the violence escalated along ethnic lines, between Moorish and non-Moorish segments of the Mauritanian population. Thus, this cleavage will be explained first.

The Moorish, i.e. Arab-speaking population of Mauritania can be divided into two groups: the (usually light-skinned) *Beydan* ‘masters’, on the one hand, and their former *Haratin* ‘slaves’ of black origin, on

the other hand. While the *Beydan* had traditionally lived from herding, trade and *razzias* against sedentary farmers, the *Haratin* took care of their masters’ herds and cultivated oasis land. Culturally assimilated and economically dependent, the *Haratin* remained in a patron-client relationship with their former masters even after their (repeated) official liberation as slaves. The non-Moorish, or “black-African”¹⁷ farmers – having fled the Moorish emirates to the left side of the Senegal River – returned to the Mauritanian shore only after the French ‘pacification’ of the valley. The *Halpulaar* constituted the majority of black Africans in Mauritania, which also comprised significant numbers of *Wolof* and *Soninké* (Wegemund 1991: 104–111).

Since independence, Mauritanian politics were heavily influenced by the power struggle between Moorish and *Halpulaar* groups. While the better-educated, French-speaking black Africans originally dominated the public administration, the Moors took over control of the state from the French (Baduel 1989: 26). Promoting the Arab language in school and public life, the *Beydan* succeeded in stabilizing their “monopoly of politics” (Leservoiser 1994: 192). The increasing black resistance peaked in an unsuccessful coup attempt of *Halpulaar* officers in 1987, leading to a purge of the security forces, thereafter completely controlled by the Moors (Park/Baro/Ngaido 1993: 97).

Moreover, the economic base of the *Halpulaar* was increasingly put into question: Due to pressing demands from the overwhelmingly poor and landless *Haratin*, on the one hand (Ould Bouboutt 1989: 137; Bâ 1991: 261; Ruf 1995: 37), and to the plans of irrigated farming in the Senegal Valley, on the other hand (Park/Baro/Ngaido 1993: 109; Leservoiser 1994: 166–167; Wegemund 1996: 292), the Mauritanian Government adopted a new land code in 1983, abolishing the traditional system of land tenure, which had organized flood-recession farming in the Senegal Valley before. Control over land was transferred from the *Halpulaar* land aristocracy to the Mauritanian State, which was supposed to distribute the land among the farmers who actually cultivated it.

After a slow start to the land redistribution, however, the *Beydan* elite itself seems to have gained interest in irrigated farming in the Senegal Valley. Thus, the Government accelerated the land redistribution by issuing *circulaires* permitting a simplified

17 Their usual self-designation is “négro-africain” (Stewart 1989: 168).

procedure for land concessions (Park/Baro/Ngaido 1993: 109–110). The *Beydan* dominance in the public administration made sure that land concessions were almost exclusively granted to Moors (Leservoisier 1994: 184). As *Beydan* investors from Nouakchott rushed into the valley, land prices exploded (Homer-Dixon 1994: 12; Libiszewski 1999: 136), and more and more Mauritanian *Halpulaar* and cross-border farmers from Senegal¹⁸ were expropriated. This led to increasing tensions between Senegal and Mauritania, creating an enabling environment for the pogroms in the cities and the military skirmishes, which in turn provided a *window of opportunity* for the deportation of non-Moorish farmers from Mauritania in order to “free” their land for Moors (Magistro 1993: 203; Dessler 1994: 105; Homer-Dixon 1999: 74).

How can this “land grab” (Horowitz 1991: 172) be explained? The Mauritanian Government had invested considerable sums into SONADER’s irrigation perimeters since the end of the 1970’s. After only 10 per cent of overall public investment in 1976–1980, the respective proportion increased to 18 per cent in 1981–1985 and 26 per cent in 1985–1988 (Leservoisier 1994: 143–144). This “capital transfer from the core to the periphery” (Magistro 1993: 214) increased the value of the *Halpulaar* economic assets, contributing to the growing discrepancy between the distribution of political power, on the one hand, and the control of valuable economic resources, on the other hand. Finally, “[t]he Mauritanian elite, too impatient to await the legal process of eviction, has begun more forcibly to remove people from the land” (Horowitz 1989: 5).

If it seems to be clear that control over land was the driving force behind the deportation, what role did the growing water availability thanks to the OMVS dams play? Traditional flood-recession farming in the Senegal Valley was commercially uninteresting, producing no more than 400–800 kg of grain per harvest. Land under controlled irrigation, however, could yield much higher results. Whereas revenues from flood-recession farming did not exceed 29,000 FCFA/ha per harvest, gains from irrigated rice cropping could bring up to 209,000 FCFA/ha per harvest (Horowitz 1991: 173). Nevertheless, due to high capital and operation costs, irrigated agriculture still was not sufficiently profitable in the absence of a regulation of the river: “These perimeters have

been costly to prepare, maintain, and operate, in part because the river often does not contain enough water for efficient irrigation; as river levels go down, the cost of pumping water to the fields increases markedly” (Horowitz 1989: 4). Thanks to the OMVS dams, however, water for irrigation became available all year, enabling farmers to bring in up to three harvests. Thus, return on capital increased three-fold, and irrigated farming became economically highly interesting, even more so considering the lack of economic alternatives in Mauritania. Therefore, many authors identify the surplus of water provided by the dams as a main cause of the Mauritanian ‘events’ (Nikolaj 1990: 473; Horowitz 1991: 172; Leservoisier 1998: 130). Others go even further, considering the ‘events’ primarily as “a conflict triggered by dam-induced pressure on land” (Adams undated: 27; Bosshard 1999; WEC 2002).

In the end, however, it is not clear if the increased water availability was a truly necessary condition of the Mauritanian conflict. The historical struggle for influence between Moorish and non-Moorish segments of the Mauritanian society already provided incentives for the deportation, and the public investment in the Senegal Valley created valuable objects of ‘greed’. Nevertheless, the dam-induced growing water availability surely was a reinforcing factor of the conflict, considerably deepening the incongruence between the control of political power and the distribution of economic assets, which was finally rebalanced by the expropriation and expulsion of the politically under-privileged black Africans.

51.5 Conclusion: Strengthening the Water Peace

The process analyses have shown that the ‘Anti-Malthusian’ correlation of water availability and conflict or cooperation in the Senegal Basin can indeed be explained by causal linkages: Without the Sahelian drought of 1968–1973, the OMVS member states would not have been able to realize their plans for developing the economic potential of the Senegal River. International donors would have been much more reluctant to fund the controversial dams. For this reason alone, growing water scarcity was a necessary condition for the intensification of international cooperation on the Senegal River. In addition, in absence of the drought, the OMVS member countries’ interest in developing their common river would have been less pressing. This would have diminished the

18 Before the events, approximately 30,000 Senegalese cultivated land in the Mauritanian part of the valley, according to traditional land use patterns from colonial times (Seck 1991b: 305).

riparians' efforts to overcome their controversies and to mobilize the needed funds.

Regarding the Mauritanian conflict, it was demonstrated that the dam-induced increase in water availability was at least a reinforcing factor, if not surely a necessary condition. The rise of land prices due to improved opportunities for highly profitable irrigated farming partly motivated the expropriation of the valley's black farmers and their bloody expulsion. This 'land grab' by the Moorish elite was eased by the historical conflict between Moorish and *Halpulaar* segments of the Mauritanian society, which had led to the total control of the security forces by the Moors and polarized the Mauritanian society. In addition, the escalating conflict between Mauritania and Senegal provided the 'fog' needed for the realization of the expulsion plan.

What do these results imply in *political terms*? The study has shown that external actors – here: donors – can indeed be crucial for intensified international water cooperation. It seems that bilateral development agencies and multilateral lending institutions may strengthen the 'water peace' and falsify Neo-Malthusian determinisms in developing regions. However, their involvement in favour of water cooperation is not positive *per se*.¹⁹ Indirectly, donor support for the OMVS infrastructure programme contributed to the Mauritanian conflict of 1989 and 1990. Although it is unclear if this consequence could have been foreseen 15 years in advance, this insight underlines the need not to consider international water cooperation as a purely technical affair. Effects on domestic politics can be considerable,²⁰ and respective impact assessments are needed to ascertain that support for specific cooperation projects is globally beneficial to riparian societies. Where political risks are significant, support for the water cooperation in question should be reconsidered if no adequate counter-measures – such as tough political conditionalities – can be taken.

Regarding *consequences for future research* on water security, the Senegal River case study has illus-

trated the need for a more precise operationalization of variables in comparative qualitative and large-N quantitative studies. While Aaron Wolf states vis-à-vis conflict and cooperation over the Senegal River that "it is clearly an exceptional example of political tensions following the climatic trend" (Wolf/Stahl/Macomber 2003: 6), our research has shown the exact opposite. Wolf's erroneous judgement can be explained by the fact that he counts the ambitious, but basically empty political declarations on regional integration between the riparian states adopted in the 1960's, but does not consider the concrete decisions on the infrastructure programme taken *after* the onset of the Sahelian drought.

For assessing the causes of conflict and cooperation between riparians of international watercourses, there is a need not only to consider the respective degrees of water scarcity and upstream-downstream constellations, but also to specify the interests in water use and the technical as well as financial capacities of riparian states. A country like Mali, for instance, which lacks both the interest in the consumptive use of the Senegal River's water and the financial capacities to realize large-scale water abstraction from the river, is unlikely to struggle for water distribution with its downstream neighbours.

Furthermore, the role of external actors in regional water cooperation has not received sufficient attention up to now. Although several authors make allusions to the importance of external incentives like rents from development assistance (e.g. Perritt 1989: 205; Andersen/Rangeley 1993: 151), systematic research on this issue is lacking. However, respective studies might give indications on the degree of riparian states' ownership of cooperation projects and thus on the prospects for their sustainability.

Finally, the nature of the state needs to be taken seriously in order to understand hydropolitics. Research on water cooperation and water conflicts mostly adopts a biased "European" perception of the state. In many developing countries, however, (pre-) colonial legacies such as the land aristocracy of the *Halpulaar* or the patron-client relationship between *Beydan* and *Haratin* are key to most political processes.

In short, research on hydropolitics must get more precise in order to produce more reliable results. If better research is to improve life for people in the world's river basins, however, we cannot do without a strong political will to make 'water peace' more stable.

19 The Green Cross seems to suggest exactly this, when it states that "all movement towards collaboration must be taken as a step in the right direction" (Gorbachev/Masire/Carlsson/Ramos 2000: 14).

20 See: "The economic benefits and costs that every water-related policy or project can and does create bring into existence new interest groups and constituencies that can seriously undermine or threaten the power and privileges of the established stakeholders" (Elhance 2000: 209).

52 The Centrality of Water Regime Formation for Water Security in West Africa: An Analysis of the Volta Basin

Maëlis Borghese

52.1 International Rivers in Africa: Imperative for Co-operation

Because water is so essential for physical survival and no human activity can be sustained without water, and because of the growing water scarcity in many regions of the world, transboundary water has often been regarded as a potential source of insecurity, tension or even violent discords among riparian states (Falkenmark 1986; Cans 2001; Larbi Bouguerra 2003). The *Economist* argued in 2000 that “water shortages will grow even more serious, the stuff of future wars. ... With 3,5 billion people affected by water shortage by 2050, conditions are ripe for a century of water conflicts” (Dinar/Dinar 2000: 193).

The freshwater dispute database (Wolf 1999b; Wolf 1998, Wolf/Stahl/Macomber 2003; Wolf/Yoffe/Giordano 2003) challenged this view, arguing that shared water was a powerful incentive for international co-operation. Wolf and his colleagues registered 261 international river basins shared by two or more riparian nations. Only few basins are characterized by inter-state conflicts: the Aral Sea Basin, the Nile Basin and the Okavango Basin in Southern Africa. Their analysis argues, seeking water security definitely leads states with shared international water resources to co-operate rather than to enter into conflict. Although their thesis is empirically based, it does not analyse its roots, the co-operation mechanisms. Their analysis remains legalistic, stating that co-operation exists because countries sharing transboundary lakes or rivers sign agreements. They do not explore the genesis of these agreements and omit answering the following question: What leads the countries sharing freshwater resources to co-operate?

Addressing this problem is particularly crucial for Africa and vital for human beings and in their energy and food production. Freshwater is an indispensable resource for economic development. Given the high demographic and economic growth rate and the pro-

jected climate change, a considerable part of Africa will soon face freshwater scarcity or stress, according to forecasts by United Nations agencies.¹ It is therefore becoming increasingly clear that key goals of the international community – sustainable economic development, environmental well-being and security, peaceful co-existence, human security, and human rights – cannot be achieved in Africa, until bilateral and multilateral agreements can be negotiated and implemented to manage the water resources of international river basins in co-operative, sustainable and equitable ways (Elhance 2000: 202). In Africa transboundary international waters cover 62 per cent of the continent. In West Africa² tensions on water resources often have geopolitical impacts. Transboundary water resources tie up all states in a river basin into a highly complex web of environmental, economic, political, and security interdependencies. Any manipulation of water flow of a shared river by a riparian state has economic, environmental and security impacts on other riparian countries. A sustainable management of shared water resources implies international co-operation (Marty 1997, 2000).

-
- 1 According to the definition of the United Nations Development and Environmental Programmes (UNDP; UNEP), an area is experiencing *water stress* when annual water supplies drop below 1,700 m³ per person. When annual water supplies drop below 1,000 m³ per person, the population faces *water scarcity*.
 - 2 Although it covers only a quarter of the African continent, West Africa has 25 international river basins, nearly half of African international rivers. Among these basins are the Niger basin (11 countries), the Chad Basin (8 countries), the Volta Basin (6 countries) and the Senegal Basin (4 countries). West African countries have water resource dependence (part of renewable water resources produced outside the country) of 40 per cent, but for Mauritania and Niger the dependence is 90 per cent (Niasse 2004: 5).

Africa has a long history of transboundary water management based on its own water laws regulating at least partially the use of many basins (IUCN 2004). While an understanding of the scope and nature of African transboundary water law supplies an important tool to improve the management of its shared basins, there is a need to understand why and under what condition co-operation occurs. The literature on international water co-operation in Africa is often technical and based on descriptive monographs. Although studies exist on trends in international water management and international development (Hajer 1996) and on conditions in Africa's transboundary waters³, only few offer political analyses of African international co-operation processes on shared basin (Niasse 2004; Borghese/Giordano/Lautze 2005). This chapter will partially fill this knowledge gap with a focus on the Volta River Basin.⁴ An examination of the factors accounting for the formation of transboundary water treaties in this shared basin can be used to contextualize the developments in African transboundary water law, to understand better the environmental co-operation mechanisms, and thus enhance incentives for future co-operation in transboundary basins.

The Volta River Basin is the 9th largest in sub-Saharan Africa covering an estimated area of 400,000 km² in six West African countries: Benin, Burkina Faso, Ivory Coast, Ghana, Mali and Togo. The area coverage ranges from 1 per cent in Mali to almost 70 per cent in Ghana. The 6.5 per cent of the total basin in Togo represents over 40 per cent of its land. In Mali (UNEP 2002a) the area within the basin holds an abundance of natural resources for the entire country. Whereas its resources are a determinant for the riparian states' economy and development, the Volta Basin remains one of few basins in Africa without any regional management authority. Although no serious conflict on its shared waters has been recorded, since the 1990's riparian countries have initiated a co-operation process that should lead to a regional authority for the integrated management of the Volta Basin by end of 2006. This co-operation dynamic on the Volta river basin offers an opportunity to analyse some explanatory factors of international environmental co-

operation in African transboundary basins⁵ to address this question: What realities, actors and mechanisms do encourage states to co-operate on international basins? Backing on the regime formation theory (52.2), this chapter explores the drivers for international co-operation looking at the specific case of the one-going negotiation process in the Volta River Basin in West Africa (52.3).

52.2 Regime Theory as the Research Framework

Co-operation has been a major research field for international relations. In the late 1970's, the concept of 'international regime' has emerged and has become a structural concept of international co-operation (Keohane/Nye 1977). Viewing international politics with sceptic optimism, it denies neither the state's egotism that they are motivated by their own interests, nor their violence potential. Given the growing interdependence of states this model believes in the possibility to control international violence through institutionalized international co-operation. Defined as "sets of principles, norms, rules and decision-making procedures around which actors' expectations converge in a given area of international relations" (Krasner 1983: 22), the concept of international regimes offers an analytical tool to comprehend the reality of international co-operation and the importance of international institutions. Combining the neo-liberal and *cognitivistic* approaches of regime theory (Hasenclever/Mayer/Rittberger 2000)⁶, and analyzing the co-operation on the Volta Basin as an environmental regime formation dynamic, this chapter intends to check the model of regime formation against an on-going empirical West African reality.

3 See for details: Godana (1985a); Rangeley/Thiam Bocar/Andersen/Lyle (1994); Hirji/Grey (1998); Okaru-Bisant (1998); Ilomaki (1999); UNECA (2000); Sadoff/Whittington/Grey (2002); IUCN (2004).

4 This chapter summarizes a comprehensive study of the author (Borghese 2005).

5 The co-operation process in the Volta Basin has barely been documented in the academic literature. Information was therefore collected in the field from September to November 2004. 25 interviews were conducted with Ghanaian and Burkinabe representatives from national authorities, international organizations, NGOs and research institutes and expatriate representatives of multilateral and bilateral donor organizations involved in the Volta basin co-operation process (Borghese 2005). This added personal testimonies and data, including project reports, figures and unpublished research or project documents.

52.2.1 State Interests as Determinants of Regime Formation

According to the realist hypothesis, a homogenous interest constellation among the states sharing a common problem is the key determinant for launching international co-operation and regime formation (Zürn 1998). Different ideal type models can explain this particular interdependence and related outcomes in terms of regime formation probabilities, such as game theory or the theory of public goods. While the first model focuses on existing power distribution between negotiators, the second insists on the nature of the common problem to determine the probability of co-operation. Backed on empirical studies, the international relations specialists at Tübingen University have elaborated a theory of regime formation, which partly integrates both explanatory dimensions in a single model (Mayer/Rittberger 1993). They concluded that the existing combination of the 'situation structure' (constellation of states interests determining the 'games' they play) and the 'problem structure' (nature of the common problem confronting them) must be analysed case by case, in order to assess the scope of possibilities for regime formation in a specific problem area.

For the case of international river basins, some general trends can be identified regarding the determinants of previously defined 'situation' and 'problem' structures. For instance, the geography of the basin, understood in its wide meaning of physical, economic and human geography, is crucial for assessing riparian states' interest or lack of interest in co-operation. It determines their national dependence on the water resources (freshwater supply), as well as the international level of their mutual dependence. The

up- and downstream morphology of transboundary basins creates asymmetric interests and bargaining power structures, which reduce the chances for regime formation (Niasse 2004).⁷

Many other factors determine the 'situation structure' of the riparian states of international river basins. In West Africa, the strong demographic growth and industrialization have increased the pressure on natural resources and have a direct influence on water stress and scarcity, often creating an urgent need for concerted efforts among states sharing these resources. Specific social, cultural, historical, political, and other circumstances may equally play a role but their relative weight on national preferences differs.

On the 'problem structures', two main problems should be distinguished, whose respective influence on the interests and incentive structures of riparian states and thus on co-operation in the basin is strictly opposite (Marty 2001: 35–38). While collective problems (water scarcity, floods, untapped opportunities for river development and poor river navigability), create symmetric incentive structures and homogenous interests easily lead to co-operative solutions, negative or positive transboundary externalities (transboundary pollution or the unilateral construction of a dam) correspond with an asymmetric incentive structure and a heterogeneous interest constellation, which may hamper cooperation.

The realist-oriented liberal school analyses international co-operation in shared river basins mainly as the result of a win-win interest constellation among riparian states, relying on the given 'situation' and 'problem structure' (see figure 52.1).

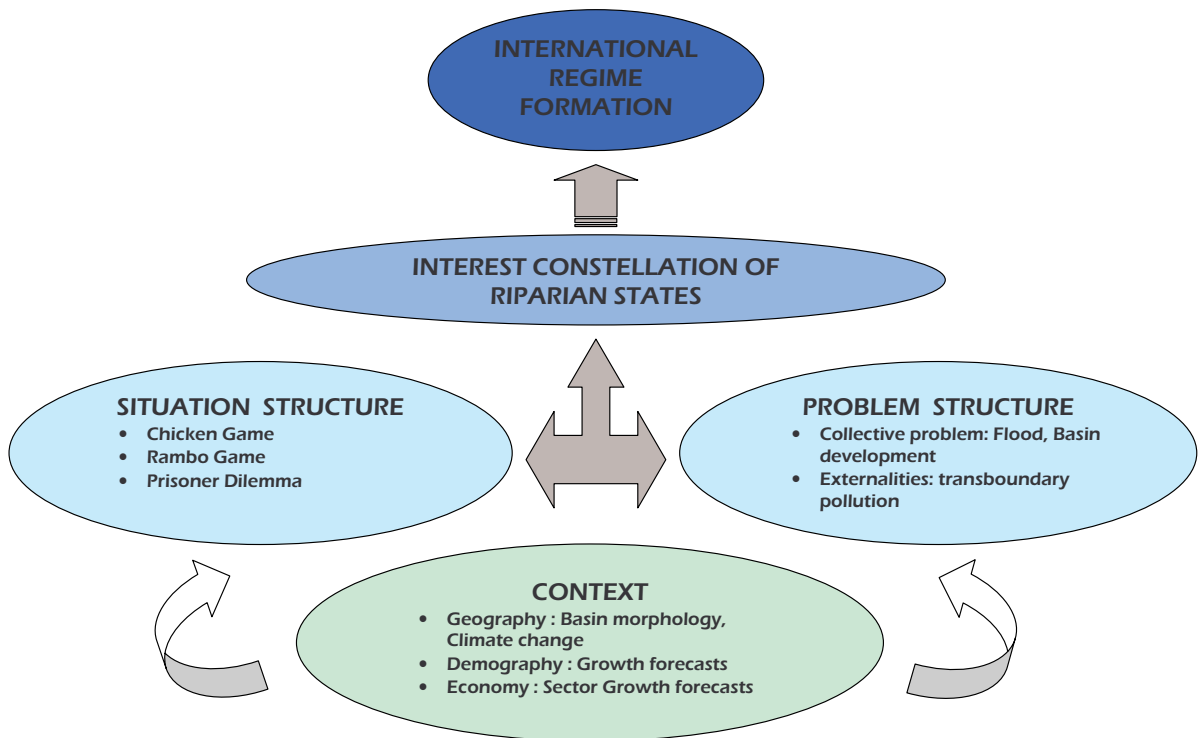

52.2.2 The Influence of Process Factors

Given the complex reality in international relations, the simple and rational regime formation scheme should be nuanced: A positive interest constellation does not represent a sufficient condition for regime formation (Osherenko/Young 1993: 11). Even if the 'problem' and 'situation structures' influence the probabilities for regime formation, it cannot be auto-

6 The author deliberately chose to set the purely realist-oriented vision of regimes aside, since its central hypothesis is not compatible with the Volta Basin riparian states. According to this school, regime formation and resilience relies on the involvement of a strong leader among the states confronted with one common problem. Such a 'hegemon' does not exist in the Volta region whose countries have largely weak economies: The region is one of the poorest in Africa, with average annual income estimated at US\$ 800 (UNEP 2002a). However, a co-operation process has been initiated in the Volta region. Considering the inadequacy of the realist model for the African reality, the chapter focuses primarily on neo-liberal (which is based on some realist hypothesis but does not consider power as the only driver of international relations) and cognitivist explanations.

7 Observing the Niger Basin Organization's great difficulties in implementing effective co-operation in comparison to the success of the Senegal River Development Organization in the Senegal River Basin (see: chap. 51 by Kipping), Niasse argues that co-operation is easier to implement in international boundary basins such as the Senegal River Basin than in international boundary-crossing basins.

Figure 52.1: Scheme: Realist-Oriented Regime Formation Process in Transboundary Basins. **Source:** Developed by the author based on Borghese (2005).

matically expressed in a clear and deadlocked preferences constellation. The success of regime creation results from a progressive process that lightens and transforms states' preferences to, finally, let appear "win-win" agreement opportunities (Müller 1993: 35-37).

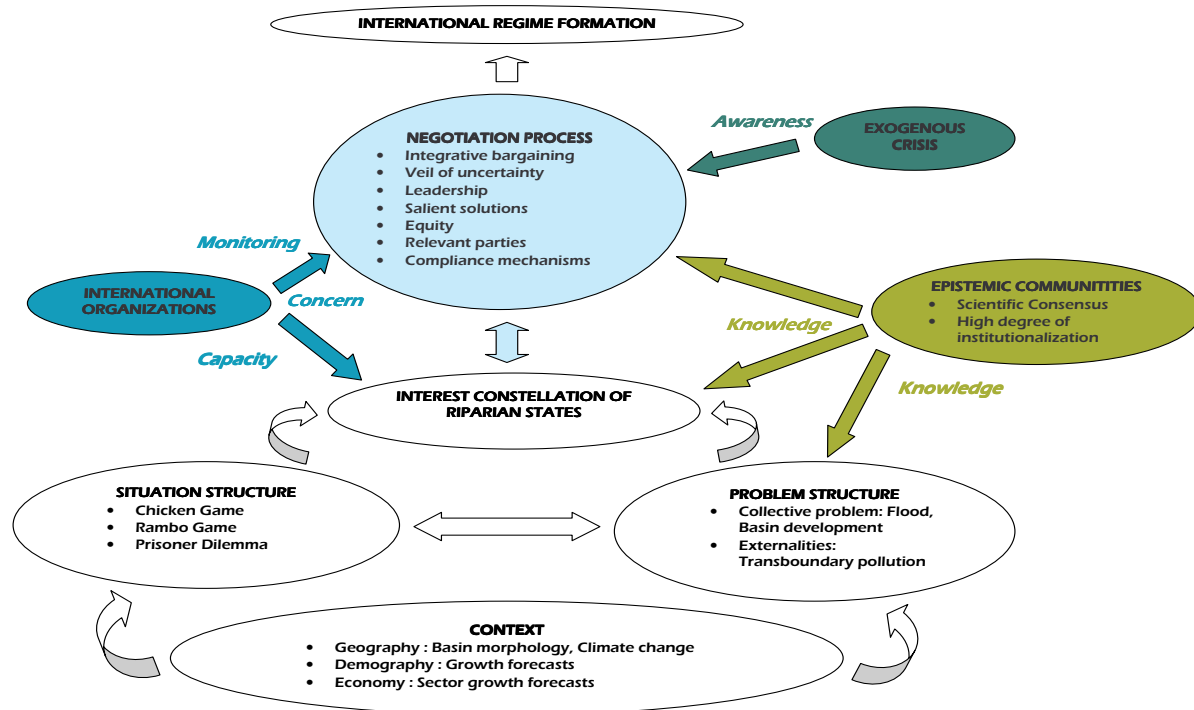

Young⁸ has developed a model of regime formation focusing on the determinant role of negotiations, which he refers to as "institutional bargaining" (Young 1989b, 1994, 1998). His key argument is that a so-called "veil of uncertainty" covers the negotiation process. This concept designates "all factors that make it difficult for individual participants to foresee how the operation of institutional arrangements will affect their interest over time" (Osherenko/Young 1993: 13). Referring to Rawls's philosophical concept of "veil of ignorance", this "veil of uncertainty" encourages negotiating parties to formulate institutional agreements that are acceptable to all, inducing the actors to engage in "integrative" rather than "distributive" bargaining. Together with this central hypothesis, from various case studies he drew these factors

influencing the course of the bargaining process: the equity of the negotiations, the definition of salient solutions, the participation of relevant parties, the formulation of accurate compliance mechanisms, as well as the role of political leadership during discussions. The particular combination of these elements strongly determines the success or failure of any regime formation process (Osherenko/Young 1993).

The *cognitivist school* gives a more substantial criticism of the neo-liberal explanation of regime formation. It stresses the limits of considering state interests as exogenously given and only dependant on determined situational factors (Haas 1992: 1-2; Hasenclever/Mayer/Rittberger 2000). Emphasizing the limits of an analysis that omits to grasp the origin and dynamics of states' common understanding (Goldstein/Keohane 1993)⁹, it proposes to fill this gap by providing an explanatory theory for states' changing perception of their common interest. They point to the role of ideas and knowledge in shaping states' preferences and therefore influencing the demand for international co-operation. Regarding the growing influence of specialists in today's complex and uncertain world,¹⁰ the role of "epistemic communities", defined as "a network of professionals with recognized expertise and competence in a particular domain and

8 Oran Young is "one of the pioneers of regime analysis" and "one of the most innovative and productive scholars in that field" (Hasenclever/Mayer/Rittberger 1997: 68).

Figure 52.2: Scheme: Integrated Model of Regime Formation. **Source:** Developed by the author based on Borghese (2005).

an authoritative claim to policy-relevant knowledge within that domain or issue-area” (Haas 1992: 3) appears crucial. Epistemic communities are likely to convey their common understanding of a problem and the related political solutions to decision-makers. As a result, their influence on the political process increases the chances for building an international consensus and, in turn, an international regime.

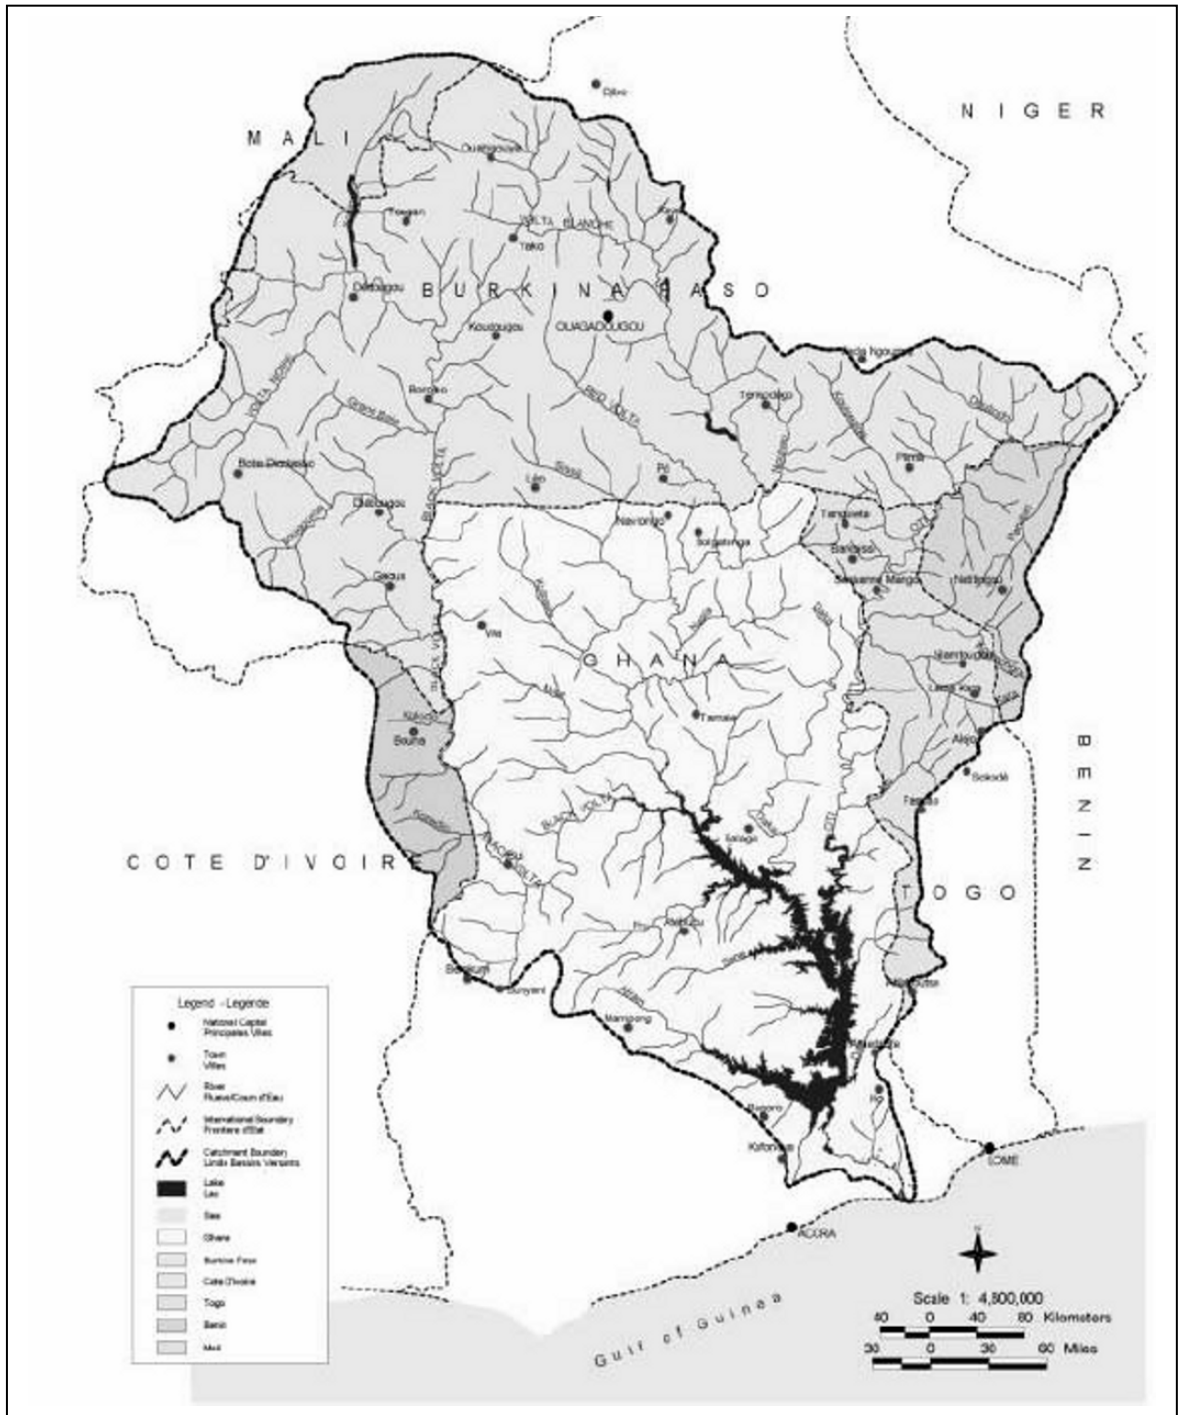

9 The impact of ideas on international policy has been analysed by Goldstein and Keohane who explained various evolutions in international relations history, such as the construction of an open world economy in the 1950’s and the abolition of colonialism after the recognition of the norm of people self-determination, under the hypothesis that the actions described can be understood on the basis of egoistic interests in the context of power realities: that variation of interests are not accounted for by variations in the character of the ideas that people have (Goldstein/Keohane 1993: 26). They concluded that interest-based theories of international co-operation cannot provide complete explanations of changes in states’ preferences.

10 Peter Haas argues that the increasing complexities of problems of global concern and the expansion of the administrative spectrum of modern states and their political intervention since World War II has increased the demands for scientific information and expertise (Haas 1992: 7-16).

Finally, international organizations – both international non-governmental organizations (NGOs) and international multilateral organizations – are another type of influential non-state actors in the environmental regime formation processes. The *United Nations Environmental Programme* (UNEP) aims at identifying new environmental problems, assessing their density and their causes, and developing guidelines to enhance the problem awareness among concerned states and can therefore be described as “an organization dedicated to regime production”¹¹ (Müller 1993: 96). But also the impact of Greenpeace on developing international North Sea, Wales or Ozone layer protection, illustrates the ability of NGOs to enhance the states mobilization for international environmental protection (Müller 1993: 95-98). Three major influence patterns of international organizations on international co-operation processes can be identified: Increasing governmental *concern* by creating, collecting and disseminating scientific knowledge among others; enhancing the *contractual environment* by providing a bargaining forum such as the UN-conferences; increasing national *capacity* by transferring financial as-

11 Translation by the author of the German term: regimeerzeugende Organisation (Müller 1993: 96).

sistance, especially in developing countries (Haas/Keohane/Levy 1995: 399-408).

Figure 52.2 illustrates the complex interaction of process, context and knowledge mechanisms at the roots of international co-operation. It offers an inte-

grated model of regime formation combining existing theories on the issue into one single causal network.

52.3 Why Do States Co-operate in the Volta Basin?

The process of international co-operation among riparian states in the Volta River Basin in West Africa gives the opportunity to empirically test this theoretical model.

52.3.1 Geographic, Demographic and Economic Trends in the Volta Basin

The total basin is spread over six West African countries (figures 52.3 and 52.4). The relative proportion of the basin area found within a country does not necessarily reflect the relative importance of that part of the basin in that country. While a country may only have a small percentage of the total basin within its borders, as in the case of Togo, this area might comprise a significant proportion of the entire country. Additionally, the area of the country within the basin might hold an abundance of natural resources with respect to the entire country, such as in the case of Mali, Burkina Faso, Ghana and Togo.

Table 52.1: Distribution of the Basin in the Six Riparian Countries. Sources: Data for the Volta River Basin are from respective UNEP National Reports (UNEP 2001a, 2001b, 2001c, 2001d, 2001e, 2001f).

Country	Area of Volta River Basin (km ²)	% of Basin	% of Country in the basin
Benin	17,098	4.10	15.2
Burkina Faso	178,000	42.65	63.0
Cte d'Ivoire	12,500	2.99	3.9
Mali	15,392	3.69	1.2
Togo	26,700	6.40	47.3
Ghana	167,692	40.18	70.0
Total	417,382	100.00	

The climate in the Volta Basin is characterized by high temperatures and high evaporation rates, especially in the Sahel zone with an average of 2,334 mm per annum in the North of Burkina Faso (table 52.2). The area is drought prone: Any time rainfall is below average, rivers dry up. During the last decade rainfalls decreased, and the river run-off declines. Given global climate change forecasts, this trend may be confirmed in the coming decades: Climate scenarios showed a 15.8 per cent and 37.0 per cent reduction in the run-

off of the White Volta Basin¹² for the years 2020 and 2050, respectively (Opoku-Ankomah 2000). The high average population growth rate (2.54 per cent) will lead to a major increase of the population in the basin from about 18,600,000 in 2000 to approximately 33,900,000 in 2025, or of 80 per cent within 25 years (Barry/Obuobie/Andreini/Andah/Pluquet 2004: 18-24; table 52.3).

The riparian countries of the Volta Basin are among the poorest in the world with underdeveloped economies concentrated in the service (42 per cent) and agricultural (37 per cent) sectors in 1999. These countries are projecting major improvements in their development plans. Given the vital role of water, these will lead to an increasing use of the Volta River's resources. Agricultural water requirements may increase considerably: Burkina Faso, Cte d'Ivoire and Mali presently irrigate only a little over 10 per cent of their irrigable land area.¹³ Urbanization and the development of the industrial and service sectors will also increase water demand. In the basin, dams and reservoirs have increased to mobilize water for agricultural, industrial, and electricity generation: The largest dam was built at Akosombo in Ghana in the early 1960's primarily to generate electricity that created the Volta Lake (8,500 km²). In Burkina Faso, there are now approximately 600 dams and lakes with a total storage capacity of 4.7 billion m³ (UNEP 2002a: 3). Large and small dams have continued to expand in the basin with increasing population pressure and economic development.

12 The Volta basin encompasses four main tributaries, forming four sub-basins, which converge in Ghana to feed the Volta Lake: the Oti River, the Red, Black and White Voltas. The latter spreads over Northern Ghana and Togo and the South of Burkina Faso.

13 The realization of the Ghanaian development plan *Ghana's Vision 2020* would require to enlarge the agricultural area under irrigation from 10,000 to 100,000 hectares by 2020. This would imply a future water consumption of up to 4,114 million cubic meters (MCM) (Ghana, Ministry of Works and Housing 1998b: 14). At the same time, the industry's share of GDP is expected to increase to 37 per cent and therefore the demand for industrial and urban water is projected to rise from 63 MCM in 2000 to 272 MCM in 2020 (Van Edig/Engel/Laube 2002: 34, Ghana, Ministry of Works and Housing 1998c: 3). With regard to other riparians, the consumptive demand for Cte d'Ivoire in 2025 is projected as 9,400 MCM. For Burkina in 2010 the demand is estimated at 860 MCM. No projection could be obtained for Togo and Benin (Ghana, Ministry of Works and Housing 1998a: 7)

Average					2.54	23.30	76.70

52.3.2 Common Interests of Riparian States in Integrated Water Management - Analysis of Problem and Situation Structures

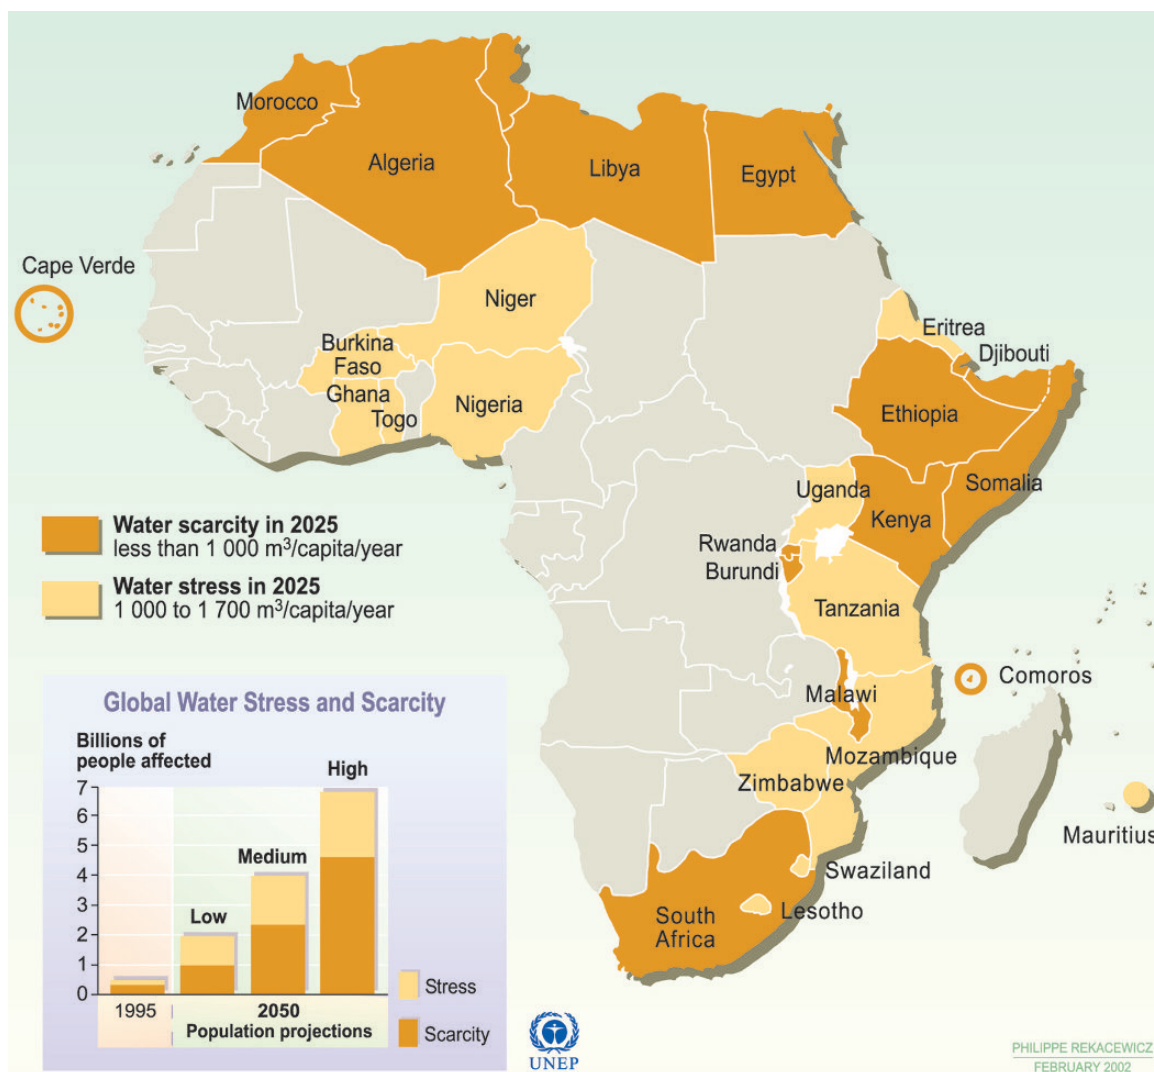

The combination of geographic, demographic and economic features leads to a higher pressure on the Volta Basin's water resources and therefore to problems of water scarcity in each country: The water demand for domestic and industrial activities is projected to increase by about 300 per cent by 2025, and Burkina Faso, Ghana and Togo will be subjected to freshwater stress by 2025 (UNEP 2002a: 3-4, figure 52.4).

Several environmental problems are already raging in the Volta Basin: the proliferation of invasive aquatic weeds affecting water quality, the prevalence of water-borne diseases such as Bilharziasis and Onchocerciasis, bush fire destructions, regular flooding, forest and land degradation leading to soil erosion and affecting

the water quality, transboundary pollution from industrial and agricultural wastes, as well as biodiversity losses are interrelated causing serious environmental, economic and social damages.

These matters are 'collective' problems (Marty 2001: 35-38) that create symmetric interests among the riparian countries and foster their motivation for co-operation. To avoid the tragic over-exploitation of the Volta Basin's scarce resources (resulting from uncoordinated and egoistic interest-oriented national policies) an integrated management policy must be drawn up and its implementation must be monitored by a multilateral regional international organization. A closer study of the Volta basin shows that co-operation has seldom been considered by riparian states as a priority and exclusive solution. Some problems such as water stress are only forecasts and will be felt only in the long term. Thus, they may not be high enough on the political agenda to lead governments to the difficult process of regime formation. Most of interview

Figure 52.4: Freshwater Stress and Scarcity in Africa by 2025. **Source:** UNECA (2000); UNEP (1999g). The permission to use this map was obtained from the copyright holder.

partners underlined that the short-term political strategy does not adapt well to the long-term imperative of a sustainable management of the Volta basin.¹⁴ The national administrations in charge of water management have often tried to get funds from international donors to support projects of transboundary co-operation but they had difficulties to obtain endorsements from their ministers¹⁵. Apart from environmental degradations spreading over the borders through the ri-

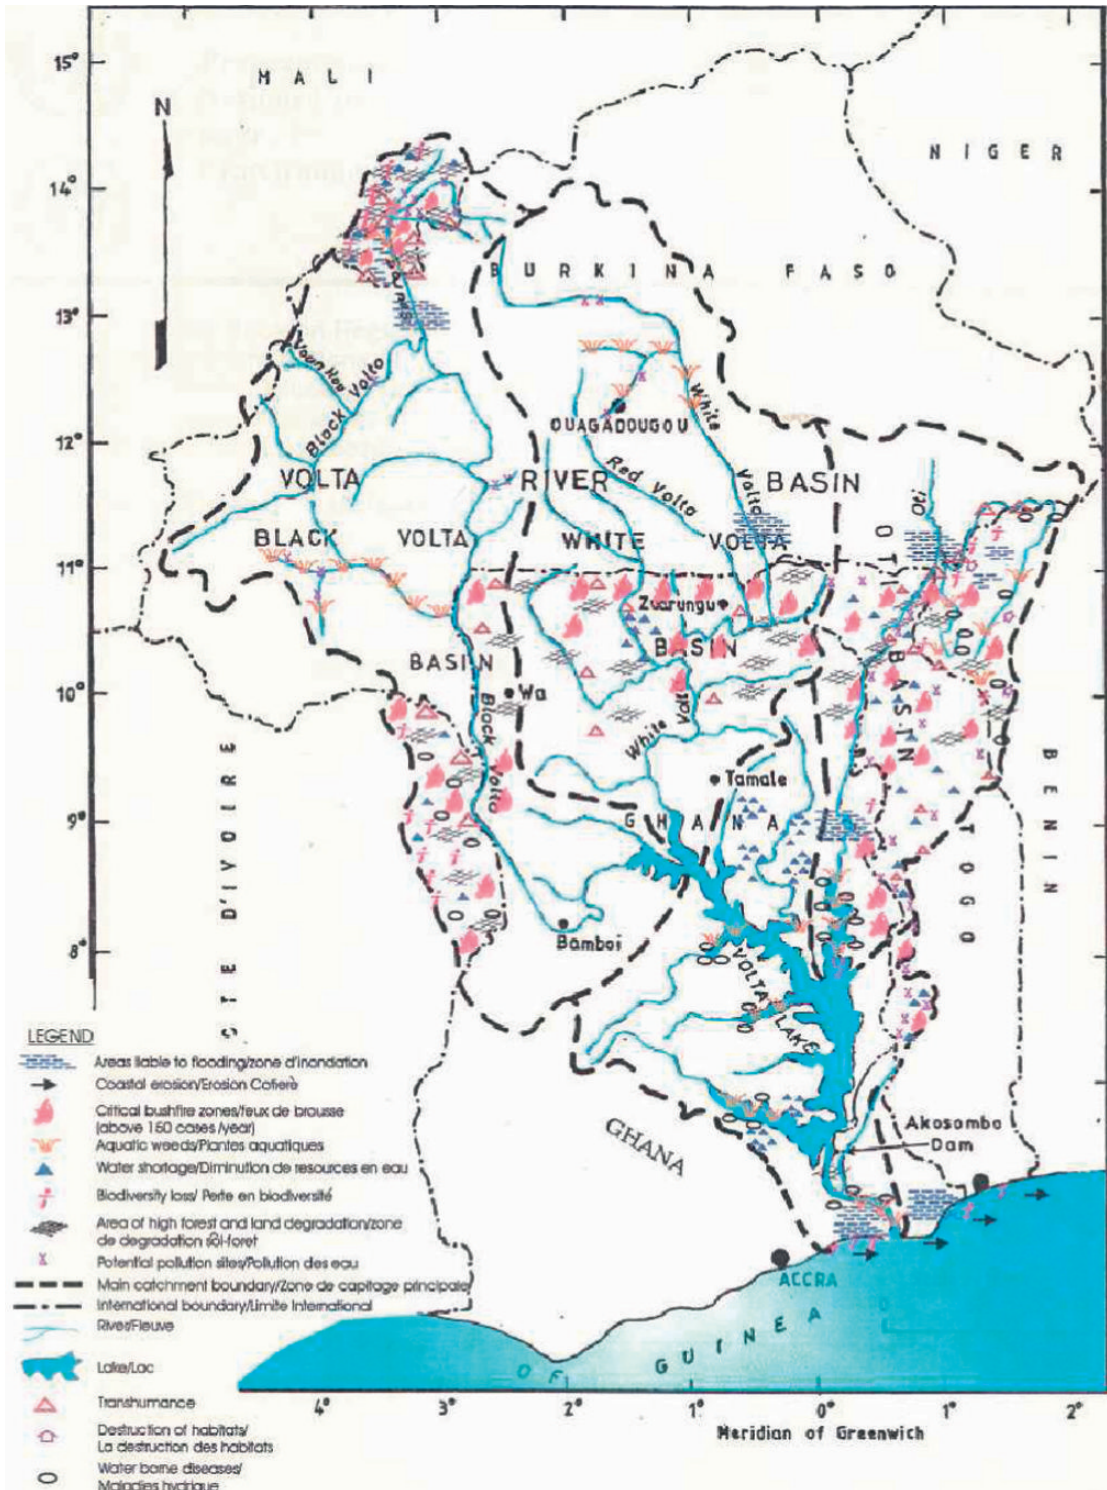

ver flow, other environmental problems do not necessarily require co-operation in a first stage. Negative international externalities (pollution) have created asymmetric interests and do favour international co-operation, since upstream countries rather prefer to keep the status quo than constrain themselves to find sustainable solutions.

But the up/downstream geo-morphology of the Volta basin reduces further the probabilities of co-operation since riparians are developing incompatible uses of the basin's resources. While Burkina Faso (upstream) bases its development on irrigated agriculture, Ghana (downstream) has based its economic development on its industrial and mining sectors, which need the hydropower from the Akosombo dam. According to the realist-oriented view of international re-

lations, this asymmetric ‘game structure’ should strongly shrink Burkina Faso’s incentives for co-oper-

ation (Andreini/Van de Geisen/Van Edig/Vlek 2001; Odame-Ababio 2004).

In spite of this unfavourable constellation of preferences, first steps have recently been taken to create an integrated management organization for the Volta Basin. In April 2004 the governments of Ghana and Burkina Faso signed the *Ghana-Burkina Faso Joint Declaration* that acknowledged common water and environmental issues and stated a desire to collaborate on the management of shared water resources in a *Volta Basin Technical Committee* (VBTC) involving all riparian countries. These first commitments were followed by a conference in Ouagadougou in July 2004, attended by the Ministers in charge of water issues in Benin, Burkina Faso, Cote d'Ivoire, Ghana, Mali, and Togo. They approved a series of agreements acknowledging the need for a transboundary management institution, defining a timeframe for its creation and creating the *Direction Gnrle de l'Inventaire des Ressources Hydrauliques* (DGIRH 2004). This body brings together experts and high officials from the national water management administrations of all six riparian countries with the task to set up the political, legal, institutional and financial framework of the future international organization of the Volta Basin.¹⁶ An international organization for the sustainable management with a permanent secretariat should subsequently be established by end of 2006.¹⁷

Since the study of 'situation' and 'problem factors' is not conclusive enough to explain this regime genesis, an understanding of the recently initiated co-operation developments in the Volta Basin calls for an analysis of the previously defined 'process factors'.

52.3.3 Process Factors on Volta Basin's Co-operation Trend

According to Young's theoretical model of "institutional bargaining", exogenous shock or crisis are considered as decisive process triggers for the initiation of a co-operation process: They contribute to reveal the nature and scope of shared problems to the concerned states and their public opinions and may also increase their sense of urgency. In the case of the Volta Basin, the 1998 crisis on the Akosombo dam has definitely played this role. During the dry season of 1998, the Volta sub-region suffered a severe drought. An acute fall in the level of the Volta Lake in Ghana

made it impossible for the Volta River Authority¹⁸ to generate enough electric power from the Akosombo hydroelectric plant to meet Ghana's growing demand. The 1998 crisis was so severe that it provoked a chaotic situation in the economy and living conditions of the society not only in Ghana, but also in neighbouring Benin and Togo, whose electricity resources are mainly imported from the Akosombo dam¹⁹.

The crisis not only underlined the common problem of water scarcity but also the existing conflict potentials on the Volta basin's water resources between the agricultural users of Burkina Faso and North Ghana and the industry of the coastal region. Due to the lack of information the President of Ghana, Jerry Rawlings, claimed the unilateral dam development policy of Burkina Faso caused the water shortages observed at the Akosombo reservoir²⁰. But a few days later, scientific analyses revealed that the low level of Volta Lake was mainly due to the drought and that water retention infrastructures in Burkina Faso had a negligible impact on downstream inflows in Ghana, compared with small variations in rainfall. This diplomatic incident stressed even more the need for improved scientific communication among riparian states, in order to enable the authorities to identify the sources of transboundary problems. In this crisis, the imperative for co-operation became clear to the water administrations in all riparian countries:²¹ High officials expressed a strong political will for enhanced co-operation:

There must exist, especially in developing countries, adequate structures, institutions and organizations for dealing with these urgent matters in order to achieve inter-state regulation and control of international water resources (Ghana, Ministry of Works and Housing 1998a: 22).

Burkina Faso shows solidarity with Ghanaian, Beninese and Togolese people in a situation which concerns all of us. The truth is that the whole sub-region has to cope with [water] deficits, especially the White Volta sub-basin. Since we encounter common water-related problems, we must seek for common solutions.²² (Salif Diallo, Burkinabe Minister of Water and

Beyond this event, the role of ideas, as stressed by the *cognitivist school*, has also been a long-term determining factor for enhancing the states' perception of their common interest and political will to co-operate in the Volta Basin. Since the mid-1990's, *Integrated Water Resource Management* (IWRM) has become a concept in the international scientific community. According to this approach, the basin should be considered as a systemic unit composed of several sub-units such as the hydrologic system and the ecologic system. As an integrated ecosystem, the basin should therefore be addressed and managed holistically, irrespective of whether it is domestic or international (Marty 1997: 22-25). Considering the basin as the only effective geographic management scale, this approach therefore prompts the riparian states of international river basins to co-ordinate and to integrate their water management policies, ideally by forming a separate international basin organization (Burton 2001).

This concept and its implementation modalities were developed during international workshops and conferences in developed and developing countries. Several policy and research networks have been established, such as the *International Network of Basin Organizations*, the *Global Water Partnership* etc. After this phase of scientific diffusion, the concept was adopted by the international community as the key international reference for river and international basin management at a UN conference in Dublin in 1992 (Burton 2001). The IWRM approach has been widely endorsed by African public administrations and research centres in the water sector. Most experience with the implementation of IWRM in international basins was gained on river basins in Sub-Saharan Africa. Several institutions have been formed in this region such as the *Organisation de Mise en Valeur du Fleuve Sngal* (OMVS) on the Senegal River, the *Niger Basin Organization* etc. Many African governments have also initiated reforms of their water administration to better implement IWRM principles. The two main riparian countries of the Volta Basin, Ghana and Burkina Faso underwent an IWRM-oriented restructuring of their water institutions during the 1990's (Lautze 2004).²³

The development and diffusion of the IWRM concept confirms the crucial role of ideas and epistemic

communities in the process of regime formation: Ideas can change policy-makers' preferences and perception of their national interest, especially when they are supported and spread by scientific international networks and national advisory bodies.

However, both the restructuring of the water institutions of the Volta Basin's riparian countries and the subsequent initiation of a co-operation process effectively result from the massive financial and technical support provided by international organizations and donors. The spectre of increasing water scarcity and the related threats to the international peace order has increased the awareness of the international community. A large spectrum of international organizations involved in environmental protection, international solidarity and development have consequently identified access to drinking water and the sustainable management of water resources as policy priorities. The *Millennium Development Goals* and the action plan adopted at the UN summit in Johannesburg in 2002 have committed the international community to implement a sustainable water resources management plan in each country by 2005 and by 2015 to reduce by half the population without access to drinking water and sanitation.

As a direct consequence of this international mobilization, many initiatives have been undertaken by multilateral organizations, bilateral development agencies, international research centres or international NGOs to support the sustainable management of water resources in the Volta River Basin. Both Ghana and Burkina Faso the majority of the author's interview partners²⁴ mentioned that they had no exhaustive overview of the scope of actors. Regional and international organizations and initiatives that are concerned with sustainable water resources management in the Volta Basin seem to have mushroomed.

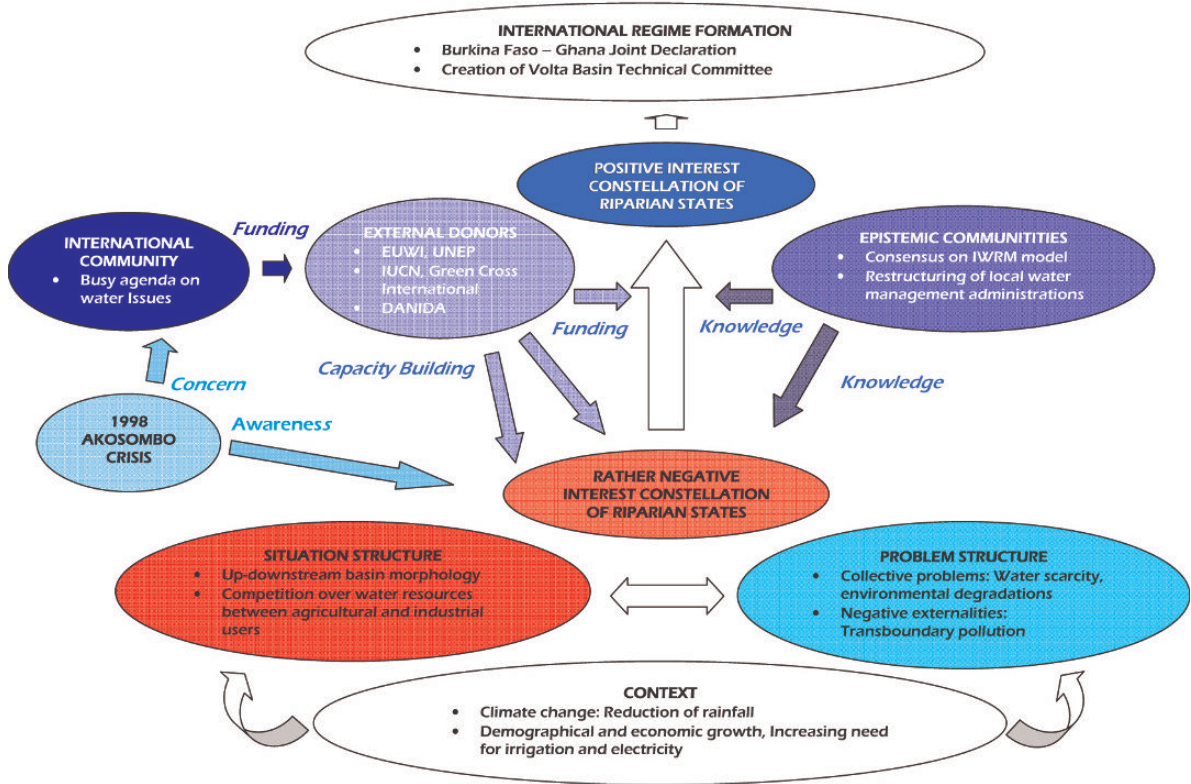

The actors listed below are not exhaustive, but they illustrate the strong involvement of the international community in support of the integrated man-

24 Interviews with Mr. Lorenzo Suarez-Pose Minta Abo-ge, Mr. Marc Andreini, Dr. Charles Biney, Dr. Pay Drechsel, Ms. Veronika Fuest, Mr. Niels Henrik Ipsen, Mr. Sven Jacobi, Mr. Jonathan Lautze, Mr. Mogens Mehta, Dr. Opoku Ampomah, Mr. Olivier Robinet, Mr. Steven Sandiford, Mr. Saintraint 2004, Mr. Bougare, Mr. Niasse and Mr. Diallo (Borghese 2005: 95-98). Most of the persons interviewed were very experienced with respect to water research/policy and all of them were working either in one of riparian countries' national authorities in charge of water resources or for one of the projects mentioned further.

agement of the Volta Basin and for creation of a regional basin management organization. Bilateral donors such as the *Danish International Development Agency* (DANIDA) and the *French Global Environmental Fund*²⁵, as well as *multilateral organizations like the New Economic Partnership for African Development* (NEPAD), the *World Bank* and the *European Union*, international NGOs such *International Union for the Conservation of Nature* and *Greencross*, and research centres such as the *German Centre for Development Research*²⁶, the *International Management Institute* or the *French Development Research Institute*²⁷ are currently preparing or funding the implementation of many projects on the Volta Basin. All these projects try to identify the existing transboundary problems of the Basin, to formulate technical solutions and set subsequent programmes of actions, and/or to strengthen the institutional dialogue, cooperation and data-sharing for the sustaina-

ble management of the Volta Basin. These initiatives and significant funding have obviously widely contributed to the genesis of an integrated management regime in the Volta Basin. Mr Ampomah, an economist at the *Ghanaian Water Resources Commission* (WRC) explains that:

The quest for an agreement to provide for a joint management structure on the Volta was largely driven by donors' involvement in the national water strategies of the riparian countries from the 1990's to satisfy lending conditions.²⁸

Through a proliferation of more or less co-ordinated projects, international organizations and donors have thus been strongly supporting the spreading of the IWRM model and the current process of regime formation in the Volta Basin with financial and technical²⁹ means. Their role has been absolutely essential to raising awareness about the advantages of co-operation and to effectively initiating the first steps of a co-operation process in the Volta Basin. Figure 52.6 summarizes the complex network of interest and process factors, which have led to the initiation of a

negotiation process for the establishment of a Volta Basin management regime.

52.4 Key Role of International Organizations for Preventing Water Insecurity in Developing Countries

The study of the Volta River underlines the predominance of process over interest explanatory factors for international co-operation efforts in this transboundary basin. Although a thorough analysis of the geographic, economic and demographic context in the Volta Basin reveals co-operation-prone collective problems such as environmental degradation and water scarcity threats, the geo-morphology of the Volta Basin and the low ranking of environmental issues in the political agendas of riparian states' governments constitute a rather negative constellation of interest for international collaboration. From a realist point of view, upstream riparian states, such as Burkina Faso, which can arbitrarily control and use the water flow, should have only reduced incentives to constrain themselves to solve problems such as transboundary pollution or transboundary competition over basin's water resources.

However, the current co-operation process initiated by the six Volta River's riparian states proves that political will for the formation of a regional management regime exists and that other explanation factors must therefore be taken into account to comprehend this regime genesis. Although there was a local desire to collectively manage these shared water resources, particularly after the 1998 energy crisis, the fact that both agreements for the creation of a regional basin organization were signed during the period when numerous international actors arrived, and more generally that these agreements were signed when the international community paid attention to concerns of transboundary water management and to environmental issues, leads to the conclusion that external drivers have played the dominant role in the Volta Ba-

sin's regime formation. The close connection between epistemic communities, supporting the IWRM model, and the projects funded by the international donors' community, promoting a sustainable management of water resources at basin-scale, has transformed the perception of riparian states of their interest. Spreading of knowledge on IWRM concepts through the formation of local water institutions', capacity building through the provision of technical assistance and funding supporting international dialogue have convinced governments of the advantages of co-operation.

This conclusion reconciles the *cognitivist* with *neo-liberal* views of co-operation theories. The role of ideas and knowledge is essential to comprehend the realities of the formation of environmental co-operation in developing countries. But their impact depends on their linkage with funding enabling them to effectively spread and shape states' preferences.

For research on environmental security, these results stress the crucial role that the international community should play to prevent conflict and to enhance co-operation among states sharing a common resource in poor countries. Although the analysis of a single case does not allow systematic generalizations for the regime formation process, the impact of international actors appears to have been a key determinant for the creation of transboundary basin management regimes in developing regions, since they can offer sensitivity for environmental problems in countries that usually conduct short-term development policies and usually have a low environmental awareness. They can also provide technical and financial capacities to cope with these problems. Through significant financial means (compared with budgets of poor countries) international donors can give ideas (such as the IWRM model), concrete diffusion and implementation opportunities that subsequently shape the preferences of developing states and support their willingness for environmental co-operation.

29 Most of the mentioned projects bring technical assistance and funding for capacity building. For instance, DANIDA's support to the implementation of IWRM in Ghana includes the work of two permanent and three rotating technical assistants within the office of the main Ghanaian public organization in charge of water resources management: the *Water Resources Commission* and the *Water Directorate* (Interviews with Mr. Jacoby and Mr. Jensen 2004, Borghese 2005: 95–98).

53 Success and Failure in International River Basin Management – The Case of Southern Africa

Stefan Lindemann

53.1 The Challenge of International River Basin Management¹

Almost all of the world's largest rivers cross national borders. According to recent estimates, there are 263 international river basins² that account for 60 per cent of the global freshwater resources, cover 45,3 per cent of the world's land area and host 40 per cent of the global population (Klaphake/Scheumann 2001: 7). The use of these international river basins leads to numerous problems and conflicts among riparian countries that include disputes over water quantity, pollution, dam schemes, flood protection or navigational issues. The great majority of these conflicts derive from the upstream-downstream structure of international rivers. While most water-related conflicts arise upstream where abstractions or pollution compromise the availability of water downstream, activities downstream can also lead to conflict since they may create an obstacle of upstream actors' access to the sea (Bernauer 1997: 162).

One can generally identify two approaches in resolving water-related conflicts in international river basins. On the one hand, there are general principles of international water law through which victims of water conflicts might seek remedy. Unfortunately, this 'vertical' water law remains essentially a 'soft law' that has provided little guidance in resolving transboundary water conflicts (Birnie/Boyle 2002).³ Against this background, this chapter focuses on 'horizontal' initiatives for international river management between two or more riparian states at the river basin level, which seem to hold more potential for the resolution of transboundary water conflicts. Horizontal coopera-

tion along international waterways is omnipresent. The FAO has counted 3.600 international water treaties for the period between 805 AD and 1984 (Wolf 1997). If one excludes the numerous treaties on navigational issues, there are still more than 400 different treaties on international rivers (Wolf/Yoffe/Giordano 2003: 32).

These treaties vary substantially according to both the subject and the extent of the agreed cooperation (Hartje 2002: 22). The great majority is functional in scope, which means that the adopted approach focuses on the resolution of specific problems in the river basin (Marty 2001: 22). Functional forms of cooperation include (1) agreements on the development of joint projects such as dam schemes or flood protection – a type of cooperation that is still dominant as it reflects the traditional, infrastructure-oriented development paradigm (e.g. Rio Grande, Senegal). Furthermore, there are (2) agreements on the allocation of water, comprising the allocation of specific water quantities between riparians in mostly semi-arid or

1 This article builds on and summarizes the detailed findings in Lindemann (2005).

2 River basins or catchment areas are defined by a common mouth, which is either the point where the river flows into the sea or into an inland delta.

3 The UN Convention on the Law of the Non-Navigational Uses of International Watercourses, which took 27 (!) years to develop, establishes a series of principles for international water cooperation but has neither entered into force nor does it provide clear guidance in resolving transboundary water conflicts (Beach/Hammer/Hewitt/Kaufman/Kurki/Oppenheimer/Wolf 2000: 9). Among many problems, it institutionalizes the inherent upstream/downstream conflict by calling for both "reasonable and equitable use" and an "obligation not to cause appreciable harm." These two principles are in implicit conflict in the setting of an international waterway: up-stream riparians have advocated that the emphasis between the two principles be on "reasonable and equitable use," since this gives the needs of the present the same weight as those of the past. In contrast, down-stream riparians have pushed for emphasis on "no significant harm," which effectively protects the pre-existing uses generally found in the lower reaches of most major streams (Wolf 1998: 1).

arid regions (e.g. Aral Sea, Incomati). Functional forms of cooperation finally also include (3) agreements on water pollution problems, which have been growing in number since the late 1960's (e.g. Rhine, Tijuana). Beyond functional cooperation there are also (4) integrated approaches to international river basin management that focus on the river basin as a whole and try to resolve the existing hydrologic, ecologic and socio-economic problems through holistic policies. The integrated approach has been widely endorsed and promoted by international organizations, NGOs and scientists (Teclaff 1996: 384) but suffers from a so far very limited practical application (Hartje 2002: 23).

Southern Africa is certainly among the world's most interesting regions in the field of international water since few regions offer as much contrast. Due to the region's relative water scarcity⁴, the 15 international basins in the *Southern African Development Community* (SADC) are regularly included among the world's hydropolitical hot spots, second only to the arid and hostile Middle East (Wolf 2003: 1). Water scarcity in Southern Africa is firstly a problem of inadequate supply since levels of water availability are highly volatile due to climate and weather extremes.⁵ But water scarcity is also demand-induced since – *ceteris paribus* – the water available per capita tends to

4 Recent calculations for Southern Africa reveal that water is already scarce in a number of local basins, reaching availability levels of 1000 m³ or less per capita per annum (see Ashton/Turton in this volume). "By 2025, based on renewable supplies and demographic data, it is expected that Malawi and South Africa will face absolute water scarcity, and Lesotho, Mauritius, Tanzania and Zimbabwe will be water stressed; while Angola, Botswana, DRC, Mozambique, Swaziland and Zambia are likely to experience water quality and availability problems in the dry season" (Hirji/Mackay/Maro 2002: 7). Despite undeniable deficits – the designation of entire countries as water scarce is methodologically problematic since water scarcity is a complex and regionally varying phenomenon (Schiffer 2001: 4) – the indicators give an impression of Southern Africa's current and coming water crisis.

5 The climate in the region is characterized by staggering evaporation rates, extreme variations in precipitation over the year and recurrent floods and droughts (Chenje/Johnson 1996). These extremes – that are expected to worsen in the context of global climate change – make that the North and the East of the region are relatively wet (Democratic Republic of Congo, Angola and Zambia), while the South and the West receive very little rainfall (Namibia, Botswana, South Africa, Zimbabwe).

diminish due to both increasing industrial/agricultural development and average annual population growth of more than 3 per cent (Mohamed 2003: 213). Lastly, there is also a structural aspect to the problem of water scarcity in Southern Africa: Due to colonial and postcolonial settlement policies, the available water resources are extremely unequally distributed and mostly located far outside the urban areas (Swatuk 2002). Altogether, water resources are relatively scarce, extremely volatile and mostly located in international river basins – a fact that makes the international river basins crucial for the development of the entire region (Granit 2000: 2).

On the other hand, Southern Africa now has more experience in negotiating water treaties and implementing joint management bodies than any other region on earth, save the European Union (Wolf 2003: 1). While some of the management schemes in Southern Africa's international river basins date back to colonial times, most of the 24 international water treaties in the region have been negotiated since the mid 1980's. In the light of the Southern African water crisis, the existing efforts for international river management are of great importance. This is why I ask *if and how* these initiatives have provided guidance for the resolution of transboundary problems along international waterways. To what extent have the existing international river basin management schemes been successful in resolving the problems that prompted their creation? And what are the pathways to success and failure in the managing of international rivers?

53.2 Theoretical and Methodological Framework

Problems of international river basin management have so far been discussed in a mostly descriptive and unsystematic way (Bernauer 2002). Below a research framework is developed for a more systematic and theoretically guided comparison (54.2.1). This is followed by methodological considerations on how to apply this framework to regional case studies (54.2.2).

53.2.1 The Research Framework

In order to explain success and failure in international river basin management, I make use of international regime theory⁶. Treaties on international rivers are conceptualized as *water regimes* defined as norm- and rule based cooperation for the political resolution of problems and conflicts in the field of international

river basin management. Asking for the conditions for success of these international water regimes involves two interrelated, but analytically separated questions: (1) Under which conditions are the riparian states prepared to form institutions to address transboundary problems? (2) And what are the determinants of the effectiveness of those institutions? The focus is therefore on the determinants of (water) regime formation and (water) regime effectiveness – the two dependent variables.

The concept of regime formation is almost self-evident. A water regime is formed when riparian countries engage upon norm- and rule-based cooperation for the political resolution of problems and conflicts in the field of international river basin management. The concept of regime effectiveness, on the other hand, is more problematic. The most intuitively appealing sense of effectiveness centres on the degree to which a regime eliminates or alleviates the problem that prompts its creation (Young 1999: 4). However, this ‘problem-solving approach’ is misleading since it is usually very difficult to establish a causal relation between the effects of a regime and the state of a given problem.⁷ Against this background, I complement the ‘problem-solving approach’ with a political interpretation of regime effectiveness that focuses on behavioural change (e.g. Keohane/Levy 1996; Young 1999): Regime effectiveness becomes the extent to which the water regime prompts behavioural change on the part of the relevant actors leading to an improved management of the respective problem.

But what are the determinants – the independent variables – of water regime formation and effectiveness? Drawing on regime theory – especially the work by Frank Marty (2001) who, from a social sciences perspective, has contributed one of the very few theoretically guided analyses of international river basin management – five groups of independent variables are distinguished: problem factors (53.2.1.1); process factors (53.2.1.2); institutional factors (53.2.1.3); country-specific factors (53.2.1.4); and (5) factors of international context (53.2.1.5).

53.2.1.1 Problem Factors

It is intuitive to assume that problems of international river basin management are not equally easy to resolve. In general, one can distinguish between problems related to transboundary externalities and collective problems (Marty 2001: 35–36). Most problems are related to *transboundary externalities* due to the ‘upstream-downstream structure’ of international rivers. Negative externalities arise when the upstream country imposes costs on the downstream country without compensating it for the inflicted harm (e.g. in the case of water abstraction or pollution upstream). Positive externalities, on the other hand, are less frequent and exist when one riparian country produces a public good without receiving full compensation for its efforts (e.g. the provision for flood control upstream). Other problems in international river basins are of a *collective nature* (e.g. floods or common development projects). These problems are collective in that they impose (more or less equal) costs on all affected riparian countries – direct costs in the case of transboundary floods, opportunity costs in the case of under-utilized river development potentials. Problems related to transboundary externalities and collective problems differ fundamentally with respect to the underlying incentive structure of the relevant actors: In the case of collective problems, incentives tend to be symmetrical, while transboundary externalities are usually characterized by asymmetric incentive structures. This is why there is reason to believe that problems related to transboundary externalities are more difficult to resolve than collective problems (Marty 2001: 37).

Beyond incentive structures, problems in international river basin management vary according to the amount of *problem pressure* involved – that is, the perceived visibility of a given problem (Jänicke 1999: 77). Recurrent floods, for example, involve more problem pressure than the threat of water scarcity in the year 2025 and should therefore lead to more political pressure to tackle the given problem.

Hypothesis 1: Problem factors – the underlying incentive structures and problem pressure – influence the prospects of water regime formation: While collective problems facilitate the formation of water regimes, the latter are more difficult to achieve in the case of transboundary externalities. The higher the problem pressure involved, the better the prospects for the creation of effective water regimes.

6 “International regimes are sets of implicit or explicit principles, norms, rules and decision-making procedures around which actor’s expectations converge in a given area of international relations” (Krasner 1983: 2).

7 Environmental problems typically lead to a multitude of initiatives, which have an impact on the problem but are not necessarily linked to the existence of a related environmental regime (Young 1999: 5).

53.2.1.2 Process Factors

Moving beyond the purely functional logic of the early 1980's (e.g. Keohane 1984), regime analysis has come to realize that incentive structures do not entirely determine the prospects of regime formation – a “turn to process in regime analysis” (Schramm Stokke 1997: 58). This is why there is reason to focus on political tools that help to transform the given constellation of interests and thereby promote international water cooperation. These “process factors” can be divided into mechanisms to balance incentive structures and instruments to reduce the transaction costs of regime formation (Marty 2001: 38ff.).

Mechanisms to balance incentive structures facilitate the resolution of problems related to transboundary externalities. Balancing incentive structures involves the provision of new or additional incentives: A party which has an incentive to externalize cost, for example, must be given the expectation that it would not be rewarding for her to continue that behaviour. The provision of new incentives usually happens in form of direct or indirect costs. While direct cost incentives comprise the benefits a party expects to gain from a proposed arrangement in the specific issue area (e.g. side-payments), indirect cost incentives refer to all forms of issue linkages, that is the promise of costs or benefits in an issue-area other than the one at stake (e.g. sanctions). Secondly, the formation of water regimes generally requires the development of *instruments to reduce the perceived transaction costs of regime formation*. Here, one can distinguish between information costs and negotiation costs. Information costs are related to uncertainty about (a) the nature of the respective problem; and (2) the behaviour of the other parties and/or third actors. Negotiation costs, on the other hand, derive from communication problems, fragmented decision-making procedures or a high number of involved actors. Political tools to minimize both information and negotiation costs are manifold and can include confidence-building meetings at the technical level, the exchange of data or the implication of independent experts.

Hypothesis 2: Asymmetric incentives and transaction costs are important obstacles to regime formation. The creation of international water regimes therefore requires the development of political tools that (1) balance asymmetric interests through direct or indirect cost incentives; and (2) minimize the underlying information and negotiation costs.

53.2.1.3 Institutional Factors

Problem and process factors determine the prospects of regime formation. But what determines the effectiveness of international water regimes? Most authors assume a causal relationship between the institutional design of a regime and its effectiveness (Brown-Weiss/Jacobson 1998; Victor/Raustiala/Skolnikoff 1998; Mitchell 2001) – institutional design matters. Again drawing on Marty (2001: 45ff.), I assume that successful water regimes need to be specific, feasible, flexible, open and equipped with a centralized organization structure.

Specific regimes are problem oriented and incorporate precise rules and procedures that structure the relevant actors' behaviour with a view to a better management of the problem at hand. If these precise rules and procedures are missing, there is scope for interpretation and rule avoidance and the effectiveness of the regime is bound to suffer. Feasible regimes choose their goals according to the available financial and personal resources: If the respective goals do not take account of the resources at hand, the regime effectiveness can be expected to decrease. Given the fact that resources to solve problems related to international river basin management are usually limited, there is reason to assume that water regimes tend to be more effective if their goals are of limited scope (Marty 2001: 47). Flexible regimes include institutional mechanisms that allow adapting to changes in the problem structure. A lack of flexibility is likely to lead to reduced regime effectiveness since the existing problem solving strategy may prove inadequate to cope with changing circumstances. Furthermore, effective water regimes need a centralized organization structure. In such a case, one central actor exercises the regime functions – usually an international organization. This should facilitate coordination, communication and monitoring and lead to more regime effectiveness. Open regimes allow for a high degree of public participation. If non-state actors are involved in the decision-making process, this should increase the available knowledge as well as the legitimacy of the respective regime and foster its effectiveness.

Hypothesis 3: The effectiveness of a water regime varies with its institutional design: The more specific, feasible, flexible and open and the more centralized its organization structure, the higher the effectiveness of the water regime.

53.2.1.4 Country-specific Factors

Determinants of international regime effectiveness are not restricted to institutional regime design but also include country-specific characteristics (Mitchell 2001: 13). The latter comprise all those specific features of regime member countries that influence the implementation and thereby the success of the respective regime (Brown-Weiss/Jacobson 1998: 7). Despite the obvious difficulty to integrate country-specific factors into an analytical framework – they range from cognitive-informational capacities, political-institutional attributes and economic-technological context to aspects of political culture and individual leadership – I make an attempt to consider and systematize their influence.

Of central importance is the concept of capacity (Jänicke 2002): Regime member countries have very different capacities to implement the agreed standards and/or to impose behavioural change on relevant national actors. Against this background, deficits in the effectiveness of environmental regimes can to a considerable extent be attributed to insufficient implementation capacities (Haas/Keohane/Levy 1993; Brown-Weiss/Jacobson 1998). But what exactly are the capacities that determine water regime effectiveness?

First, I consider the *economic-technological capacities* of regime members as an important influencing factor. It is an intuitive assumption that the socio-economic situation of a member country will affect the prospects of a regime: Levels of economic development vary a lot between countries and lead to very different scopes of action, especially between developed and developing countries. More specifically, I look at the economic-technological capacities of the national water sectors. If the latter do not possess sufficient (1) financial and administrative resources to plan and administer international water projects; and (2) technical capacities for data generation and project implementation, water regime effectiveness is likely to suffer. Secondly, there is reason to take into account the impact of *political-institutional capacities*. Given the impossibility to consider the influence of different political systems and regime types in this paper, I limit my analysis to the role of political stability. If the regime member countries are characterized by high levels of political stability, there are good prospects for high water regime effectiveness.

Hypothesis 4: The effectiveness of water regimes varies with country-specific factors: The higher the (1) economic-technological; and (2) political-institutional

capacities of the member countries, the more effective is the water regime.

53.2.1.5 Factors of International Context

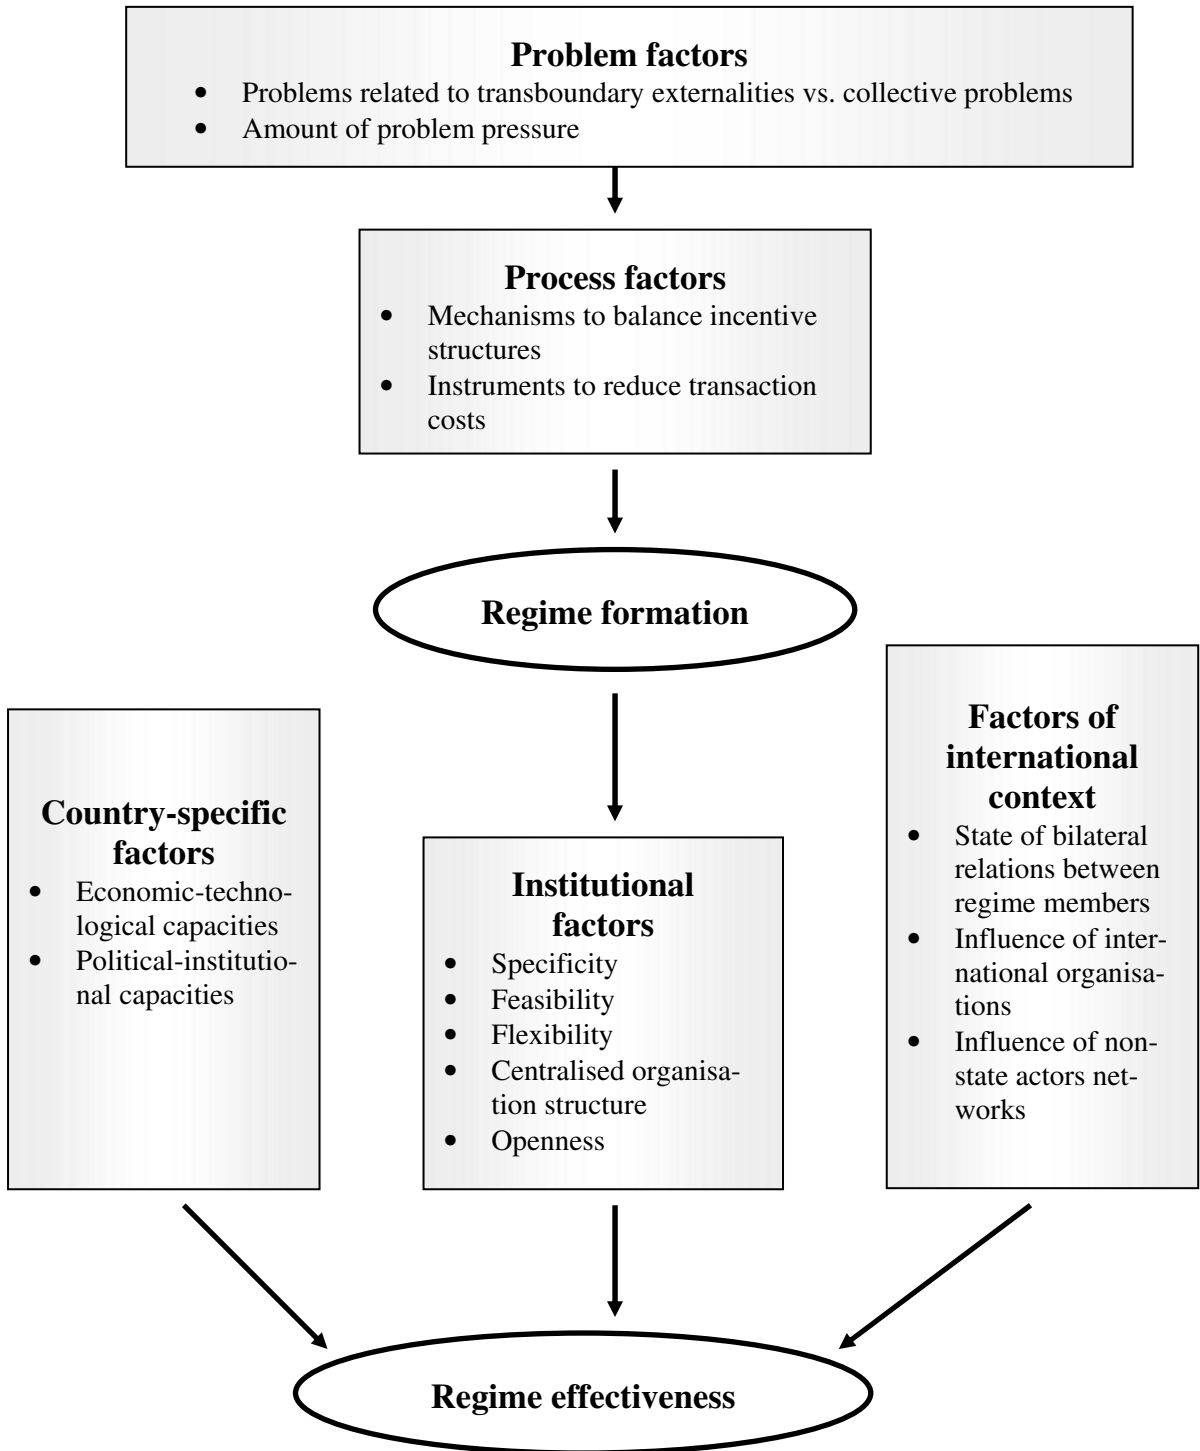

Beyond country-specific factors, the effectiveness of international regimes is influenced by factors related to international context (Mitchell 2001: 12). Here, I first need to take into account the *state of the bilateral relations between regime member countries*, which results from historical and current interactions and conditions, the patterns of communication, and the level of trust. The state of bilateral relations is judged by the existence or non-existence of foreign policy conflicts between member countries. If bilateral relations are strained by historical or current foreign policy conflicts, there is no trust basis for the implementation and/or further development of the water regime and its effectiveness is bound to suffer.

Furthermore, the effectiveness of international regimes varies with the *influence of international organizations* (Breitmeier 1997; Brown-Weiss/Jacobson 1998). This influence is exercised through multiple channels: International organizations provide financial resources, offer their technical and cognitive expertise and act as ‘independent’ mediators between conflict parties. Even though these activities are not per se positive, there is reason to assume that the support of international organizations promotes water regime effectiveness, especially in the developing world where financial, technical and cognitive resources are particularly scarce. In analogy, the effectiveness of international regimes is influenced by the *activities of non-state actors’ networks* that comprise international NGOs, local interest groups, journalists, policy experts or academics (Brown-Weiss/Jacobson 1998: 7; Mitchell 2001: 13). These networks mobilize and transfer knowledge about the problem at hand, initiate political campaigns and thereby contribute to a public debate that impacts on the evolution of the respective regime and should usually enhance its effectiveness.

Hypothesis 5: A water regime depends on its international context. Water regime effectiveness increases (1) the better the state of bilateral relations between regime members; and the higher the support by (2) international organizations; and (3) non-state actors’ networks.

Figure 53.1 summarizes the different components of the outlined research framework.

Figure 53.1: Political determinants of water regime formation and water regime effectiveness. **Source:** The author.

53.2.2 Methodological Considerations

In order to test my research framework, I conduct qualitative case studies based on a “structured and fo-

cused comparison” (George/McKeown 1985) defining and standardizing the data requirements for each case study according to the theoretically deduced variables. Afterwards, I engage in process tracing, that is,

I focus “on whether the intervening variables between a hypothesized cause and an observed effect move as predicted by the theories under investigation” (Bennett 2004: 22). Due to the indeterminacy of the research design – I have more inferences to make than implications observed (King/Keohane/Verba 1994: 119) – I cannot identify causal effects. However, this apparent shortcoming stems from a conscious decision: I think of the developed research framework as a means to systematize the most important determinants of water regime effectiveness – not as an empirical generalization.

With respect to the selection of cases, it is necessary to ensure variation in the explanatory variables, while allowing for the possibility of at least some variation on the dependent variable (King/Keohane/Verba 1994: 140ff.). On the basis of these criteria, I select four cases of Southern African water regimes: (1) The Permanent Water Commission on the *Okavango River Basin* (OKACOM); (2) the *Zambezi Action Plan* (ZACPLAN); (3) the *Zambezi River Authority* (ZRA); and (4) the *Lesotho Highlands Water Project* (LHWP).

The findings of these four case studies are based on the examination of primary and secondary sources. Where necessary and possible, additional data were generated through telephone interviews and email exchange with selected water experts in the region.

53.3 Empirical Findings

In this section, I first assess the effectiveness of the four water regimes (53.3.1) and then go on to identify the political determinants of water regime formation and effectiveness (53.3.2).

53.3.1 Assessing Water Regime Effectiveness

The first water regime under investigation is the *Permanent Water Commission on the Okavango River Basin* (OKACOM). The Okavango River originates in Angola, crosses Namibia and then discharges into the Okavango Delta in Botswana. While so far little Okavango water has been used, growing water needs since the early 1990's have led to plans for an increased water use and provoked tensions between the three riparian countries (Ashton 2003: 170). Thus, the riparian countries created OKACOM in 1994 for the conservation, development and utilization of common water resources (OKACOM Treaty 1994). Since then,

OKACOM has successfully institutionalized conflict potential, generated continuous dialogue at the political level and conducted a transboundary diagnostic analysis. While some behavioural change can be observed, the three riparian countries remain mainly concerned with national interests and sovereignty (Swatuk 2003: 129) and a river basin wide political perspective is far from being achieved (GEF 2002: 12). Despite some achievements and undeniable potential for improvement, OKACOM's effectiveness remains therefore rather limited.

The situation along the Zambezi River is even more difficult. Shared by Angola, Zambia, Zimbabwe, Namibia, Botswana, Malawi, Tanzania and Mozambique, the Zambezi is the region's largest river basin and “a veritable artery of life and development” (Söderbaum 2002: 118) for the eight riparian countries. While the Zambezi is generally rich in water, both weather extremes and population growth have put increasing pressure on the available water resources. As early as in 1987, the Zambezi riparian countries agreed on a *Zambezi Action Plan* (ZACPLAN) aiming at an environmentally sound management of the *Zambezi River basin* (ZACPLAN Treaty 1987). The comprehensive action plan consists of 19 sub-projects and envisages, among others, the development of a regional water law, the creation of a common monitoring system and the elaboration of an integrated management plan for the entire basin. However, the “ZACPLAN has not functioned as a powerful locomotive to promote environmentally sound management of the Zambezi river basin with participation of riparian countries, to the extent it was originally supposed to do” (Nakayama 1999: 398): The implementation of the ambitious water regime has been considerably delayed and only two of the sub-projects have led to visible results. Almost 20 years after the creation of the ZACPLAN, an integrated basin wide management is still a distant vision and the basin remains an “arena of different national interest in which the various riparian states are developing diverging policies and plans that are usually not compatible” (Chiuta 2000: 153). Since no behavioural change can be observed, the ZACPLAN can be qualified as ineffective.

While the ZACPLAN has so far been a failure, bilateral attempts for an international management of the Zambezi stretch between Zambia and Zimbabwe have proved more successful. Faced with electricity shortages after World War II, North and South Rhodesia felt the urgent need for a coordinated development of the common water resources – a need that led to the construction of the huge Kariba Dam be-

tween 1955 and 1976 (Tumbare 2002: 107). After the end of the federation in 1963, the two countries established the *Central African Power Corporation* (CAPCO) to allow for the continued operation of the Kariba Dam. In 1987, Zambia and Zimbabwe decided to replace the CAPCO with the *Zambezi River Authority* (ZRA) “to obtain for the economic, industrial, and social development of the two countries, the greatest possible benefit from the natural advantages offered by the waters of the Zambezi River and to improve and intensify the utilization of the waters for the production of energy and for any other purpose beneficial to the two countries” (ZRA Treaty 1987). The focus of the ZRA remains on the operation of the Kariba Dam but is extended to additional river development projects and environmental measures to combat the increasing water pollution. Within its limited mandate, the water regime can be regarded as relatively effective. The ZRA is “well established in its role as an operation and maintenance organization” (Rangeley/Thiam/Ander-sen/Lyle 1994: 42) and has recently done environmental capacity-building through the elaboration of an *Environmental Monitoring Programme* (EMP). On the downside, the water regime has failed to plan and implement additional river development projects, which indicates that the ZRA “could be perceived as a single task regime with little scope for spill over into broader co-operation” (Mutembwa 1998).

The *Lesotho Highlands Water Project* (LHWP) is situated in the Orange River basin shared by Lesotho, South Africa, Botswana and Namibia. The upstream part of the river basin features two fundamentally different riparian states: The mountainous Kingdom of Lesotho, a least developed country but relatively rich in water, and South Africa, the region’s political and economic giant suffering from mounting water scarcity – especially in the Gauteng Area that hosts 40 per cent of the country’s population and produces half of its wealth (Turton 2004a: 272–273). In this context, South Africa has since the late 1950’s pursued plans to transfer water from the water rich Senqu River in the Lesotho Highlands to the Vaal River in the Gauteng Area – a project that materialized with the signing of the LHWP between South Africa and Lesotho in 1986. The LHWP aims to enhance the use of the Senqu River by transferring – in four phases until 2020 – 70 m³/s of water to South Africa and by utilizing the transferred water to generate hydro-electric power in Lesotho, which also receives financial compensation in the form of royalties (LHWP Treaty 1986). Phases 1a and 1b of the LHWP have been successfully imple-

mented establishing a complex delivery system of dams and tunnels that currently diverts 29 m³/s of Senqu water to South Africa (Colombani 2003: 93). The LHWP can be considered as highly effective in the sense that it creates a ‘win-win situation’ for both countries “which would both be losers otherwise” (Conley/van Niekerk 2000: 137): While South Africa receives cost effective water to back up its economic growth, Lesotho benefits from both royalties and hydro-electricity to accelerate the development process of the country.

53.3.2 Political Determinants of Water Regime Formation and Effectiveness

How can one explain these different levels of water regime effectiveness? First of all, the case studies show that the underlying incentive structures do indeed influence the prospects of water regime formation. In the cases of OKACOM and ZACPLAN – both characterized by the threat of transboundary externalities – the initial constellation of interests proved an obstacle for cooperation, while the relatively symmetric incentive structure in the case of the ZRA – a collective problem – clearly facilitated the establishment of a water regime around the Kariba dam. However, one should not exaggerate the importance of incentive structures, which do not entirely determine the prospects of regime formation but rather serve as an indicator of a given initial situation that can be transformed during the negotiation process: As seen in the case of the LHWP, initially asymmetric incentives can be transformed into ‘win-win situations’. Also, taking a closer look at the ZRA case, one realizes that the incentives of cooperation partners are almost never fully symmetric. Even if two riparian states are affected by the same problem – electricity shortages in the case of the ZRA – the degree of their affectedness or their preferred solutions may differ and thus hinder water regime formation.

Furthermore, the empirical findings confirm the amount of problem pressure as a relevant influencing factor. As the case of ZACPLAN clearly illustrates, a lack of problem pressure may prevent far-reaching water cooperation:

[T]here is not a real issue on the Zambezi. The Zambezi has got so much water and so little is used, and there is no real threat. You can manufacture threats if you want, but nobody is interested in that (Piet Heyns, Interview 17 August 2004).

In the ZRA and LHW cases, on the other hand, high problem pressure linked to the visible problems of

electricity or water shortages facilitated the creation of more comprehensive problem solving mechanisms. These findings indicate that purely proactive initiatives for international river basin management that are not linked to clearly identified problems may lead to half-hearted solutions and implementation deficits.

With respect to the role of process factors, I had expected that asymmetric incentive structures were to be balanced by direct or indirect cost incentives to pave the way for water regime formation. This assumption was only confirmed in the case of the LHWP where Lesotho agreed to arrange for a water transfer when South Africa offered the payment of royalties and the provision of hydroelectricity in return. In the cases of OKACOM and ZACPLAN the riparian states created rather weak problem solving mechanisms that do not touch upon incentive structures. This is due to low problem pressure (as for ZACPLAN) as well as to high transaction costs resulting from a lack of hydrological data (especially for OKACOM). Also, one has to take into account the time perspective since it took several decades to balance incentive structures in the case of the LHWP.

Secondly, I had assumed that the establishment of water regimes required the use of political tools to reduce the transaction costs of the regime formation process – an assumption that was confirmed by all cases under investigation. Information costs are usually reduced through shared (feasibility) studies that generate new information and establish a common knowledge basis, while preferred strategies to reduce negotiation costs include the implication of ‘independent’ experts as well as confidence-building meetings at the technical level. Nevertheless, it is striking to note that the formation of all four water regimes under investigation was to an important extent facilitated by ‘situative’ political events: The ‘post-apartheid democratic moment’ in the case of OKACOM, the first *African Ministerial Conference on the Environment* (AMCEN) in the case of the ZACPLAN, the establishment of the federation between Rhodesia and Nyasaland in the case of the ZRA and the regime change in Lesotho in the case of the LHWP. This indicates that the formation of international water regimes is not entirely in the hands of the riparian countries, but also requires favourable situative events that can hardly be integrated in explanatory frameworks.

With view to explaining the effectiveness of the four water regimes, I first need to emphasize that regime formation and effectiveness are closely interrelated in the sense that problem and process factors do not only determine the prospects of regime formation

but also impact on the effectiveness of the problem solving mechanisms: While the balancing of incentives in the case of the LHWP leads to a mutual interest in implementation and thereby promotes regime effectiveness, asymmetric interests and the absence of problem pressure in the ZACPLAN case lay the foundation for the ineffectiveness of the water regime.

As regards to the hypothesized importance of institutional regime design, the empirical findings firstly confirm that specificity is advantageous: While the LHWP and the ZRA are problem-oriented and contain specific rules and procedures that effectively guide the actors’ behaviour, the ZACPLAN is little more than a series of vague projects that do not include any concrete rules and procedures. Furthermore, especially in light of the region’s limited resources for international river basin management, it is not advisable to burden a water regime with the multiple and highly complex goals of the integrated management approach since this may endanger the feasibility of the undertaking (as seen in the case of the ZACPLAN). This does not affect the desirability of integrated river basin management but raises questions concerning its feasibility. The case of the LHWP demonstrates that it may be more promising to start with limited but problem-oriented regimes that can then be extended over time.

Also, the case studies indicate that water regimes should contain elements of flexibility. The strictly ‘output-oriented’ ZACPLAN with its 19 subprojects proved overly rigid and little conducive to implementation (Granit 2000: 7–8). The advantages of a flexible approach are further illustrated by the LHWP that allows for a continuous monitoring and adjustment of regime provisions: In light of changing circumstances – the water needs in South Africa had initially been overestimated – the project phases two to four were put on hold in a problem-oriented manner. Furthermore, the empirical findings confirm the hypothesized importance of a centralized organization structure. As seen in the OKACOM and ZACPLAN cases, the lack of a centralized institution for project planning and coordination – for example in form of a river basin secretariat – has a clearly negative impact on water regime effectiveness. This is confirmed by the LHWP experience where the initially decentralized organization structure proved ineffective and had to be centralized. With respect to assumed need for regime openness, the case study findings are less clear. While the ZACPLAN is the only water regime that provides for public participation, openness has not been a characteristic of the decision making process of the

regime and decisions have been taken in groups of limited representation (Lamoree/Nilsson 2001: 35). Even though recent attempts to increase public participation in OKACOM and the LHWP have proved beneficial, the findings do not allow definite conclusions on the relevance of regime openness.

Assessing the relevance of country-specific factors, I find that water regime effectiveness indeed varies with economic-technological capacities. The OKACOM and ZACPLAN case studies unveil striking capacities deficits in the national water sectors, which lack the financial, technical and administrative capacities to plan and implement projects of international river basin management. The high capacities of the South African *Department of Water Affairs* (DWAF), on the other hand, have proved crucial for the success of the LHWP. With regard to the influence of political-institutional capacities, one can observe a striking lack of political stability: Almost all countries in the region having suffered from protracted civil war and violent conflict throughout the past decades, political instability is a major obstacle to effective water cooperation. The case of Angola in the context of OKACOM is exemplary: Due to decades of civil war that only ended in 2002, the Okavango Basin in Angola is still littered with landmines and hardly accessible – a situation that prevents project preparation, in particular the generation of hydrological data (Porto/Clover 2003: 78), and thereby limits OKACOM's effectiveness.

Finally, the case studies reveal the importance of factors of international context. The region is characterized by a history of political tensions, which go back to the anti-colonial liberation wars, the conflict with the Apartheid state in South Africa and the dynamics of the Cold War. Even though tensions have eased since the early 1990's, bilateral relations are still strained by historically rooted conflicts and distrust. This problem has exercised a very negative impact on the water regimes under investigation. In the case of the ZRA, for example, the historical debate about the benefits of the federation between North and South Rhodesia – now Zambia and Zimbabwe – created the perception of historically disadvantaged states and communities, issues that still inform debate about the ZRA and prevent more far-reaching water cooperation (Mutembwa 1998). Lastly the empirical findings underline the relevance of third actor support. In a region suffering from considerable development deficits, the activities of international (donor) organizations are of great importance: The GEF in the case of OKACOM, the World Bank in the case of the LHWP

as well as UNEP in the case of the ZACPLAN all play an important role with respect to the mobilization of financial resources and/or national capacity building. Despite the undeniable benefits of these activities, one should not overlook their negative side-effects, for instance, problems related to slow and overly bureaucratic project implementation (GEF in the OKACOM case) or a lack of ownership (UNEP in the case of ZACPLAN). Beyond international organizations, the cases of the LHWP and especially of OKACOM illustrate that the activities of non-state actors can significantly contribute to capacity-building and to the launch of an informed public debate.

I think that the activities of organizations that are working together with OKACOM (...) are complementing the activities of OKACOM in areas where OKACOM would not have been effective. OKACOM is a government organization but it is much better for an NGO to work with people on the ground than for government officials to do it. So it is a huge advantage to have this complementarity in the activities of these other organizations (Piet Heyns, Interview 17 August 2004).

53.4 Conclusions

The findings of the four case studies can be summarized as follows:

- The characteristics of a given problem in international river basin management influence the chances of water regime formation: If the underlying cooperation incentives are largely symmetric and the involved problem pressure is high, there are good prospects for the creation of effective water regimes.
- To reduce the transaction costs of water regime formation, countries typically rely on common studies for data generation and project preparation, the mediation of international experts and trust-building meetings at the technical level. If in addition asymmetric interests are balanced through cost incentives, one can expect far-reaching and effective water regimes.
- Effective water regimes need adequate institutional design: Water regime effectiveness is enhanced by problem-oriented and flexible management approaches that take account of the available resources and are equipped with a centralized organization structure.
- The effectiveness of international water regimes varies with country-specific capacities: Sufficient economic-technological capacities in the national

water sectors and political stability lay the foundation of water regime effectiveness.

- The successful management of international river basins requires a favourable international context: If the bilateral relations between regime members are characterized by mutual trust and cooperation and third actors – international organizations and/or non-state actors – support capacity building and civil society participation, there are good prospects for water regime effectiveness.

How can one judge the relevance of these findings? As already mentioned, I am unable to draw causal conclusions since the developed research framework does not allow for the identification of single effects. This means that I do not know to what extent the failure of the ZACPLAN can be attributed to asymmetric incentives, the lack of problem pressure, inadequate regime design or national capacity deficits. Also, I face a typical dilemma of multi-case comparisons: As the nature, scope and context of the water regimes under investigation are quite different; one might question the comparability of the four cases:

Regimes are specific and embedded in history, geography and culture. There is no one size fits all. They are needs driven. This is where many commentators make a mistake in my view by comparing apples to eggs... (Anthony Turton, Email 30 July 2004).

Nevertheless, this is no reason to abandon multi-case comparisons. When understood as a systemization of the most important driving forces and not as an empirical generalization, the findings do offer some valuable insight into the conditions for success of international river basin management. Here, it is especially the integration of country specific and contextual factors – so far largely neglected in the literature on international river basin management – that is of particular interest: The high relevance of national capacity deficits, political instabilities and strained bilateral relations illustrates that success and failure in international river basin management need to be discussed beyond the traditional ‘institutional design matters’ approach. Of course, one may object that capacity deficits and instabilities are unusually developed in the Southern African region. But since large parts of Asia, Latin America and Eastern Europe face at least similar problems, there are good reasons to pay greater and more systematic attention to these influencing factors.

With view to giving practical policy advice, it may seem unattractive to recommend the build-up of national capacities or the creation of a favourable politi-

cal context since this is less feasible than the adoption of a certain institutional design – at least in the short term. Nevertheless, there is reason to believe that national capacity building and the creation of a favourable political context both at the national and international level is the key to success in international river basin management – in Southern Africa but also in the developing world as a whole. This means that ‘neutral’ third parties (international organizations and non-state actors) need to intensify their efforts for capacity building and mediation between conflict parties (Turton 2003: 98). Finally, the findings of the Southern African case studies should lead to caution with respect to the today omnipresent claims for integrated river basin management – especially in the context of developing countries. This does not mean that one needs to question the general practicability of the integrated approach as done by Marty (2001: 398). But against the background of the experiences with the ZACPLAN, it seems more promising to first bundle the scarce resources and capacities in a problem-oriented and functional manner before considering extending and integrating the management approach over time.

54 Can 'Integrated Water Resources Management' Silence Malthusian Concerns? The Case of Central Asia

Martin Kipping

54.1 Introduction^{1, 2}

The debate on international water problems is largely dichotomous. It is split between the more analytical perspective of *International Relations* (IR) and related social sciences, on the one hand, and rather prescriptive, problem-solving contributions, on the other hand. While the IR discourse focuses on resource conflicts, the prospects of water wars, and opportunities or problems of international water regimes, the prescriptive discourse concentrates on normative concepts like the 'Dublin Principles'³, international water law, or '*Integrated Water Resources Management*' (IWRM)⁴.

This chapter will explore how these rather separate spheres can link up productively to ease solving international water problems. Therefore, it demonstrates the complementary character of Malthusian analyses⁵ of resource conflicts and the concept of IWRM by scrutinizing a regional example of severe water-related problems.

Central Asia – and the Aral Sea basin in particular – clearly constitutes a water 'hot spot'. Malthusian analysts highlight international upstream-downstream conflicts over relative water distribution (hydropower generation in upstream countries vs. irrigation in downstream countries), growing transboundary conflicts over absolute water distribution (notably caused by ambitious Turkmen development projects and the expected recovery of Afghan agriculture), as well as regular intra-state violence motivated by competition over scarce water resources.

This chapter shows how most of these problems could effectively be handled by adopting IWRM principles for water management: Basin-wide inter-sectoral integration would create opportunities for win-win solutions; demand-management could largely reduce overall pressure on water resources; and decentralized management structures would mitigate local water conflicts.

However, neither Malthusian analyses nor the concept of IWRM contain receipts for effectively implementing these potential solutions. On the contrary, a perspective of political economy – the liberal strand of IR – reveals how vested interests prevent reforms within downstream cotton-growing agriculture, which are prerequisites to inter-sectoral flexibility, a shift towards demand-management and the decentralization and democratization of local water management. In consequence, both Malthusian IR approaches and prescriptive concepts like IWRM need to be complemented by a profound knowledge of domestic politics within affected states if they are to identify realistic ways for solving water scarcity problems. In the context of global environmental change in general and cli-

1 An earlier version of this chapter has been accepted for publication in *Water International*. The author would like to thank WI's editor for granting him the right of pre-publishing it within this volume.

2 This chapter expresses the author's personal opinion and cannot be attributed to the German Federal Government.

3 These four key principles of good water management have been enshrined at the 1992 International Conference on Water and the Environment in Dublin. They highlight environmental concerns, stakeholder participation, gender considerations as well as the need to manage water as an economic good. Cf. <<http://www.gwpforum.org/servlet/PSP?iNodeID=1345>> (24 August 2007).

4 See section 55.4 for a discussion of this broadly accepted concept of good water management. Argawal/det al. 1999 provide a comprehensive, authoritative introduction to IWRM.

5 See box 54.1 for a description of the Malthusian discourse. Since 'Malthusianism' as such does not provide a full-fledged analytical framework or theory, the term 'Malthusian analysis' should be read as 'analysis informed by the Malthusian philosophy'.

Box 54.1: The Malthusian Discourse. The text was written by the author.

The (Neo-)Malthusian approach derives its name from Thomas Malthus' *Essay on the Principle of Population* (1798), which draws a gloomy picture of demography-induced resource scarcity, necessarily leading to either famine or war. Generally speaking, Malthusians are concerned with conflicts induced by a mismatch of (increasing) demand and insufficient offer of natural resources, due to demography, changing consumption and production patterns, combined with a shrinking resource base caused by overexploitation or global phenomena such as climate change, or the infinity of natural resources in general. With regard to water conflicts, (Neo-)Malthusians

point out the conflictive consequences of growing water scarcity. While both Malthusians and Neo-Malthusians share this general conviction, classic Malthusians perceive water conflicts as a direct consequence of increased competition over water (cf. Starr 1991), whereas Neo-Malthusians stress that water scarcity rather indirectly leads to conflicts via its socio-economic consequences like decreasing agricultural productivity or overall economic decline (cf. Homer-Dixon 1999). For a critique of Malthusian approaches to 'hydropolitics', see Kipping (2005, chap. 51).

mate change in particular, respective problem-solving capacities are becoming even more urgent to develop.

The next section lays out the overall structure of the chapter after a more detailed explanation of the problem at hand.

54.2 Analytical vs. Prescriptive Views on International Water Problems

If problems related to freshwater have grown in past decades due to demography, economic development and the internationalization of river basins, so has the number of concepts aiming to explain and alleviate these problems. On the one hand, analytical concepts like 'water stress' (Falkenmark 1989), 'adaptive capacity' (Turton/Ohlsson 1999), 'virtual water' (Allan 2003b) or 'environmental security' (Brauch 2003, 2003b, 2008a) have been developed in the realm of social sciences, including IR. Many of these contributions were to clarify in how far Malthusian assumptions about scarcity-induced water conflicts are justified. On the other hand, rather prescriptive concepts such as the 'reasonable and equitable utilization' of transboundary waters, the minimum ecological flow requirement, the 'Dublin Principles' or the 'Bonn Keys'⁶ have resulted from diverse political fora, where policy-makers and practitioners have formulated recommendations, guidelines and norms for better water management. Based on these principles, IWRM has emerged as the state-of-the-art model of ideal water management.

One has to note, however, that the water discourse's analytical and prescriptive layer remain disconnected. Despite first efforts to bridge the gap

(Merrett 2005), both constitute largely separate spheres, although they should ideally be complementary and build on each other: Analytical approaches are meant to identify, forecast and render intelligible water problems. Based on their analyses, prescriptive guidelines and practical tools can be developed or chosen in order to solve these problems. In practice, however, this complementary relationship rarely materializes. Most work on water problems either concentrates on empirical analysis or focuses on principles of 'good' water management. Although this dichotomy is not surprising considering the different origins of the analytical and prescriptive concepts, it certainly constitutes a missed opportunity.

This chapter explores ways for overcoming the dichotomy by scrutinizing a well-known regional example of severe water-related problems: Central Asia (chap. 55 by Raket; chap. 56 by Wunderer; chap. 57 by Martius/Froeblich/Nuppenau). This region – with its highly symbolic Aral Sea (partly) turned into Aral Desert – is a 'hot spot' for Malthusian analysts, who highlight serious inter- and inner-state water conflicts (Klötzli 1996, Giese/Sehring 2007: 10–20). In addition, Central Asia is probably the region where international donors have deployed most efforts to improve water management. Among others, programmes under the label of IWRM are implemented in the Ferghana Valley (Swiss Development Cooperation; IWMI/SIC 2005) and in the Chu and Talas River basins (TACIS). Transboundary water cooperation is also meant to play a prominent role within the European Union's 2007 Central Asia Strategy (<<http://register.consilium.europa.eu/pdf/en/07/st10/st10113.en07.pdf>>, 16 February 2008). Linking the water discourse's analytical and prescriptive layer, this chapter investigates in how far IWRM actually offers adequate answers to Malthusian concerns vis-à-vis Central Asian water problems.

6 See: <http://www.water-2001.de/outcome/BonnKeys/Bonn_Keys.pdf> (24 August 2007).

Figure 54.1: The Aral Sea Basin's Main Watercourses. **Source:** McKinney (2003: 189); reprinted with permission of the copyright holder.

The text proceeds as follows: First, water conflicts in Central Asia are analysed under a Malthusian perspective (55.3). Second, components of IWRM are discussed as potential solutions to these conflicts (55.4). The question then arises what impedes the implementation of IWRM-inspired solutions. Respective obstacles are identified third (55.5). The chapter concludes with a recommendation for future research on 'hydropolitics' (55.6).

54.3 Malthusian Concerns Regarding Central Asia

Central Asia in general and the Aral Sea basin in particular might be the region where humankind has most consequently realized its 'hydraulic mission'. While the Syr Darya and the Amu Darya have seen ir-

rigated agriculture for more than 2,000 years (Glazovsky 1995), it is not until Soviet times, however, that development planners have fundamentally changed the basin's ecological balance. Responding to the Soviet Union's striving for autarky in cotton production, irrigation expanded from about 2.5 million hectares to 7.5 million hectares of irrigated area (O'Hara 1998: 4). In consequence, the river water inflow into the Aral Sea decreased from about 56 km³/year prior to 1960 to 43 km³/year in the 1960's, 17 km³/year in the 1970's, and it almost ceased in the 1980's (O'Hara 1998: 4). The resulting desiccation of the Sea and the complete halt to its fishing industry did not come as a surprise but were deliberately taken into account as negative side-effects of the ambitious irrigation programmes.

Despite its enormous ecological costs, this development scheme did work until the end of the 1980's.

Table 54.1: Socio-economic Indicators of the Aral Sea Basin's Riparian Countries (2005). **Source:** CIA Factbook (2005).

	GDP (PPP) billion \$	Population thousands	GDP/capita \$ (PPP)	Surface area km ²	Irrigated area km ² (est.)
Afghanistan	21.5	29,930	800	647,500	23,860 km ²
Kazakhstan	132.7	15,190	8,700	2,717,300	23,320 km ²
Kyrgyzstan	9.3	5,150	1,800	198,500	10,740 km ²
Tajikistan	8.8	7,160	1,200	143,100	7,200 km ²
Turkmenistan	29.4	4,950	5,900	488,100	17,500 km ²
Uzbekistan	52.2	26,850	1,900	447,400	42,810 km ²

With the split-up of the Soviet Union in 1991, however, the Moscow-led overall management of the basin's resources disappeared and competing interests stopped being balanced by cross-Union compensations. The Amu Darya basin had been international even before, with Afghanistan and Iran as non-Soviet riparians. Nevertheless, this had had only minor consequences if compared to the independence of Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan and Uzbekistan. The dismantling of the Soviet Union led to a constellation where the Syr Darya, for instance, crosses four international borders before reaching the Aral Sea (figure 54.1). Towards the end of the Soviet Union, regional water management had already turned increasingly conflictive, leading to the establishment of two basin management organizations – one for the Syr Darya and one for the Amu Darya –, both based in Uzbekistan (Sehring 2002: 11). Yet, the main directives were still received from Moscow, quotas being set by the Ministry of Land Reclamation and Water Management in close coordination with the Ministry of Energy (ICG 2002: 6). In addition to the full-fledged internationalization of the Aral Sea basin in 1991, demography and the post-Soviet economic crisis led to increased pressure on agriculture, accompanied by a sharp deterioration due to lacking maintenance and repair of irrigation infrastructure. In this context, diverse inter- and intra-state water conflicts got apparent, which will be discussed in the following sections.

54.3.1 International Conflicts over Relative Water Distribution

The key conflict regarding the Syr Darya is over seasonal flow regulation, as the latter commands the availability of water for hydropower generation in upstream countries and irrigation in downstream countries. The ENCOP environmental conflicts research group has termed the distribution of water over time

“relative water distribution” (Libiszewski 1996a: 128–131). Hence, the Syr Darya's waters are cause of a relative distribution conflict. How did this conflict develop?

In Soviet times, numerous reservoirs were built in the two upstream Soviet Republics of Kyrgyzstan and Tajikistan in order to guarantee sufficient irrigation water downstream in late summer, when the natural water flow from snow and glacier melt decreases. Hydropower generation only came as an additional gain from the reservoirs, while priority was clearly given to irrigation needs in Uzbekistan, Kazakhstan and Turkmenistan. This perspective changed when the former Soviet Republics gained independence (Wegerich 2004): As supply of energy resources from downstream countries (electric power and coal from Kazakhstan, fuel oil and gas from Uzbekistan) switched to world market prices and the two comparatively less developed upstream countries started to feel the financial burden of maintaining the large dams on their territory, their interest in changing river management priorities towards hydropower generation increased. In this context, the newly independent riparian states adopted a provisional agreement in 1992 to uphold the Soviet-time management scheme, fearing the unexpected consequences of uncoordinated water use. Since 1995, bilateral barter deals were concluded on an annual basis, rewarding river regulation services by Kyrgyz dams with the free delivery of energy resources from downstream states and a purchase guarantee for surplus Kyrgyz electricity in summer months. In March 1998, this cooperation scheme was renewed within the framework of the *Central Asian Economic Community* (CAEC), when the Prime Ministers of Kazakhstan, Kyrgyzstan, and Uzbekistan signed a treaty on the use of water and energy resources of the Syr Darya basin. They were joined by Tajikistan in 1999 (Antipova/Zyryanov/McKinney/Savitsky 2002).

However, these agreements proved unreliable (De Martino et al. 2005: 22). Kyrgyz authorities responded

to unmet promises of energy supply from downstream states by prioritizing hydropower generation in the regulation of the main Toktogul reservoir (Giese/Sehring 2007: 16). Consequently, the share of Toktogul releases for irrigation needs decreased from 69 per cent to 34 per cent since 1993, while winter releases for hydropower generation increased from 31 per cent to 66 per cent (Giese/Sehring/Trouchine 2004: 8). This led to downstream flooding in winter months – due to the frozen and dammed river bed – and to downstream water shortages in the crop-growing season.

The lack of compliance with regional agreements can be explained by the prisoners' dilemma in which the riparian states are trapped (cf. Haftendorn 2000 and Marty 2001 as prominent examples for the institutionalist perspective on international water conflicts). In absence of an overall authority compliance with agreed-upon rules becomes a rather risky undertaking. If Kyrgyzstan reduces hydropower production in winter, for instance, it nevertheless cannot be sure that subsequent compensations materialize in case that the following summer's irrigation needs are below average thanks to above-average rainfall. Consequently, the riparian states lack trust in each other, thus increasing the unreliability of their common agreements.

This upstream-downstream conflict over relative water distribution is a good illustration of Aaron Wolf's argument on the importance of institutions for the successful management of international water conflicts (Wolf 2001: 10): The pace of change (i.e. the internationalization of the river basin) exceeds the institutional capacity to absorb that change. The two river basin organizations created in Soviet times are not recognized by riparians other than Uzbekistan and factually operate only on Uzbek territory. With the *International Fund for the Aral Sea* (IFAS) and the *Interstate Council for the Aral Sea Basin* (ICAB), international donors have set up externally-driven institutions without real capacity to influence regional water policies (Sehring 2002: 16–18). The *Interstate Commission for Water Coordination* (ICWC) performs better in this regard, but is also lacking substantial authority (Giese/Sehring 2007: 18). It seems that only the old Soviet network of water experts prevents an escalation of the water conflict (Dukhovny 2004: 103). Bilateral negotiations take place annually at the level of (vice) prime ministers, where seasonal water distribution and the delivery of energy resources are decided upon.

Correlating with Malthusian theses, the relative distribution conflict got virulent with the river water's increase in importance for the riparian states in general and for Kyrgyzstan in particular. As industry almost completely collapsed after independence and other natural resources – with the exception of some limited gold reserves – are scarce in this largely mountainous country, water is perceived as Kyrgyzstan's only wealth. A growing nationalist discourse in Kyrgyz politics demands payments for the water from downstream users just like Kyrgyzstan has to pay for fuel imports. In 1997, the Kyrgyz parliament even adopted a law postulating this principle for regional water cooperation (O'Hara 1998: 6).

54.3.2 International Conflicts over Absolute Water Distribution

While the relative distribution conflict between upstream hydropower generation and downstream irrigation clearly is at the centre of the region's water problems, issues of absolute water distribution progressively gain importance. Together with the management regime of the big reservoirs, the quotas for water abstraction from Soviet times were confirmed in 1992 (table 54.2).

The quotas potentially restrict water use mostly in agriculture, as irrigation accounts for over 90 per cent of regional water consumption (defined as the amount of water abstracted and not returned to the original water body). Currently, however, not all riparian states make full use of their quota, since the deterioration of irrigation infrastructure limits their capacities for water abstraction. Kyrgyzstan, for instance, leaves more than 2 km³ of its water share to downstream neighbours. Yet, this does not lead to additional water reaching the Aral Sea, as most water unused by upstream regions is consumed by irrigated agriculture in the Sea's delta area, where canal tail ends already suffer from regular water scarcity in dry years.⁷ In addition, water consumption upstream is supposed to rebound in the future, as the Kyrgyz and the Tajik economy recover from post-independence economic crisis, respective civil war. What is more, the recovery of Afghanistan from civil war and Taliban rule raises some additional concerns.

7 Even hydropower-driven winter releases from Toktogul do not necessarily reach the Aral Sea, as large volumes of water need to be directed to the Arnasaj-depression in order to lessen flooding problems in Uzbekistan (Giese/Sehring 2007: 16)

Table 54.2: Origin of River Flow and Water Allocation in the Aral Sea Basin. **Source:** Adapted from McKinney (2003: 193).

Country	Amu Darya		Syr Darya	
	Originating river flow (km ³ /year)	Quota (km ³ /year)	Originating river flow (km ³ /year)	Quota (km ³ /year)
Afghanistan	11,6	0	0	0
Kazakhstan	0	0	2,4	12,3
Kyrgyzstan	1,6	0,2	27,6	4,0
Tajikistan	59,9	9,1	1,0	2,5
Turkmenistan	1,5	22,0	0	0
Uzbekistan	4,7	33,9	6,2	19,7
Total	79,4	65,2	37,2	38,5

It is expected that Afghan water consumption will increase soon, as its rural population has few economic alternatives to irrigated agriculture besides poppy cropping. This will significantly reduce the flow of the Amu Darya, where competition over absolute water distribution is already intense. International development agencies accelerate this trend by assisting with the rehabilitation of Afghan irrigation infrastructure, aiming at stabilizing the war-torn country (Giese/Sehring/Trouchine 2004: 20–23).

Further pressure on the Amu Darya results from ambitious development projects in Turkmenistan. First, the Turkmen government is currently extending the Karakum Canal, the world's longest canal (1,300 km), which accounts for 19 per cent of total water abstraction from the Amu Darya. As the canal is not lined with cement, just dug into the desert sand, water losses through infiltration are enormous (Giese/Sehring/Trouchine 2004: 13–16). Second, the former Turkmen president Niyazov has announced the creation of an artificial 'Lake of the Golden Century' in the Karakum desert, which is planned to provide additional opportunities for irrigation, but also for recreational activities until 2010. Although the Turkmen side affirms that the Lake will be alimented solely by drainage water, this does not seem to be realistic. In order to guarantee a minimum quality of the Lake's water – if possible at all – additional water will have to come from the Amu Darya (Giese/Sehring/Trouchine 2004: 17–19).

Increasing Turkmen water abstraction from the Amu Darya risks escalating already existing conflicts with Uzbek farmers in the river's delta. Near the Tuyamuyun Hydroengineering Complex, where irrigation canals routinely cross the Uzbek-Turkmen border, competition over irrigation water has already motivated Turkmen authorities to construct an additional – highly inefficient – primary canal, located

exclusively on Turkmen territory, intended to decrease dependence on Uzbek water delivery (Giese/Sehring/Trouchine 2004: 17). As Turkmen and Uzbek farmers in these downstream regions are increasingly insecure of getting sufficient irrigation water, they sometimes deliberately block drainage canals in order to assure at least a minimum of soil moisture for the following year, though being aware of the fact that this significantly accelerates the salinization of their soil (personal communication, Elke Herrfahrtdt).

Although transboundary skirmishes between local communities have already been reported, competition over scarce irrigation water has not led to inter-state violence up to date. However, the foreseeable sharp increase of water scarcity in downstream regions augments the prospects of further deteriorating relations between Turkmenistan and Uzbekistan: "There have ... been continued problems in shared irrigation zones. Confronted with water shortages, Uzbeks and Turkmen in the lower Amu Darya region have sent raiding parties across the border to destroy pumping stations and irrigation canals" (O'Hara 1998: 7). It is not necessary to adhere to water-war scenarios to suppose that conflicts over absolute water distribution will contribute to regional instability and create enormous challenges for international cooperation. The realist school of IR in particular predicts harsh reactions by downstream Uzbekistan – the region's dominant power – in case its national water security is seriously threatened by upstream states (cf. Lowi 1993; Waterbury 1997).

54.3.3 Intra-state Scarcity Conflicts

Research has revealed that water conflicts tend to be more intense the lower their geographical scale. While no international water war has ever occurred in

modern times⁸, local water conflicts can turn extremely violent (Wolf 1998).

This also shows to be true for Central Asia (ICG 2002: 5), where violent conflicts over water are already reported from ancient times (O'Hara 1998: 3). In areas where overall river flow, storage capacities and distribution networks cannot guarantee sufficient irrigation water for all farmers, water distribution gets a highly conflictive issue. Water-stealing among farmers and village communities is a usual phenomenon, and distribution points frequently need to be guarded during the irrigational season. Similar to the Turkmen-Uzbek case referred to above, it is not uncommon to see physical solutions to water-stealing problems: Water users suffering from water stealing dig alternative canals in order to better control water delivery to their fields. Although these non-lined and uncovered canals lead to enormous water losses (usually up to 80 per cent), their beneficiaries still regard them as the only and thus rational way for solving their problems with water stealing (Herrfahrdt/Kipping/Pickardt/Polak/Rohrer/Wolff 2006). The inability to reach consensual and viable agreements between competing water users illustrates the severity of local water conflicts. Inter-personal violence occurs when guards confront water thieves or in cases individual farmers or whole village communities resort to violence against competing water users: Conflicts over local water distribution frequently end up in brawls (Giese/Sehring 2007: 17). Casualties are not exceptional, although these conflicts normally stop short of becoming deadly. As rivers and canals frequently cross international borders - most visibly in the Ferghana Valley - these essentially local conflicts often contain a transnational dimension, what makes them even more difficult to resolve. Polarization and escalation along ethnic lines occurs as well (De Martino et al. 2005: 28), although these cleavages seem to be overstated in the media.

In addition, competition over water indirectly leads to conflicts via migration, a causal mechanism stressed by Thomas Homer-Dixon (1999: 93-96). Competition over water is often concealed by competition over land, as agricultural land in Central Asia normally means irrigated land due to the semiarid and arid climate. Pressure on cultivable land is highest

in the densely populated Ferghana Valley, sometimes aggravated by soil degradation such as water-logging and salinization. In combination with lacking economic alternatives, people either look for work abroad (Russia and Kazakhstan are frequent destinations) or move to less densely populated areas like the Kyrgyz Batken Oblast. However, there is hardly any unused but usable land left over. Thus, these scarcity-induced migration movements result in increased competition over resources in the places of destination, sometimes causing violent conflicts, too. This occurred in Kok-Tash and Shorsu as well as in the Arka and Kistakuz regions of south-west Kyrgyzstan, for instance (De Martino et al. 2005: 18-19, 25-28). The well-known Osh clashes between ethnic Kyrgyz and ethnic Uzbek in 1990 also appear to have been motivated by competition over irrigated land. These (intra-state) riots, in which over 300 people perished and more than a 1,000 were injured, occurred after a Kyrgyz co-operative was given permission to use irrigated lands on an Uzbek Kolkhoz to construct residential buildings (O'Hara 1998: 6).

54.4 IWRM as a Possible Answer to Malthusian Concerns?

As explained above, serious water conflicts - international relative and absolute distribution conflicts as well as intra-state scarcity conflicts - do exist in Central Asia, and several factors make us believe that their intensity is likely to increase in the future. How could regional water (and related) policies prevent or mitigate these conflicts in order to contribute to a more peaceful and cooperative development of the region?

IWRM figures as the 'mantra' (Waterbury 1997: 279) of ideal water management and is promoted as such in Central Asia. What options does the concept offer for handling the water conflicts described above? In order to answer this question, the concept of IWRM will be shortly presented in the following paragraphs before its applicability to the different types of Central Asian water conflicts will be discussed.

IWRM developed in response to the traditional 'engineering', supply-side approach to water management: Traditional water policies mostly focussed on technical solutions for increasing quantitative water supply (i.e. by building barrages), without caring much about social aspects, efficiency or environmental concerns. IWRM instead pursues a holistic, integrated approach to water management. The *Global*

8 This does not imply that there are no inter-state armed skirmishes over water (see i.e. Gleick 1993). However, no scholar has yet convincingly shown that an international war (according to any of the established definitions) has been fought primarily over water.

Water Partnership (GWP) defines IWRM as “a process which promotes the co-ordinated development and management of water, land and related resources, in order to maximize the resultant economic and social welfare in an equitable manner without compromising the sustainability of vital ecosystems” (Argawal et al. 1999: 22; cf. also WWAP 2003: 299; GWP 2005). But what does this mean in practical terms? Following the understanding of IWRM put forward by Herrfahrdt, Kipping, Pickardt, Polak, Rohrer and Wolff (2006), IWRM requires three-fold integration: ecological, sectoral and regulatory integration.

Ecological integration demands that water management adopts an eco-system approach, systematically taking into consideration ecological interdependencies. In consequence, water should be managed according to hydrological boundaries, i.e. within catchment and sub-catchment areas, not along artificial administrative delimitations (Argawal et al. 1999: 24). Managing hydrological units as a whole eases the internalization of positive and negative externalities arising downstream, such as reduced water flow, pollution, but also flood protection by upstream dams. Furthermore, questions of water quantity should not be isolated from aspects of water quality (Argawal et al. 1999: 25), as both are important, and they are inter-linked: Available water might be sufficient in quantity but of insufficient quality for household consumption or even for irrigation. Water users might also compensate poor water quality by increasing their quantitative demand. If irrigation water is saline, for instance, the risk augments that fields salinize. In this case, considerable amounts of water are needed for leaching the fields. In the past, water quantity issues have dominated water policies, whereas problems of pollution, changes in temperature, or eutrophication have received much less attention. Ecological integration also demands that development planners consider the impacts of land use on the water cycle and the consequences of water use for land areas (Argawal et al. 1999: 24). Key issues of water-land interaction include altered flow regimes due to modified land cover (most acute in the case of deforestation or over-grassing), erosion, the siltation of reservoirs and canals as well as water-logging and the salinization of irrigated land.

Sectoral integration, reframing the objectives of water management, signifies that ecological, economic and social externalities of water use are internalized in order to maximize the overall, societal benefit of water use. While the conventional engineering approach to water management did not think of na-

ture as a legitimate water user, IWRM does. In periods of water scarcity, for example, minimum ‘ecological flows’ are to be guaranteed in order to sustain vital functions of the ecosystem. In relation to the economic sphere, sectoral integration demands that the benefits of water use be weighted against the costs of water supply and sewage treatment. In general, full-cost pricing should be aimed at. This principle enhances overall economic efficiency and reduces public financial burdens, thus guaranteeing financial sustainability of water services (Argawal et al. 1999, 41–42). In addition, all water-using activities (such as agriculture, fishing, power generation, manufacturing, household provision with drinking water, transport, tourism, etc.) should be jointly taken into account. By this means, water allocation can be oriented towards the most beneficial economic uses. In practice, scarce water resources have often been directed to economically less productive, but politically powerful actors, most often agriculture. Finally, sectoral integration requires that the social consequences of water management are not lost out of view. These include effects on poverty, gender relations or public health, which should all be taken into account by water managers.

Regulatory integration in turn concentrates on the managerial aspects of water governance. In contrast to the conventional top-down, centralized approach to water management, IWRM states that decision-making structures should be organized according to the principle of subsidiarity. Decisions should thus be taken at the lowest appropriate level (Argawal et al. 1999: 15–17). Participation of water end users is to be increased in order to limit transaction costs, to boost the ‘user-friendliness’ of management institutions, and to improve communication between water managers and water users. In addition, decisions need to be based on adequate data. As IWRM is holistic in its ambition, data requirements for its realization are considerable (Argawal et al. 1999: 51–54). Even in cases where ecological data are available and used, socio-economic variables – such as the amount and timing of water demand by different economic sectors, the elasticity of demand in function of water prices, reactions of water users to rationing, water use efficiency, etc. – continue to be widely ignored. The integration of these two types of data constitutes a particular challenge, as the ‘human factor’ still does not receive sufficient attention in water management (Kluge 2005: 36–37). Finally, water management should combine supply-side measures with demand-management, which aims at enhancing efficiency of water use and at prioritizing demands. Respective instruments in-

clude reducing water losses by rehabilitating infrastructure, adapting irrigation norms, and providing incentives for water saving. Economic tools like cost-effective, volumetric water fees and water markets are possible means for encouraging water-saving and selecting between competing demands.

IWRM cannot provide a detailed blueprint of ideal water management, as the broad framework of IWRM always needs to be operationalized in function of the affected society's specific preferences and conditions. However, the concept offers a whole set of broadly applicable tools for improving water management. Hence, it can assist societies with overcoming second-order - or 'structurally induced' (Turton/Ohlsson 1999) - water scarcity. In how far IWRM can consequently contribute to solving the Central Asian water conflicts will be analysed in the following sections.

54.4.1 Contributions of IWRM to Solve Conflicts over Relative Water Distribution

The relative distribution conflict in Central Asia is a problem of inter-sectoral integration, in essence: between hydropower generation upstream and irrigation needs downstream. This conflict remained latent in Soviet times: The unified sovereignty over most of the Aral Sea basin assured final arbitration, generally in favour of irrigation needs. At the same time, overall Soviet planning provided a satisfactory level of compensatory transfers to the upstream Soviet Republics. The relative distribution conflict only got acute when this overall sovereignty and planning disappeared in 1991 and gave way to the political fragmentation of the Aral Sea basin. This made the inter-sectoral cleavage largely coincide with international borders, turning *Kyrgyz* hydropower interests against *Uzbek* and *Kazakh* agricultural interests. In consequence, inter-sectoral externalities became international externalities, diminishing the interest in internalizing these externalities in order to maximize the overall benefit of water use: Upstream users lack incentives to reduce the negative externalities of hydropower generation, while downstream users have little interest to reward positive externalities from flow regulation upstream as long as they cannot effectively control dam management in the flow-generating countries.

A typical upstream-downstream conflict thus arose due to the predominance of artificial international boundaries over hydrological units. The promotion of *river basins as the adequate level of water management* - a key component of IWRM - is the logical an-

swer to this problem. Basin-wide integration would ease the *integration of all water-using economic activities* (in this case, mainly hydropower generation and irrigated agriculture), a further key element of IWRM. The consideration of these two principles would increase the economic rationality of water use and thus augment the total economic "benefits from the river" (Sadoff/Grey 2002: 393p). This in turn means that win-win solutions for solving the relative distribution conflict would become possible. The Toktogul and other dams' flow regimes could be turned towards generating the highest absolute gains, independently of the economic sector and nation-state where these profits accrue. Thanks to the resulting upwards move of the 'Pareto frontier'⁹ - speaking in economic terms - all basin countries could improve their position compared to the current situation. For this to become feasible, an adequate rule and trustworthy mechanisms for distributing the surplus gains would need to be found. Furthermore, a type of basin-wide authority would have to enforce the agreed-upon rules, solving the current prisoners' dilemma.

While this appears to be a rather idealistic and theoretical solution, some progress in this direction has already been made: Under the heading of IWRM, two water-energy consortia have been established for managing the Talas and Chu River basins, which cross the *Kyrgyz-Kazakh* border. Thanks to *Kazakh* funds invested in hydropower projects on *Kyrgyz* territory, *Kazakhstan* will gain partial control over upstream flow management. Joint decision-making structures in turn will ease a holistic management of these two rivers. Although the latter are of minor importance if compared to the *Amu* or *Syr Darya*, their cooperation schemes could still serve as examples for the whole *Aral Sea* basin. Despite IWRM-inspired declarations by IFAS or ICWC, basin-wide integration along the two major streams remains limited to the inherited quota system from Soviet times and the barter agreements mentioned above. *Uzbekistan* has recently begun to contribute in kind to the maintenance of the Toktogul reservoir. However, this might result more from fear of an ill-maintained dam upstream than

9 The 'Pareto Frontier' is a concept broadly used in economics. It describes a society's state in which nobody's resource endowment can be increased without at the same time decreasing the resource endowment of somebody else, i.e. without redistributing the available wealth. Hence, aggregate wealth is at a maximum when a given society is on its 'Pareto Frontier'. 'Moving up the Pareto Frontier' thus means increasing the (potential) maximum wealth of a society.

from a genuine recognition of the flow regulation services provided by Kyrgyz infrastructure.

54.4.2 Contributions of IWRM to Solve Conflicts over Absolute Water Distribution

If IWRM can defuse international conflicts over relative water distribution in the Aral Sea basin, what can it contribute to settling the international conflicts over absolute water distribution? In order to answer this question, one needs to recall the origin of these most 'Malthusian' conflicts. Examining water use patterns in Central Asia, the extremely high per capita consumption can hardly be overlooked. High dependence on irrigated agriculture (> 90 per cent of regional water consumption) together with highly inefficient irrigation practices account for one of the highest per capita water consumptions in the world. In Uzbekistan, for example, 8,000–10,000 m³ of irrigation water (water used for leaching not included) are abstracted for one hectare of cotton – compared to 1,500 m³ physiologically needed by the plants. With the same amount of water, 6 times as much as cotton can be produced. Only this enormous waste of water is able explain the absolute distribution conflicts described above, which persist in spite of an overall water availability that can be deemed satisfactory. Although Uzbekistan and Turkmenistan suffer from 'absolute' respective 'chronic' scarcity of *internal* water resources (according to Falkenmark's Water Stress Index), *external* inflows from Tajikistan and Kyrgyzstan would be largely sufficient to satisfy average water needs (ICG 2002: 4; Mason/Bichsel/Hagmann 2003: 10; De Martino et al. 2005: 21).

Considering the fact that the region's renewable water resources are already overused (hence the fate of the Aral Sea), conventional supply-side measures – intended to increase overall water availability – offer no solution to this problem. Better suited is the *demand-side approach* IWRM promotes. Potential for water saving is enormous in Central Asia, since more than half of the abstracted irrigation water is lost through infiltration and evaporation from irrigation canals before reaching the fields. The predominant but highly inefficient surface or furrow irrigation leads to additional losses. Deliberate over-watering, induced by outdated irrigation norms, is a frequent phenomenon as well. On average, the Central Asian countries use 1.5 times more water on the fields than recommended by water experts (ICG 2002: 12).

Introducing hard – i.e. physical – and soft – i.e. regulatory and institutional – measures of demand-management might significantly reduce rivalry over absolute water distribution. Initial investments into water-saving technology and infrastructure (lined and covered canals, sprinkler or drip irrigation) can be provided by public authorities, assisted by donor agencies if necessary. The main efforts, however, would have to come from the water users themselves. Consequently, appropriate incentives for water-saving must be created. They would include the introduction of water fees, covering at least operation and maintenance costs of irrigation infrastructure – ideally also capital costs and ecological externalities. Currently, water fees are either inexistent or largely symbolic in Central Asia. The fees should be calculated according to actual water use (volumetric or quasi volumetric fees) rather than in function of the number of irrigated hectares. Theoretically, water markets would most efficiently provide incentives for water saving, but they are ambitious to establish. Adapting irrigation norms to crops' real water needs would also significantly contribute to decreasing water demand.

In addition to demand-management, two further components of IWRM would help solving the problems behind the absolute distribution conflicts: First, a better *integration of water quality aspects* could moderate quantity problems. At the moment, huge amounts of drainage water cannot be re-used for irrigation because of their high salinity levels and pollution by fertilizer and pesticides. This water is directed into desert depressions where it feeds ecologically dead lakes. If irrigation norms and techniques as well as the application of agro-chemicals are adapted to quality concerns, drainage water might constitute additional irrigation water. Second, a better *consideration of water-land interaction* would decrease water needs as well. The current patterns of over-watering create a vicious circle of water-logging, salinization and the need of annually leaching the fields before the crop-growing season. Up to 30 per cent of total water abstracted from the rivers are used for leaching. These volumes could be saved for irrigation needs or ecological flows if irrigation practices improve.

54.4.3 IWRM Contributions to Solve Intra-state Scarcity Conflicts

The causes of the absolute distribution conflicts between the riparian states are usually similar to the causes of intra-state conflicts over absolute water distribution: The bad state of irrigation infrastructure,

highly inefficient irrigation practices and inadequate irrigation norms lead to water scarcity amid globally sufficient water. Again, measures of *demand-management* are the adequate response within the context of ongoing irrigation management reforms (cf. Malano/Van Hofwegen 1999 for a general discussion of irrigation management).

In comparison to primary canals of national importance, infrastructures at the secondary and tertiary level are in even worse conditions, however. Insufficient maintenance and repair lead to frequent breakdowns of conveyance and distribution systems, leaving whole communities without water. While a minimum funding of primary infrastructure is normally secured by the state, water end users are usually left on their own. This means that the principle of *cost-recovery* – a key component of IWRM – gains particular significance at the local level. More adequate pricing of irrigation services at the secondary and tertiary level can halt the decay of irrigation infrastructure and enable water managers to improve service quality. In consequence, the economic sustainability of water management promoted by IWRM can reduce local grievances and rivalry caused by water scarcity.

However, as economizing water and irrigation service improvements cannot be realized ad hoc and overall water availability might remain insufficient in some places, distribution conflicts between end users will continue to arise. Adequate mechanisms for conflict management are needed for these cases. It is generally agreed that the responsiveness of water management to users' grievances and needs is best where management decisions are taken at the lowest appropriate level – corresponding to the *principle of subsidiarity*, another feature of IWRM. While water management was extremely centralized in Soviet times, district water administrations are increasingly overburdened by dealing with the growing number of private farmers. This is particularly acute in Kazakhstan and Kyrgyzstan, where the land privatization process is well advanced. In these cases, local distribution conflicts are most likely to be solved if allocation decisions are made by decentralized management structures and based on broadened users' participation.

One possible – and widely used – instrument to facilitate users' participation is the creation of *Water User Associations* (WUAs): Irrigation farmers are encouraged to unite within these organizations to manage their own water supply at the local level (Svendsen/Trava/Johnson III 1997; Vermillon/Sagar-doy 1999). They are expected to decide on water distribution themselves and to care and pay for infra-

structure operation and maintenance. Similar to other forms of decentralization, this direct implication of end users in service provision is supposed to improve the quality and promptness of water management through the strengthening of bottom-up communication and control (Wegerich 2000; Mott MacDonald 2003). The WUA model promoted by international donors (e.g. World Bank and Asian Development Bank) also foresees the establishment of a specific conflict resolution committee within each WUA, composed of several elected WUA members. Due to the recent establishment of most Central Asian WUAs, it is too early to judge on the success of these bodies. But if they gain strength and ownership – building on existing traditions and inherited institutions (cf. O'Hara 2000: 373) – these participatory arbitration mechanisms could significantly contribute to preventing local scarcity conflicts.

54.5 Barriers to the Implementation of IWRM-Solutions to Malthusian Concerns

The analysis above has shown that IWRM generally has the potential to enhance 'second order resources' and thus the adaptive capacity riparians need to de-escalate and constructively manage their water conflicts. IWRM-inspired reforms offer substantial gains to all water users and could decrease tensions over water in Central Asia.

However, progress into this direction has been limited up to date. Official declarations routinely make reference to IWRM, but concrete action is lacking. Thus, the question arises how this gap between the conceptual appeal of IWRM on the one hand and the lack of governmental action towards its (in theory mutually beneficial) implementation on the other hand can be explained.

Simply put, IWRM is politically blind (Swatuk 2005), although it has been developed in explicit response to technocratic, 'engineers' water management. With regard to the prospects of international basin-wide management, creating 'win-win' solutions by re-allocating water presupposes that property rights are defined in advance (Van der Zaag/Seyam/Savenije 2002: 20). If the initial distribution of water use rights is already controversial, it remains unclear how benefits from joint management will be distributed and individual losses compensated. Overcoming cooperation problems for realizing win-win solutions also presupposes a minimum of mutual trust and confi-

dence as well as a strong arbitrating authority, as the institutionalist perspective of IR emphasizes. IWRM neither provides answers to asymmetries of power – the realist IR scholars' main concern: Uzbekistan as the regional hegemonic power is much less dependent on the other riparians' cooperation than vice versa.

However, these typical problems of international cooperation – highlighted by the institutionalist and realist schools of IR – do not seem to constitute the core of the problem in Central Asia. Property rights are more or less formally defined by the Soviet quota system and subsequent agreements (Ryabtsev 2003: 1). The principle of win-win exchanges of irrigation water against energy resources has been accepted and partly implemented. Uzbekistan's military and economic power is balanced by Kyrgyzstan's control over the Toktogul dam, illustrated by the fact that the Kyrgyz did already change its flow regime in Uzbekistan's disfavour. Personal networks from Soviet times make sure that the international conflicts do not escalate, and the Central Asian states display impressive solidarity in applying for funds from international donors for the generalized 'conferencitis' and 'workshopitis' of IFAS and ICWC (Sehring 2002: 13–15, 18; Mason/Bichsel/Hagmann 2003: 21).

By far more challenging is the implementation of demand-management as a means for mitigating absolute distribution conflicts, which represent a much acuter danger than the international conflicts over relative water distribution. Besides public investment into better infrastructure, incentives for water-saving are key in this regard. These incentives are however difficult to implement in the economic context of Tajikistan, Turkmenistan and, most importantly, Uzbekistan. In contrast to Kazakhstan and Kyrgyzstan, land privatization has remained superficial or virtually non-existent (Turkmenistan) in these three countries. The lack of secure and long-term land rights diminishes farmers' interest to invest into better, water-saving infrastructure, which would prevent water-logging and salinization of the soils.

In addition, agricultural markets are strictly regulated, if not to say repressive. Farmers are not free to choose what they plant, and production targets are maintained until today. Most importantly, farmers are ordered to grow a high percentage of cotton, a rather water-intensive crop. The cotton market in turn is controlled by official (Turkmenistan) or unofficial (Uzbekistan, Tajikistan) monopolies, which buy the produce at prices far below the world market and thus pick up significant rents. Forced labour – mostly

school children and students – is widely used by authorities for the cotton harvest in order to further reduce production costs (ICG 2005: 17–25). In the end, the miserable prices paid to farmers¹⁰ do not allow introducing or raising water fees, a crucial element for increasing water use efficiency.

Consequently, significant advances in demand-management presuppose more liberal land and agricultural markets in Tajikistan, Turkmenistan and Uzbekistan (ICG 2002: 2). Substantial liberalization is however unlikely to occur, since the cotton business plays a key role in the countries' political economy (ICG 2005: 12–16; Mason/Bichsel/Hagmann 2003: 21). In Uzbekistan, for example, half of the national hard currency revenues come from cotton exports. National elites monopolize the rents from this lucrative business. At the same time, farmers are increasingly trapped in debt, as they are less and less able to pay back loans for agricultural inputs provided by the same cotton companies. Due to this increasing dependence, national and local elites successfully control the rural population, whose economic situation has significantly worsened since Soviet times while their Kolkhozes and Sovkhozes have not changed much more than their legal form.

This political economy of the cotton industry also provides explanations for the fact that the decentralization of irrigation management hardly advances in Uzbekistan and Turkmenistan. Even where the political context is more liberal – in Kazakhstan and Kyrgyzstan – and numerous WUAs have been created, they face serious difficulties. Similar to most decentralization efforts, WUAs are appealing in theory but more difficult to make work in practice. Local power asymmetries do not disappear with the simple establishment of these associations, and their conflict-preventing potential thus struggles to materialize (Herrfahrdt/Kipping/Pickardt/Polak/Rohrer/Wolff 2006).

The realist and institutionalist school of IR cannot account for these intra-state factors of political economy, as they tend to regard states as black boxes. In order to identify blockages and ways how to implement IWRM at the transboundary level, analyses need to take a closer look at national politics. This is what Andrew Moravcsik (1997) has promoted under the label 'republican liberalism': taking seriously how governments' specific preferences are shaped.

10 The average monthly income of those working in the cotton field is US\$ 2 (information kindly provided by one of the anonymous reviewers).

54.6 Conclusion: How to Advance?

The Malthus-inspired, social science discourse on resource conflicts is able to adequately describe Central Asia's main water conflicts: the international upstream-downstream conflict over relative water distribution, the international upstream-downstream conflicts over absolute water distribution as well as the diverse local scarcity conflicts. As we have seen, the prescriptive concept of IWRM is complementary to the social science analyses in general and IR analyses in particular: It suggests promising ways for managing the conflicts in question: Basin-wide integrated management and resulting inter-sectoral re-allocation of water resources would create win-win-solutions to the relative distribution conflict. The integration of quality aspects, a better consideration of water-land interaction and, above all, demand-management could mitigate the causes of absolute distribution conflicts. Finally, decentralization of and user participation in water management would support conflict management at the local level.

However, a third element - in addition to the conflict analyses and IWRM - is lacking up to date: strategies how to implement the proposed solutions. While IWRM in theory creates opportunities for compensating short-term losers of water management reforms, illegitimate, vested interests in maintaining the status quo can hardly hope to gain from it. In our example, the national elites benefiting from the political economy of cotton will not be willing to accept far-reaching, IWRM-inspired reforms, however beneficial they would be for their respective societies and Central Asia as a whole.

If social science analyses of water problems in conjunction with prescriptive concepts like IWRM are meant to have impact 'in the real world', efforts need to be intensified in the area of implementation strategies (cf. GWP-TEC 2004 as a positive example). Based on an adequate problem analysis, IWRM indicates the direction to take, but it cannot tell how to make decision-makers choose this direction. If the gap between analytical tools and prescriptive concepts can indeed be bridged, as demonstrated in this chapter, the gap between theory and action is a more challenging one. Conventional IR approaches and prescriptive concepts like IWRM need to be complemented by a profound knowledge of domestic politics and power structures within the societies in questions - as proposed by Moravcsik's 'republican liberalism' - if they are to identify realistic ways for solving water problems. Both analytical and prescriptive thinking in hyd-

ropolitics should keep this in mind in order to improve prospects for seeing possible solutions materialize in action. Due to the pressure global environmental change is increasingly exerting on human livelihoods worldwide¹¹ - and especially in developing regions - solving water problems in practice will indeed be key to alleviate human suffering and enhancing social and economic development.

11 For Central Asia cf. Giese/Sehring 2007.

55 Environmental Security in Central Asia and the Caspian Region: Aral and Caspian Seas

Eva Rakel

55.1 Introduction¹

This chapter identifies the main environmental risks in Central Asia (CA) for the five former Soviet republics of Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan, and Uzbekistan, as well as for the Caspian Region (CR) of Azerbaijan, Kazakhstan, Iran, Russia, and Turkmenistan, addressing potential or existing areas of conflict. The main question is: Will Central Asia and the Caspian Region be areas of conflict or of cooperation in the near future, and what are the prospects for joint environmental management?

Regional cooperation among states in Central Asia and in the Caspian region is necessary both to reduce environmental pressure and the related security risks. Inter-state cooperation particularly on water allocation has been the subject of various regional and bilateral negotiation processes in recent years, often resulting in formal agreements, joint commissions, and the development of policies and measures for joint water management. Yet, agreements are not enough if they are not efficiently implemented.

During the Cold War 'security' was a military-dominated concept closely related to national security based on the (neo)realist school of international relations (Morgenthau 1948; Thompson 1960; Carr 1939; Waltz 1959, 1979). National security meant the construction of identities 'under threat' and how to contain such threats to 'political order'. In the (neo)realist school the main subject of analysis is the state. According to this theory international relations is the space where states struggle with one another to enlarge their power by increasing their control of territory. These theories do not offer any framework to better understand different societies and groups of people that are unevenly threatened by the forces of

environmental degradation in a world that is increasingly interdependent, but highly asymmetrical.

Efforts to reconceptualize security include new 'critical geopolitics' (Agnew/Corbridge 1995; Ó Tuathail 1996; Amineh/Houweling 2004/2005) and discourses by political scientists, sociologists, political geographers, peace researchers, and strategic studies experts where security is conceived as a contested concept that involves not only military, but also socio-economic and environmental components (figure 55.1).

Contrary to the neorealist school, critical geopolitics does not take only the state, but also non-state actors (transnational corporations, human rights activists, environmental organizations, terrorist groups), as referents. Environmental insecurity is the result of a growing number of ecological problems such as global warming, resource depletion and trans-boundary pollution. Simon Dalby (1992, 2002, 2006) relates environmental security to social and political practices of dominance in local, national, and international politics. He argues that knowledge and presentation of economic degradation is neither scientifically neutral nor politically innocent. Thus, a new understanding of the relationship between human economic activity, ecosystems, and our perception of human 'progress' is needed beyond the state-centric discourse on 'national security' that is often limited to the military security dimension.

The regions of CA and CR are confronted with many serious environmental problems, most of which come from the Soviet period. Among these environmental problems are the desiccation of the Aral Sea, as a result of wasteful irrigation procedures for the cotton monoculture, as well as the extraction of petroleum and related pollution in the Caspian Sea, the pollution of drinking water, salinization of the soil, soil erosion, and consequences of nuclear weapons testing at Azgzyr, Lira, Aral, Say-Utes, and Semipalatinsk-Kurchatov in Kazakhstan.

1 I thank Mehdi Parvizi Amineh for providing me with material, criticism, and comments.

Figure 55.1: Map of Central Asian Countries. **Source:** Everett-Heath, Tom (Ed.): *Central Asia-Aspects of Transition* (London – New York: Routledge Curzon 2003). Permission was granted by the publisher.

These environmental problems were already serious political issues during the Soviet period, and their solution is now crucial for political and economic development and stability in the region. Environmental risks may become security risks when there is a lack of access to resources for basic needs (water, soil, air, and energy), when widespread negative impacts on public health become evident, and when agricultural productivity, energy security, and economic development are prevented. They do not necessarily trigger violent conflict, but tension could increase drastically when the environmental pressures accumulate and coincide with unfavourable social, economic, and political conditions such as an overall lack of democratic political culture, a weak governance structure, poverty, mass migration, high unemployment, demographic pressure, terrorism, and ongoing border disputes (Brauch 2003).

Regional cooperation among the CA and CR states and non-governmental organizations (NGOs) is

necessary to reduce environmental pressure and resulting risks. Inter-state cooperation particularly on water allocation has been subject to various regional and bilateral negotiation processes, often resulting in formal agreements, joint commissions, and the development of policies and measures for joint water management.

This chapter offers an overview of the social, political, and economic developments in the eight post-Soviet Republics of Central Eurasia (CE: Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan, and Uzbekistan) (55.2). Then environmental risks (55.3) are identified; national, regional, and transnational policy measures to counter these risks are discussed (55.4); and the prospects for joint environmental management of environmental problems by the CE countries are reviewed (55.5), with a special focus on the Aral Sea and the Caspian Sea as two main ecological systems at risk. While the role of NGOs in CE is acknowl-

edged, the main focus will be on the governments and their role in environmental management.

55.2 Post-Soviet Central Eurasia

Since the fall of the Soviet Union several Eastern European countries have embarked on a transition to market economy and democracy. But this process has not yet reached CE. In 1991 the eight CE republics² for the first time in history became independent nation states. Although it was expected by some that independence would automatically lead to democracy, in all eight states authoritarian regimes have emerged.³ The causes for the rise of such 'strong presidentialism' were a fragmented and weak society, related social forces, and backward economic structures, in contrast to most of the Eastern European countries (Amineh 1999).

Independence came almost overnight and confronted these newly independent states with a complex rapid economic and social transition, and the establishment of a new political order. Their response to these challenges is similar, due to their common experience of more than 70 years of Soviet rule. The challenges of dismantling the Soviet power structure and launching a socio-economic development programme is complemented with the struggle for survival of various social forces. The top priority on their political agenda has been the prevention of ethnic and social conflicts rather than the introduction of Western-style democratic procedures or the management of environmental risks. This has several reasons:

- the challenge to create nation states while preserving the multiethnic character of the countries;
- the dismantling of the Soviet power structure while being confronted with social upheavals and rising radical Islamic forces;
- the economic imbalances between urban and rural oriented areas;
- becoming politically and economically independent from Russia⁴;
- the existence of weak legal structures preventing the needed large scale Foreign Direct Investment (FDI), especially in the energy sector, as well as the implementation of agreements of management of environmental risks.

While there has been movement in the transition to a market economy, the years since 1991 have also been a period of social and moral disaster. The problems

of transition attract much international attention due to the region's huge energy resources. Transnational Oil Corporations (TNOCs) already have made large-scale investments. Competing export pipeline projects create tensions among various state actors interested in the region (the United States, the European Union, China, Japan, Turkey, and transit countries such as Georgia and Armenia). Whether it will be possible to attract FDI to fully exploit the region's economic

2 *Kazakhstan* is the largest CE country, with an area of 2.7 million km² but a population of less than 15 million, of which about half is ethnically Kazakh. In the north lives a strong Russian minority. Other ethnic minorities include Ukrainians, Uzbeks, and Germans. Kazakhstan is rich in oil, gas, and mineral resources. It comprises a large diversity in landscapes and ecosystems. Kazakhstan's geographic destiny is primarily shaped by China and Russia as well as the Caspian Sea. *Kyrgyzstan* is mountainous and inaccessible. The majority of its population lives in the peripheral areas of the country. Kyrgyzstan has a complex ethnic composition, apart from ethnic Kyrgyz, are Uzbeks, Russians, and others. Kyrgyzstan has only limited natural resources. The country shares borders with China, Kazakhstan, Tajikistan, and Uzbekistan. *Tajikistan* has emerged from a civil war during 1992–97. Tajikistan has a population of 6.2 million people of which about 64 per cent are Tajik, and a large Uzbek minority of 25 per cent. The country borders Afghanistan, China, Kyrgyzstan, and Uzbekistan. *Turkmenistan* covers an area of 488,100 km². The country has large reservoirs of gas and substantial oil reserves. The country has the smallest and ethnically most homogenous population of the CA republics. Turkmenistan has borders with Afghanistan, Iran, Kazakhstan, and Uzbekistan. *Uzbekistan*, has the highest population density. The majority of the population is Uzbek, with ethnic minorities of Russians, Tajiks, and Kazakhs. Uzbekistan has a variety of resources; including natural gas, oil, gold, and silver. Both the Aral Sea and the Ferghana Valley—two of the main areas of conflict in CA—lie in Uzbekistan (Amineh 2003: 39–43, OSCE/UNDP/UNEP 2003). Only in Georgia and Armenia does the Muslim population amount to less than 50 per cent of the total population. Compared to its neighbours, Armenia had an advantage in its effort of nation building because of its homogeneous society. It also had no legacies of autonomous and regional separatist movements like in other CE countries, a fact which promoted political consensus and mobilization. Furthermore, religion serves as a unifying national force. More than 94 per cent of its population are Christians, most being Armenian Orthodox. Linguistically and culturally Azerbaijan has a long Turkic and Persian tradition. Almost 94 per cent of Azerbaijanis are Muslim, most of whom are Shi'i Muslim. Georgia is an important link and transit country between Asia and Europe.

potential will largely depend on the political stability in these countries. Economic growth is not necessarily a reliable indicator for economic or social health, because it is often based on a sharp rise in inequality and an explosive growth of intense misery and poverty. The experience of the past 15 years has often been discouraging. The people in CA and the CR have paid a high price with the rapid rise in unemployment and fall in real wages and pensions that have plunged millions into poverty. Today there is a wide income gap between rich and poor (Amineh 2003: 29–55; Kaser 2004/2005: 145–159). This situation might worsen if environmental problems such as the desiccation of the Aral Sea as well as the pollution of the Caspian Sea, are not solved.

55.3 The Aral Sea crisis

The most visible environmental disaster in CA is the desiccation of the Aral Sea, once the world's fourth largest brackish inland water reservoir. Now, it is one of its most devastating environmental problems, with an almost collapsed ecosystem. Within 30 years (1960–1990) the surface of the Aral Sea shrank to a half of its original size from 66,900 km² to 36,500 km². Its volume shrank by two thirds from 1,090 to 310 km³. By 2010 the Aral Sea's size may decline to 21,058 km² and its volume to 124 km³ (Spoor/Krutov 2004/2005: table 55.1).

During the Soviet period great amounts of water were diverted from the Amu Darya and Syr Darya rivers for the expansion of cotton production. The Amu Darya (Oxus) and Syr Darya (Jaxartes) originate in the eastern mountains and then cross the Kara Kum and Kyzyl Kum deserts before reaching the Aral Sea. With a length of 2,212 km the Syr Darya is the longer river, but it carries less water than the Amu Darya. It

flows from the Tyan Shan Mountains in northern Pamir then crosses Tajik and Uzbek territory, turning northwest through Kazakhstan to the Aral Sea (Micklin 2000: 7).

In the Aral Sea Basin (consisting of Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan, Uzbekistan, Afghanistan, and Iran) the five CA countries are confronted with an environmental and human catastrophe. In the short-term, damage control rather than a reconstruction of the Basin's original ecosystem will be on the agenda. This can only be reached if all five CA countries cooperate. The strategically most important countries in the Aral Sea Basin are Tajikistan, whose complete territory lies within the Aral Sea Basin, and Kyrgyzstan, that controls the flow of the Syr Darya.

Prior to the Soviet period 75 per cent of Central Asia's population lived from the Aral Sea, which contained almost 90 per cent of its surface water. The Aral Sea Basin was a cultural, economic, and geographical centre for the region (Allison/Jonson 2001: 70), the Amu Darya and Syr Darya were living space for numerous flora and fauna, and the magnitude of the Aral Sea balanced the climate which was relatively mild in the Aral Sea region compared to other areas in CA (Engelman/Pavlakovic 2001: 149; figure 55.2).

When the Soviets started the massive cultivation of cotton crops in the upstream regions of the Amu Darya and the Syr Darya, this harmonious balance was disturbed. While the immediate disaster of the Aral Sea is the result of inefficient irrigation, the roots of the problem can be found in the inappropriate strategy of economic development in CA during the Soviet period, when the Soviet planners stressed the production of agricultural primary products (mainly cotton, that needed most of the irrigation) instead of finished products or other traditional crops (Levintanus 1992; Rumer 1989). Between the 1950's and 1980, cotton production in CA rose from 2.6 million tonnes annually to 5.6 million tonnes (Gleason 1990). In Uzbekistan alone the tonnage of cotton per hectare rose from 1913 via 1960 to 1980 from 1.2 via 2.0 to 2.7 respectively (Spoor 1993: 19).

In 1980, 84 per cent of the water for irrigation in CA came from the Amu Darya and the Syr Darya rivers, of which 62 per cent was lost to evaporation and irrigation, and only 38 per cent returned to the rivers (Micklin 1991: 13). Consequently, the Aral Sea received less than 1,000 cubic kilometres of river water in the last 35 years, the sea level declined and the Aral Sea's volume of water was reduced (Engelman/Pavlakovic 2001: 149). Although in 1927 Soviet scientists

3 The recent popular events in some of the former Soviet countries, first the Rose Revolution in Georgia in November 2003, then the Orange Revolution in the Ukraine in November 2004, and finally in Kyrgyzstan in March 2005, have swept away the old Soviet and post-Soviet order. How far these events have been a clear step towards democracy in these countries remains to be seen. The brutal suppression of protests in the Andijan province of Uzbekistan in May 2005 by Uzbek President Islam Karimov has shown us that, in contrast to the other leaders, he is not willing to yield to the people's will (see various articles on: <<http://www.eurasianet.org>>).

4 The CE states still depend on Russia for economic development and military assistance.

Figure 55.2: Imagess of a Shrinking Aral Sea (1960-2010). **Source:** Spoor, Max; Krutov; Anatoly: "The Power of Water in a Divided Central Asia", in: Amineh, Mehdi Parvizi; Houweling, Henk (Eds.): *Central Eurasia in Global Politics: Conflict, Security and Development* (Leiden, Boston: Brill Academic Publishers, 2004/2005): 285.

were aware already of the environmental consequences of these irrigation practices, the USSR continued to emphasize short-term production over long-term sustainable development (Glantz 1999: 3). Thus, disastrous Soviet planning led to serious environmental, economic, and social consequences. Six environmental risks resulting from these practices can be identified in the Aral Sea Basin:

1. Lowering of the sea level of the Aral Sea by an average of 17 metres and reduction in the volume of water in the sea by two thirds.
2. Disruption of the climatic balance with temperatures in January 1980 to 1988 being 3 to 3½ °C lower than the previous annual average, and in July during the same period 1-4 °C higher. Simultaneously the frequency of dry and hot seasons has significantly increased, while the vegetative season has decreased to 170 days.
3. Increase of dust storms and a higher amount of dust on glacial surfaces resulting in the melting of glaciers.
4. Damage of the biological diversity in the Aral Sea Basin. Before 1960 the Aral Sea Basin was home to over 70 kinds of mammals and 319 types of birds. Now only 32 kinds of mammals and 160 types of birds exist in the Aral Sea Basin.
5. The changes in the Basin affect mainly the disadvantaged poor of 3-4 million of 44 million in an area of 440,000 square kilometres, mainly in the Ferghana Valley. However, consequences are worst near the shores of the lake, like in Karakalpakstan.
6. An increase in dust storms containing toxic salt residue. People who inhale these carcinogens have

a higher risk of experiencing infant mortality, respiratory illnesses, esophageal cancers, typhoid, and hepatitis (Peachery 2004: 4–6).

Additionally, the salinization of the soil makes the land in the Aral Sea area unusable for agricultural production. As Spoor and Krutov note: “The drying out of the Aral Sea is having far reaching consequences for the climate and biodiversity of the surrounding regions, while desert winds are transporting sand and salt over long distances, depositing millions of tonnes of (often polluted) salts on agricultural land all over the Basin area. Due to inadequate and badly maintained drainage systems, water logging is widespread and soil salinity is an increasing environmental problem. The worsening ecology of the region makes living in many areas – such as Karakalpakstan in Uzbekistan and Kyzlorda in Kazakhstan, where poverty and environmental degradation are linked in a vicious downward spiral—quite inhospitable” (Spoor/Krutov 2004/2005: 595).

The economy of Karakalpakstan used to depend on fishery in the Aral Sea. The withdrawal of water for irrigation led to a rapid increase in salinity of the Aral Sea, an effect to which many of the native fish could not adapt. By the 1980’s commercial fishing came almost to a halt. In 1959 the fishermen fished 50,000 tonnes of fish (mainly carp, bream, and pike-perch). In 1994 those few fishermen that still fished there retrieved 5000 tonnes of carp alone (IFSAS/UNDP/World Bank 1997: 23–24).

In Uzbekistan the agricultural heritage of the monoculture of cotton production makes land deterioration and contamination its second largest problem for human security. The deterioration of the Aral Sea leads to severe health problems, and the lack of employment to migration from the Aral Sea to other regions in the country, which now have to cope with an immense increase in population density (OSCE/UNDP/UNEP 2003: 25). This could lead to violent confrontations on the intra and inter-state level.

55.3.1 Possible Areas of Conflict due to the Aral Sea Crisis

When the Soviet Union collapsed domestic water crisis became an international problem for the countries of CA. The two rivers that constitute the Aral Sea Basin became international waters comprising five countries. The Amu Darya affects Tajikistan, Uzbekistan, Turkmenistan, and Afghanistan, while the Syr Darya affects Kyrgyzstan, Uzbekistan, Tajikistan, and Kazakhstan as well as Afghanistan. Physically the rivers

unite these countries, but since 1991 they demarcate borders. These political borders between the five republics had direct socio-economic and political consequences for the 35 million people in the Aral Sea Basin. In the downstream areas, e.g. in Karakalpak, it became unclear who would be responsible for the environmental crisis in the Aral Sea Basin. Would it be Russia that – in accordance with earlier Soviet agreements – would help the Central Asian republics restore the Aral Sea, or would the five CA states have to find a solution to the water crisis by themselves (Weinthal 2002: 6)?

The demarcation of boundaries, a significant population increase, limited water resources, and poverty are important factors that could lead to intra and inter-state conflicts. Since the independence of the CA states, over 50 per cent of the water supplies for Uzbekistan and the Kazakhstani ‘oblasti’ (provinces) of Kyzi-Orda and Shymkent and 98 per cent of Turkmenistan’s water supplies, come from foreign resources, namely Tajikistan and Kyrgyzstan. Kazakhstan, Uzbekistan, and Turkmenistan are the three downstream states of the Aral Sea Basin and they rely on water from Kyrgyzstan and Tajikistan where 90 per cent of the Basin’s water resources are located (Allison/Jonson 2001: 70–71).

The *Syr Darya River* comes from the mountainous region of Kyrgyzstan; it flows through Uzbekistan and Kazakhstan before it reaches the Aral Sea. *Kyrgyzstan* is the region’s main supplier of water for irrigation. Having a great amount of water it lacks coal, oil, and gas. In exchange for providing the other CA countries with water Kyrgyzstan receives natural gas, coal, and oil from Kazakhstan and Uzbekistan (Toursonof 2004).

Since the disintegration of the Soviet Union Kazakhstan and Uzbekistan charge Kyrgyzstan for supplying gas and oil, and Kyrgyzstan runs the Toktogul dam for power generation in the winter to satisfy its energy shortages because Kazakhstan and Uzbekistan do not fulfil the delivery of heating resources according to the agreement mentioned above. As a result, Kazakhstan started to contain the water behind the Chardana dam. When the capacity of its reservoir was exceeded the water broke through into the Arnsai depression in Uzbekistan. This depression filled up creating lakes out of the former lowland marshes of Aidar and Tuzkon. Now, every year these lakes fill up with water, flooding the surrounding countryside, villages, pasture lands, and infrastructure (power and communication lines, roads, and gas pipelines).

In Uzbekistan the costs of flooding in 2001 were estimated at US\$ 3.8 million (Lange 2001). In early 2004 the Chardara dam almost broke, due to extremely high water flows from Kyrgyzstan.⁵ Kyrgyzstan has been accused several times, in 1993, 1998 and 2001, for releasing too much water from the Toktogul dam down to the Syr Darya in the winter and releasing not enough during the summer. As a consequence many cotton fields in Uzbekistan and Kazakhstan were flooded in the winter and died out in the summer (Allouche 2004: 99).

Like Kyrgyzstan, Tajikistan has only limited oil, gas, and coal resources, and relies on its neighbouring countries for these resources. Thus, Tajikistan wants to develop its hydropower potential and is confronted with the problem that sufficient water has to be ensured for irrigation in Uzbekistan and Kazakhstan in spring and summer. In recent years access to contested water supplies have led to tensions and violence between Kyrgyz and Tajik villagers on the borders of the two countries (ICG 2002a: 5, 7).

The *Amu Darya River* is of great importance for the irrigation systems of Turkmenistan and Uzbekistan. In Turkmenistan 80 per cent of the land is desert. All but one province in Uzbekistan depend from 71 to 100 per cent on external water supply (Bushkov 1990: 4-5, 7-9). Although gas is the main export product in Turkmenistan, the amount that cotton exports contribute to the state budget has continued to rise since 1991 (IMF 1994: 125). Because of its great reliance on agriculture, irrigation is a main security issue for Turkmenistan (ICG 2002a: 2).

Intensive cotton farming in the last decades has drained freshwater reserves and caused the salinization of the Amu Darya River, soil erosion, water and soil pollution by pesticides, and the building of dams. This has led to the pollution of drinking water and has affected agriculture in Turkmenistan. The Amu Darya River provided drinking water for Dashoguz province. According to Arslan Berdiyev, project officer of the United Nations Children's Fund in Ashgabat, only about 20 per cent of the population living in the Dashoguz province (1.2 million people in total) have access to clean drinking water. It is estimated that about 40 per cent of the people living in the region of the Aral Sea have kidney problems due to salinated drinking water (Blua 2004).

Turkmenistan and Uzbekistan have experienced tensions on water allocation from the Amu Darya.

For example, the Dashhowuz province (Turkmenistan), Khorazm province (Uzbekistan), and the Autonomous Republic of Karakalpakstan (Uzbekistan) depend for their water supply on the lower Amu Darya. Here, tensions arose when Turkmenistan after independence in 1991 built a canal away from the Tuyamuyun Reservoir to improve water delivery for the oasis in the lower reaches of the Amu Darya, and also to improve its control over the water supply within Turkmenistan (Kloetzli 1994; Smith 1995).

In Uzbekistan the relation between ethnicity and territory is the most accentuated and the most fragile to conflict in CA. Uzbekistan has only little control of its water supply and has a large Tajik population that dominates its source. Two out of four areas with the highest water vulnerability in Uzbekistan are located in the Ferghana Valley (Smith 1995: 361-62) where the interrelation between resource issues, ethnicity, economic development, and state formation in the post-Soviet context becomes obvious. The fertile Ferghana Valley covers only 5 per cent of the territory in post-Soviet CA but is home to 20 per cent of the region's population, including large minorities of ethnic Kyrgyz, Tajiks, and Russians. It is split among three countries: Uzbekistan, Kyrgyzstan and Tajikistan (figures 55.3, 55.4).

The Ferghana Valley produces a major share of the country's cotton and grain, and contains numerous manufacturing plants as well as natural gas and oil fields (Amineh 2003: 163). Forty-five per cent of the irrigated area of the Syr Darya Basin lies in the Ferghana Valley. The Ferghana Valley contains several of the most vital and productive irrigated areas, e.g. Jalal-Abad and Osh in Kyrgyzstan; Andijan; Namanagan, and Ferghana in Uzbekistan, as well as Leninalbad (Khujand) in Tajikistan. All these areas rely on the Syr Darya for irrigation. In June 1990, clashes over access to land and water broke out between Kyrgyz and Uzbeks in the Osh province, leaving 300 people dead (Spoor 1998: 425) and 1,000 people wounded. As a result of these clashes the Uzbek minority in Kyrgyzstan claimed an independent status for the Osh region (O'Hara 1998).

When the USSR disintegrated, the territorial borders that had only been created during the Soviet period gained in significance and became particularly sensitive between the three countries that share the Ferghana Valley (ICG 2002a). This valley, which is one of the poorest areas in CA with high unemployment rates, is also a breeding ground for radical Islamist groups, such as the Islamic Movement of

5 Interview in July 2004 with Jenniver Sehring, PhD student at Giessen University, Germany.

Figure 55.3: Water Issues in the Ferghana Valley. **Source:** Victor Novikov/Philippe Rekacewicz, UNEP/GRID-ARENDAL, April 2005, see at: <<http://www.relief-web.int/rw/RWB.NSF/db900LargeMaps/AHAA-6CYLV7?OpenDocument>>.

Uzbekistan and the *Hizb-ut Tabrir al-Islami* (Party of Islamic Liberation).

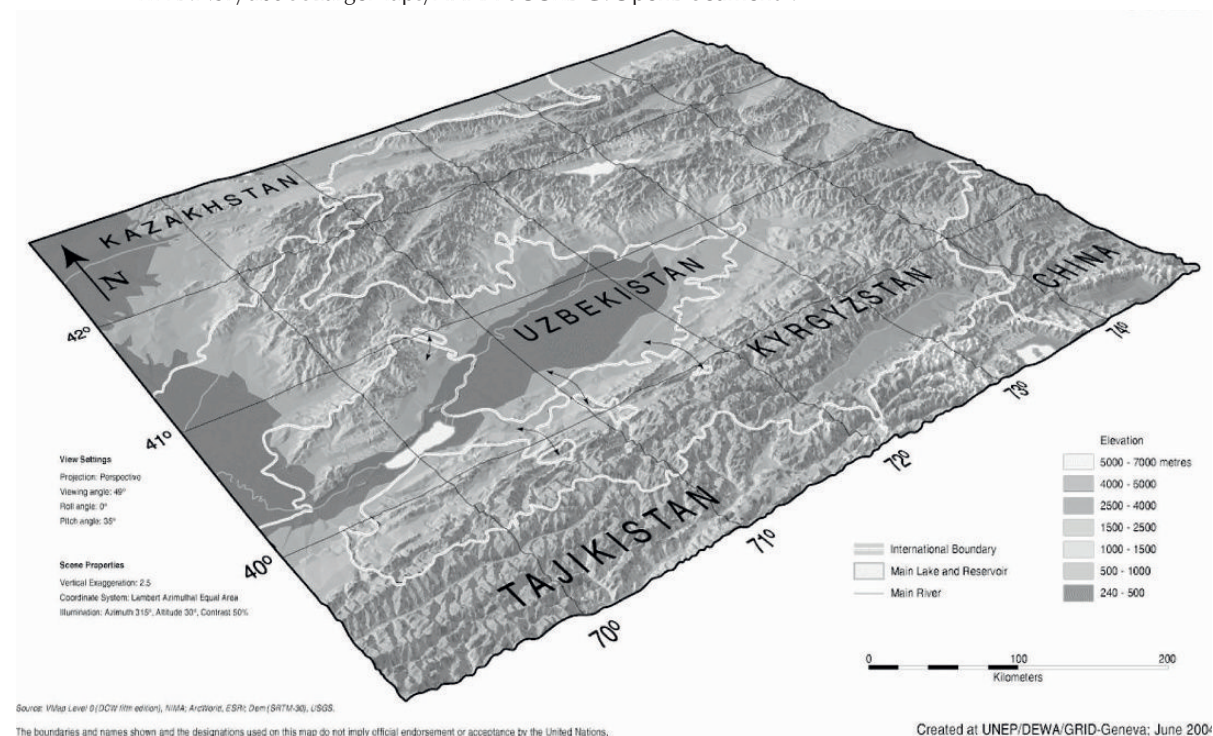

The competition for scarce resources between the different ethnic groups in the Ferghana Valley could have great effects on inter-state relations. Particularly, the predominance of Uzbeks (three-fourths of the population) in the Ferghana Valley contributes to tensions among different ethnic groups. Water from Kyrgyzstan flows through the Ferghana Valley. A reduction of the water flow by Kyrgyzstan could exacerbate

tensions between ethnic Uzbeks and ethnic Kyrgyz (Weinthal 2002: 121–22).

55.4 Caspian Sea Crisis

The Caspian Sea is the largest inland sea in the world. It has a length of more than 1,100 km and a width of about 200 to 400 km. It covers an area of 386,000 km². The environmental risks in the Caspian Sea are different in nature but equally severe as in the

Figure 55.4: Three Dimensional View of the Ferghana Valley Region. Source: UNEP and: <<http://www.reliefweb.int/rw/RWB.NSF/db900LargeMaps/AHAA-6CCRDG?OpenDocument>>.

Aral Sea. The deterioration of the Caspian Sea is another environmental risk to human security for the five littoral states of Azerbaijan, Iran, Kazakhstan, Russia, and Turkmenistan. In the region around the Caspian Sea live about 14.7 million people thereof 6 million in Iran, 4.1 million in Azerbaijan, 3.5 million in Russia, 0.8 million in Kazakhstan, and 0.4 million in Turkmenistan (CEP 2002: 5). Most of these people live directly from the sea, especially from fishing.

The Caspian Sea has a low salinity, about one-third of the salinity of seawater. Due to this low salinity it has developed an extraordinary but also very vulnerable ecological system. The various types of fish that live in the Caspian Sea are among others the sturgeon, herring, mullet, carp, bream, pikeperch, roach, and salmon. It is inhabited by one of two species of freshwater seal and has great bird life of different species. The sturgeon is used for the production of caviar. In the past, 80 per cent of the world's caviar originated from the sturgeon in the Caspian Sea. Due to the overexploitation of the sturgeon since the fall of the Soviet Union, the annual catches have fallen from over 30,000 tonnes in the 1980's to less than 5,000 tonnes by 2000 (ITOPF 2003).

The Caspian Sea is also believed to have huge oil and gas resources. British Petroleum (BP 2004) esti-

mates the Caspian littoral states' proven oil reserves to be 216.3 billion barrels of oil (18.8 per cent of the world's total). Proven natural gas reserves are estimated at 2819.2 trillion cubic feet (44.6 per cent of the world's total).

Oil production started in Russian Azerbaijan more than 100 years ago, but it is only since the dissolution of the Soviet Union in 1991 that the Caspian region gained significantly more international interest, particularly among TNOCs which previously had been excluded from activities there. With the great attention paid to Caspian oil and gas resources since the dissolution of the Soviet Union, what became obvious also to a large public was the appalling state of the environment in and around the Caspian Sea. The petrochemical and refining complexes on the Absheron Peninsula in Azerbaijan have caused heavy land-based pollution. Spills from oil and gas drilling both onshore and in the sea itself have caused serious environmental problems. Untreated waste from half of the Russian population and most heavy industry in the Volga River empties directly into the Caspian Sea. Pesticides and chemicals used in the agriculture are threats to the Caspian Sea's flora and fauna. The existing and planned extraction of the Caspian hydrocarbon resources - heavily promoted by TNOCs - is a

direct as well as indirect source of environmental problems in CA and the Caspian region. Environmental risks include: fluctuations in the sea level, surge effects, the increasing salinity of groundwater, industrial pollution, loss of biodiversity, spills caused by transport of oil through the Caspian Sea by undersea pipelines and/or tankers. Little regional cooperation exists due to the unsettled dispute around the legal status of the Caspian Sea. Weak environmental laws and regulations or the unwillingness by local government to enforce them have great effects on the environment of the Caspian Sea. As industrial production declined in the first half of the 1990's due to economic decline there was also a reduction in the flow of industrial waste into the Aral Sea. Since the economic upturn from the mid 1990's pollution has risen again. The pollution of beaches and coastlines makes swimming almost impossible, and toxic waste threatens to contaminate drinking water. In the area close to the Caspian Sea a higher rate than average of cancer has been noted, and a decline in sturgeon catch threatens the survival of the caviar industry (EIA 2003).

A main obstacle for a solution of the environmental problems in the region is the unsettled dispute on the legal status of the Caspian Sea among the five littoral countries (Peimani 2004/2005: 261-278; Amineh 2003). Their interests to profit most from their hydrocarbon resources have led to a neglect of environmental issues hampering a co-ordinated regional policy on environmental security and management of the Sea's resources. Such a policy is necessary to improve the environmental situation and reduce the potential for conflict among the five neighbouring countries (Zonn 2001: 69-70).

55.4.1 Possible Areas of Conflict on the Caspian Sea Crisis

The Caspian Sea's oil and gas resources must be transported long distances either by undersea pipelines or tankers (Winrow in this volume). Production and export of the offshore oil reserves has been limited due to the unsettled legal dispute (Amineh 2003). If production should increase, the areas at risk to be polluted are first a belt of deep-water oil fields between Azerbaijan and Turkmenistan, and the area around the Kashagan oil fields in the north Caspian off Kazakhstan, which is considered as the largest oil field that was discovered during the last 40 years. Most of the infrastructure needed to bring the offshore oil to international markets is not yet existent.

A large capacity undersea pipeline is planned for the oil fields in Azerbaijan. Other export options are the transportation of oil by rail, ship, or a combination of one of the two with pipelines. For example, the Baku-Tbilisi-Ceyhan pipeline that is expected to have a capacity of 1 million bbl/d (Amineh/Houweling 2004/2005). The Baku-Tbilisi-Ceyhan pipeline was officially opened on 25 May 2005. Another possibility is to connect a long-distance undersea oil pipeline to several shorter pipelines that serve offshore facilities. Such an option would increase the risk of oil release into the Caspian. Until now, there have been no major oil spills, a threat exists due to substantial pressure from exploratory drilling, offshore production, shipment of refined products, and increases in crude oil shipment (ITOPF 2003).

According to the Caucasus Environmental NGO Network (CENN) the Baku-Tbilisi-Ceyhan pipeline is economically, politically, and environmentally not viable. The construction costs are much higher compared to other transportation options such as through Iran to the Persian Gulf. Moreover, the pipeline passes various areas of conflict (Nagorno-Karabakh, South Ossetia, Abkhazia, Chechnya, Dagestan, Ingushetia, and the Kurdish territory in Turkey), where a possibility of pipeline destruction exists. Additionally, European environmental legal standards are not met. The pipeline might threaten the Georgian Borjomi Valley, a natural resort through which it passes (Amineh 2003: 197).

The legal uncertainty on the Caspian Sea affects the ownership of many offshore oil fields and potentially investing TNOCs. Disputed oil fields cannot be developed and tensions among littoral states are possible on the ownership question. There is even a possibility for military confrontation, given the hostile bilateral relations among some Caspian states due to their security interests. For example, Iran and Russia are concerned about US political, economic, and military expansion in other Caspian littoral states. These concerns affect also their relations with the other Caspian littoral countries. The tensions in Azeri-Iranian relations divide the littoral countries into different camps, e.g. the United States and Turkey siding with Azerbaijan while Iran has supported Armenia with military equipment in the Nagorno-Karabakh conflict. Iran fears unofficial claims by Azerbaijan to its own Azeri provinces and the harassment by Azeri police and border guards of Iranian truck drivers, along with Azerbaijan's good relations with Israel. Both countries accuse each other of supporting political opposition groups. In July 2001 these differences

between Iran and Azerbaijan almost resulted in a military confrontation between both countries (Peimani 2004/2005: 263). On 23 July 2001 two Iranian Air Force planes overflew a BP/Amoco survey ship that was exploiting the *Araz-Alov-Shargh* bloc licensed by Azerbaijan. The same day an Iranian gunboat entered Azerbaijan's territorial waters and threatened to fire on the survey ship. Iran aims to enforce its own claims on this part of the Caspian Sea (Olson 2002). As a result BP/Amoco suspended their work in the Araz-Alov-Shargh/Alborz bloc. These developments could have a negative effect on joint environmental management in the Aral Sea Basin and the Caspian region.

55.5 Environmental Management in Post-Soviet Central Eurasia

During the Soviet period environmental issues often had a nationalist underpinning, as Horsman notes: "Grassroots opposition to environmental degradation and exploitation; inter-ethnic competition for land, water and other resources, [...] [served] as a conduit for nationalist and republican elite challenges to Moscow's authority" (Horsman 2001: 1).

In the late 1980's, the major political movements that were closely linked to environmentalism were *Nevada-Semipalatinsk* in the Kazakh Soviet Socialist Republic, and *Birlik* in the Uzbek SSR. Nevada-Semipalatinsk was founded in 1989 after 5,000 people listened to the Kazakh poet Suleymenov in Almaty who denounced nuclear testing and called for a public meeting. This movement contributed to the suspension of nuclear testing in Semipalatinsk and developed links with international organizations opposing nuclear testing, and organized investigations on the level of radiation sickness in the area (Ruffin/ Waugh 1999; Jalling 2003: 169). In 1991 President Nazarbayev declared the test site closed. Like Nevada-Semipalatinsk *Birlik* (see: <<http://www.birlik.net>>) opposed environmental degradation in Uzbekistan but was explicitly more nationalistic (O'Hara 1998).

Since independence in 1991 environmentalism is no longer tied to political issues. Horsman explains this with these three developments: a) the nationalist aspect has been removed since Moscow no longer is a focus of common action for republican elites, nationalists, and environmentalists; b) political and economic problems in post-Soviet CE outweighed environmental activism; c) the current political elites that also belonged to the Soviet elite discourage criticism

of their former and present roles in their countries' economic and environmental mismanagement (Horsman 2001: 2).

Several NGOs have emerged since 1991. Among these NGOs are the *Green Salvation* in Kazakhstan, the *Tabiat* of Tajikistan, the *Ashgabad Ecological Club* in Turkmenistan, *Ecology* in Kyrgyzstan and Uzbekistan, the *Union in Defence of the Aral Sea* and *Amudarya* in Karakalpakstan, and the regional *International Central Asian Biodiversity Institute*. Most NGOs are grassroots organizations formed by people with local knowledge. Environmental NGOs must act cautiously and are often considered as political opposition by their governments. And somehow this is true, considering that some groups have sought parliamentary representation (Jalling 2003: 172).

On the state level several regional and bilateral inter-state agreements, joint commissions, and common development of policies and measures on the allocation of water have been concluded and carried out among the CE countries. Conflicts on access to water seem less likely than previously thought (OSCE/UNDP/UNEP 2003: 30).

55.5.1 Environmental Management: The Aral Sea

During the 1980's the Aral Sea crisis was recognized by the Soviet Union and in the transition period considerations to solve the problems were discussed. But due to lack of funding and the economic crisis any environmental initiatives were stalled. One plan was to divert water from the river Ob to increase irrigation and provide some water for the Aral Sea. This project would have been very uneconomic but could also not be realized anymore in 1991 when the Aral Sea region was divided among the newly independent states (Tantont/Heaven 1999: 364). This project would have replaced one environmental disaster by another one (Brown 2002).

The Aral Sea crisis has forced the seven states of the Aral Sea Basin (the five Central Asian republics as well as Afghanistan and Iran) to find a common solution to it. For the CA countries this is a rather new situation. During the Soviet period all directives came from Moscow. So far, the involvement of the seven countries in the Aral Sea Basin in addressing environmental issues has been uneven. Kazakhstan and Uzbekistan are most involved, Kyrgyzstan, Tajikistan, and to a lesser extent Turkmenistan are hardly involved, and Iran and Afghanistan are not involved at all. These levels of difference in involvement have

made cooperation difficult. Between 1991 and 1994 ca. 300 agreements were signed on the Aral Sea crisis. On 18 February 1992 the five CA states signed the *Almaty Agreement* to solve water disputes (Allison/Jonson 2001: 70–71, 73). Based on this agreement these five countries established a working group to oversee its enforcement (Elhance 1997: 214). While the Almaty Agreement is the central regional framework of cooperation on the Aral Sea crisis, so far it has not become an effective plan of action.

To get World Bank funding for their water resource management projects the five CA states have established additional organizations, such as the *Interstate Council for Addressing the Aral Sea Crisis* (ICAS) and the *International Fund for the Aral Sea* (IFAS). The ICAS members are 25 high-level representatives from the five CA countries who meet twice a year to develop policy strategies related to water use and its distribution among its member states. Its legal status remains unclear and its jurisdiction overlaps with the *Interstate Water Management Coordinating Commission* that was created prior to the ICAS at the Almaty Conference in February 1992. The IFAS's main task is to fund Aral Sea programmes and channel funds from donor countries and international agencies. The share of the five Central Asian countries' contribution to the agency is very low (0.3 per cent of GNP of Kazakhstan, Turkmenistan, and Uzbekistan, and 0.1 per cent of GNP of Kyrgyzstan and Tajikistan), and they have been slow in paying their contributions (Allison/Jonson 2001: 73).

The disputes between the different regional organizations over authority of managing the Aral Sea crisis have complicated the situation, and the activities of international donors worsened the situation further. The World Bank, the United Nations Development Programme (UNDP), and the United Nations Environment Program (UNEP) have agreed as one of their main objectives to strengthen the institutional capacity of ICAS and IFAS, but they disagreed on what instruments to use. USAID has worked through the *Interstate Council for Kazakhstan, Kyrgyzstan and Uzbekistan* (ICKKU), an economic cooperative organization created in 1993 to strengthen cooperation among the Syr Darya states (Weinthal 2000: 2). USAID argues that by supporting the ICAS/IFAS the World Bank would also support the former 'nomenklatura' instead of propagating a reform of these organizations.

In 1991 the United Nations Environmental Programme (UNEP) published a *Diagnostic Study for the Development of an Action Plan for the Aral Sea*.

In September 1992 a preparatory World Bank Mission was established whose main aims were: "Stabilisation of the Aral Sea levels in a sustainable range; rehabilitation and development of the Aral Sea disaster zone; strategic planning and comprehensive management of the water resources of the Amu and Syr Darya and; building of institutions for planning and implementing the above programs" (World Bank 1993). Its goals should be achieved in three phases. In the first phase an *Emergency Aral Sea Environment Assistance Plan* (ESEAP) should be completed within two to three years to quickly restore the decreasing productivity of human and other resources in the Aral Sea area.

Phase 1 started in 1994 with an estimated value of about US\$ 200,000,000. It was hoped that this amount would attract donors to finance different aspects of the proposed programme. Although some useful proposals were submitted, the programme itself was only a compilation of projects submitted by different institutions. Some donor organizations undertook projects unrelated to this programme. There was no clear objective, and even though some projects achieved good results, the overall programme did not make a significant contribution to the solution of the Aral Sea crisis (Tantont/Heaven 1999: 364). In 2000 UNDP concluded that donor assistance for capacity building was ineffective, that the regional institutions have no clear mandate and that they depend too much on donor assistance (UNDP 2000a: 5–6).

55.5.2 Environmental Management-The Caspian Sea

In the Caspian region joint environmental management is even more difficult due to the unsettled dispute on the legal status of the Caspian Sea. Thus, no regional agreement was signed by all five littoral states, and conditions, protection and sustainable management of the Caspian Sea environment and its resources remains largely dependent on national legislation combined with international cooperative initiatives. Such a missing regional agreement that defines the ownership and usage of the Caspian Sea's oil and gas resources even worsens the relations among littoral states.

As all five states have claims to oil and gas resources and many TNOCs are active or willing to invest in the Caspian oil and gas business, there is an urgent need for finding a solution to these problems. Several efforts have been made to encourage regional

and international cooperation on the management of the environment of the Caspian Sea, but the results are not always good. All five littoral states have national laws on environmental protection and on the use of natural resources, but they have no specific laws for the protection of the Caspian Sea. Several multilateral agreements are worked out in 2005, e.g. "On the Protection of the Environment of the Caspian Sea", "On the Preservation and Management of biological resources of the Caspian Sea", "On the Co-operation of the Caspian states in the field of hydrometeorology and monitoring of pollution of the Caspian Sea". Iran, Kazakhstan, and Russia are signatories to the Stockholm Convention on persistent organic pollutants. The five littoral states participate in various other international environmental conventions (SAP 2003: 7).⁶

Kazakhstan, Russia, and Turkmenistan have adopted national contingency plans (NCP). Iran is finalizing its NCP, and Azerbaijan must still begin its NCP. Another initiative is to develop a regional contingency plan for the Caspian Sea led by the Caspian Environment Programme (CEP, at: <www.caspian-environment.org>; ITOPF 2003). The CEP is a joint organization of all five littoral states, the European Union (EU), United National Development Programme (UNDP), and the World Bank. Its goal is sustainable development and management of the Caspian environment (SAP 2003: 4).

The World Bank and the European Commission are also involved in other environmental programmes such as the *Emergency Response Caspian Region Thematic Centre* (ERCRTC) established in Tehran under the CEP. In 2005 ERCRTC has been working on reports for each littoral state, dealing with the emergency response arrangement as well as risks and sensitive resources in each Caspian state. It also encourages regional cooperation in spill response, improved communications strategies, the collection of incident information for databases, and the organization of spill-response-related courses and workshops. This includes a refinement of the Caspian Sea Plan concerning Regional Co-operation in Combating Oil Pollution in Cases of Emergency. Regional Workshops have been held so far in Tehran (April 2002) and Baku (November 2001, November 2002). Without a resolution of the legal status of the Caspian Sea

any regional effort on spill response remains unlikely in the short-term. No Caspian country possesses adequate technology to clean up oil spills. Except for Iran, the other four Caspian countries expect oil companies and transport companies to implement adequate response equipment and materials for small spills. In Baku a Tier 2-3 oil spill response base has been established providing emergency back-up to the Azerbaijan-Supsa pipeline on land and emergency response for offshore drilling and production activities off Azerbaijan. In Kazakhstan response vessels are ready and personnel is trained. Turkmenistan and TNOCs active there have updated their response capacity. For large spills the littoral states rely on international assistance (ITOPF 2003).

Due to their severe economic problems, in the coming years the littoral governments will give higher priority to FDI, economic reform, job creation, and education than to environmental protection. Environmental problems are not dealt with by many ministries and local governments. The countries often lack the financial resources and skills to carry out monitoring and enforcement activities necessary to manage environmental crises. Limited financial contributions by international donors to the region are a major constraint (SAP 2003: 8).

55.6 Prospects for Environmental Management and Conflict Avoidance in Central Eurasia

The CE region is confronted with many environmental problems with decisive implications for the region's future. It is unlikely that environmental problems could lead directly to violent confrontations within and between the CE states. Environmentally related conflicts in CE are related to other factors such as ethnicity, political instability, and declining and/or diverging economic and living standards. The management of environmental problems depends to a large extent on political, and not on environmental considerations. Most members of the political elites of the eight CE republics were part of the former Soviet elite. They decide now on economic, health, and environmental policies. Popular participation in environmental management is resisted. Unsuccessful policies of political and economic reform, as well as unsuccessful environmental management, could erode popular support for the current leadership in CE and even lead to political instability. Existing inter-state agreements are many, but hardly implemented. They

⁶ Strategic Action Programme for the Caspian Sea-Caspian Environment Programme, as approved at the Tehran Steering Committee Meeting of November 5, 2003.

may also be not sufficient to manage future environmental crises. Inter-ethnic relations could become tenser, if resource scarcity, environmental degradation, migration, and lack of substantive economic and political reforms continue. These factors combined could lead to social tensions and provide a

source of identification with radical political Islam. Thus, environmental issues in CE could act as major catalysts in intensifying already existing divisions, as well as having serious ecological, developmental, and health implications.

56 The Central Asian Water Regime as an Instrument for Crisis Prevention

Julia Wunderer

56.1 Introduction

Most large rivers in the former Soviet Central Asian states of Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan, and Uzbekistan are either border-crossing or border-shaping. Such transboundary river systems increase the political complexity of a fair distribution of the essential water resources. Consequently, the geographical conditions of a region may amplify already existing conflicts. Hydrologically classified as arid to semi-arid, Central Asia even in the Soviet period has had to deal with a situation in which the demand for water is much higher than the available supply. Considering the increase in population and the intention of all Central Asian governments – except for Kazakhstan – to further extend their irrigation agriculture, the discrepancy between water demand and water supply tends to increase (Micklin 2002: 522). However, the environmental problems in the Central Asian region result less from a natural shortage of water; rather, they are caused predominantly anthropogenically by the dependence on the intensive irrigation agriculture (see chap. 55 by Rakel and chap. 57 by Martius/Froebrich/Nuppenau).¹

Since their independence in the second half of 1991, the Central Asian states have signed numerous agreements concerning water issues at both the bilateral and regional levels. Moreover, they established a number of water management institutions, mainly supported by the international community of states. The regional water regime in Central Asia goes beyond national laws, but is limited in its effectiveness. Obviously, the difficulties in implementation correspond to an inadequate formulation of the agreements' rules and targets.

Because of their capacity to address this complexity and to sanction undesirable behaviour of governments or communities, institutionalizing the terms of water distribution and developing norms and rules may contribute to peaceful conflict resolution. The Central Asian case is a good example for the necessity of water regimes and institutional settlements, but also for the fact that regimes are not sufficient to reduce security risks. Furthermore, water regimes require normative implications if peaceful effects are desired.

This chapter assumes that regulated conflict resolution by international regimes and their crisis reducing effects will only be successful if the inherent components are adequately addressed. Intergovernmental arrangements will be the reference point for the following analysis, whose main question is: Which are the conflict regulating effects of the regional water regime in Central Asia to resolve the environmental, economic and socio-political water-related problems, and which circumstances act as obstacles to regime implementation?

The first step to answer this question is to identify the existence of water-related conflict triggering indicators along the border-crossing courses of the Central Asian rivers. The analysis proceeds from the assumption that conflict resolution can only be sustainable when all dimensions of the crisis situation are identified, concerning both their probability of violence and their opportunities for regulation. The analytical pattern comprises the environmental, economic and socio-political dimensions, which may trigger conflicts or contribute to conflict resolution. The second step is to evaluate the regime frameworks and the progress of regime implementation with the leading premise of effects conducive to peace.

This chapter identifies the dimensions of conflicts over water in a politically instable environment and their correlations to the assumptions of the conflict-centred regime theory. A framework of conflict di-

1 Concerning the links between water, conflicts, and security in Central Asia see: Klötzli (1996); Horsman (2003); Micklin (2000, 2002); Weinthal (2002); Seidelmann/Giese (2004).

mensions is developed to analyse the multi-dimensional factors, and regime theory is introduced with its theoretical assumptions of conflicts (56.2). Then the Central Asian water regime is outlined with a focus on transboundary river systems (56.3) and an evaluation of the status of its implementation and success (56.4). To answer the question about the main obstacles for crisis prevention and affirmative effects of the water regime, the conclusions will deal with the conflict-conducive effects of the water regime within the three conflict dimensions as specified before (56.5).

56.2 Water Regimes and Conflict Dimensions

56.2.1 Theoretical Aspects and Effects Conducive to Peace of Water Regimes

The distribution of environmental resources such as water is basically problematic because it refers to a specific constellation of interests in which individual players do not possess an exclusive right to benefit from common goods. Due to water shortage, there is a potential for competition about water use. Rational players aim at the highest possible individual profits, whereas the resulting damage is equally distributed among the whole community. However, a restriction of the own use would lead to a profit for the other party, so that every consumer aims at most intensive possibly utilization of this good. International or regional institutions and regimes are needed to resolve this dilemma, as they create reliability in expectations and guarantee a common use of the water, with the effect that the exploration by other parties is not to be feared, or is at least restricted (Oberthür 1997: 35ff.).

Conflict settlement by cooperation seems to be an understandable pattern of response, as the affected players are interested in an intact environmental system and the usability of water resources, whereas “war over water seems neither strategically rational, hydrographically effective, nor economically viable” (Wolf 2001a: 29). Conflict-centred regime theory is suitable for the analysis of environmental conflicts due to its emphasis on regulated conflict resolution and the consideration of cooperative behaviour in water conflicts, due to its positive understanding of cooperation in an anarchic international system and the emphasis on the civilizing function of institutions. “Regimes can be defined as sets of implicit or explicit principles, norms, rules, and decision-making procedures around which actors’ expectations converge in a given area of

international relations” (Krasner 1989: 2). Referring to this definition a regulated conflict settlement is given “when the affected states to a conflict observe a set of rules designed to reduce conflict caused by use, pollution or division of a water resource or the reduction of the standing costs and the observance over time of these rules” (Haftendorn 2000: 65; for regime formation see chap. 52 by Borghese). Due to the characteristic of international and regional regimes as political institutions, a political component of the effectiveness of institutionalized arrangements is preferred that includes behaviour changes but does not renounce the ability to resolve conflicts² (Young/Levy 1999: 6).

Potentially peace-stabilizing outcomes of regional regimes are identified across three dimensions: *Stabilization of cooperation, capacity of problem-solving and civilizing impacts* (Zürn 1997: 469). First, water regimes contribute to negative peace – the absence of military violence – as their function as regulated and peaceful conflict regulation mechanism is given (Efinger/Rittberger/Wolf/Zürn 1990: 275ff.). Regimes prescribe instructions for behaviour, which reduce the probable deployment of violent. Second, regimes as institutions for problem-solving ensure that conflict potentials are lessened, thus curtailing the potential for violence. Third, interactions between international regimes may contribute to the civilization of total relations, overcoming potentially violent and national egoism by orientating the behaviour of states towards a new logic of interdependence (Zürn 1997: 476).

56.2.2 Dimensions of Conflict

The crux of regime effectiveness is their capacity for problem-solving, which corresponds to the social problems of the water issue. Conflicts over scarce natural resources are mainly traced to multidimensional conflict factors (Eberwein 1998), demonstrating the need for a complex strategy for dealing with the destructive effects of those conflicts. Put simply, the regulated conflict resolution by international or regional regimes and their crisis reducing effects will be successful when adequately addressing the inherent components. Otherwise, regimes are likely to prove ineffective.

2 This contribution is based on the work of Krasner, the Tübingen research group (Rittberger, Zürn, Efinger, Mayer, and Hasenclever), as well as on the results of Oberthür (1997) and Young/Levy (1999). Zürn (1997) gives a particularly relevant example of the function of regimes for peace order.

Table 56.1: Framework of Conflict Dimensions. **Source:** Developed by the author.

Context factors	Proximate factors
Environmental dimension	
Geographical situation, hydrological and climatic conditions	Supply-centred solutions
Vulnerability of societies concerning water scarcity	Environmental sustainability as guiding principles
Economic dimension	
General economic situation	Sustainable development strategies
Economical water use	Demand-centred solutions
Socio-political dimension	
General political conditions	Aspects of cooperation
Previous conflicts over water	International aspects

The following framework of conflict dimensions attempts to define a systematic approach for the classification of the relevant factors into the three social sectors, environment, economy, and politics. Such an approach is needed to assign each indicator a social sphere. Within these dimensions, different indicators can be divided “into context factors, that are harder to influence directly, and the more malleable proximate factors, directly influencing water relations between and within riparian states” (Mason/Bichsel/Hagmann 2003: 1).

Context factors are the variables situated in the surroundings of water scarcity. They concern naturally or socially caused preconditions or general conditions, which determine and possibly restrict the conflict parties’ options for effective action. Context factors include natural circumstances as well as general political and economic conditions, the existence of previous conflicts, and dependence on irrigation agriculture. The interacting parties face these conditions, and may influence the context factors only indirectly.

In comparison, *proximate factors* directly influence the water-related issues and constitute entry points for constructive conflict resolution. They relate to the political steering level and may consult national, regional or international measures. National or international politics, sustainable approaches or measures to improve water provision are subsumed under the category of proximate factors. Both kinds of factor can be identified in the three main conflict dimensions as defined below.

First, the *environmental dimension* outlines the geographical and hydrological preconditions of the availability of water, and describes the natural effects of water scarcity. The crucial question is whether the naturally given, unequal distribution of the essential

resource influences the transnational political constellation of conflicts. A central aspect within this dimension is the vulnerability of the societies in terms of water scarcity. These criteria refer to the physical conditions of the scarce water resources, and to the mitigation of this scarcity by improved water management or provision of new resources.

With regard to the problem-solving of anthropogenically caused environmental problems or environmentally induced conflicts the *economic dimension* is of most importance and refers to the social environment of water conflicts. The availability of the freshwater resources is very important for the economic development of a country, as agriculture and industry directly depend on water. Water scarcity is after all a function of supply and demand (Loneragan 2005: 28). On the one hand, an economic capacity is needed to respond adequately to water scarcity, and on the other hand, the economic activities as irrigation of agriculturally cultivated areas bear joint responsibility for the causation of water scarcity.

The third part of the relationship between water and conflict comprises the *socio-political dimension* of historical, political, and social aspects. Politically undesirable developments result in unsustainably dealing with the freshwater resources, for example by the refusal to sign regional agreements. Moreover, the perceptions of water scarcity or unjust water distribution should not be underestimated during the process of conflict resolution. The interests and the strength of political will to cooperate are of great importance within this dimension.

56.3 The Central Asian Water Regime

There is considerable consensus that international agreements are indispensable for problem-solving in transboundary water conflicts (Horsman 2003: 87). When the former agreements became invalid in the early 1990's, the rudiments of a Soviet water allocation scheme served as a basis for the Central Asian water regime. This existing system made its establishment easier at the time, but nowadays the international relations are still influenced by the legacy of the

Soviet system, while the new republics refused to adapt the new conditions within the agreements. The current Central Asian water regime consists of a mesh of political declarations, legal agreements, and various water management institutions.³

Title of the Agreement	Date of Signing	Signatory Parties
Statement of Heads of Water Economy Organizations of Central Asian Republics and Kazakhstan	12 October 1991	Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan, Uzbekistan
Agreement on Cooperation in Interstate Sources' Water Resources Use and Protection Common Management	18 February 1992	Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan, Uzbekistan
Agreement on Joint Activities in Addressing the Aral Sea and the Zone Around the Sea Crisis, Improving the Environment, and Ensuring the Social and Economic Development of the Aral Sea Region	26 March 1993	Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan, Uzbekistan
Nukus Declaration of the Central Asian Republics and the International Community on the Sustainable Development of the Aral Sea Basin	20 September 1995	Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan, Uzbekistan and Representatives of the World Bank and United Nations
Agreement on Cooperation in the Area of Environment and Rational Nature Use	10 January 1997	Kazakhstan, Kyrgyzstan, Uzbekistan
Agreement on Joint, and Complex Use Water and Energy Resources of the Naryn Syr Darya Cascade Reservoirs in 1998	17 March 1998	Kazakhstan, Kyrgyzstan, Uzbekistan
Agreement on the Use of Water and Energy Resources of the Syr Darya Basin	07 May 1998	Kazakhstan, Kyrgyzstan, Uzbekistan
Protocol on Inserting Amendments and Addenda in the Agreement of 17 March 1998	07 May 1999	Kazakhstan, Kyrgyzstan, Uzbekistan

The formal regulations of the Central Asian water regimes can be registered according to their object. First, the *Almaty Agreement*⁴ of 18 February 1992 fixes general principles and acknowledges the right to water use by all states. The Almaty Agreement was caused mainly by political reasons, such as regional stabilization factors, and was less guided by environmental principles. It is a strong indicator for the political motives that the adoption of the agreement took place straight after the gain of sovereignty by the republics. Confusion and imponderability, conditioned by the transition process, forced the mutual affirmation to renounce national solos (Weinthal 2002a: 96). By this agreement, the governments elected the way of negotiated settlements regarding the water distribution in an early phase, before armed conflicts could occur.

Second, the following arrangements focusing on the Aral Sea crisis should be mentioned: The *Aral Sea Agreement*⁵ of March 1993 predominantly deals with the Aral Sea crisis and its context as well as the destructive consequences for the entire Central Asian region (for the specific conditions of the Aral Sea and its surroundings see Rakel in chapter 63 of this book). Complementarily, the *Nukus Declaration*⁶ of 1995 relies on the political principles of sustainability and acknowledges international environmental agreements. These settlements were reached mainly by support of international players such as the World Bank and are closely connected with the setting up, reforming, and establishing of the various water management institutions.

6 Nukus Declaration of the Central Asian Republics and the International Community on the Sustainable Development of the Aral Sea Basin, 20 September 1995.

Third, in the second half of the 1990's various agreements concerning the *exchange of water and fossil energy resources* were reached between Kazakhstan, Kyrgyzstan, and Uzbekistan as riparian states of Syr Darya. In the context of round tables, the heads of state endorsed an agreement in March 1998, which refers to the usage of water and energy resources in the Syr Darya basin⁷ (McKinney 2003: 198f.). An agreement of July 2001 within the *Council of the Central Asian Energy System* for establishing a common energy system to include the five national supply systems and connect them with the Russian energy system was promising for the time being. However, it could not prevent single states from pursuing their own interests, as the sudden ending of Uzbek deliveries of gas to Kyrgyzstan, or the Kyrgyz threat to cut off the water deliveries to Uzbekistan in the summer months (Gleason 2001).

In general, these agreements regarding water distribution and water use are rather unsystematic or even inconsistent with bilateral settlements or the national law. To sum up, it can be said that the water regime in Central Asia is not homogenous in its formation (Smith 1995: 364). This reduces the possibility of regime effectiveness, on which the following section focuses, while the conditions for regime formation have been described in various ways by other authors (cf. chap. 52 by Borghese; chap. 53 by Lindemann; and Weinthal (2002) on Central Asia).

56.4 Evaluating the Central Asian Water Regime

56.4.1 The Environmental Dimension

The environmental dimension impacts on the supply side of water scarcity and is outlined by the region's geographical and hydrological conditions. The total quantity of water resources in the Aral Sea basin should not be scarce, but factors such as population growth, land degradation, and water-intensive agricultural methods reduce the availability of water resources (Micklin 2000: 68; chap. 57 by Martius/Froeblich/Nuppenau). Weak water management institutions and insufficient water agreements deteriorate a situation where conflict potential is geographically

given by the difference between the water-rich and hydroelectricity-dependent states Kyrgyzstan and Tajikistan, and the fossil energy-rich but water-poor countries such as Kazakhstan, Uzbekistan, and Turkmenistan (Klötzli 1996: 281; Sehring 2004: 313; due to possible areas of conflict see chap. 55 by Rakel).

The improvement of efficient availability, mentioned in the Almaty Agreement and the later settlements, but hardly put into concrete terms, would require sufficient financial capacities and the political will to make investments. Apart from this, the targets and principles of the water management institutions are too insufficient to contribute to an effective water administration in the Central Asian region.

Economic interests, attempts to improve the living standard, and the introduction of context conditions to solve the socio-economic problems dominate the Almaty Agreement, while the environmental stress caused by the water deficit is hardly mentioned. To conclude, the leaders of the new republics were predominantly motivated by the interests of economic and security policy. However, within the Aral Sea Agreement for the regional cooperation concerning water management (see preamble of Aral Sea Agreement), the ecological problems in the Aral Sea region are the reference point. The Nukus Declaration contains some remarkable innovations, such as the acknowledgement of water and land as a basis for sustainable development, the objective of a more balanced forestry, and the improvement of water use efficiency (paragraph I, Nukus Declaration). The actual importance of the declaration is, however, reduced by its lack of reference to the Aral Sea and of any legally binding character (Klötzli 1997: 185). The means of problem-solving in the mentioned agreements are already scarce, but the intention to implement the confessions of sustainable environmental policy are even more meagre.

56.4.2 The Economic Dimension

Socio-economic and economic crisis factors may affect water conflicts as catalysts, transforming latent crisis situations into violently settled conflicts. The increase in social inequality – poverty, income differentials between classes and regions, weak economies – is one of the dramatic trends in Central Asia and may trigger violent conflicts, particularly if combined with inter-ethnically composed populations as in the Fergana valley (for the economic situation see chap. 57 by Martius/Froeblich/Nuppenau; Halbach 2001: 18).

⁷ Agreement between the Governments of the Republic of Kazakhstan, the Kyrgyz Republic, and the Republic of Uzbekistan on the Use of Water and Energy Resources of the Syr Darya Basin, 17 March 1998.

Beside these factors, the irrigation agriculture of cotton fields remains the predominant cause of water scarcity in Central Asia. The high share of water consumption for agriculture (93–98 per cent⁸) is just as problematic as are the losses of water by obsolete and ineffective irrigation systems (Micklin 2000: 36). The economic importance of the cotton cultivation and high export rates concern above all the republics of Uzbekistan and Turkmenistan, but its environmental side effects are distributed over the whole region.⁹

The republics that are poor in resources, such as Kyrgyzstan and Tajikistan, give priority to hydroelectric plants, since the share of hydroelectricity is more than 80 per cent of the total energy production.¹⁰ The Soviet water and energy systems were based on a centralistic administrative system of compensation between the Soviet republics. Thus, the problem of distribution of water resources and sources of fossil fuels only became relevant when the Soviet Union disintegrated, dividing this geographic area into several sovereign states.

Demand-centred solutions such as the reduction of irrigated land, the decline of cotton monoculture, and the diversification of agricultural products, as well as the improvement of irrigation efficiency, require a change in the behaviour of the local political and economic elites. In principle, these measures are suitable to counteract the tremendous water usage and resulting water scarcity in the region. The most formidable obstacle remains the dependency on cotton exports, which effectively renders the necessary reforms impossible.

The Almaty Agreement emphasizes the economic importance of water resources, but does not mention limitations of irrigation monoculture as a necessity (Preamble to the Almaty Agreement). In the Nukus Declaration the excessive water use from the rivers Amu Darya and Syr Darya for irrigation purposes is both criticized and acknowledged as the main reason

for the Aral Sea crisis (Preamble Nukus Declaration). The required measure is named as well: the “transition to a balanced and scientifically based system of agriculture and forestry” (paragraph I of the Nukus Declaration).

Overall, the influence of the regional water regime on national agriculture policy is limited; particularly as the Central Asian states are hardly dependent on each other in economic terms.¹¹ The regional agreements of cooperation are scarcely capable of regulating the high water usage by agriculture, while the national players are responsible for the fundamental changes in cultivating practices (Weinthal 2001: 68).

In comparison to the minor progress concerning the cotton monoculture, the regulation of water and energy is more successful. It is supposed that the direct effects of different water usages have strengthened efforts towards conflict settlement. Especially in the Fergana valley, the need for hydroelectricity and irrigation constitutes a high risk of conflict, with threatening gestures regularly made. At the same time, both pressure groups have a strong interest in problem-solving: on the one hand, the middle and lower downstream countries of the Syr Darya would like to limit the Kyrgyz controlling power of the flowing off. On the other hand, the withdrawal quotas resulting from the water agreements do not meet the requirements of Kyrgyzstan.

56.4.3 The Socio-Political Dimension

In the upheavals of the early 1990's, the Central Asian countries were challenged by the explosive tensions created by parallel demands for state-building processes and for developing structures and institutions of regional cooperation (List 2004: 95). The issue of water distribution along transboundary courses of rivers requires a particularly high measure of cooperation. As the proclamation of independent policymaking within the state borders means an essential part of state building, these simultaneous needs for state building and international cooperation are one of the main difficulties impacting on the development of regional cooperation over water resources (Weinthal 2002b: 46). Not least because of their common history and geography, the Central Asian republics are bound up with one another. The cross-border water-

8 In Kazakhstan the share amounts to 81 per cent and is therefore below the average (World Resources Institute 2003: “EarthTrends, Water Resources and Freshwater Ecosystems, Country Profiles”; at: <http://earth-trends.wri.org/pdf_library/country_profiles>, 11 February 2005).

9 Regarding the economic, social, and environmental costs of the Central Asian cotton monoculture, see International Crisis Group (2005).

10 World Resources Institute 2003: “EarthTrends, Data Tables, Energy and Resources”; at: <http://earth-trends.wri.org/pdf_library/data_tables/ene2_2003.pdf> (30 March 2005).

11 For example, the Turkmen and Uzbek cotton exports are mostly transacted with extra-regional states and companies.

Table 56.4: Central Asian Participation in International Water Law. **Source:** Compiled by the author.

Title of the Agreement	Date of Signing	Behaviour of Central Asian Republics
Convention on the Protection and Use of Transboundary Watercourses and International Lakes	17 March 1992	Kazakhstan: ratified on 23 October 2000, not signed yet
		Kyrgyzstan, Tajikistan, Turkmenistan, Uzbekistan: members of UN-ECE, but not signatory parties of the Convention
Convention on the Law of the Non-Navigational Uses of International Courses	21 May 1997	Kazakhstan: voted pro Convention, but did not ratify or sign yet
		Kyrgyzstan: no activities reported (neither consent nor refusal, abstention or absence)
		Tajikistan: absence at voting
		Turkmenistan: absence at voting
		Uzbekistan: supported the resolution, but abstained at voting

courses necessitate an agreement not only over water use, but also over establishing mechanisms for dispute resolution.

By joining the *Commonwealth of Independent States* (CIS) in December 1991, the Central Asian republics temporarily renounced regional cooperation. In view of such a problematic beginning of general cooperation, it is remarkable that the requirement for cooperation concerning water issues was identified at a relatively early moment: the first regional water agreement was signed in February 1992, and further settlements followed. The change in behaviour necessary for the success of regimes can only be attained if the political leadership is willing to cooperate. That applies to all kind of strategies for coping with environmental, socio-economic, or political causes and effects of water scarcity. Breaches of contract by Central Asian republics were reported regularly. For example, water quotas had been exaggerated, the guaranteed withdrawal of water had been withheld, or deliveries of sources of energy had not been made. As the regional water agreements and management institutions managed to become decisive by the influence of international players, the regional endeavours were not very serious from the beginning.

The transboundary watercourses trigger conflicts because two contradicting principles of International Law apply here: sovereignty and integrity. The use of water resources on state-owned areas may affect the integrity of other states, since upstream countries control water withdrawal and may even stop it. The Central Asian republics are very reserved about participating in international debates and regulations, as can be seen in the status of two important water conventions: The *Helsinki Convention*¹² of *UN Economic*

Commission for Europe (UN-ECE) of March 1992, and the *United Nations' Water Convention*¹³ of May 1997.¹⁴ Altogether, the Central Asian republics did not succeed in going far beyond declarations of intent: "The shortfalls between the promises (...) and the reality that no state even penned a draft treaty for the Aral Sea highlights this lack of effort" (Sievers 2003: 141f.). Crisis prevention could be improved if the Central Asian water regime were complemented by components of the international water laws, because the latter are linked with procedures for dispute settlement and sanctions.

56.4.4 The Environment and Security Initiative (ENVSEC)

When three international organizations agree on a coherent strategy regarding the links between environment and security, this may appear auspicious. The *Environment and Security Initiative* (ENVSEC) combines experiences and competences in the field of crisis prevention and democratic development: the *Organization for Security and Cooperation in Europe* (OSCE), in promoting development of peace within the context of economic development of the *United Nations Development Programme* (UNDP) and con-

12 Convention on the Protection and Use of Transboundary Watercourses and International Lakes, 17 March 1992.

13 Convention on the Law of the Non-Navigational Uses of International Courses, 21 May 1997.

14 Status of the Watercourse Convention as of 15 August 2002, in: <http://www.internationalwaterlaw.org/Intl-Docs/Watercourse_status.htm> (16 April 2005).

cerning environmental issues in Central Asia which is a focus of the *United Nations Environment Programme* (UNEP).¹⁵

The integrated approach of the ENVSEC Initiative¹⁶ meets the challenges posed by the Central Asian water crisis, even though the financial and personnel endowment is unclear and the acceptance by the Central Asian players questionable. However, it is possible to nourish hope for the following affirmative aspects: *First*, the cooperation between the three international organizations tends to have success as the different experiences are combined. *Second*, the explicit inclusion and capacity building of civil society is of outstanding importance, fostering democratic participation, individual responsibility, and freedom of information. In this context, the project 'Awareness Rising and Public Participation in Decision-Making through Improved Access to Information and Environmental Education' is worth mentioning (Rampolla 2004: 53). *Third*, the multi-level consulting and participating process could lead to improvements in sustainable effects of the water regime. Strengthening the political will of national decision-makers will be the crucial point for internal measures, as well as for cooperation at the regional and international level. *Fourth*, the advantage of the ENVSEC Initiative could be the combination of environmentally induced factors as well as economic and security issues related to the water crises (see chap. 71 by Cheterian).

56.5 Conclusions

Until now, international conflicts or serious diplomatic incidents over the distribution and usage of water resources could be avoided. However, it is necessary to inquire to what extent this development was promoted by the regional water regime. Security interests took priority over environmental problems concerning the regional agreements in former Soviet Cen-

tral Asia, and as a result, violent ethnic conflicts over scarce water resources were avoided (Weinthal 2002b: 203f.). By including the water question in the agenda at the regional level, the water regime succeeded in creating a regular basis for mutual meetings and talks. Summits of secretaries of leading politicians and technological cooperation within regional water institutions ensure continuity of cooperation, which is indisputable for stabilizing security and peace. The regular dialogue counts as one of the main achievements of the Central Asian water regime. Except for single enforcements of unilateral interests with sad consequences for the neighbours, such as breaches of contract, a start has been made for regional cooperation. The unalterable border-crossing character of watercourses as an object of regulation determined these early attempts of regional cooperation. *It seems certain that the swift institutionalization of the water issue in the regional agreements and institutions in the early 1990's resulted in conflict-preventive effects.*

In the field of problem-solving it was found that the declared targets of the Almaty Agreement of February 1992 failed. The catalytic factors for regional vulnerability of conflicts could not be reduced by the agreements, mostly for the insufficient political will of Central Asian governments and their insufficient financial and technological capacities.

Within the *environmental dimension*, the blatant water scarcity caused mainly by anthropogenic factors has negative social and health effects on the local population, and the environmental damages are alarming. Inevitable differences of positions are conditioned by the natural space and the regional inequality of the water resources. The asymmetric water availability between the upstream countries, Kyrgyzstan and Tajikistan, and the downstream countries, Uzbekistan, Turkmenistan and Kazakhstan, corresponds to the abundance of other resources in the latter countries. The water conflicts became obvious only after the Soviet Union collapsed and the frontiers were internationalized, so that conflict regulation at the bilateral and international levels became necessary.

For providing sufficient water resources and their distribution in a just manner, the *economic dimension* is relevant, because the main cause of water scarcity is the intensive irrigation agriculture, which is traced to the dependency on the export of cotton. Therefore, a programmatic approach to problem resolution has to aim at changes in behaviour concerning the irrigation of arable lands by water saving and reducing losses of water, while ineffective water management increases the unsatisfactory water distribu-

15 The ENVSEC Initiative was founded in 2002 and focuses on Central Asia and South East Europe, in the meantime as well on Southern Caucasus and Eastern Europe. The NATO joined the Initiative as an associated member.

16 The Initiative proceeds on the assumption that the degradation of the environment and the unequal access to scarce resources on the one hand, and the conflict potentials of these factors on the other hand, are closely linked. Accordingly, the approach promotes environmental cooperation as a suitable instrument for crisis prevention (ENVSEC 2003a: 5, Rampolla 2004: 52).

tion and quality. The conflict potential caused by the differing needs for using the scarce water resources may be reduced, provided that a functioning system for the exchange of fossil energy resources and water resources can be introduced.

Water-related problems within the *socio-political dimension* are the Soviet legacy of water allocation and the process of transition, which has not been completed yet. The increased potential of conflict over the distribution of scarce water resources occurred by closing the compensation system of water and energy, and by a lack of an accepted regional arbitration authority. The repeated threats against neighbouring countries to use water as a mean to achieve economic benefits or political aims, or to attack hydroelectric plants, caused a distrustful and non-cooperative political atmosphere in Central Asia. Linked with authoritarian structures, the prevalence of economic interests and a lack of serious attempts to save water, the intended extension of irrigation areas is alarming. As a result, the growing demand further reduces scarce water resources and increases the relative potential for conflict.

Some success concerning short-term and medium-term stabilization cannot alter the fact that the crucial conflict potential and causes were merely addressed and regulated as the continuing differences in interests indicated. *The specifically named targets of the water agreement were achieved only to a limited extent. In terms of environmental problems, the improvement was nearly none, and the socio-economic effects on poverty and internal differentiations were merely reduced.*

Civilizing impacts of the total relations means the overcoming of national egotism with its tendency to violence, so that non-violent conflict resolution as a way of conduct is fostered by the recognition of enduring interdependencies. However, such peace-conducive effects of international or regional regimes should be observed and evaluated over longer periods of time to obtain reliable results. Because the regime genesis is still neither coherent nor completed, the impact of the Central Asian regime is not to be assessed finally. *But it is foreseeable that the tense international relations, the mutual blaming for the desiccation of the Aral Sea, and the repeated gestures of threat do not work towards such lasting impacts.*

The initial assumption was that the inherent design of a regional regime corresponds with its chance for success. The success of a regime is not only defined by its adherence to the agreed norms and rules, but also by a high capacity for problem-solving. In

both respects, the Central Asian water regime has many defects. The frequent unilateral breaches of regional contracts and the financial contributions for the regional water management institutions, which are often only fractions of the promised amount (World Bank 1998: 9), are indicators for the difficulties in implementation of the Central Asian water regime. Deficiencies in the political intentions of the Central Asian governance systems to improve the conditions for solving the water crisis are obvious. Furthermore, the difficulties in establishing a standardized common water regime and its insufficient problem-solving capacity are caused by the fact that the aims of sustainability and socially acceptable development were subordinate to economic profit-maximization.

In conclusion, the assumption of the conflict proneness of the Central Asian societies by water scarcity is proved true, explaining the interdependencies between the environmental, economic, and political conflict dimensions. Legal arrangements can create reliable expectations and provide the framework for diplomatic and non-violent regulations of the water issue. The renunciation of violent measures is a decisive success of the established institutions and agreements. However, the Central Asian case also indicates that the authority of legal agreements is rather low if there is no common goal of sustainable development and no true will of the state leaders to take extensive actions over all water-related dimensions. Regime success is already limited by their failure to reach fundamental changes of behaviour, so that water-related security risks in Central Asia continue to exist.

Water Resource Management for Improving Environmental Security and Rural Livelihoods in the Irrigated Amu Darya Lowlands

Christopher Martius, Jochen Froebrich and Ernst-August Nuppenau

57.1 Introduction¹

Reliable and safe supply of fresh water resources is one of the most important global environmental challenges (Rechkemmer 2004). Water resource management must become economically more efficient, ecologically sustainable, and also socially justifiable, especially so in the water crisis regions.

The Amu Darya River basin in *Central Asia* (CA) is one of these crisis regions where management of water resources is unsustainable and uneconomic, bearing great potential for social conflicts. CA is a region in economic and political turmoil, change, and transition. Whereas most countries of the region have adopted a fast transition to some form of market economy, the government of Uzbekistan has tried to pursue an 'Uzbek way' that relies on strong government control of its economy and a 'taxation', via a state order system, of the agricultural production (Pomfret/Anderson 2002). Agriculture accounts for 38 per cent of the GDP and is therefore the largest economic sector. It depends almost completely on irrigation, and especially in the lower Amu Darya region, water is the basis of the livelihoods of the 3.6 million people living here. Although the Amu Darya completely originates outside, in the mountain glaciers of the upstream countries Tajikistan and Kyrgyzstan, its water is the source of wealth.

Due to their tail-end situation, the irrigated *Amu Darya lowlands* (ADL) in eastern Uzbekistan and northern Turkmenistan pose particular challenges to water management. These lowlands are relatively

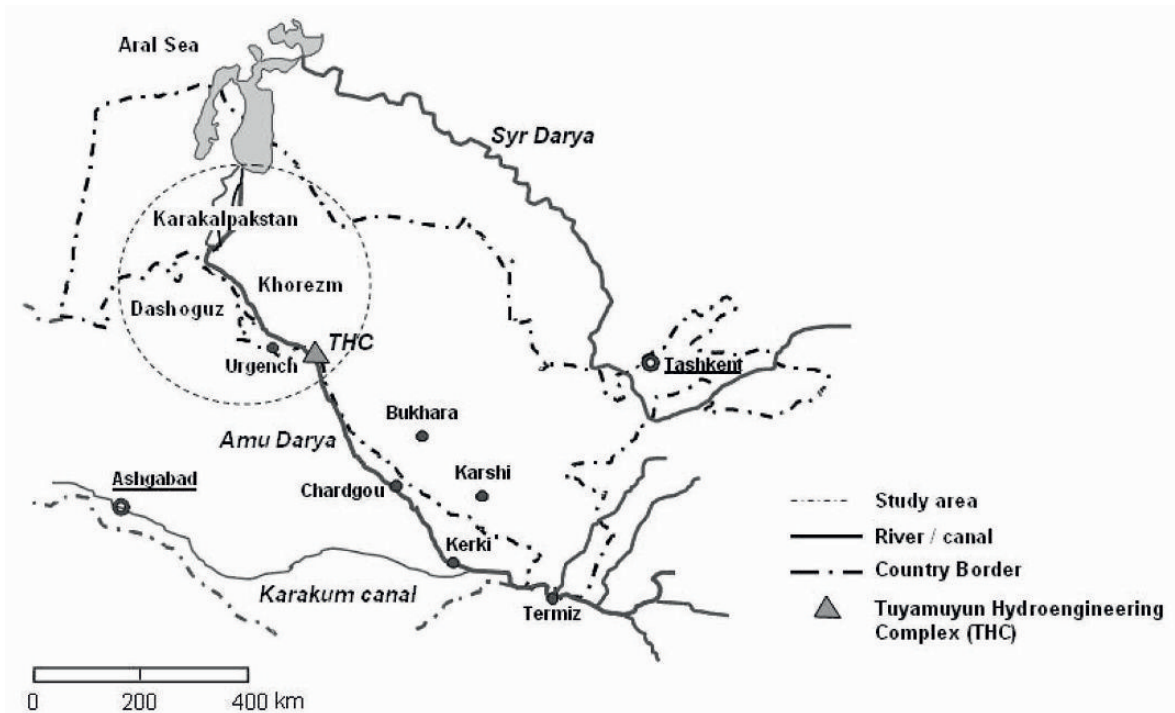

small oases of irrigated land amidst vast deserts (figure 57.1), but nevertheless account for roughly 25 per cent of all irrigated land in the Amu Darya basin. Here, water and land resources are at much higher risk of deterioration than upstream. This is aggravated by the present water resource management aiming at providing water for agriculture, but not addressing a more integrated, sustainable resource management.

After their independence in 1991, the Central Asian countries found themselves facing a situation characterized by inherited salinized, polluted and impoverished soils, huge and partly dysfunctional irrigation systems, and a 'path dependency' on cotton. In terms of quantity, water should not be a scarce resource in the Aral Sea basin, not even in dry years. However, several factors put water, as a resource, 'under stress'. Four factors (Tickell 2003; Brauch 2003, 2005, 2005a and chap. 4) drive the intertwined environmental and economic development in the irrigated lands of Central Asia (Giese/Sehring 2007, 2007a; Sehring/Giese 2009):

1. *Demography*: population growth has been high in all Central Asian countries in the 1990s, and continues so in Tajikistan with a 2.1 per cent population growth in 2006, but has been slowing down to average rates in Uzbekistan, Turkmenistan, Kyrgyzstan, and Kazakhstan (ADB 2007). Nevertheless, a high share of young people (e.g. 64% of the population is below 30 years of age in Uzbekistan) represents a future legacy for development. Increased food demand due to high population growth rates will prompt further expansion of irrigated lands, whilst increasing the risk of water unavailability (MA 2005a). Also, an increasing urbanization pressure on agricultural land is to be observed.
2. *Climate change*: the above-average climatic change predicted for CA will bring short-term gains in wa-

¹ This study was in part funded by the German Ministry for Education and Research (BMBF). We thank John Lamers, Oliver Olsson, Melanie Bauer, Bernd Kuzmits, Konrad Kellner, and Andreas Beyer for valuable input and discussions.

Figure 57.1: Irrigated Lowlands of the Amu Darya (Amu Darya Lowlands or ADL). **Source:** This map was drafted by the authors.

ter availability downstream (due to melting glaciers), but will on a long-term scale translate into lower water inflows from the mountains, higher water losses to the atmosphere, and larger vulnerability of agriculture from droughts.

3. *Increased water demand:* The lowlands, in the watershed, are particularly vulnerable to increased water diversions upstream. The upstream countries (Tajikistan, Kyrgyzstan) will be increasingly claiming 'their' water resources for themselves (chap. 55 by Rakel; chap. 56 by Wunderer). The lowland countries Uzbekistan and Turkmenistan consume 83 per cent of all water of the basin. Turkmenistan is insisting on its share of the water resources, used in ambitious 'development' projects. Further demand will be created if Afghanistan proceeds with developing its own irrigation systems at the Amu Darya, which may divert up to 10 per cent of the total water budget of the region.
4. *Land degradation:* The first three factors will likely result in reduced water availability in the irrigated ADL. This will trigger land degradation, reduce 'ecosystem services', the ability of the land to sustain human, and ecological well-being. Ecological degradation is already an issue; many former wetlands have been destroyed (Treshkin/Kamalov/

Bachiev/Mamutov/Gladishev/Aimbetov 1998), the Aral Sea has been depleted, and the irrigated agricultural land is suffering from nutrient mining and over-irrigation during the last 45 years. The annual costs of land degradation have been estimated by the ADB (2004) at about 7 billion US Dollars for all five Central Asian countries.

Failing water supplies and the interests of several countries in the water resources bear a certain potential for trans-national conflicts over the distribution of water resources. Nevertheless, we see a very low risk for this at present, as, historically, the 5 CA states have managed their water resources jointly, if not without friction, then well enough to avoid major conflicts. We argue here that it is the past and ongoing ecological deterioration which, given the linkage between the environment, human well-being and security (DFID 2006), provides much more reason for concern. Also, if the water resources are not managed in a sustainable way, that satisfies the needs of all users, conflicts may arise between differently endowed individuals rather than states.

Integrated water resource management (IWRM), an approach that balances technology-oriented water management with environmental, economic and social aspects, in our view provides a promising tool to

specifically address the complex situation in CA. For its intertwined problems of demographic growth, climate change, water demand and land degradation, IWRM is a suitable approach. We will show here that the specific background – the history of water management in the region (that produced the present large, formerly centrally managed irrigation systems), the present institutional set-ups, and the existence of a well-informed class of technicians – favours the step-wise implementation of key actions. Additionally, the emphasis is on key technologies in an inter-disciplinary framework. Such a framework is needed because isolated sectoral approaches have proven to be unsuitable to achieve resource-saving, economically adapted, and socially acceptable resource management. For example, privatizing water distribution and introducing water markets is unrealistic when implemented as an isolated measure. Reasons are: *First*, the prevailing rural poverty, poor nutrition status, and widespread health problems require that water is distributed as a social asset, being cheap and readily available, not an economic commodity². *Second*, most farmers lack the necessary capital for direct investments in water saving technologies. *Third*, the organizational and institutional set-ups in the management of river and canal systems do not address the ecological sustainability of the resource. Though local actors possess high-quality, although often under-estimated, know-how that can be gainfully employed, market approaches are beyond their skills. The local water administration's weak side is lack of modern concepts (such as a systems view), adequate planning instruments, regulatory mechanisms and equipment. There is a clear need to find entry points for putting in practice a system approach for IWRM.

This contribution is based on the authors' experience in the ADL.³ We will first describe the region and its specific problems (57.2), and then proceed to outline a scenario of how to achieve IWRM in the specific situation of the ADL (57.3).

57.2 The Lower Amu Darya Basin

The Aral Sea, once the fourth-largest fresh water lake in the world, today has been reduced to 15 per cent of the water volume and 35 per cent of the surface it had 45 years ago. The well-known cause is the huge expansion of the artificially irrigated area during the Soviet period. In fact, the 'Aral Sea Syndrome' (WBGU 1998) has often been analysed (Vlek/Martius/Werheim/Schoeller-Schletter/Lamers 2003) and elsewhere in this book by Rakel (chap. 55) and Wunderer (chap. 56).

The Amu Darya River is the major former tributary to the Aral Sea. With a length of 2540 km it is the longest river in Central Asia and starts in Tajikistan, runs through Uzbekistan, where it forms the border to Afghanistan, enters Turkmenistan, and returns to Uzbekistan (figure 54.1). On the way, huge water quantities for irrigation are extracted, primarily for the irrigated areas of Surkhandarya, Kashkadarya, and Bukhara (Uzbekistan), and mainly (through the Karakum canal) for Turkmenistan. The remainder is intercepted in the Tuyamuyun reservoir that marks the entrance of the ADL. The water is mostly being used up in the ADL, only eventual surpluses flowing to the Aral Sea.

Here we specifically focus on the *Amu Darya lowlands* (ADL), which we define as the whole of the irrigated lands between the Tuyamuyun reservoir and the Aral Sea, a region under intensive agricultural cultivation. This region belongs to two countries and consists of three administrative areas (figure 55.1). The province of Khorezm and the Autonomous Republic of Karakalpakstan are part of Uzbekistan and make up 250,000 and 500,000 ha of irrigated area, respectively, while the district of Dashoguz (310,000 ha irrigated) belongs to Turkmenistan. The total area (1,060,000 ha) corresponds to roughly one tenth of the Aral Sea Basin's area. In total, 3.5 million people live here, also corresponding to roughly 10 per cent of the Aral Sea Basin population.

The water supply to the ADL is controlled by the Tuyamuyun reservoir system. About 95–98 per cent of the Tuyamuyun's outflow is used for agricultural irrigation water, the remainder for private households and industry. The Tuyamuyun, completed in 1983, supplies water through a canal network that in Khorezm, alone, spans 16,000 km, not counting on-farm channels. Likewise in Khorezm, a network of 7,500 km of drainage canals collects the saline drainage water running off agricultural fields.

2 This is actually reflected in the present system of 'free' water supply to the farmers

3 See; Froebrich/Bauer/Ikramova/Olsson 2006, Froebrich/Kayumov 2004; Martius/Lamers/Ibrakhimov/Vlek 2004a, Martius/Lamers/Werheim/Schoeller-Schletter/Eshchanov/Tupitsa/Khamzina/Akramkhanov/Vlek 2004b; Vlek/Martius/Werheim/Schoeller-Schletter/Lamers 2003; ZEF 2003.

The annual agricultural water use in the Aral Sea basin of 54.4 km^3 is higher than the average availability of 50.4 km^3 (UN, WWAP 2003); drainage water re-use accounts for the difference (Froebrich/ Kayumov 2004). For the ADL, below Tuyamuyun, an average water volume of $38.9 \pm 13.6 \text{ km}^3/\text{year}$ is available (1981–2001; Ibrakhimov 2005); Drought years with a total water volume of less than 20 km^3 are statistically expected once every ten years (note that in 2001, the last drought year, total water volume was $13 \text{ km}^3/\text{year}$). As the entire water demand in the ADL amounts to about $20 \text{ km}^3/\text{year}$, droughts may entail serious yield losses of up to 33 per cent (Mueller 2006).

CA is experiencing a global warming above average, as exemplified by an average temperature gain of 1.2 to 2.1 °C in the region since the 1950's (far in excess of the 0.5 °C increase in global temperature; Giese/Mossig 2004), and by the 1–2 °C/century increase observed in Central Asia; this is much higher than the Asian average of 0.7 °C (Watson/Zinyowera/Moss/Dokken 1998). The IPCC also projects a temperature increase of 1–2 °C until 2030–2050 in the region. Glacier-melt runoffs have already increased by 15 per cent in the period 1959–1992. The same IPCC report predicts that an extra runoff may persist for decades, and in very large glaciers such as those found in CA even for a century or more.⁴ This will substantially increase the regional water resources. Nevertheless, there is no reason for relaxing the move towards greater sustainability of resource use, as water diversion is likely to be increasing, and on the long run, climate change will strongly reduce the overall water availability (McCarthy/Canziani/Leary/Dokken/White 2001).

Land degradation is an economic, social, and environmental problem in the transition economies of all five CA countries, seriously affecting the livelihood of the rural population by reducing the productivity of land and leading to agricultural losses as well as to increased costs for the agricultural production. In the ADL, land degradation manifests itself mainly through secondary soil salinization and water logging (Ibrakhimov 2005, Akramkhanov 2005), decreased fertility of pastures (ADB 2004), and reduction in forest areas (Worbes/Botman/Khamzina/Tupitsa/Martius 2006).

57.2.1 Agricultural Water Use as a Major Driver of Environmental Insecurity

Agriculture without irrigation is almost impossible in Central Asia. The irrigated land has been steadily expanded from 4.5 million ha in 1960 to 7.9 million ha today. In Khorezm, for example, there has been an increase from 200,000 ha in 1982 to 276,000 ha in 1999, i.e. a 38 per cent increase in 17 years. At the same time, the average probability of a farmer to obtain sufficient irrigation water declined by 16 per cent; i.e., the farmer has now a substantially higher risk of losing his crops due to insufficient water supply than 20 years ago. This is exacerbated by a strong year-to-year and regional (e.g. higher risks at the tail-end of the irrigation system) variation of water availability (Mueller 2006).

Cotton is the major crop in Uzbekistan. It is produced following a so-called 'state order' system, by which the government controls the distribution of crops on the fields; water supply and delivery of other inputs; prices, processing, and export are also controlled. Every region and farm must attain prescribed production goals. It has often been repeated that the Uzbek government finances a large portion of the state budget from the difference between local prices and world market prices of cotton (Rudenko/Lamers 2006; Guadagni/Raiser/Crole-Rees/Khidirov 2005). But farmers also benefit from the state order system. As many rural operations are poorly capitalized and non-state markets are still underdeveloped, the system functions as an effective credit system for important inputs (seeds, fertilizer, diesel, machines, water), guarantees stable input prices, and ultimately works as a risk protection strategy. For instance, state organizations were instructed to cancel debts incurred by farmers during the droughts of 2000 and 2001. Note that water is delivered for free, except for a small land-based fee.

The free water supply in the state order system provides no incentives for water saving. Similarly, the lack of land rights – land belongs to the state and is leased out for a maximum of 49 years – also does not stimulate sustainable resource use. Under pressure to meet production targets, the state farms in the past did not spare inputs for cotton cultivation such as irrigation water, fertilizers and pesticides, and nowadays, in spite of privatizations, the prevalent agricultural production system remains extremely uneconomic. This is not surprising, since most 'new' farmers are insufficiently prepared to run a farm enterprise.

4 This was confirmed by working group 2 (Cruz/Harasawa/Lal/Wu/Anokhin/Punsalmaa/Honda/Jafari/Li/Huu Ninh 2007).

Due to heavy irrigation, the groundwater levels rise quickly in spring every year, which results in capillary groundwater rise and salt encumbrance in the soil (Ibrakhimov 2005; Akramkhanov 2005). Cotton yields have only partially decreased due to worsening soil conditions, because the - widespread - leaching of salt from the fields in spring can partially compensate the degradation (Mueller 2006). In addition, since independence, investments in the operation and maintenance of the irrigation system have been extremely scarce. This has led to major losses in the water relocation system; Uzbekistan and Turkmenistan belong to the eight countries with the greatest per capita water usage in the world (WWF 2002). On the costs of cotton production, Uzbekistan performs very poorly compared with other countries with similar climate and conditions (World Bank 2003d, 2003b).

The risk of failing or untimely water supply for irrigation forces ADL farmers to rely on groundwater contributions and to secure as much water as possible once this is available. Farmers often reduce the outflow to the drainage channels as a strategy to save their crops during periods of insufficient water supply. This is a rational decision at the field scale, given the actual supply system functioning, but translates into emergent higher-level problems such as high groundwater tables and secondary soil salinization, which consequently prompts more leaching⁵. Consequently, hydrological textbook recommendations focusing on hydrologically 'sound' solutions alone will do little to improve water use efficiency, as long as they do not address the farmer's risk of not having sufficient water.

Altogether, the build-up of these vast irrigation systems during the last 70 years constitutes a "path dependency" that can not be rolled back today. Therefore, efforts need to be undertaken that fit the system, but are concerted to reform the water sector towards more rational and sustainable management. We suggest that the existing water management agencies and irrigation infrastructure represent - in contrast to many other regions - a promising entry point for a stepwise implementation of IWRM principles.

5 High groundwater tables lead to capillary water transport to the soil surface and evaporative losses to the atmosphere, while salts dissolved in the water build up the salt load in the soil, reducing soil fertility and crop growth. This is often combated with 'leaching', the flooding of the fields before planting them in spring.

57.2.2 Socio-economic Conditions: Poverty, Food Insecurity and Health Problems

As is expected from their history, the five Central Asian republics show a mixed picture regarding various development indices. For example, they all rank high on adult literacy rate (98.7–99.5%) and all rank low in life expectancy at birth (62.6–66.8 years), and human development index at 0.67–0.79. However, with regard to indicators of technology diffusion, e.g. number of telephone landlines, cellphones, or internet users, Tajikistan trails far behind all the other New Independent States (NIS) (all data from UNDP 2007). Uzbekistan⁶, which is most relevant here with regard to the ADL, ranks higher in GDP than Kyrgyzstan and Tajikistan, but lower than Turkmenistan and Kazakhstan (FAO 2004, World Bank 2003d, 2003b). With regard to the Environmental Performance Index (Esty/Levy/Kim/Sherbinin/ Srebotnjak/ Mara 2008) which gauges several aspects of environmental health and ecosystem vitality into one figure, all Central Asian countries rank in the third quarter of the list (occupying the ranks 79 to 107 of the country list).

Poverty is a particular problem in the peripheral and naturally disadvantaged (low-productivity drylands) rural regions of Uzbekistan where unemployment (25 per cent) is far above the national average (7 per cent; World Bank 2001). This was not always the case. In 1993 only 3.3 per cent of the rural population was below the poverty line of 1 US\$ per day, but in 2003 poverty has already reached 27.5 per cent or 6.8 million people (Sievers 2003).

Low income in the agricultural sector leads to nutritional problems in rural areas, where 78 per cent of the average income is spent on food (Herbst 2006). Note that the small scale production in household gardens is not sufficient in the ADL as in other countries because the productivity of home gardens is the lowest among the NIS (World Bank 2003d, 2003b).

Half of the drinking water supply in the ADL comes from the Tuyanumyun reservoir, where drinking water is withdrawn from the Kaparas basin and routed on to the cities of Nukus and Urgench, notably through pipelines. The quality of drinking water from the Tuyanumyun satisfies the Uzbek norms, but does not meet international quality standards. Notwithstanding, more than 90 per cent of the rural population in Karakalpakstan gain their drinking wa-

6 The economics of Turkmenistan are not being discussed here

ter directly from the open irrigation channels. This especially affects children under five years of age which are most susceptible to diarrhoeal diseases (Herbst 2006). The open waters are often fecally contaminated, have high salinity levels, or are polluted with pesticides (Herbst 2006; O'Hara/Wiggs/Hubbard/Wegerdt/Falzon/van der Meer 2001). Pesticide use in Uzbekistan has fallen due to its high costs, but the application rates in cotton remain high.

Due to low income, lack of education, inadequate nutrition and drinking water supply, and environmental pollution the health status of many citizens is critical (World Bank 2003d, 2003b). Nevertheless, the often claimed link of respiratory diseases to air pollution in the region remains unsupported (Wiggs/O'Hara/Wegerdt/van der Meer/Falzon/Hubbard 2003).

Since independence, Uzbekistan has reduced its cotton production in favour of wheat to achieve greater independence from imports and to achieve a higher food security. In 2004/2005 the country became autonomous in wheat supply, but at high economic costs (wheat could be imported at lower prices). Rice production also plays an important role in ADL; this highly water consuming crop is important in the national diet, produces high income (Rudenko/Lamers 2006) and therefore continues to be grown in spite of disincentives.

The socio-economic situation of Uzbekistan has to be seen in the context of IFPRI's cautioning (Pinstrup-Andersen/Pandya-Lorch 1998) against overlooking links between water supply, poverty and food security. In Uzbekistan, the prime challenge to food security and health problems is low water productivity; the country has one of the lowest water productivity levels in the world. The water productivity of poor farmers is often low because they lack training, equipment and funds for investing in more efficient technologies. Water productivity could be improved, for example by changing the current cropping patterns. Cai, Ringle and Rosegrant (2003) have shown that alternative crop mixes, with less cotton in Uzbekistan, would perform better in all indicators than the current crop mix, including farmers' value added. However, Rudenko/Lamers (2006) express caution against uncoordinated agricultural policy changes which are likely to have disastrous consequences.

57.2.3 Water Administration

Water distribution in the Aral Sea basin is controlled by the international *Interstate Commission for Water*

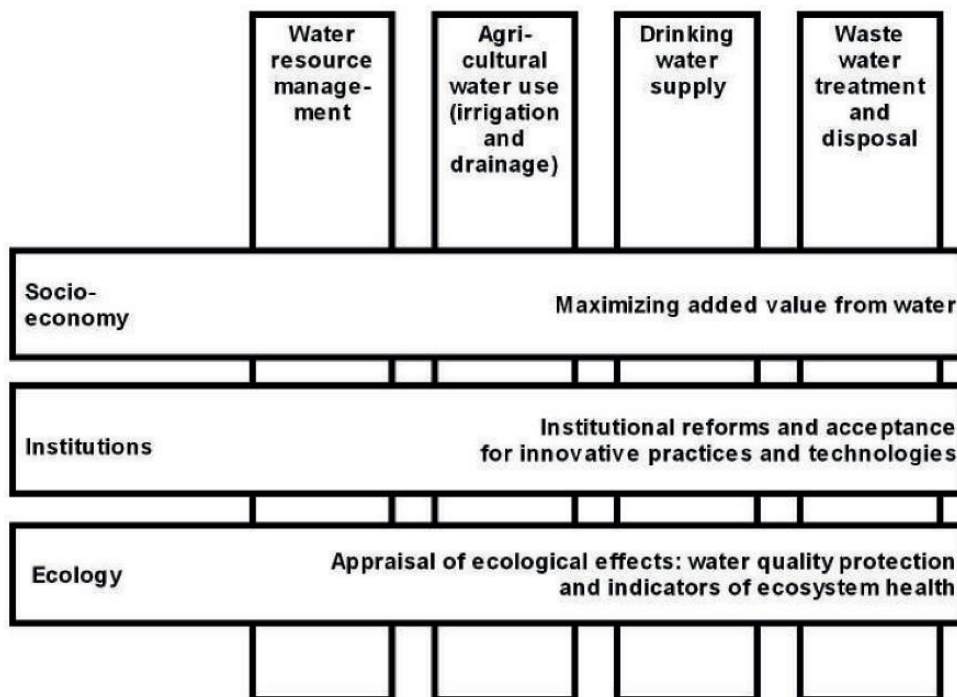

Coordination (ICWC) with Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan and Uzbekistan as members and Afghanistan as consulting partner (Sehring 2002, 2004a). The transport of the agreed water volumes in the main irrigation canals of the Amu Darya Basin is monitored by the *Basin Water Organization* (BWO) for Amu Darya (a similar BWO exists for the Syr Darya). More specifically, this is monitored by a BWO department called Upradik which also regulates the Tuyamuyun reservoir. The supply of water to Dashoguz in Turkmenistan occurs through three such large 'trans-national' canals which flow through Khorezm and Karakalpakstan. However, Turkmenistan has also built a channel that conveys water around Khorezm to Dashoguz. Giese, Sehring and Trouchine (2004) estimated that up to 80 per cent of the water in this canal is lost to infiltration in sandy soils and evaporation.

At the national level in Uzbekistan irrigation water is monitored by the *Basin Management of Irrigation Systems Authority* (BUIS), directly subordinated through the Ministry of Agriculture and Water Resources. The BUIS Lower Amu Darya, residing in Nukus, is responsible for the administration and allocation of water to Khorezm and Karakalpakstan. It is divided into 10 sub-departments (Management of Irrigation System, UIS), 6 of which are responsible for Karakalpakstan and 4 for Khorezm. These departments serve as connectors between the *Water User Associations* (WUAs, see below) and the state administration. In 2003, WUAs were introduced in the ADL, initially outlined according to hydrological criteria, but since 2005 WUAs have been designed based on the borders of the *shirkats* (former communal farms) (Zavgorodnyaya 2005). Since 2006, the introduction of water pricing schemes is being tested in pilot areas. These frequent re-organizations in the water sector indicate that distribution and allocation of water is still problematic, which represents a possible entry point for institutional improvements.

57.3 Integrated Water Resource Management (IWRM)

Analyses of many past development projects have shown that an overly narrow sectoral orientation produces solutions for water management which do not address the complex and delayed system behaviour and are therefore not sustainable (Dörner 1996). The introduction of IWRM is based on the Dublin principles, which emphasize the vulnerability of freshwater

Figure 57.2: Essential Utility Aspects of Water (vertical bars) and Cross-cutting Themes (horizontal bars) for Achieving IWRM in the Amu Darya Lowlands. **Source:** This figure was developed by the authors.

resources, the need for participatory planning and the consideration of the economic value of water (World Bank 2003c).

IWRM is defined by GWP as a process, which promotes the co-ordinated development and management of water, land and related resources, in order to maximize the resulting economic and social welfare in an equitable manner, without compromising, the sustainability of vital ecosystems (GWP 2000b). Similarly, IWRM is understood by UNDP as a cross-sectoral policy approach, designed to replace the traditional, fragmented sectoral approach to water resource management that has resulted in unsustainable resource use (and also unsatisfying services). Based on the understanding that water resources are at the same time an integral component of the ecosystem, a natural resource, and a social and economic good (UNDP 2005), the IWRM approach aims at saving water and safeguarding water quality, supporting social and economic development, while at the same time preserving ecosystems.

The IWRM philosophy is widely diffused (Gyawali/Al-lan/Antunes/Dudeen/Laureano/Fernández/Monteiro/Nguyen/Nováček/Pahl-Wostl 2006); elements such as public participation and institutional reforms have attracted much attention (Lenton 2004), and there is a common acceptance of IWRM objec-

tives. However, its implementation is only partially realized in both developed and developing countries (UNDP 2003). The IWRM concept has been criticized insofar as it may be helpful to describe the complexity, but less so in pragmatically outlining implementation strategies (Gyawali/Allan/Antunes/Dudeen/Laureano/Fernández/Monteiro/Nguyen/Nováček/Pahl-Wostl 2006). Nevertheless it is considered a major achievement that the inclusion of socio-economic aspects and the integration of water quality and quantity will contribute largely to more sustainable water resources use than past fragmented approaches.

UNDP sees IWRM as a changing process with no fixed start or end points, which seeks to shift water management systems towards improved, sustainable states. The art lies in the right mix of selecting, adjusting, and applying available tools for a given situation (UNDP 2005).

57.3.1 Setting up an IWRM Framework for the Amu Darya Lowlands

Here, IWRM is understood as a general framework in which individual measures must be integrated in an integrated multi-sectoral approach; however, the practical feasibility considerably depends on the approach chosen. As a loose framework, we offer a matrix ap-

proach (figure 57.2) that combines the most urgent water management issues (vertical bars) with cross-cutting themes (horizontal bars). The IWRM concept must address all main water-related issues in a comprehensive manner and following hydrological (instead of artificial administrative) borders. For the situation at hand, the following four topics were identified: a) integrated management of natural ground and surface water resources; b) agricultural water use; c) drinking water supply and d) waste-water treatment and disposal. All categories must be reviewed related to their interaction and their mutual impact on water quantity and quality within the cross-cutting topics i) socio-economic aspects, ii) institutional aspects and iii) their impact on the ecosystem. To improve on organizational performance, economic efficiency and ecological sustainability, we suggest going along a matrix structure.

In the following a number of specific vertical and horizontal issues with respect to the lower Amu Darya basin will be described. The specific definition of what kinds of activities should be addressed will depend on local conditions, existing infrastructure, and specific demands of players in the region.

57.3.1.1 Water related themes

Integrated Management of Natural Ground and Surface Water. The dams of the Tuyamuyun reservoir play a critical role in the integrated management of ground- and surface waters downstream. Both, seasonal water availability and water quality depend on the operation and management rules of the Tuyamuyun complex. Currently, the Tuyamuyun dams are operated only for maximizing water quantity, where management rules are more based on past experience instead of formal plans. The Kaparas reservoir is predominantly filled during the winter months, when the Amu Darya has highest salt concentrations, whereas the low salinity summer floods – which could be used for drinking water – are directly channelled downstream for satisfying the irrigation water demands (Froeblich/Bauer/Ikramova/Olsson 2006). Modified operation rules would allow storing the low saline water during summer in the Kaparas reservoir and, by this, keeping the salinity in the drinking water below WHO standards of 1000 mg of salts per litre. It was shown that a reduction of the overall water deficit can be achieved even within a sequence of dry years (Froeblich/Bauer/Ikramova/Olsson 2006).

Changes in the dam operation will affect infiltration losses, the impact of shallow aquifers downstream, and the mobilization of pollutants to shallow

aquifers. Rises in groundwater levels not only affect soil salinization, but also, locally, the contamination of groundwater through the spread of latrines (Herbst 2006) and point pollution. Therefore, interactions between dam operation and groundwater resources need to be studied more thoroughly. This goes beyond the presently applied approaches in the region, and training is essential to support local managers in operation and management and to supply decision makers with the knowledge required. Supportive training programmes are also needed to introduce modern, GIS-based and integrative water planning and distribution tools, particularly, to secure water distribution by quantity and quality according to the users' varying needs in space and time.

Agricultural Water Use. Improved water use efficiency in agriculture can be primarily achievable by using all potential and economically acceptable water saving options based on an interdisciplinary assessment of costs, benefits and needs. For farmers, water should provide maximum agricultural yields which includes avoiding economic losses due to water shortage (Martius/Lamers/Vlek/Eshchanov/Rudenko/Salaev 2005).

Reducing water losses and transportation costs would require huge investments which the CA countries may be reluctant to make, given their low GDP and national budgets (Kijne 2005). Nevertheless, reducing the overall irrigated area, improving field water use through better water management in fields (including scheduling and levelling⁷), and selection of alternative crops are options that could easily reduce overall water needs. Adopting a safer operation of the irrigation system would require the adaptation of the water supply to the water availability in the system, making use of available risk assessment strategies and decision-making tools (Bos/Burton/Molden 2005; Hillel 1997; Mollinga/Bolding 2004).

The feasibility of potential innovations must be studied in parallel. For example, some irrigation technologies such as sprinkler irrigation or modern, self-regulating drip irrigation systems, would allow reducing the time-consuming and costly levelling of fields, but their adoption might still be more costly.

7 Scheduling water application to the periods of greatest water needs of the crop can reduce water wastage. Levelling fields is necessary in flood irrigation. It is practiced prior to planting and irrigating them in order to provide for a more uniform surface, which, if properly done, greatly reduces the time and amount of irrigation water application.

Increased water efficiency and reduced secondary soil salinization can furthermore be achieved through better on-site water management, improved rotations, conservation tillage, and the adoption of less water-consuming crops (Egamberdiev 2005; ZEF 2003; Kohlschmitt/Ehschanov/Martius 2008). Additionally, the introduction of salt-tolerant trees on marginal lands, for example, offers potential benefits for farmers because these trees may contribute to the drainage of the system through their own water demand (so-called bio-drainage: Khamzina/Lamers/Worbes/Botman/Vlek 2005; Khamzina/Lamers/Martius/Worbes/Vlek 2006). Low-cost approaches to irrigation management (Hillel 1997) are often advocated but have to be adapted through field tests with farmers before they can be successfully implemented. Economic assessments should allow a balancing of costs and benefits, built on comparative advantages of the various approaches for different soil types, crops and farm sizes.

Drinking Water Supply. A major need for improving drinking water supply is to achieve better use of the existing infrastructure and to provide water of sufficient quality to remote rural areas. Urgent maintenance is needed on the pipelines connecting the major cities (Urgench and Nukus) and the Tuyamuyun reservoir. Moreover, improving the management schemes of the different dams can contribute to increasing the availability of high-quality drinking water (Froeblich/Kayumov 2004). The provision of drinking water through pipelines to all of the widely scattered rural households is unrealistic for the next years. Bottled drinking water is available, but unaffordable for poor households in the region. In the case of leaking water tubes, innovative approaches to in-line-sanitation are available but also costly and unlikely to be implemented in the near future. As a short-term solution the provision of de-centralized point-of-use filter technology might precede or partly substitute the construction of long-distance supply systems. This would require building up local supplies, but could immediately and widely improve the existing low drinking water quality. Again, including drinking water into the framework of an IWRM concept requires the protection of water resources, their efficient distribution at different scales and with different quality, and the combination of decentralized and centralized purification and supply schemes.

However, Herbst (2006) pointedly makes the case that a rigorous implementation of simple hygiene measures in households may efficiently reduce the incidence of water-related health problems such as diar-

rhoea and hepatitis, much more than costly technologies. For this purpose sensible dissemination and training plans are required.

Waste-water Treatment and Disposal. Waste-water treatment technologies play a minor role in the ADL at present where latrines still prevail. However, there is a potential for pilot demonstration units of cheap, hygienic and decentralized water treatment facilities that may predominantly be installed in schools, kindergartens, hospitals, office buildings and small villages. They can serve as entry points for a later and wider implementation (Sasse 1998). Also, biogas produced from them may be an additional asset in energy supply (Eshchanov 2006), whereas the provision of distant villages with de-central biogas would provide increased energy supply security and independence from long distance pipe transfers.

57.3.1.2 Cross-cutting Themes

Socio-economic Assessments. Goal-oriented water management (McKinney/Cai 1997) aims at maximizing the overall welfare from the scarce resource, water. Also, economically optimizing water distribution (including a fair regional water distribution and the recognition of the 'social' role of water in poverty alleviation) has to be mentioned. Two important aspects need to be reconciled in this respect: the long-term priority of economic and ecological efficiency with the short-term adoption of technologies that fit the actual socio-economic and financial contexts of actors such as farmers and water authorities. The latter is extremely important to provide an entry point to get the IWRM started at all levels and this leads to our first step in the implementation strategy outlined below (58.3.3.1). However, under transition from central planning to market economy, as in CA countries, it is important to make water management to fit the emerging new structures of farming while combating poverty. A socio-economic approach to IWRM in the ADL should therefore be built on three main activities:

First, returns on investment and efficiency of technologies (Umetsu/Chakravorty 1998) must be calculated and the best strategies for introducing low cost technologies have to be identified. To assure an economically viable adoption of appropriate water saving technologies, pricing and incentive systems must be known (Cai/Ringler/Rosegrant 2001) and established on the micro level (WUAs) to ensure overall efficiency of competing farms. Prices are to be socially and economically determined. Water scarcity indicators and implicit water pricing will then allow decisions on in-

troducing of certain technologies by avoiding those that are expensive and inefficient, or modify technologies to make them cheaper.

Second, necessary economic tools must be made available to local actors for enabling them to maximize value added from scarce water and to minimize water provision costs. Available spatial water allocation models (Fang 2004; Schieder 2008) can help to reveal optimal flows of water from the river through canals to end users. The micro-level (WUAs) and the macro-level water-distributing organizations (BWO, BUIS) must be linked through appropriate scaling and may be integrated into an overall water demand model that analyses the impacts of technologies and distribution regulations.

Third, a monetary evaluation of willingness-to-pay for drinking water at different scales and with different user groups needs to be carried out, notably within a stratum of related income levels and poverty indicators, which can show how water pricing affects the welfare of population. The aim is to find solutions for an economization of water use that minimizes negative impacts for vulnerable downstream groups, e.g.; checking cross-subsidization opportunities.

All three activities should address both the quantitative and the qualitative aspect of water management. Since salinity is the most prominent water quality problem in the region, water pricing and incentive schemes must recognize the value differences of water at different quality levels, at different locations and at different periods of the year

Institutional Analysis and Institution-building. Reforming water management is a complicated process that needs monitoring of institutions (Saleth/Dinar 2004) and requires approaches which fit specifically into local cultures and policy frames. Institutional analyses should address four issues. *First*, the organizational structure of the current water management needs to be analysed in line with IWRM objectives and principles. *Second*, WUAs (or their follow-up organizations) must be assisted and trained in management because of their limited administrative experience (2005). *Third*, institutions in the water sector must be based on the principles of subsidiarity. *Fourth*, guidelines guaranteeing participation and involvement in local and decentralized decision should be part of the institutional change. Participative methods for planning of water distribution are new to the region. Therefore, the specific consideration of local decision-making structures is crucial, and necessitates training for introducing these approaches (58.3.3.4).

Ecological Monitoring. Ecological work in the IWRM context would need to be provided and indicators for monitoring the success in water saving, water quality improvements, and ecosystem health are in critical demand. Critical environmental health parameters that describe the situation before the start of innovations (baseline) should allow for measuring and documenting improvements. This requires a 'holistic' view; e.g. the agro-ecological aspects of land-use (crops, techniques and rotations) and its relationship to water management (more specifically the reduction of soil salinity through better water and land management) must be put forward. Furthermore, the role of pesticides (both residues from former applications and present practice) and their relation to human health needs to be further investigated, as few comprehensive data exist on this often debated issue. Uzbek laboratories must conform to international quality standards (ISO, GLP). Authorities must be assisted in setting up thresholds and guidelines for pollutants in accordance with international laws, and with the additional requirements of the specific CA situation (cold winters, hot summers) which may influence the behaviour of pesticides.

57.3.2 A Stepwise Implementation Concept

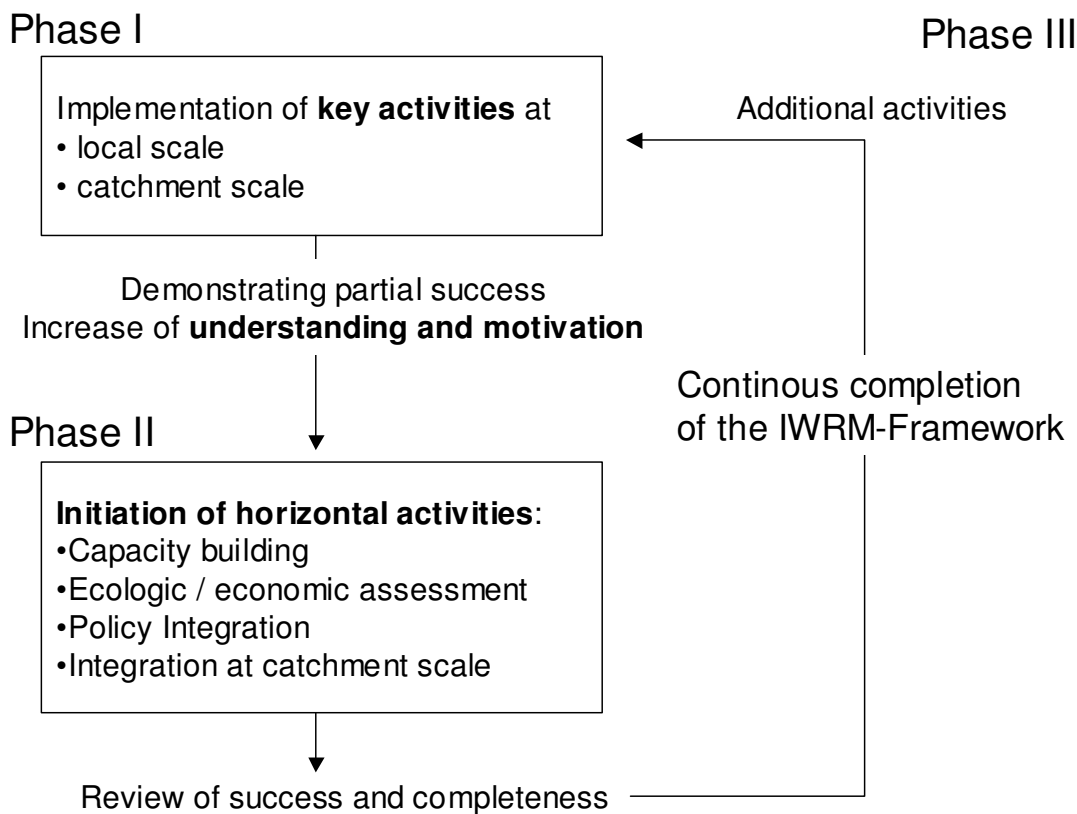

Apart from integrating the various water themes and cross-cutting issues, an approach towards better water management in CA should be strongly grounded on the following strategic principles of action:

57.3.2.1 'Implementation as-you-go'

Realizing the need for a multi-sectoral effort will require substantial changes in all water related issues, which quite obviously would not be achieved in one stroke. There is thus a substantial need to firstly reach a continuously growing understanding of and identification with IWRM principles at the decision making level and secondly to provide room for modifications and adaptations to experiences gained during the implementation process.

In this sense, we envisage an approach towards successful implementation of IWRM principles that builds on the stepwise implementation of feasible key technologies and links them into the general theoretical IWRM framework (we call this 'implementation as-you-go'). The importance of guaranteeing feasibility using a hierarchy of goals and a stepwise implementation of solutions has been highlighted in Kaiser/Rothenberger (2004) as well as by the GWP (2000b). Not only Uzbekistan, but also other transi-

Figure 57.3: Generalized pattern for implementing key activities as partial elements within an IWRM framework.
Source: Authors.

tion and developing countries need to solve water issues in the shortest time and with visible success. The central element behind this approach is to build the motivation for non-technical instruments by demonstrating the success of the concept as well as promote more easily accepted technological measures.

Figure 57.3 shows how different individual initiatives may be sequentially implemented. Provided that the link to the other vertical and horizontal themes is known, Phase I sees the initiation of key activities and technologies. Their successful adoption will lead to Phase II, which - building on the experience gained in Phase I - will address specific capacity building measures and first institutional reforms. After careful revision, Phase III may comprise either additional practical measures or further non-technical reforms.

Within the realization of the different measures and phases, it is also important to integrate the scales: the various levels of water management need to be addressed: the micro-level of field, farm and village as well as the regional large scale water attribution problems at the macro-level.

57.3.2.2 Introducing Key Technologies

Key technologies (table 57.1) are the major building blocks during the initial phase of implementation of the IWRM concept. They need not to be necessarily very sophisticated. Integrating those key technologies within the IWRM concept framework would provide visible results early on, but avoid falling back upon merely technological approaches without considering the cross-cutting social, economical and environmental issues.

This is not about delivering standard technologies blindly to inadequate, low-tech and low capitalization environments, rather an approach that has been criticized before as 'the crisis of innovation' in the water sector (Thomas/Ford 2005) has to be avoided. It will be required to take up the needs and requirements of the users in a stakeholder-oriented development scheme and refer to them during Phase II. This should include involving wherever possible, local, low-cost production facilities, service and maintenance that may provide additional incentives for investments and economical diversification. Private-public partner-

Table 57.1: Examples of key technologies to be implemented in the framework of an IWRM concept for the ADL.
Source: Compiled by the authors.

Sector	Key technology	Benefit
Water management	Automatic monitoring stations	Precise knowledge on temporal variability, on proportion and impact of polluted return water flows, input data for basin management including dam operation
	Remote sensing	Essentially required knowledge on water balance, water use and crop production for different scales (entire basin, region, farm)
	Dams and distribution weirs	Redistribution of water resources availability, multi reservoir complexes provide practical means to differentiate storage of high and low quality water
Irrigation	Levelling	Improvement of irrigation efficiency and reduction of water use for salinity reduction
	Mobile plastic canals	Cost effective reduction of water losses
	Self-regulating drip irrigation	Most precise water allocation, water saving and avoidance of soil salinization
Sanitation and drinking water supply	Rehabilitation of wells and Protection of well areas	Reduction of disease propagation, efficient system functioning
	Hand pump/motor pump wells	Decentralization of water supply with reduction of direct withdrawals from collectors
	Robust sewage water treatment	Eradication of fecal pathogen distribution and stabilization of oxygen consumption
	Pipe sealing	Reduction of recontamination, avoidance of new building and better use of existing infrastructure
	Point-of-use purification	In-line filter technology for reduction of pathogens, persistent organic pollutants (POPs) and heavy metal contamination. Enabling house water storage for irregular water supply

ships could lead to a fast-track approach to innovation according to the ‘leap-frogging’ paradigm in development⁸, provided that appropriate incentives are given.

57.3.2.3 Stakeholder Orientation

The involvement of regional stakeholders (farmers, water users, and representatives of water distributing agencies) in any of these activities is the key to success and sustainability of measures. The literature on partner orientation in development abounds with different approaches and concepts (van der Pol 2004) but shows a steady change in paradigms (Douthwaite/de Haan/Manyong/Keatinge 2001). However, the area of water management has been and is still especially prone to a predominant focus on technical solutions. The first necessary change would be to divert from

donor-driven projects to a stronger involvement of the local partners, such as has been quite successfully initiated by the CACILM⁹ initiative (ADB 2004). On a project level this would need to be translated into moving away from technology prescriptions to more equitable approaches for joint technology development (e.g., Douthwaite/de Haan/Manyong/Keatinge 2001).

57.3.2.4 Human Capacity-Building

An improved and more professional performance of actors in water distribution institutions has been repeatedly solicited by representatives of institutions in the Amu Darya. Therefore the stepwise implementation concept needs to be accompanied by capacity

⁸ Leapfrogging denotes the notion that regions with poorly developed technology or little economic basis can improve rapidly through the adoption of modern systems without going through intermediary steps (Bedi 1999; Seibel/Müller-Falcke/Bertolini 1999).

⁹ The *Central Asian Countries Initiative for Land Management* (CACILM) is an international effort to streamline the efforts for setting up national action plans for implementing the *UN Convention to Combat Desertification* (UNCCD) in the five CA countries, supported by, among other donors, the *Asian Development Bank* (ADB).

building as regards to horizontal and vertical issues. Since the Uzbek independence, funds for upgrading training capacities of teachers and trainers have been scarce. Local extension services are only slowly being building up. The training and education institutions often lack modern didactical approaches. Therefore, not only farmer schools and agricultural colleges must be set up, but also training facilities for the trainers themselves, which need to learn and adopt modern principles of adult education, problem-oriented analytical thinking, and stakeholder-orientation.

57.3.2.5 Long-term Commitment

Development projects are often characterized by short timeframes dictated by budgetary concerns, rather than development needs. The lessons learned from innovation transfer endeavours elsewhere (Douthwaite 2002) indicate that the necessary timeframe for innovations to hold is often underestimated, and may easily attain the time scale of decades.

Particularly in the ADL, only long-term commitment of international donors will provide the necessary incentives and signals to improvements and allow for the necessary follow-up on all levels. Hopefully, more long-term cooperative joint research and extension programmes will be established in the near future in CA; a few examples of long-term commitments are the ZEF/UNESCO project on land and water management in Khorezm (Vlek/Martius/Werheim/Schoeller-Schletter/Lamers 2003), the CACILM programme mentioned in 58.3.3.3, and the presence of institutions of the CGIAR system in the region.

57.4 Conclusions - Why Central Asia?

The declared Uzbek development policy of gradual change does not make this country a member of the so-called 'fast-track countries' among the CA states (WBGU 2005), an approach that has often been criticized. However, as the report of the *Commission on Human Security* (CHS) stated, security should centre on people - not on states (CHS 2003), and the advisory council of the Federal German Government on global environmental issues (WBGU) argues that, for security and humanitarian reasons, the international community should not write off countries like Uzbekistan (WBGU 2005). Similar arguments have been raised by the Human Security Network (HSN 1999), the CHS (2003) and in UNESCO documents (Goucha 2003).

For millennia, the people of CA have been highly dependent on agriculture for meeting their needs. They have learned to cope with an ever-changing environmental, institutional and economic framework. Today, however, the situation in the water sector - which has the largest impact on the natural resources - is characterized by strong path dependencies and an increasingly bleak economic and environmental outlook, particularly so for people in the lowlands. Even if the risk of trans-national conflicts should be regarded as low, the region still suffers from poverty linked to environmental degradation.

We have presented here an approach which, while building on an integrated, trans-national, systemic view on the problems, is pragmatic enough to 'implement doable things first'. We see this as the only way to achieve more human and environmental security. A stepwise implementation of key activities and technologies as a first move is intended to produce visible results that help to provide the ground for reaching acceptance for more advanced, institutional changes which must be considered as an prerequisite for implementing IWRM.

The authors believe that the presented IWRM approach is a viable avenue for improving livelihoods, restoring ecosystem services, and providing safety for the people and natural resources not only in the Amu Darya lowlands, but also in other comparable regions - throughout CA and elsewhere - suffering from similar human and environmental security problems.

58 Water Security in Times of Armed Conflicts

Mara Tignino¹

58.1 Introduction

With the end of the Cold War, international institutions such as the United Nations have been involved in a reconceptualization of security. While until the 1980's, states dealt with security issues focusing on military dimensions, during the last two decades, the linkages between environmental and security issues have progressively emerged (Brauch 2003c, 2005a, 2005b, 2005c). Parallel to these developments, the concept of human security has also appeared in the discourse of several international actors. This concept introduced by the United Nations Development Programme (UNDP) in 1994 postulates a shift from the security of the state to the security of the people.

The widening of the concept of security is reflected in the 2004 Report of the *High-Level Panel on Threats, Challenges and Change* established by the UN Secretary General which identifies "poverty, disease and environmental degradation" as being among the threats confronting the international community (UN, High-level Panel, 2004: 26–31). The Report mentions the concept of human security on several occasions (Brauch 2005). Although the place accorded to environmental threats in the 2004 Report is limited and the main subject of security policy still remains the state, national and international institutions increasingly highlight that security policies are analysed in a wider context that includes social and environmental dimensions. A special mention should be made to the UNEP Post-Conflict Environmental Assessment in Sudan. This study explicitly recognizes that among the root causes of the conflict are shortage of water and land degradation (Sudan: Post-Conflict Environmental Asssment 2007: 220–249).

In the debate on the security reconceptualization, water plays an important role. With continuing popu-

lation growth, economic development, and climate change, the challenges facing water are tremendous. It is worth noting that over 245 river basins are shared by two or more states covering an area of roughly 45 per cent of the earth's surface, and affecting approximately 40 per cent of the world's population (Boisson de Chazournes/Salman 1998). International organizations, experts, and the media have repeatedly underscored the role of water in international relations and the concomitant risks of tensions between countries for its utilization and management (Westing 1986; Falkenmark 1986; Homer-Dixon 1991; Gleick 1993; Remans 1995). On this ground, the twenty-first century has often been labelled as a period that is likely to experience wars over water. However, such a prophecy needs to be at best nuanced, at worst, rejected. Historical evidence shows that water has rarely been the primary reason for armed conflicts. Scholars, such as Thomas Homer-Dixon, director of the Peace and Conflict Studies Program at the University of Toronto, have already pointed out that water can be among the causes of a war, but is very rarely the sole cause and he went as far as to denounce "the myth of global water wars" (Homer-Dixon 1998). This approach has also been taken at the Second and Third World Water Forums held in 2000 and 2003.² In the course of the latter, several sessions were held under the theme "Water for Peace" where it was concluded that: "The vital nature of water makes it a possible cause of tension, but more importantly, a potential source of cooperation" (UNESCO/Green Cross International 2003: 106). In the same vein, the UN Secretary General (Annan 2005a) highlighted that water can be a "catalyst for cooperation" and that the com-

1 The author would like to thank her friend and colleague Ms. Lindsey Cameron for help in the preparation of this chapter.

2 See "Water Security in the 21st Century," Ministerial Declaration, Second World Water Forum, The Hague, 22 March 2000, para. 3, available at: <http://www.thewaterpage.com/hague_declaration.htm>; Ministerial Declaration, Third World Water Forum, Kyoto 23 March 2003, para. 11, available at: <<http://www.mofa.go.jp/policy/environment/wwf/declaration.html>>.

peting growing demands between uses and users can encourage cooperation on a regional basis.³

It is most often in this light that water is considered in relation to armed conflict: as a reason for going to war. However, this chapter will leave aside such issues related to *ius ad bellum* and it will focus on the consequences of armed conflicts on water and water installations. In this context, it will deal with the legal framework provided by *ius in bello* or International Humanitarian Law (IHL) regarding water.⁴

Armed conflicts are one of the causes of water insecurity in many parts of the world.⁵ Many factors cause water insecurity during armed conflicts. Such insecurity is often created by the destruction of dams, water pumping stations, treatment and sewage systems. The collapse of a high storage dam, for example, takes thousands of lives and has devastating economic and financial consequences (Westing 1986, Bergström 1990). Military activities often cause the insecurity of water supplies as well as of economic sectors dependent on this natural resource, such as agriculture, industry, fishing activities, and the transportation of goods and people through rivers. Furthermore, water security is also threatened by the environmental damage caused by the conduct of hostilities. Such damage leaves in its wake the negative impacts on the aquatic environment of rivers and on their ecosystem resulting in the destruction of natural habitats and in the loss of biodiversity. These various aspects of water insecurity will be dealt with in this chapter. In this context, the human and environmental dimensions of security (Brauch 2005a), which are interdependent, will be taken into account.

In times of war, IHL deals with the protection of water security through various provisions dealing with different aspects of armed conflicts. While having as their primary purpose safeguarding the life of people and property from wanton destruction, rules of IHL also provide a basis for preserving water as an integral

part of the natural ecosystem. The fact that the word ‘water’ did not occur until the 1970’s in instruments of IHL⁶ does not mean that before that date there was no protection of water security.

However, the regime on water security built up by the IHL does not address water security as an autonomous issue. The IHL deals with water through its objectives, namely the protection of the victims of war and the regulation of the conduct of hostilities. Thus, water is dealt with as a basic need of people, as a weapon or as an objective of military activities. This chapter will outline some of the main rules provided by the IHL dealing with water and it will suggest the need for a comprehensive protection of water security in times of armed conflict.

58.2 Water Security in the Conduct of Hostilities

Before considering the rules which deal with water security during armed conflicts, it may prove useful to identify some general principles of IHL which govern the conduct of hostilities. Most of these principles have a role in the protection of water. Such principles, identified by the International Court of Justice (ICJ) in 1996 in the Advisory Opinion on the Legality of the Threat or Use of Nuclear Weapons,⁷ include: the principle of the distinction that must be made between civilians and combatants and between military objectives and civilian objects;⁸ the prohibition of the use of weapons that cause superfluous injury or unnecessary suffering;⁹ the principles of humanity contained in the Martens Clause;¹⁰ and the principle of necessity, under which belligerents may only use that degree of force necessary to weaken or defeat enemy forces.¹¹ The principle of proportionality is also an underlying general principle of the IHL. This princi-

3 Message of the United Nations Secretary General for the World Water Day, 22 March 2005, available at: <<http://www.un.org/waterforlifedecade/waterforlifebklt-e.pdf>>.

4 This chapter will focus exclusively on freshwater issues and not on aspects of naval warfare. It will not deal with water issues in the terms of the aid to wounded and sick as well as in the context of the protection of water engineer.

5 In this regard, it should be noted that that the International Committee of the Red Cross (ICRC) conduct water-related activities in 40 countries affected by armed conflicts. See the map reproduced in the chapter (fig. 66.1).

6 It should be noticed that the 1949 Third and Fourth Geneva Conventions contain some explicit water-related provisions. They include the supply of water to prisoners of war, internees, and of persons whose liberty has been restricted during non-international armed conflicts. See Articles 20.2, 26.3 and 46.3 of the Third Geneva Convention and Articles 89.3 and 127.2 of the Fourth Geneva Convention. “Convention (III) relative to the Treatment of Prisoners of War,” Geneva, 12 August 1949; “Convention (IV) relative to the Protection of Civilian Persons in Time of War,” Geneva, 12 August 1949 in: ICRC: 75–152, 153–221.

7 ICJ, “Legality of the Threat or Use of Nuclear Weapons,” Advisory Opinion, 8 July 1996, *ICJ Reports* (1996), para. 78.

ple, prohibiting military action in which the negative effects clearly outweigh the definite military gain, is an important means for assessing whether or not the ‘collateral damage’ caused by attacks against legitimate military objectives are admissible under IHL.¹²

General principles of IHL, finding their first expression in some of the oldest instruments of IHL such as the *St. Petersburg Declaration* (1868) and the *Hague Conventions* (1899, 1907), have been reiterated in numerous instruments and in various forms. Laying down the basis of IHL, such principles have contributed to the development of this branch of international law. At the same time, they constitute principles that in their own right impose obligations on the belligerents (Sassòli/Bouvier 1999). Each of the general principles of IHL points to the conclusion that military attacks on water installations and damage to water resources are questionable, even in the

absence of specific rules of IHL addressing water issues in detail.

58.2.1 The Prohibition of Poisoning

In ancient and recent conflicts, the poisoning of water has been used as a method of warfare. Belligerents often deliberately render water unusable by disposing of chemicals, dead animals, and even human corpses into the water.¹³ Yet already in 1588, Alberico Gentili in his book devoted to *De jure belli* claimed that the prohibition of poisoning water was a well-established rule of international law (Gentili 1612). This prohibition was founded on the conviction that poison was prohibited because of its clandestine and insidious character. In 1758, Vattel described the point in this way: “There is even more general agreement in condemning the poisoning of streams, springs and wells. Certain authors give as a reason that thereby innocent persons, who are not our enemies, may be killed” (Vattel 1758, vol. III: 289).

The prohibition of using poison and poisoning weapons has been codified in Article 23 (a) of the 1907 Hague Regulations.¹⁴ The relevance of the prohibition of using poison to water protection is asserted in various national military manuals. For example, the UK military manual states that “poison and poisonous weapons ... are forbidden. Water in wells, pumps, pipes, reservoirs, lakes, rivers and the like,

8 The 1868 Saint Petersburg Declaration affirming that “the only legitimate object which States should endeavour to accomplish during war is to weaken the military forces of the enemy” was the first multilateral instrument to embody the principle of distinction. Since then it has been reiterated in numerous instruments. For instance, in its Article 48, entitled “Basic rule,” the 1977 Additional Protocol I of the Geneva Conventions (hereafter AP I) states: “In order to ensure respect for and protection of the civilian population and civilian objects, the Parties to the conflict shall at all times distinguish between the civilian population and combatants and between civilian objects and military objectives and accordingly shall direct their operations only against military objectives.” See “Declaration Renouncing the Use, in Time of War, of Explosive Projectiles Under 400 Grammes Weight” Saint Petersburg, 29 November/11 December 1868, in: Schindler/Toman, 2004: 91–93. “Protocol Additional to the Geneva Conventions of 12 August 1949, and relating to the Protection of Victims of International Armed Conflicts (Protocol I),” 8 June 1977, in: ICRC 1977: 3–87. State practice establishes the principle of distinction as a norm of customary international law applicable in both international and non-international armed conflicts. As regards to non-international armed conflicts, see: Bothe/Partsch/Solf 1982; Sassòli/Cameron 2005. See also *infra*.

9 See Article 23 (e) of the “Convention (IV) respecting the Laws and Customs of War on Land and its annex: Regulations concerning the Laws and Customs of War on Land” (hereafter the 1907 Hague Regulations), The Hague, 18 October 1907 in: Schindler/Toman, 2004: 55–87. See also Article 35.2 of AP I stating that: “It is prohibited to employ weapons, projectiles and material and methods of warfare of a nature to cause superfluous injury or unnecessary suffering.”

10 The Martens Clause, named after the Russian delegate to the 1899 Hague Peace Conference was first introduced in the preamble of the 1899 and 1907 Hague Regulations and it appears in various instruments. In this regard, Article 1.2 of AP I states that: “civilians and combatants remain under the protection of and authority of the principles of international law derived from established custom, from the principles of humanity and from the dictates of public conscience.” See also the Preamble, paragraph 4 of the Additional Protocol II of the Geneva Conventions (hereafter AP II). “Protocol Additional to the Geneva Conventions of 12 August 1949, and relating to the Protection of Victims of Non-International Armed Conflicts (Protocol II),” 8 June 1977, in: ICRC 1977: 89–101.

11 See the 1868 St. Petersburg Declaration.

12 See Article 57 (2) (a) (iii) of AP I.

13 According to the ICRC, which ran a water-sanitizing operation in Kosovo in 1999: “Of the 20,000 wells in Kosovo, over half are believed to have been contaminated with animal or human remains or with rubbish, or have simply grown stagnant through lack of use.” See: “Balkan Crisis: Cleaning Wells in Kosovo” in: *ICRC News*, 99/37, 8 September 1999.

from which the enemy may draw drinking water, must not be poisoned or contaminated. The poisoning or contamination of water is not made lawful by posting up a notice informing the enemy that the water has been thus polluted” (UK Military Manuals 1958: para. III-112).¹⁵

The prohibition of using poison is one of the oldest rules in the means of warfare. Its status in customary international humanitarian law has been dealt with by several authors and it has also recently been restated in the book devoted by the ICRC to Customary International Humanitarian Law (ICRC, Customary International Humanitarian Law 2005, vol. I: Rule 72). Although the prohibition to use poison has been conceived for protecting people, such prohibition also has a bearing on the environmental protection of water. In this context, as an example one may mention the 1925 *Geneva Protocol for the prohibition of the use of asphyxiating, poisonous or other gases, and of bacteriological methods of warfare*.¹⁶ This instrument provides one basis for asserting the illegality of forms of chemical and bacteriological warfare having a harmful effect on water resources and it may be regarded as a special prohibition of the general rule codified by Article 23 (a) of the 1907 Hague Regulations.

14 See also: Article 70 of the 1863 “Lieber Code”; Article 13 (a) of the 1874 “Brussels Declaration” and Article 8 of the 1880 “Oxford Manual.” Moreover, Article 8 (2) (b) (xvii) and (xviii) of the 1998 International Criminal Court Statute (hereafter ICC Statute) declares the employment of poison and poisoned weapons as a war crime during international armed conflicts. “Instructions for the Government of Armies of the United States in the Field (Lieber Code),” 24 April 1863; “Project of an International Declaration concerning the Laws and Customs of War,” 27 August 1874, “The Laws of War on Land,” 9 September 1880. ICC Statute, 17 July 1998. These instruments are reprinted in: Schindler/Toman 2004: 3-40, 1309-1395.

15 See also the US Field Manual 1956: para. 37 (a); Colombia’s Basic Military Manual 1995: 49.

16 “Protocol for the prohibition of the use of asphyxiating, poisonous or other gases, and of bacteriological methods of warfare,” 17 June 1925, in: Schindler/Toman 2004: 95-97. Several instruments of disarmament law prohibiting the uses of certain weapons play an important role in protecting water resources. For example, see “Convention on Prohibitions or Restrictions on the Use of Certain Conventional Weapons Which May be Deemed to be Excessively Injurious or to Have Indiscriminate Effects” Geneva, 10 October 1980, in: Schindler/Toman, 2004: 179-189. On the role of disarmament law for protecting environment, see: Roberts 2000; Brauch 2003a.

58.2.2 Protection of Objects Indispensable to the Survival of Civilian Population

Military attacks launched by the belligerents often have as a consequence the cutting-off of aqueducts and water distribution systems. In many cases, the collapse of water-related systems is not caused by the direct impact of bombs, but by the destruction of electrical networks. The bombing of the electric power grid and the ensuing cutting-off of water distribution, treatment and sewage systems, lead in many cases to the outbreak of water-borne diseases causing a great number of casualties.¹⁷ This must be considered in the analysis of whether an attack was proportionate. In addition, the IHL deals with these issues in another way: by providing a legal framework on the protection of objects having a civilian character and conferring a special protection of ‘objects indispensable to the survival of the civilian population.’

IHL confers a general protection, codified, *inter alia*, under Article 52 of AP I, on objects having a civilian character. This provision is of considerable importance in order to apply the basic rule contained in Article 48 stating the principle of distinction between civilian objects and military objectives. Civilian objects are defined negatively in that civilian objects are “all objects which are not military objectives.” According to Article 52, the definition of military objectives comprises two elements: “the nature, location, purpose or use which makes an effective contribution to military action” and “the total or partial destruction, capture or neutralization which in the circumstances ruling at the time offers a definite military advantage.” These elements must be considered in each attack against a military objective. Moreover, the belligerents also must take precautionary measures in the attacks “with a view to avoiding, and in any event to minimizing, incidental loss of civilian life, injury to civilians and damage to civilian objects.”¹⁸ The military advantage has to be concrete and direct and must be weighed against the civilian losses and damage resulting from an attack.

For certain categories of objects, IHL provides for special protection and it sets out specific rules limiting military attacks. The technique of conferring special protection on specified objects has been used in other instruments of IHL, such as in Article 27 of the

17 See Center for Economic and Social Rights: “Special Report: Water under siege in Iraq,” April 2003, available at: <<http://cesr.org/node/view/18>>.

18 AP I, Article 57 (2) (a) (iii) titled “Precautions in attack.”

1907 Hague Regulations devoted, among others, to the protection of historical monuments and in the 1954 “Convention for the Protection of Cultural Property in the Event of War and Armed Conflict.”¹⁹

In IHL, the category of objects having special protection includes “objects indispensable to the survival of the civilian population.”²⁰ According to Article 54 (2) of AP I: “It is prohibited to attack, destroy, remove or render useless objects indispensable to the survival of the civilian population, such as foodstuffs, agricultural areas for the production of foodstuffs, crops, livestock, drinking water installations and supplies and irrigation works, for the specific purpose of denying them for their sustenance value to the civilian population or to the adverse Party, whatever the motive, whether in order to starve out civilians, to cause them to move away, or for any other motive.” The list given by this provision is merely illustrative and it aims to give some examples regarding objects which are necessary for the life of people. In this regard, the ICRC Commentary states that “an exhaustive list could have led to omissions or an arbitrary selection” (ICRC Commentary 1987: 655).

The special protection conferred by Article 54 on objects such as drinking water installations and water supplies develops the prohibition of using starvation as a method of warfare (ICRC Commentary 1987: 655). This prohibition came up in the context of the necessity to prohibit methods of total warfare. Violation of the prohibition of starvation may constitute the crime of genocide when this act is committed with intent to destroy, in whole or in part, a national, ethnical, racial or religious group.²¹ Moreover, under the Statute of the International Criminal Court, the intentional use of starvation of civilians by depriving

them of the objects indispensable for their survival is a war crime.²²

Although Article 54 of AP I may be viewed as ensuring a broad protection of water, this provision establishes some exceptions. The first exception is contained in paragraph 3 of this provision, stating that the immunity of indispensable objects is lifted in cases where they serve as sustenance solely for members of the armed forces or as direct support for military action. Although some water supplies could serve to sustain armed forces, this exception is not a sufficient reason for depriving the civilian population of water. This view is confirmed by the restriction contained in paragraph 3 (b) *in fine*, which states that belligerents must refrain from acts which may be expected to reduce the civilian population to starvation or force them to move away. Paragraph 5 of Article 54 contains the second exception. This is related to the so-called ‘scorched earth policy’ applied in defence of national territory against invasions. However, derogation from the protection accorded to objects indispensable for the survival of the population is subject to strict limitations. The derogation may not be used in territories under occupation and imperative military necessity is required (ICRC Commentary 1987: 658).

In the context of non-international armed conflicts, Article 14 of AP II also protects “objects indispensable to the survival of the civilian population.”²³ The protection conferred by this provision of AP II has particular importance given that this instrument does not state a general protection of civilian objects such as those ensured by AP I. Although an explicit rule concerning a general protection of civilian objects is not expressly mentioned in AP II, the principle of distinction between military objectives and civilian objects also applies in non-international armed conflicts (Sassòli/Cameron 2005: 45). In this context, it should be underscored that Article 13 of AP II, codifying the general principle that protection is due to the civilian population against the dangers of hostilities, allows covering a general protection of civilian objects (Bothe/Partsch/Solf 1982: 677).²⁴ According to the ICRC Commentary, ensuring a general protection for

19 Article 27 of the 1907 Hague Regulations confers a special protection to “buildings dedicated to religion, art, science, or charitable purposes, historical monuments, hospitals and place where the sick and wounded are collected, provided that they are not being used at the time for military purposes.” See also: “Convention for the Protection of Cultural Property in the Event of Armed Conflict,” The Hague, 14 May 1954, in: Schindler/Toman 2004: 999–1025.

20 This category also includes installations containing dangerous forces such as dykes and dams. See *infra*.

21 See Article 2 of the “Convention on the Prevention and Punishment of Genocide,” Resolution 260 (III) A, United Nations General Assembly, 9 December 1948, in: Schindler/Toman 2004: 839–863. On the intent requirement, see ICTY, Krstic, Appeals Chamber, Judgement, 19 April 2004, Case No. IT-98-33-A, para. 134.

22 Article 8 (2) (b) (xxv), ICC Statute.

23 Article 14 of AP II reads as follows: “Starvation of civilians as a method of combat is prohibited. It is therefore prohibited to attack, destroy, remove or render useless, for that purpose, objects indispensable to the survival of the civilian population, such as foodstuffs, agricultural areas for the production of foodstuffs, crops, livestock, drinking water installations and supplies and irrigation works.”

the civilian population implies: on the one hand, “an absolute prohibition of direct attack against the civilian population as such, or against civilians”; on the other hand, “reducing the effects of military operations which could affect protected persons” (ICRC Commentary 1987: 1449). Article 14 of AP II implements thus the general protection against the effects of the hostilities provided for by Article 13. At the same time, these provisions are also strictly linked to Article 3 common to the four 1949 Geneva Conventions stating that parties to a non-international armed conflict have the obligation to guarantee humane treatment for all persons not participating in hostilities.

The general protection conferred by IHL regarding objects having a civilian character and the special protection given by Articles 53 of AP I and 14 of AP II play a significant role in protecting water security in times of armed conflict. In this regard, it can be observed that some objects such as electrical facilities used for pumping or treating water may nevertheless be used by belligerents for both civilian and military purposes. In this case, belligerents may argue that such objects become military objectives. However, such attacks shall become illegal if the attack is expected “to cause incidental loss of civilian life, injury to civilians, damage to civilian objects, or a combination thereof, which would be excessive in relation to the concrete and direct military advantage anticipated.”²⁵ Therefore, when planning such attacks general principles of IHL such as those of proportionality shall be considered by belligerents (Lewis 2003: 487; Sassòli/Cameron, 2005: 57–58).

58.2.3 Protection of Installations Containing Dangerous Forces

Article 56 of AP I on international armed conflicts and Article 15 of AP II on non-international armed conflicts, conferring a special protection on dams,

constitute an important innovation in the limitations on the conduct of hostilities. Apart from the use of poison, the breaching by belligerents of water installations would be a devastating means of warfare. In old and modern wars, dams have been used as a defensive and an offensive weapon. Since the seventeenth century, the Dutch did not hesitate to breach the dams and flood their land with the aim of protecting their towns against invasion. This strategy, known as the Dutch Water Line, was used until the twentieth century. Another example is the breaching of the dykes by the Chinese during the 1930’s to stop the invading Japanese troops. On the other hand, the breaching of water installations has also been used as a dreadful offensive weapon. The destruction of the dams in the Eder and the Möhne in Germany in May 1943 resulted in the destruction of factories, in the loss of cultivated land and livestock, and in the killing of 1,300 persons (ICRC Commentary 1987: 666; Westing 1990a: 6; Bergström 1990, 40–41). Still, during the Vietnam War, 661 sections of dyke had been either damaged or destroyed during the course of the war (ICRC Commentary 1987: 666).

As a consequence of the impact of the destruction of such installations, it was necessary to include a special protection for water installations in the Additional Protocols to the 1949 Geneva Conventions. Conversely to the case of Article 54 of AP I which provides a list of objects indispensable for the survival of the civilians which is merely illustrative, Articles 56 and 15 of the AP I and AP II, respectively, contain an exhaustive list of the installations which may release dangerous forces. These provisions grant special protection to dams, dykes, and nuclear electrical generating stations. However, other installations can release dangerous forces in the case of attack; for example, one may think of factories manufacturing chemical or oil products which, if released, could endanger the natural environment and cause severe damage to the civilian population. Such incidents, which can sometimes be serious, have recently occurred in various countries in peacetime.²⁶ Although the special protec-

24 Article 13 of AP II, titled “Protection of the civilian population,” reads as follows: “1. The civilian population and individual civilians shall enjoy general protection against the dangers arising from military operations. To give effect to this protection, the following rules shall be observed in all circumstances. 2. The civilian population as such, as well as individual civilians, shall not be the object of attack. Acts or threats of violence the primary purpose of which is to spread terror among the civilian population are prohibited. 3. Civilians shall enjoy the protection afforded by this Part, unless and for such time as they take a direct part in hostilities.”

25 Article 57 (2) (b), AP I.

26 For example, see the benzene spill that occurred on 13 November 2005 in China as a result of the explosion of a petrochemical plant adjacent to the Songhua River. That spill, after having caused water contamination in the water supplies of the city of Harbin in China, would reach the Heilongjiang River, called the Amur River in Russia, and it would probably cause hazards to Russian towns. “China warns Russia of toxic slick”, 24 November 2005, available at: <<http://www.cnn.com/2005/WORLD/asiapcf/11/24/china.city>>.

tion accorded by the 1977 Additional Protocols is limited to specific installations, the considerations guiding such special protection should also apply to other installations such as chemical plants and petroleum refineries given the effects of these attacks (ICRC, Customary International Humanitarian Law, 2005, vol. I: 142). Moreover, when, under certain circumstances, these installations may become a military objective, measures of precaution shall be taken by the belligerents.

Articles 56 and 15 of AP I and AP II, respectively, place the security of water installations at the heart of their regime of protection. Installations containing dangerous forces are objects protected against attacks in conformity with Article 49 of AP I. These installations are *a priori* objects having a civilian character and they benefit therefore from the general protection granted by Article 52 of AP I. Article 56 of AP I establishes immunity for these objects “even where these objects are military objectives.” This immunity also covers military objectives located at or in the vicinity of these objects. The conditions for triggering the regime of special protection accorded to water installations are that the attack “may cause the release of dangerous forces” and “consequent losses among the civilian population.”

The protection of such water installations is, nevertheless, not absolute. As in the case of Article 54, Article 56 of AP I also contain some exceptions. This protection ceases, at least in international armed conflicts, if the dams or the military objectives situated in the proximity of water-related installations are “used for other than its normal function and in regular, significant and direct support of military operations” and if the attacks on these targets “is the only feasible way to terminate such support.”²⁷ The *German Military Manual* (1992) interprets “significant and direct support of military operations” as comprising “for instance, the manufacture of weapons, ammunition and defence materiel. The mere possibility of use by armed forces is not subject to these provisions” (ILA, 2004: 45).

In the case of “regular, significant and direct support of military operations,” the exigencies of military necessity may prevail and the special protection ceases. However, even when the special protection ceases, belligerents are required to take due precautions in military operations at or near the installations containing dangerous forces in order to avoid severe

collateral losses among the population and damaging properties.²⁸

The criteria established by Article 56 of AP I are stricter than those enshrined in Article 54 of AP I. It should be observed that some dams or dykes might have multiple functions, having both irrigation purposes and supplying electrical power. In this case, they benefit from the protection of Articles 54 (having the character of an irrigation work in the terms of this provision) and 56 of AP I. In such situations, water installations benefit from a double protection.

Paragraph 3 of Article 56 underscores that “in all cases, the civilian population and individual civilians shall remain entitled to all the protection accorded them by international law” and paragraph 4 prohibits reprisals against such installations and other installations containing dangerous forces mentioned in paragraph 1 of this provision. Finally, “launching an attack against works or installations containing dangerous forces” is a grave breach of IHL – a particularly serious war crime.²⁹

Dams and dykes may only be attacked in case they qualify as military objectives. In this case, practice shows that states are conscious of the high risk of severe incidental losses which can result from attacks against such installations when they constitute military objectives. Consequently, even states which are not parties to AP I, such as the US, stress the importance of the proportionality principle in assessing the legality of an attack against a dam or a dyke which is a military objective.³⁰ This assessment under the principle of proportionality reflects sensitivity to the severe losses that may ensue among the civilian population when dangerous forces of dams and dykes are released. It appears, therefore, that attacks could be envisaged in situations where they are indispensable to obtain an important military advantage, which could not be obtained in any other way, and all necessary precautions are taken.

58.3 Water Security under the Regime of Occupation

The conduct of hostilities through aerial bombardments, explosions, and gunfire clearly threatens water security in time of armed conflicts. Moreover, other risks to the security of water in occupied territories exist.

Dates	Instruments	Quotations
1949	"Geneva Convention (III) relative to the Treatment of Prisoners of War"	Article 26: "3. Sufficient drinking water shall be supplied to prisoners of war ..."
1949	"Geneva Convention (IV) relative to the Protection of Civilian Persons in Times of War"	Article 55: "1. To the fullest extent of the means available to it the Occupying Power has the duty of ensuring the food and medical supplies of the population; it should, in particular, bring in the necessary foodstuffs, medical stores and other articles if the resources of the occupied territory are inadequate. 2. The Occupying power may not requisition foodstuffs, articles or medical supplies available in the occupied territory, except for use by the occupation forces and administration personnel, and then only if the requirements of the civilian population have been taken into account..."
1966	International Law Association, "Helsinki Rules on the Uses of the Waters of International Rivers"	Article XX: a.) "In time of war, other armed conflict, or public emergency constituting a threat to the life of the State ... The riparian State shall in any case facilitate navigation for humanitarian purposes."
1976	International Law Association, "Resolution on the Protection of Water Resources and Water Installations in Times of Armed Conflict"	Article I: "Water which is indispensable for the health and survival of the civilian population should not be poisoned or rendered otherwise unfit for human consumption." Article II: "Water supply installations which are indispensable for the minimum conditions of survival of the civilian population should not be cut off or destroyed." Article VI: "3. In occupied territories, seizure, destruction or intentional damage to water installations should be prohibited when their integral maintenance and effectiveness would be vital to the health and survival of the civilian population."
1977	"Additional Protocol to the Geneva Conventions of 12 August 1949, and Relating to the Protection of Victims of International Armed Conflicts" "Additional Protocol to the Geneva Conventions of 12 August 1949 Relating to the Protection of Victims of Non-International Armed Conflicts"	"Additional Protocol to the Geneva Conventions of 12 August 1949, and Relating to the Protection of Victims of International Armed Conflicts", Article 54: "2. It is prohibited to attack, destroy, remove or render useless objects indispensable to the survival of the civilian population, such as foodstuffs, agricultural areas for the production of foodstuffs, crops, livestock, drinking water installations and supplies and irrigation works, for the specific purpose of denying them for their sustenance value to the civilian population or to the adverse Party, whatever the motive, whether in order to starve out civilians, to cause them to move away, or for any other motive." "Additional Protocol to the Geneva Conventions of 12 August 1949, and Relating to the Protection of Victims of International Armed Conflicts", Article 56: "1. Works or installations containing dangerous forces, namely dams, dykes and nuclear electrical generating stations, shall not be made the object of attack, even where these objects are military objectives, if such attack may cause the release of dangerous forces and consequent severe losses among the civilian population. Other military objectives located at or in the vicinity of these works or installations shall not be made the object of attack if such attack may cause the release of dangerous forces from the works or installations and consequent severe losses among the civilian population."
1997	"United Nations Convention on the Law of the Non-navigational Uses of International Watercourses"	Article 29: "International watercourses and related installations, facilities and other works shall enjoy the protection accorded by the principles and rules of international law applicable in international and non-international armed conflict and shall not be used in violation of those principles and rules."

Dates	Instruments	Quotations
2002	United Nations Committee on Economic, Social and Cultural Rights, General Comment No. 15, "The right to water (arts. 11 and 12 of the International Covenant on Economic, Social and Cultural Rights)"	"22 ... during armed conflicts, emergency situations and natural disasters, the right to water embraces those obligations by which States parties are bound under international humanitarian law. This includes protection of objects indispensable for survival of the civilian population, including drinking water installations and supplies and irrigation works, protection of the natural environment against widespread, long-term and severe damage and ensuring that civilians, internees and prisoners have access to adequate water."
2004	International Law Association, "Revision of the Helsinki and other International Law Association Rules on International Water Resources"	<p>Article 52: "Combatants shall not, for military purposes or as reprisals, destroy or divert waters, or destroy water installations, when such acts would cause widespread, long-term, and severe eco-logical damage prejudicial to the health or survival of the population or if such acts would fundamentally impair the ecological integrity of waters."</p> <p>Article 54: "1. An occupying State shall administer water resources in an occupied territory in a way that ensures the sustainable use of the water resources and that minimizes environmental harm. 2. An occupying State shall protect water installations and ensure an adequate water supply to the population of an occupied territory."</p>

Over-exploitation of water resources as well as the destruction of water networks, pipelines, and containers threatens the security of water in occupied territories. For example, these risks are illustrated by the situation in the Occupied Palestinian Territory. In this context it has been reported that in April 2002 during the Israeli incursions in the Old City of Nablus, "tanks and bulldozers completely destroyed the water networks, causing water shortage and floods."³¹ In dealing with such risks, the rules of IHL regarding the regime of occupation – especially those on the protection of property – have a bearing on water security.

The protection of property ensured by IHL would seem at first sight not of great utility in dealing with water protection in times of armed conflict. The extent to which the term property can be interpreted as encompassing public goods, such as water, may seem debatable. However, this term should be interpreted broadly. It is generally agreed that water installations and water *per se* constitute public or private property within the meaning of IHL and they cannot be destroyed "unless such destruction or seizure be imperatively demanded by the necessities of war."³² This pro-

hibition applies to the conduct of hostilities and to the administration of occupied territories.

In the context of the regime of occupation, the main source of IHL dealing with the protection of property is provided by the 1907 Hague Regulations.³³ This instrument reflects customary international law, binding therefore on all states.³⁴ This instrument distinguishes between public and private property. On one hand, private property is immune to confiscation.³⁵ On the other hand, movable public property and immovable state-owned property can be used by the occupant.³⁶ Regarding the uses of public

31 Palestine Hydrology Group, Fact Sheet "Water assaults during the last incursions", available at: <http://www.palestinemonitor.org/factsheet/palestinian_hydrology_group_water_assaults.htm>.

32 The 1907 Hague Regulations, Article 23 (g). See: Cassese 1992, Zemmali 1995, Roberts 2000, Boutruche 2000, Benvenisti 2003.

33 The negotiators of the 1949 Geneva Conventions included nevertheless some provisions on property. See 1949 Fourth Geneva Convention, Article 53. Moreover, Article 147 of the 1949 Fourth Geneva Convention, states that an extensive destruction and appropriation of property not justified by military necessity and carried out unlawfully and wantonly, constitutes a grave breach of IHL. See also ICC Statute, Article 8 (2) (b) (xiii) and Article 8 (2) (e) (xii), which includes the protection of property in international and non-international armed conflicts.

34 Judgements of international tribunals and national courts, including the Israeli High Court of Justice, confirm that the Hague Regulations are customary international law. See, for example, "Ayub v. Minister of Defence", H.C. 606/78, excerpted in: Sassoli/Bouvier 1999: 812–816.

35 Article 46 of the 1907 Hague Regulations provides that: "private property ... must be respected. Private property cannot be confiscated." Moreover, Article 33 prohibits pillage.

property, two conditions should be highlighted. The first condition relates to the purposes of the uses by the occupant. The occupant may use property for meeting its military needs “within the limits of what is required for the army of occupation and the needs of the local population” (Stone 1954: 697). In many respects, water is similar to the treatment of oil under IHL, and as such is subject to controversy. Despite that, in light of the Memorandum of Law concerning the “Israel’s right to develop new oil fields in Sinai and the Gulf of Suez”³⁷ elaborated by the United States in 1976, exploitation of natural resources for furthering domestic purposes is prohibited. For example, the occupant cannot extract water for its own population or ship it home.

The second condition deals with the limitations set up by Article 55 of the 1907 Hague Regulations and it refers only to public immovable property. This provision states: “The occupying State shall be regarded only as administrator and usufructuary of public buildings, real estate, forests, and agricultural estates belonging to the hostile State, and situated in the occupied country. It must safeguard the capital of these properties, and administer them in accordance with the rules of usufruct.” The doctrine of usufruct, embodied in Article 55, is derived from Roman Law and it may be found in national legislation of civil law countries and in common law countries through concepts such as life tenancy. The right of a usufructuary is, literally, the right to use the fruits of the property without depleting the corpus or the substance of the property. A case brought before French national courts during the 1920’s concerning the felling of French trees during the German occupation of Alsace between 1917 and 1918³⁸ dealt with Article 55. In that case, the Court affirmed that according to this provision, “the occupying State is only entitled to the rights of administration and usufruct of the real property, including the forests, of the enemy State. It should protect the substance of such property and administer it in accordance with the rules of usufruct.” The doc-

trine of usufruct plays an important role for determining the limitations of the occupant in the exploitation of natural resources, such as water. Water resources qualify as public immovable property.³⁹ Therefore, the usufructuary rights and duties apply to their uses.

The rules on property stated in the 1907 Hague Regulations are an important foundation for dealing with the threats to water security in occupied territories. The fact that these rules are contained in instruments such as the 1907 Hague Regulations that have universal acceptance by states, adds to its significance.

58.4 Protection of the Environment in International Humanitarian Law

An important facet of water security deals with the protection of the environment. The rules already analysed provide an indirect basis for preserving natural resources such as water. However, during the 1970’s, IHL included some provisions dealing expressly with the protection of the environment (Brauch 2003a). The 1976 “Convention on the Prohibition of Military or any Other Hostile Use of Environmental Modification Techniques” (hereafter ENMOD) and AP I, in its Articles 35 (3) and 55, addressed directly environmental aspects of warfare.⁴⁰ In both cases, the use of a wider range of means and methods of warfare during the Vietnam War (such as the defoliant Agent Orange), as well as the rise of environmental consciousness at a global level reflected in the 1972 Stockholm Declaration,⁴¹ had an important role in stimulating the inclusion of the protection of the environment during armed conflicts. The inclusion of explicit pro-

36 Regarding public movable property, Article 53 of the 1907 Hague Regulations provides that: “An army of occupation can only take possession of cash, funds, and realisable securities which are strictly the property of the State, depots of arms, means of transport, stores and supplies, and, generally, all movable property belonging to the State which may be used for military operations.”

37 “United States: Department of State Memorandum of law on Israel’s right to develop new oil fields in Sinai and the Gulf of Suez”, 1 October 1976, 16 “International Legal Materials” (1977): 733.

38 “Administration of Waters and Forests v. Falk”, French Court of Cassation, Criminal Chamber, 2 February 1927, extracts reprinted in: McNair/Lauterpacht 1981, vol. 4, Case no. 383: 563. A similar case also arose during the Franco-Prussian War, see: Oppenheim, 1952, vol. II: §282. The Military Tribunal of Nuremberg also dealt with the felling of trees in Poland during the German occupation. See: Falk, 1984: 36–37.

39 See the case: “N.U. Da Bataafsche Petroleum Maatschappij and others v. War Damage Commission”, Singapore Court of Appeal, 13 April 1956, in: *International Law Reports*, 1956, vol. 23: 810–849. In this case the Singapore Court of Appeal held that oil in the ground was a state-owned immovable property. Drawing a parallel between the exploitation of oil and water resources, the latter should be considered as immovable state-owned properties. See: Cassese 1992, Scobbie 1994/1995, Benvenisti 2003.

visions was prompted by the need to protect the life and the health of civilian population, as well as by the need to prohibit certain methods of warfare. In this manner, they develop the rules such as the principles of distinction and proportionality included in older instruments of IHL.

58.4.1 The 1976 ENMOD Convention

In the history of humankind one of the first environmental modification techniques is illustrated in the Bible. In the Book of Exodus, the Bible, describing the manner in how Moses and the Israelites escaped from Egypt, traversing the Red Sea which was dried up, gives an example of such techniques and of its consequences. When the powerful Egyptian army tried to follow Moses and its people, “Moses stretched out his hand over the sea, and at daybreak the sea went back to its place. The Egyptians were fleeing toward it, and the LORD swept them into the sea. The water flowed back and covered the chariots and horsemen – the entire army of Pharaoh that had followed the Israelites into the sea. Not one of them survived.”⁴² Seas and oceans can be nevertheless difficult for human beings to control without divine intervention. This is exemplified by the failure of attempts to provoke tidal waves or tsunami for hostile uses (Westing 1992). However, belligerents have often attempted to modify the course of rivers for hostile uses. For instance, in 1503, Leonardo de Vinci plotted with Machiavelli to divert the Arno River in the war between Pisa and Florence. Although this plan failed, in recent conflicts belligerents have also tried to resort to such techniques. In the course of the Iran-Iraq war, the latter tried to change the course of some rivers in order to

stop the enemy Iranian troops (Mollard-Bannelier 2001).

In this context, ENMOD provides rules for dealing with environmental modification techniques used for hostile uses both in peacetime and in times of armed conflicts. Article II of ENMOD defines the term “environmental modification technique” as: “any technique for changing – through the deliberate manipulation of natural processes – the dynamics, composition or structure of the Earth, including its biota, lithosphere, hydrosphere and atmosphere, or of outer space.” Some states have included in their interpretive declaration of this instrument some interesting elements for dealing with the issue as to whether environmental modification techniques such as changing the natural state of rivers, falls within the scope of ENMOD⁴³. For instance, the declaration of the Republic of Korea when acceding to ENMOD affirmed that changing the natural state of rivers or other environmental modifications techniques such as flooding and inundation are covered by ENMOD provided they have widespread, long-lasting or severe effects.⁴⁴ The formula used by ENMOD establishes that it would be sufficient to fulfil one of the three conditions to be covered by this instrument.

In order to facilitate the interpretation of this instrument, the Parties to the ENMOD Convention have clarified the meaning of the terms “widespread”, “long-lasting” or “severe”. In particular, these terms have been interpreted as follows: “‘widespread’: encompassing an area on the scale of several hundred square kilometres”; “‘long-lasting’: lasting for a period

40 ENMOD Convention adopted by Resolution 31/72 of the United Nations General Assembly on 10 December 1976, in: Schindler/Toman 2004: 163–177. See also Article 8 (2) (b) (iv) of the ICC Statute providing that “intentionally launching an attack in the knowledge that such attack will cause incidental loss of life or injury to civilians or damage to civilian objects or widespread, long-term and severe damage to the natural environment which would be clearly excessive in relation to the concrete and direct overall military advantage anticipated” is a war crime.

41 See: principle 26 of the Stockholm Declaration, United Nations Conference on the Human Environment, Stockholm, 1972, U.N. Doc. A/CONF.48/14/Rev.1, in: 11 “International Legal Materials” (1972): 1416.

42 Exodus 14: 26–28.

43 In this context it should be recalled Article 31 (2) (b) of the Vienna Convention on the Law of Treaties states that the means for interpreting the purpose of a treaty comprises “any instrument which was made by one or more parties in connection with the conclusion of the treaty and accepted by the other parties as an instrument related to the treaty.”

44 The interpretive declaration of the Republic of Korea reads as follows: “It is the understanding of the Government of the Republic of Korea that any technique for deliberately changing the natural state of rivers falls within the meaning of the term ‘environmental modification techniques’ as defined in Article II of the Convention. It is further understood that military or any other hostile use of such techniques, which could cause flooding, inundation, reduction in the water-level, drying up, destruction of hydrotechnical installations or other harmful consequences, comes within the scope of the Convention, provided it meets the criteria set out in article I therefore.” Text reprinted in: Schindler/Toman 2004: 176

of months, or approximately a season”; “severe’: involving serious or significant disruption or harm to human life, natural and economic resources or other assets.”⁴⁵

The ENMOD Convention is the first instrument of IHL which explicitly dealt with the environment. It is particularly relevant in cases where belligerents plan to resort to methods of warfare using the environment as a weapon, such as the diversion of rivers.

58.4.2 The 1977 Additional Protocol I

Articles 35 (3) and 55 of AP I represent an important development in the protection of the environment during armed conflicts. One can debate whether they provide identical protection or they are distinct. Although the preoccupations at the origins of these articles are the same, their *ratio* is different. On one hand, Article 35 (3) protects the environment as such and its protection is considered under the perspective of the methods and means of warfare. On the other hand, Article 55 - having the aim to protect the civilian population - relies on the protection conferred on objects having a civilian character. This provision deals with the environment in relation to the life of human beings. The close relationship between the environment and human beings emerges from the wording of Article 55 stating that damage to the environment would “prejudice the health or survival of the population.”

The articles of AP I which deal with the environment have an important place in the regime of IHL devoted to the protection of water, given that this resource is an essential component of the environment and damage to this resource may prejudice the health and the life of the population. Given that any war is susceptible of provoking damage to the environment, the issue of the threshold provided by articles 35 and 55 is important in order to determine whether there is a breach of IHL. The drafters of this instrument have chosen to refer to damage that is ‘widespread, long-term, and severe’ in both provisions of the AP I. Contrary to the provisions of ENMOD, these adjectives are joined by the word ‘and’, meaning that it is a triple, cumulative standard that needs to be fulfilled. Moreover, the meaning of these adjectives is not the same as the corresponding words used by ENMOD. In particular, the phrase “long-term” was understood by the adopting states to mean decades.

45 Understandings regarding the Convention, in: Schindler/Toman 2004: 168.

Given the high threshold of application established by these provisions of the AP I, some principles of IHL such as that of proportionality may prove to be of utility for lowering the criteria established by this instrument (Bothe 2001). Moreover, considering that the AP II regarding non-international armed conflicts does not contain provisions on the environment, the principle of proportionality has an especially important role in dealing with environmental damage in these situations.

The relevance of this principle, in the regime on environmental protection during armed conflicts has been underscored by the International Court of Justice, affirming that “States must take environmental considerations into account when assessing what is necessary and proportionate in the pursuit of legitimate military objectives.”⁴⁶ In this context, “collateral damage” to the environment that is disproportionate to the military advantage gained, is precluded by IHL.⁴⁷ As highlighted by one author: “what was considered as acceptable collateral damage decades or even years ago, that is, proportionate to the military advantage pursued, might not be regarded as acceptable today” (Desgagné 2000: 116). In the context of water resources, this statement is particularly true. Nowadays the strategic role of water emphasizes the vital importance and vulnerability of water, especially in times of armed conflict. While water, together with the rest of the environment, may suffer from economic activity in times of peace, the problem is far

46 “Legality of the Threat or Use of Nuclear Weapons”, para. 30. See note 7.

47 In this regard the 2000 “Final Report to the Prosecutor by the Committee Established to Review the NATO Bombing Campaign Against the Federal Republic of Yugoslavia” dealing, *inter alia*, with the assessment of the damages caused to the environment by the NATO bombing campaign against the Federal Republic of Yugoslavia, stated that: “Even when targeting admittedly legitimate military objectives, there is a need to avoid excessive long-term damage to the economic infrastructure and natural environment with a consequential adverse effect on the civilian population. Indeed, military objectives should not be targeted if the attack is likely to cause collateral environmental damage which would be excessive in relation to the direct military advantage which the attack is expected to produce.” “Final Report to the Prosecutor by the Committee Established to Review the NATO Bombing Campaign Against the Federal Republic of Yugoslavia”, 15 June 2000, para. 14-25, available at: <<http://www.un.org/icty/pressreal/nato061300.htm>>. For an assessment of the Report, see: Bothe 2001.

worse in times of war, when contamination is often deliberate rather than accidental.

In conclusion, IHL provides for explicit rules dealing with the environment. Moreover, the general principles of IHL governing the conduct of hostilities apply to the environment. In particular, the principles of distinction and proportionality are important assessment criteria for determining the legality of attacks which may have consequences on the environment. The application of these principles to the environment is set forth in the “Guidelines for military manuals and instructions on the protection of the environment in times of armed conflicts”. The Guidelines are intended as a tool to facilitate the instruction and training of armed forces and the UN General Assembly has invited all States to disseminate these Guidelines widely and to give consideration to the possibility of incorporating them into their military manuals and other instruments addressed to their military personnel.⁴⁸

58.5 Conclusions: Reflections on a Comprehensive Approach on Water Security

Although the security of water is dealt with by IHL, one may query whether the regime established by IHL is complete. Water is taken into account by IHL only when it meets its objectives. In that perspective, it is viewed only in its capacity as one of the basic needs of human beings, as a danger, or as part of the natural environment, but never autonomously. Although IHL focused on the protection of persons and their property, the rules of IHL play an important part in the security of water during an armed conflict (Zemmali 1995; Boutruche 2000). This assessment, nevertheless, does not exclude that some reflections can be made in order to develop the rules applicable to water and water installations. Different approaches could be used for qualifying water and for giving to water security another kind of protection than that conceived by IHL. In this perspective it is interesting to go beyond the protection accorded by IHL to water and to focus on the developments regarding water in peacetime as well as on the significance that this natural resource plays in the international scene.

In this context, it is interesting to mention the already cited “Water for Peace” sessions held at the Third World Water Forum in 2003. During these sessions, the view was supported that international law concerning the management and utilization of water is essential and should be developed for limiting the risks the development of future disputes over water. In this context, the role of the “United Nations Convention on the Law of Non-Navigational Uses of International Watercourses” (the UN Watercourses Convention) adopted by the General Assembly in 1997 was highlighted for preventing water disputes.⁴⁹ At the same time, these sessions focused also on the protection of water as such, given that this resource is an integral part of the ecosystem (UNESCO/Green Cross International 2003). Finally, water, as indispensable for life, is intrinsically linked with human beings and thus with the protection of human rights.

If access to water is a basic human need, its recognition as a right is still difficult. Although the “General Comment no. 15 on the Right to Water” adopted in 2002 by the UN Committee on Social, Economic and Cultural Rights recognizes the human right to water,⁵⁰ the Ministerial Declaration adopted at the Third World Water Forum (2003) does not mention this right, referring exclusively to the UN Development Goals and to the Plan of Implementation adopted at the World Summit on Sustainable Development in Johannesburg (2002).⁵¹

These considerations on water during peacetime draw attention to the complexities of this resource and to the need to develop a comprehensive approach integrating the various dimensions of water. In this context, one might wonder whether a different reading of the security of water in times of armed conflicts could be necessary in order to deal with the multiple facets of water. For instance, through the protection of the objects indispensable for the survival of

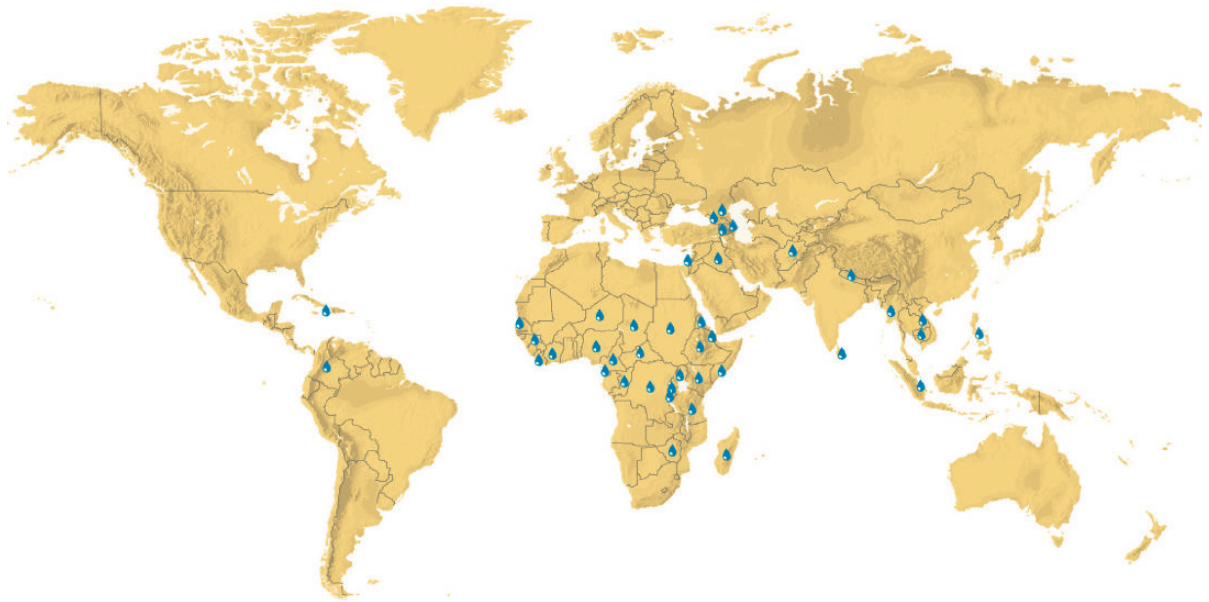

48 The Guidelines have been published as an annex to the resolution 49/50 adopted by the UN General Assembly on 9 December 1994. UN Doc. A/49/323 (1994), in: Schindler/Toman, 2004: 303–306.

49 “United Nations Convention on the Law of Non-Navigational Uses of International Watercourses”, 21 May 1997, U.N. Doc. A/RES/51/869, 36 “International Legal Materials” (1997): 700.

List of countries: Afghanistan, Armenia, Azerbaijan, Burundi, Cambodia, Cameroon, Central African Republic, Chad, Colombia, Democratic Republic of the Congo, Djibouti, Equatorial Guinea, Eritrea, Ethiopia, Georgia, Guinea Conakry, Haiti, Indonesia, Iraq, Israel, the Occupied and Autonomous Territories, Ivory Coast, Kenya, Laos, Liberia, Madagascar, Myanmar, Nepal, Niger, Nigeria, Northern Caucasus, Philippines, Republic of the Congo, Rwanda, Senegal, Somalia, Sri Lanka, Sudan, Uganda, Tanzania, Zimbabwe.

the population (Articles 54 of AP I and 14 of AP II), such protection can be read as integrating the access of water for protected people. This reading is supported by the “General Comment no. 15 on the Right to Water” affirming that during armed conflicts, “the right to water embraces those obligations by which States parties are bound under international humanitarian law.” Although IHL contains no mention of the right to water as such, many of its provisions⁵² are aimed at ensuring that persons or groups not or no longer taking part in hostilities are not denied water (Zemmali 2004). In this regard, the “Report of the International Commission of Inquiry on Darfur” has included in its analysis on the provisions relevant to the armed conflict currently undergoing in Darfur human rights violations and the right to water. Furthermore, the Commission of Inquiry on Lebanon, established the 2006 conflict, indicates the impacts of the damage or destruction of water facilities on the access to water.

52 For example the provisions protecting the objects indispensable for the survival of the civilian population or the obligations of ensuring water for specific categories of people. See note 6.

A different reading of water security in times of armed conflict should also include the security of this natural resource as such. In this context, the development of various instruments regarding shared water resources have an important role. These instruments should not be suspended in times of armed conflict, as observed by Briggs: “the mere outbreak of armed conflict (whether declared war or not) does not ipso facto terminate or suspend treaties in force between parties to the conflict” (Briggs 1985: 8).

Although there is still the lack of a general principle of international law in dealing with the effects of armed conflicts on treaties (Vöneky 2000), some water instruments, contain provisions on the effects of armed conflicts. Two ancient water instruments such as the 1921 Barcelona “Statute on the Regime of Navigable Waterways of International Concern”, focusing on the freedom of navigation and the 1923 Geneva “Convention relating to the Development of Hydraulic Power affecting more than one State” dealing with the carrying out of works for the exploitation of hydraulic power, indicate that in times of armed conflict they continue to be in force “so far as such rights and duties [of belligerents] permit.”⁵³ Moreover, the “UN Watercourses Convention” which is the first universal

instrument dealing with non-navigational uses of international watercourses,⁵⁴ in its Article 29 entitled “International watercourses and installations in time of armed conflict” also deals with these issues.⁵⁵

The provisions cited illustrate that international law includes indications on the effects of war on treaties dealing with shared natural resources such as international watercourses. Such provisions, along with the works of the *International Law Association*, provide guidance in this respect.⁵⁶ In this regard, it is also useful to mention that the *International Law Commission*, a subsidiary body of the UN General Assembly has included, since 2004, in its works, the topic of the effects of armed conflicts on treaties.⁵⁷

The works of the International Law Association and the International Law Commission could be used

as proving the formation *de lege ferenda* of a rule asserting that water treaties should continue to be in operation during armed conflicts. However, this issue is still an open question for international lawyers. As affirmed by the special rapporteur of the International Law Commission, Ian Brownlie: “It is not clear that there is a necessary implication from the object and purpose of such treaties that no effect ensues from an armed conflict, particularly when this affects the riparian State. The circumstances of each waterway vary considerably and much will depend upon the intensity of the armed conflict concerned” (ILC 2005: 32).

Although IHL deals directly and indirectly with the security of water and water installations, some reflections could be made on how to deal with these issues in a more comprehensive manner. In particular, it seems appropriate to think about the regime of protection of water during armed conflicts in light of a larger conception of water which takes into account the developments on the discourse of the qualification of water in peacetime. The point of departure of

53 Article 15 of the 1921 Barcelona “Statute on the Regime of Navigable Waterways of International Concern”, reads as follows: “This Statute does not prescribe the rights and duties of belligerents and neutrals in time of war. The Statute shall, however, continue in force in time of war so far as such rights and duties permit”. Two years later, the Geneva “Convention relating to the Development of Hydraulic Power affecting more than one State”, in its Article 9 contains an identical obligation: “This Convention does not prescribe the rights and duties of belligerents and neutrals in time of war. The Convention shall, however, continue in force in time of war so far as such rights and duties permit”. “Statute on the Regime of Navigable Waterways of International Concern”, Barcelona 20 April 1921, *League of Nations Treaty Series*, vol. VII: 37; “Convention relating to the Development of Hydraulic Power affecting more than one State”, Geneva 9 December 1923, *League of Nations Treaty Series*, vol. XXXVI: 77.

54 The states voting in support of the adoption of the UN Watercourses Convention were one hundred and two. Three states voted against, twenty-five states abstained and thirty-three states were absent. According to its Article 36, the Convention “shall enter into force on the ninetieth day following the date of deposit of the thirty-fifth instrument of ratification, acceptance, approval or accession with the Secretary-General of the United Nations”. As of December 2005, the UN Watercourses Convention has been ratified by twelve states (Finland, Hungary, Iraq, Jordan, Lebanon, Namibia, the Netherlands, Norway, Qatar, South Africa, Sweden, and the Syrian Arab Republic) and signed by eight countries (Côte d’Ivoire, Germany, Luxembourg, Paraguay, Portugal, Tunisia, Venezuela, and Yemen).

55 Article 29 reads as follows: “International watercourses and related installations, facilities and other works shall enjoy the protection accorded by the principles and rules of international law applicable in international and non-international armed conflict and shall not be used in violation of those principles and rules.”

56 See ILA 1976: “The protection of water and water installations”, Article VII, in: Report of the Fifty-seventh Conference, Madrid, 1976, (London 1978). Article VII reads as follows: “1. The effect of the outbreak of war on the validity of treaties or of parts thereof concerning the use of water resources should not be termination but only suspension. Such suspension should take place only when the purpose of the war or military necessity imperatively demand the suspension and when the minimum requirements of subsistence for the civil population are safeguarded.” ILA 2004: “Revision of the Helsinki and other International Law Association Rules on International Water Resources”, Article 55 in: Report of the seventy-first Conference, Berlin, 2004, available at: <http://www.ilahq.org/html/layout_committee.htm>. Article 55 reads as follows: “1. Treaties creating legal regimes for an international watercourse or part thereof are not terminated by war or armed conflict between the parties to the treaty. 2. Such Treaties or parts thereof shall be suspended only where military necessity requires suspension and where suspension does not violate any provision of this Chapter.”

57 ILC, 2005: “First report on the effects of armed conflicts on treaties”, A/CN.4/552, see, in particular, draft Article 7, available at: <<http://daccessdds.un.org/doc/UNDOC/GEN/No5/250/71/PDF/No525071.pdf?OpenElement>>. Draft Article 7 reads as follows: “1. In the case of treaties the object and purpose of which involve the necessary implication that they continue in operation during an armed conflict, the incidence of an armed conflict will not as such inhibit their operation. 2. Treaties of this character include the following: ... (f) Treaties relating to international watercourses and related installations and facilities.”

this reflection is nevertheless the recognition of the natural link between human beings, the environment, and water.

59 Environmental Security Concepts Revisited During the First Three Phases (1983-2006)

Simon Dalby, Hans Günter Brauch and Úrsula Oswald Spring

As we look ahead, we can see real risks that resource depletion, especially fresh water scarcities, as well as severe forms of environmental degradation, may increase social and political tensions in unpredictable but potentially dangerous ways. These new security challenges require us to think creatively, and to adapt our traditional approaches to better meet the needs of our new era.

Kofi A. Annan: Millennium Report (2000).

59.1 Introduction¹

In this chapter the authors assess the first three phases of research on environmental security (Rønfeldt 1997; Dalby 2002, 2002a; Brauch 2002, 2003, 2003b) and in chapter 97 below they outline the topics, the scope, the areas and the methods for a fourth research phase (Dalby 2006, 2007, 2008; Brauch 2005, 2005a, 2008, 2008a, 2008b).

This chapter discusses the main achievements of the three phases of environmental security research (59.2), and the lessons learned and yet to be learned with regard to the contexts of insecurity and the pillars of human security (59.3), it offers a brief review of some of the major critiques of the environmental security debate (59.4), and of the policy activities since 1990 translating research into action (59.5) and draws conclusions (59.6).

59.2 Three Phases of Environmental Security

Environmental security emerged as a discourse in the U.S. in the waning years of the cold war. Several arti-

cles (Ullman 1983; Mathews 1989; Myers 1989; Prins 1990; Rowlands 1991) stated the case for including the environment as a U.S. national security issue. Assumptions that environmental disruptions would lead to conflict were common; even more so were fears of wars to control scarce resources, and alarmist accounts of imminent chaos as environmental decay fed numerous social problems. This series of themes later found an especially vivid expression in Robert Kaplan's (1994, 1996, 2000) article on "The Coming Anarchy."

In the late 1980's, policy-makers put environment and security concerns on the international agenda. Most prominent were the authors of the '*Brundtland Report*' (WCED 1987) and Soviet President Mikhail Gorbachev who introduced the topic at the United Nations based on previous proposals by think tanks such as the *Worldwatch Institute* (L. Brown 1977). This scientific discourse and political debate focused on the environment as a threat to national and international security, and hence a matter of high politics which ought to be a priority for states concerned with preventing international conflict. National security was key here; the state was understood as the referent object in need of securing.

A second stage of the discussion emerged in the 1990's as researchers investigated the assumptions of the first phase and tried to operationalize the concepts in field research. Most high profile was a series of case studies conducted by Thomas Homer-Dixon

1 The authors are grateful to Patricia Kameri-Mbote (Kenya) and Czeslaw Mesjasz (Poland) for their very useful comments and suggestions that are reflected in this final text.

(1991, 1994, 1999; Homer-Dixon/Blitt 1998, see chap. 20 by Homer-Dixon/Deligiannis) and associates at the University of Toronto. In Switzerland, Günther Bächler (1998) as well as Bächler and Karl Spillmann (1996, 1996a, 1996b, 2002; see chap. 21 by Mason/Hagmann/Bichsel/Ludi/Arsano) led an interdisciplinary study on environmental conflict that produced complex analyses of environment and development issues. While the Canadian group focused on the linkage between environmental scarcity, stress and conflict, the Swiss group dealt with both environmental scarcity and degradation as causes of environmental conflict as well as matters of conflict resolution outcomes (Brauch 2005, 2006e).

The inductive case studies of the Toronto and Swiss groups were complemented with deductive approaches. Both focus on the complex interaction among environmental inputs, environmental-societal linkages and extreme outcomes. One difference between the second and third phase was leaving open the dependent variable - violent conflict or cooperation. During the third phase several research projects were pursued, some also addressing scarcity problems, such as:

- The *Global Environmental Change and Human Security* (GECHS 1999) project was launched as a framework for research cooperation and coordination.
- *ECOMAN*, *ECONILE* and *Environmental Change and Conflict Transformation* in Zürich and Bern continue the case study approach and focus on peaceful and cooperative management of renewable resource use in the Horn of Africa, the Nile region and other areas. This is part of a Swiss project on 'Research Partnerships for Mitigating Syndromes of Global Change'.
- The analytical and conflict theoretical syndrome approach of the *Scientific Advisory Council on Global Environment Issues of the German government* focuses on the patterned interaction of symptoms of global change with socio-economic processes (WBGU 1996, 1997; Biermann 1999; Biermann/Petschel-Held/Rohloff 1999).
- The *Transboundary Freshwater Dispute Database* at the Oregon State University and the *Global Assessment of Environment and Security* (GLASS) project at Kassel University.
- Several research teams (Peluso/Watts 2001) have analysed causes and intensity of violent conflicts, but only few have focused on environment and conflict linkages.

Other research, for example in geography (Bohle 2002), anthropology (Elwert 1990, 1999, 2003) and hydrology (Biswas 1993, 2004; Bogardi/Castelein 2002) has also produced theoretical and empirical results that are applicable to aspects of the environmental security discussion.

This scientific discourse was gradually picked up by the global peace (Oswald 1990a, 1992, 2008, 2008c; Brock 1991, 1992; Gleditsch 1997, 1998, 2001; Diehl/Gleditsch 2001, 2001a), security (L. Brown 1977; Renner 1989; 1996; Buzan/Wæver/de Wilde 1998; Wæver 2008, 2008a), environment (Carius/Lietzmann 1999) and development (Bhattacharya/Miller 1999) research communities. A joint NATO CCMS project by the U.S. DoD and the German Ministry of Environment promoted environmental security within NATO countries (Lietzmann/Vest 1999), and since then several NATO sponsored *Advanced Research Workshops* (ARWs) and *Advanced Study Institutes* (ASIs) have taken place and environmental security has become a key topic of NATO's Science Programme.²

What emerged in this debate, amid numerous methodological and empirical discussions, was a recognition that environmental change and resource scarcity and degradation was less likely to lead to international war than had been supposed in the first phase. While national security is important, and there are plausible arguments concerning threats of state collapse and internal conflict caused, triggered or intensified at least in part by environmental factors, the focus is more on state capacity and the policy dilemmas of social and environmental change.

The third phase includes analyses of global change linked to larger concerns about human security more generally rather than a focus on national security (see surveys: Brauch 2003, 2003a; Chen/Fukuda-Parr/Seidensticker 2003, Najam 2003; Dalby 2008). A new approach suggested identifying and mitigating syndromes of global environmental change.³ Furthermore, several research programmes and projects on global environmental change (IHDP, IGBP, WCRP, Diversitas, GECHS 1999, GWSP) fostered research and scientific networking on related issues. Case studies have fo-

2 See the website of NATO's Science Division, at: <<http://www.nato.int/science/>>.

cused on climate change (Stripple 2002; Page/Redclift 2002; Brauch 2002; Schwartz/Randall 2003), soil (Vlek 2005), and on cooperative resource and conflict management of water (Bogardi/Castelein 2002; Oswald 2005; UNESCO 2006) as well as case studies on transboundary water basins⁴ and water-related conflicts.⁵

This research has focused on insecurity in many places looking for policy initiatives that can mitigate disruptions caused by environmental change. The community working on hazards and disasters (Wisner/Walker 2005; IFRC 2002a, 2005; Cardona 2004) has identified environmental and social vulnerabilities (Bohle 2002) as a result of natural hazards, storms and droughts. However, so far only few studies have discussed the linkages between hazards, disasters and conflicts that occur in complex emergencies (Oswald 2005a).

Recent research on conflict, on causes of civil wars and political violence in the South has shown that some 'new wars' (Kaldor/Vashee 1997; Kaldor/Albrecht/Schméder 1998; Kaldor 1999; Münkler 2002, 2005) are about struggles to control access to plentiful and valuable resources (Klare 2001; Collier/Elliott/Hegre/Hoeffler/Reynal-Querol/Sambanis 2003; Ross 2004) while others have pointed to the complex interaction between resource scarcity and abundance for conflict and cooperation (see chap. 51 by Kipping). Within resource-rich Third World countries, the competition over the control of scarce and abundant resources has often erupted along ethnic, race and class divides (Shiva 2002; Oswald 2002a; Gaitán 2003; Saruchera 2004). This research also looks to the efficacy of political institutions as an important factor in whether these competitions lead to violent conflict; cases of state failure suggest that violence connected to demographic and environmental stress is worst where states fail to provide basic political and administrative functions (Kahl 2003, 2006).

These three phases on environmental security and additional studies on global change, development and conflict suggest a whole series of causes that may be leading to insecurity and violence. But now the discus-

sion has shifted into what appears to be a fourth phase of research. In this fourth phase the crucial point is that the focus is on human security rather than environmental factors that may cause concern for national security. The assumption cannot be sustained any longer that environmental change is an independent variable in scientific investigations of security outcomes. Rather the analysis starts with people first and works backward to understand the circumstances, social, cultural and ecological threats, challenges, vulnerabilities and risks that render them insecure and may contribute to conflicts or cooperation. Focusing on human vulnerabilities, and then working back to understand the causes of those insecurities is an approach that differs from the earlier phases although it builds on many of their insights. But as we make clear in chapter 97, this research will need to focus on the global environmental dimensions of human security if it is to place human vulnerabilities in the appropriate context.

59.3 Lessons Learned and Yet to Be Learned

59.3.1 Contexts of Insecurity

The GECHS (1999: 20) Science Plan noted that there is "increasing acceptance that environmental degradation is at least a contributor to conflict and insecurity". For GECHS the debate has also shown: "how various factors or relations of inequality and impoverishment structure threats. ... Environmental change ... is related to insecurity through conditions of inequality, institutional weakening, and impoverishment. The second phase of environment and security work has reinforced the deficiencies in the research program that were identified in the first phase." The GECHS Science Plan suggests further research "to build upon the early empirical work ... and to provide additional empirical studies on environmental change and its relationship to a broader conception of security".

These studies could not explain either why the critical socio-economic constellations escalated into violent conflict, nor when and why conflict could be avoided by bilateral and multilateral cooperation of states, experts and representatives of civil society. Inductive case-study projects have laid the foundations for a third phase of empirical and theoretical environmental security studies that focus both on the complex environmental inputs and on the societal outputs in terms of peaceful disputes and violent conflicts. A

5 See Gleick 1993, 1993a, 1994, 1998, 2000; Hamner/Wolf 1998; Amery/Wolf 2000; Wolf 1995, 1998; Wolf/Hamner 2000; Shiva 2002, 2003; Bächler/Spillmann/Suliman 2002; Oswald 2005; see chap. 41-58 in part VII in this book.

consensus emerged that environmental stress is rarely the sole factor in precipitating conflict both within and between nations.

Schwartz (2002: 139) considers population growth as closely linked with environmental stress. Among the wide-ranging environmental factors he includes ozone depletion and global warming and among the localized ones those that affect small areas at different times (desertification, water pollution). He points to “five pathways to indirect internal conflict that involve environmental stress: economic decline, migrations, social fragmentation, erosion of civil society and curtailment of the state”. A major effect of environmental stress is economic decline that will affect the poor [and the middle classes] more than the rich. A second pathway is migration that is sometimes caused by floods, droughts or locusts, by a lack of arable land that again is often the result of environmental stress, but also by water and air pollution, as well as shortage of fuel wood. The complex interaction of environmental stress and its social, economic and political ramifications has often resulted in increasing urban violence.

Global warming may affect freshwater availability and food production what will have severe impacts on poorer nations, and may have possible longer-term security implications. Direct international conflicts may result from the increasing competition over access to water while others counted only few minor skirmishes over international waters due to increasing international cooperation. Internal conflict, especially in developing countries, has also occurred as a result of environmental stress (e.g. in Sahel due to drought) that made many nomads clash with agriculturalists in neighbouring and less affected zones. Schwartz (2002: 148) argues that causal linkages between environmental stress and conflict could be shown in individual case studies, but that future research is needed “to estimate the causal effects of environmental stress.”

Hauge and Ellingsen (1998, 2001) who integrated environmental degradation (soil erosion, deforestation) into a model of civil war concluded: “that environmental degradation does stimulate the incidence of conflict, but less so than political, economic, and cultural factors, or previous conflict history.” In conclusion, Gleditsch (2002: 56) suggested that resource and environmental aspects of conflict “should be examined within the context of a broader view of armed conflict” with a special focus at politics, economics, cultural factors and the conflict history.

Environmental factors are frequently poorly incorporated in this shift from national to human security.

The narrow interpretation of human security, in terms of ‘freedom from fear’ has not yet included environmental components. Likewise the environmental security literature has ignored discussions of human insecurity. Thus both discussions frequently miss each other. In the process they forgo the possibilities of conceptual clarification and empirical comparison. There have been few attempts so far to combine the ‘environmental’ (including water, food, health, and livelihood) with the ‘human security’ approach (GECHS 1999; Barnett 2001; Barnett/Matthew/O’Brien 2008; UN/ISDR 2004; UNU-EHS 2005).

Invoking ‘human security’ has an additional difficulty when the notion of vulnerable human beings and state institutions is formulated in terms of neo-liberal approaches. Contemporary security thinking emerged from Greek and Roman origins (Arends 2008), was consolidated during the period of enlightenment and classic liberalism and developed further in recent years by international economic arrangements known as ‘the Washington consensus’ in what is now also frequently called neo-liberalism (Saxe-Fernandez 1999, 2008; Calva 2003; Cordera 2003; Stiglitz 2002).

In the doctrines of classic liberalism, the protection of individual freedoms and economic rights (protection of private property) and the preference for market forces determined much of the thinking about security (Rothschild 1995). Many of these themes have been picked up in the current discussion of human security, often without this intellectual heritage being remembered. As we will argue below there are important limitations to these formulations of security that need to be transcended in reformulating the environmental dimensions of human security.

During the contemporary neo-liberal period the objects of securitization have sometimes shifted from human beings to a defence of national interests often reflecting those of multinational enterprises and ruling elites and to a comprehensive legitimization of a widening of national security interests restraining and reducing individual rights and freedoms of classic liberalism. The offensive protection (‘pre-emption’) and promotion of economic and energy security interests by the neo-conservative ideologues have been complemented with a Wilsonian legitimization strategy to make the ‘world safe for democracy’. From this perspective, the human security debate has been perceived as a challenge to the effort to dominate and to dictate the global security agenda (Harle/Moisio 2008).

In the classic liberal thinking the knowledgeable individual property owner is the ‘person’ that stands

in for humanity in all its collective and social complexity (Rothschild 1995). But a large part of humankind lives in poverty, marginalized, and often highly vulnerable, without fundamental human rights and fulfillment of their basic human needs (Strahm/Oswald 1990). These people are confronted with a dual challenge from traditional and neo-liberal policies. With regard to the first challenge, entire communities struggle to maintain their social coherence and cultural diversity based on traditional rights and mutual solidarity (Salinas/Oswald 2003; Oswald 2008b). Neo-liberalism has forced increasing segments of urban and rural poor as well as highly trained young people to migrate (in the so called “brain drain”), destroying traditional livelihoods, social networks, economic structures, cultural bases and domestic order, thus contributing to social fragmentation, erosion of family relationships, and also organized crime that increasingly confronts parts of society with a ‘survival dilemma’ (Brauch 2002, 2003, 2008c).

Focusing on these dimensions of the human predicament suggests the need to think about security with a focus on human beings and their social networks, an approach that is loosely encompassed under the term ‘human security’. But, as the rest of this chapter suggests, we need to understand humans in their social and environmental contexts, rather than as the supposedly autonomous male property owners that traditional liberalism has assumed as ‘humans’. We also have to recognize the social disruptions that economic neo-liberalism has caused in the last few decades, a series of phenomena that are only partly captured in the critiques of ‘globalization’ (Fuentes/Rojas 2005; Kaplan 2003).

59.3.2 Pillars of Human Security

There are four ‘pillars’ of human security in the literature. The Canadian approach focuses on ‘freedom from fear’⁶, in particular on political violence. The discussion in *Responsibility to Protect* (ICISS 2001) and Canadian government policies as well as the initiatives of the Human Security Network (see chapter by Fuentes in this volume) have suggested that human security is about political rights and the necessity for governments to guarantee these freedoms by respecting civil rights and ensuring that the rule of law is fair and free from arbitrary repression.

The Japanese approach has focused on ‘freedom from want’ (Shinoda in this volume), that deals with themes of development rather than security. The Human Security Commission, headed by Sadako Ogata and Amartya Sen (CHS 2003) has tried to combine both calling for ‘protection’ and ‘empowerment’. The United Nations (Annan 2005) has suggested a third pillar of human security as ‘freedom to live in dignity’. Here the respect for cultural differences is also important in ensuring that cultures that support people are maintained intact.

UNU-EHS has proposed a fourth ‘pillar’ of human security as ‘freedom from hazard impacts’ (Bogardi/Brauch 2005). While natural hazards cannot be prevented, their impact depends both on the environmental and social vulnerability (Bohle 2002) of the affected people and on their bottom-up resilience strategies (Oswald 1991, 2005). More specifically this discussion focuses on the vulnerabilities of the poor in particular who live ‘in harm’s way’ so frequently on marginal land subject to storms, erosion, floods, or in hazardous lands on the sides of volcanoes (Cardona 2004; Pelling 2003a; chap. 87 by Nathan). Adding in technological dangers, as was seen in the 1980’s in the disaster in Bhopal (Shiva 2008; chap. 14 by Milbert) where poor people lived adjacent to a dangerous chemical plant, suggests a further vulnerability as a result of living in marginal settlements surrounding industrial facilities.

In addition to these prompt and local vulnerabilities the literature on global environmental change suggests that people in these marginal locations are now most likely to suffer from the disruptions caused by global climate change (IPCC 1998, 2001, 2007, 2007a, 2007b,). In so far as extreme weather events (storms, hurricanes, droughts, forest fires) and other hazards are more likely in the changing biosphere (Brauch 2002, 2003d, 2003e; IFRC 2002, 2005; Munich Re 2002, 2006) then the poor and marginal are made the victims of the economic and resource consumption that drives, literally, global change (Steffen/Sanderson/Tyson/Jäger/Matson/Moore III/Oldfield/Richardson/Schellnhuber/Turner II/Wasson 2004). Bangladesh is a key case to illustrate the new equity problems caused by global warming (IPCC 1998, 2001, 2007; Huq/Ali/Rahman, 1995; Huq/Asaduzzaman 1999; Huq 2001; Brauch 2002). In this case the projected sea-level rise caused by climate change is the greatest in a country that contributes the least to this new threat. In contrast those countries that have contributed most greenhouse gases, both in the past and in the present, have often objected to calls to reduce

6 See: Krause (2004, 2004a); Mack (2004, 2004a); Human Security Centre (2005); Dedring (2008); chap. 83 by Black/Swatuk.

their CO₂ output, and thus failed to fulfil their self-proclaimed obligations to developing countries.

These vulnerabilities are also sometimes enhanced when the spreading impact of the global economy disrupts local and indigenous modes of the economy (Dalby 2002). In ecofeminist formulations of this matter development is understood as a 'war on subsistence' (Mies 1998; Shiva 1988; Mies/Shiva 1993; Bennhold-Thomsen/Mies 1999; Bennhold-Thomsen/Faraclas/Werlhof 2001; Oswald 1991 and chap. 90). As the cash economy invades rural areas survival may depend on the availability of money, some of which may have to be earned elsewhere and sent back to the rural family as remittances. However, in many cases men leave to work in the cities or in foreign countries. They either never return or only intermittently send cash to support the family left behind. This situation creates manifold vulnerabilities in addition to disrupting family and community life and entrusting women with the sole responsibility for their survival (Oswald 1990; Serrano 2004; chap. 89).

Where disaster strikes marginal rural people, with little 'food' or 'economic security' except their land and the tools and animals to work it, face a dilemma of whether to leave and abandon their way of life and hope to rebuild if and when they return, or stay in hopes of being able to survive and salvage what they can as soon as the threat has passed. Any notion of 'human security' that formulates rural social systems as that which should be secured needs to focus on human rights in a way that enhances social resilience. Human rights have to include this dimension of 'freedom from want' if the environmental dimension, one that may be increasingly important as global change accelerates in coming decades, is to be incorporated into 'human security' discussions (Brauch 2006, 2006g). The urban poor living in hazard prone habitats are facing similar challenges (Cardona 2004; Pelling 2003; Davis, 2006; chap. 13 by Wisner/Uitto; chap. 14 by Milbert).

A more nuanced understanding of people as social beings aligned in networks of support and community, and one sensitive to the gendered formulation of the 'human being' in the human security discourse, is needed. Complex social networks sustain humans in normal times. Their vulnerabilities in time of change, conflict, hazard or disaster are usually a matter of disruption or failure of these networks, without which people become isolated and vulnerable, precisely because of these social disruptions.

59.4 Critiques of the Environmental Security Debate

The research on environmental security has triggered many critical replies from different scientific disciplines and competing schools. For example, from an international relations perspective Diehl and Gleditsch (2001a) have pointed to limitations and gaps in the environmental security field, including insights without evidence (empirical and theoretical shortcomings), and on primary focus on environmental conflicts rather than cooperation (Hagman 2005). Midlarsky (1998, 2001) discussed whether democracies are more successful "in protecting the environment and therefore in limiting the violence-generating conditions from environment degradation" and Conca (2001) concluded that environmental cooperation may have benefits but that it does "not help prevent or mitigate violent conflict" and that more conflict management may be needed. Homer-Dixon and Gleditsch disagreed on the maturity of environmental security research. While Gleditsch pointed to nine flaws, Schwartz, Deligiannis and Homer-Dixon (2001) defended the progress reached so far but both see more convergence on the future research agenda.

Gleditsch pointed to five crucial resources over which wars may be fought: a) territory, b) strategic raw materials, c) sources of energy, d) water, and e) food. In the Malthusian tradition population growth contribute to resource scarcity where harsher competition over resources may result in violence. Environmental scarcity has been challenged from a Cornucopian perspective (Deudney 1991; Lomborg 2001) pointing to human inventiveness, the role of trade, substitution of raw materials, price increases encouraging technological change. Gleditsch noted that environmental factors were excluded in most studies on the causes of war (e.g. Midlarsky's 1992), and that this literature ignores political (e.g. system of rule), economic (poverty, economic development) and cultural (ethnic, religious, linguistic fragmentation) variables, as well as gender issues (Oswald 2001). Gleditsch (2001) also pointed to the dangers of using the future as evidence by making inferences on the basis of future trends. The literature was also not always careful to distinguish between internal and international conflict. Possibly, many scholars suggested, environmental conflict should be analysed as a development issue. Several researchers have argued that resource abundance is more likely to lead to conflict while scarcity fosters cooperation (Berdal/Malone 2000) although such discussions need careful empirical valida-

tion looking at many case studies to make such generalizations (Ross 2004). In their reply, Schwartz, Deligiannis and Homer-Dixon (2001) called for: a) filling data gaps, b) operationalizing key variables, c) specifying contextual factors, d) dealing with complexity and e) encouraging methodological pluralism.

This eclectic critique ignores the work of the Swiss group and of many other projects of the third generation of environmental security studies and offers no alternative research design that could lead to a fourth stage of environmental security research. It ignores the methodological weaknesses of quantitative methods, and the significant contribution of comparative case study methods such as structured focused comparisons using qualitative methods, and excludes the knowledge of the natural sciences on complex often nonlinear and chaotic linkages among the natural and human, the supply and demand factors of global environmental change that cause, trigger, intensify or contribute to environmental scarcity and degradation, nor does it discuss their impact on environmental stress. Among the extreme outcomes, Gleditsch and his colleagues only focus on the least likely case: environmental conflict, ignoring the direct linkage between climate change and an increase of hydro-meteorological hazards and their potential socio-political consequences that often result in low-level violence below the level of conflicts and wars diagnosed in the literature on causes of conflicts.

Peluso and Watts (2001) challenged the Canadian environmental security school and rejected “automatic, simplistic linkages between ‘increased environmental scarcity’, ‘decreased economic activity’, and ‘migration’ that purportedly ‘weaken states’ and cause ‘conflicts and violence’”. Instead they focus on “ways that resource environments (tropical forests or oil reserves) and environmental processes (deforestation, conservation, or resource amelioration) are constituted by, and in part constitute, the political economy of access to and control over resources.” They claim that both shortage and abundance and processes of environmental rehabilitation and amelioration are often associated with violence. They offered a critique of Neo-Malthusian thinking linking Marxian political economy, cultural studies with a new political ecology, focusing on power relations in defining, controlling and managing nature and trying to re-map the relationship between environment and security. They do not look for environmental triggers of violent conflicts rather they offer “accounts of the ways in which specific environments, environmental processes, and

webs of social processes are central parts of the way violence is expressed” (Peluso/Watts 2001: 25).

Hartmann (2001: 39–62) pointed to weak definitional foundations, a one-sided case study selection (where scarcity led to violence), a moderate Malthusian thinking combined Cornucopian hopes in human ingenuity, to cultural biases with regard to Third World cases that localized the blame instead of analyzing the global context, an old-fashioned view of the state as a solitary actor, and to a lack of appropriate gender perspectives. Hartmann suggested that it was necessary to cross disciplinary boundaries and to include the results of political economy and ecology, as well as anthropology and development studies.

The case studies, for example on violence and environmental struggle in India (Bavsikar 2001), and on the Bhopal Gas Disaster (Rajan 2001), analyse three dynamic modalities of violent environments: 1) the forms, periodicities and repertoires of environmental violence, 2) the intersection of violent extraction with resource and environmental characteristics, and 3) the normalization of environmental violence. They focus on the patterns, tactics, or rhythms of violence and the changing technologies of extraction and changing loci of resource control. These case studies are not comparative nor are they able to contribute to an alternative model.

Conca and Dabelko (2002) suggested shifting the focus of research and of the policy debate from ‘ecological security’ (Pirages/DeGeest 2004) or from ‘violent outcomes’ of environmental stress to environmental peacemaking. Conca (2002) argued that the ecological security agenda in OECD countries has “constituted an obstacle to international cooperation” in those countries where the ecological insecurity is most severe, and he suggested a shift from the linkage between environmental degradation and conflict to the question “whether environmental peacemaking can trigger broader forms of peace.” He suggested two pathways first by transforming mistrust, uncertainty, suspicion, divergent interests and short horizons through practices of environmental cooperation; and second by viewing peace not as stable interstate relations but as shared identities. Environmental peacemaking should lead to confidence building and should lay the “foundation for transforming the national-security state itself”. According to Conca research should focus on: a) deepening and broadening trans-societal linkages; b) on emergence and strengthening of regionally grounded identities; and c) on the transformation of state institutions to foster cooperative interactions. Instead of analyzing the complex in-

teraction between factors of global environmental change, environmental stress and extreme or fatal outcomes, Conca and Dabelko deal only with the most optimistic cases where environmental issues have been resolved by cooperation. However, the crucial question of when and why environment security matters are resolved by cooperative policy processes and when they result in violence, is not being addressed.

The World Bank's Governance and Natural Resources Project analysed linkages between natural resources and conflict (Bannon/Collier 2003). They argue that abundance and greed rather than scarcity and grievance were conducive to civil wars that were often financed by the export of commodities, e.g. diamonds (Angola, Sierra Leone), tropical timber (West Africa), coltan, gold, drugs and oil that often financed violent secessionist movements, as well as poor governance and corruption. Bannon and Collier (2003: 8–16) assert that the best protection against civil war is economic development. By raising economic growth, diversification of dependence on one commodity, reducing the exposure to price shocks, higher transparency of natural resource revenues, exclusion of rebel organizations from markets, ending the finance of illicit commodities, tightening scrutiny of illicit payments, and attracting reputable companies to risky environments the dangers of resource wars are reduced.

In a second publication: *Breaking the Conflict Trap. Civil War and Development Policy*, Collier, Elliott, Hegre, Hoeffler, Reynal-Querol and Sambanis (2003) focus first on the economic costs during conflict and the legacy effects of civil wars (e.g. decline in GDP per capita, refugees and internally displaced persons, psychological trauma) as well as on the global effects of civil wars (economic and social spill-overs, refugees and diseases, drug production and trafficking) before they turn to the causes of civil wars. They discuss the role of rebel groups as political and business organizations, the role of ethnic factors and of the availability of natural resources but they ignore both environmental factors and the results of the environmental security research.

From an anthropological, ecological and peace perspective, Oswald (2005, 2005a, 2007a) suggested a 'hydrodiplomatic' approach as a strategy for resolving transboundary water-related conflicts with regard to the Rio Bravo (USA/Mexico). This might be done by a combination of demand-side management, technologies to increase supplies, negotiations on the local, regional and international political level (top-down) as well as by social and economic organizations (bottom-

up), institution-building for training, development of policy, norms and laws, public works and a culture of water as identity processes.

Most recently Colin Kahl (2006) has produced a comparative analysis of scarcity, abundance and political ecology hypotheses of conflict causation focusing mainly on the diverse histories of the last few decades in Kenya and the Philippines. This carefully crafted evaluation of the competing paradigms concludes that all approaches have some strengths but none of them adequately conceptualize all the factors involved in teasing out the complexity of the relationships between environment, resources and conflict within developing states. He concludes that state actions, or rather the lack of state action in the case of state failure, is a major factor in the emergence and persistence of widespread political violence.

59.5 From Research to Action: Policy Activities Since 1990

Notwithstanding many of the important criticisms of the formulation of environmental security in these academic debates, and the widespread recognition of a lack of precision in the formulation of the term 'environmental security', since the 1990's, the widening of the security concept has progressed and concepts of 'environmental security' (UNEP, OSCE, OECD, UNU, EU) have been widely used in policy discussion. Several major international reports (Brandt-Report 1980; Brundtland Commission 1987; Commission on Global Governance 1995) put the linkage between environmental stress and conflicts and conflict resolution on the political agenda of international organizations. The Millennium Report of the Secretary General mentioned several international organizations that have addressed the linkages between environmental stress and conflicts. However the World Summit on Sustainable Development in Johannesburg (2002) in its political declaration and plan of implementation referred to 'food security' but neither 'environmental' nor 'human security' were included. UN Secretary General Annan (2003: 12) pointed to the potential threats posed by environmental problems and he suggested that the UN system should "build additional capacity to analyse and address potential threats of conflicts emanating from international natural resource disparities". Most recently once again the policy discussions have been taken up by the United Nations Development Report (2007). The 2007–2008 Development Report specifically fo-

cuses on climate change and the possible impacts this may have on insecurity of various kinds, and in turn the potential difficulties this poses for human development in many places.

In this regard, UNEP has been active in three areas: a) *Disaster Management Branch* (DEPI), b) *UNEP's Ozone Action Program* (DTIE), and c) *UNEP's Post Conflict Assessment Unit* (Haavisto 2003). In January 2004 UNEP identified a "need for scientific assessments of the link between environment and conflict to promote conflict prevention and peace building" (Töpfer 2004). The UNEP Division of Early Warning and Assessment (DEWA) launched an *Environment and Conflict Prevention* initiative to stimulate "international efforts to promote conflict prevention, peace, and cooperation through activities, policies, and actions related to environmental protection, restoration, and resources (Lonergan 2004).

The *Organization for Security and Cooperation in Europe* (OSCE) has dealt with security risks from environmental stress. Among the non-traditional security risks confronting OSCE countries in Central, Eastern and South-Eastern Europe, in the Caucasus, in Central Asia and other parts of the former Soviet Union are trans-boundary pollution, shortage of drinking water, disposal of radioactive waste, reduction of human losses in man-made disasters and natural catastrophes (on ENVSEC initiative, see chap. 55 by Rakel; chap. 57 by Martius/ Froebrich/Nuppenau; chap. 71 by Cheterian).

The *Organization for Economic Co-operation and Development* (OECD) has addressed the linkages between development, environment and conflicts in several policy statements, such as *Development Assistance, Peace and Development Co-operation of the 21st Century* (OECD/DAC 1997) and in a scoping paper on the economic dimension of environmental security that are reflected in the *Guidelines on Conflict, Peace and Development Co-operation* (OECD/DAC 2000, 2001).

The European Union has pursued two strategies for 'environmental security': a) integrating environmental goals into all sectoral policies (*Cardiff process*), including in development, foreign and security policies; and b) stressing conflict prevention and management in its activities in international organizations (UN, OSCE) and for specific regions. At the Barcelona European Council in March 2002, a sustainable development strategy was adopted that emphasized the integration of environmental concerns into sectoral policies. The European Council in Seville (June 2002) approved a conflict prevention programme that

aimed both at short-term prevention and at the root causes of conflict, in its development cooperation with poverty reduction, and in its strategy against terrorism. The European Council meeting in Thessaloniki in June 2003 approved a 'green strategy' of the EU (Brauch 2003, 2005). Environmental security issues have also been put on the policy agenda of many other international organizations, such as ASEAN⁷, NAFTA, OAS⁸, and the African Union⁹.

59.6 Conclusions

While the first phase of environmental security research focused on concepts and on their legitimization and critique, the second phase has been theory-oriented and empirically-based with a strong emphasis on case studies. In the third phase a plurality of methods have been applied: from qualitative case-studies, to syndromes of global change and scientific approaches to mitigate them, to quantitative analyses of state failures, and quantitative analyses of the causes of violent conflicts, to assessments of cooperative efforts in trans-boundary fresh water dispute resolution, to simulations of the interdependence between water availability and food crises.

While quantitative methods may contribute to the recognition of complex linkages among structural determinants, and thus to an advance in our knowledge (by way of a *heuristic* function), they are nevertheless not sufficient because they exclude the complexity of the interactions between nature and humans that can be neither modelled nor predicted. As Kahl's (2006) recent work in particular suggests, the method of structured, focused comparative case studies (George 1979, 1988, 1993) can reconstruct the complex interactions among the determinants of global environmental change, environmental stress and its fatal out-

comes. Both *reactive* and *pro-active* or *anticipatory* learning for launching adaptive and mitigating responses requires knowledge and an understanding of these interactions that go beyond the competence of any discipline and can probably only be achieved by inter- and multidisciplinary research teams.

During these three phases what has not been done is notable: there is a lack of research on hazards and disasters, gender sensitivity, social vulnerability, bottom-up resilience as well as peace building. The fourth phase will need to incorporate these matters in a larger framework that encompasses many dimensions of human security in the new contexts of urbanization and climate change. Another shortcoming of the environmental security research and policy debate has been an overemphasis on research results conducted by scientists in North America and Europe. In an effort to overcome this narrow Eurocentric bias, the following chapters introduce diverse perspectives by scholars from the South.

60 Environmental Security: Academic and Policy Debates in North America

Richard A. Matthew and Bryan McDonald

60.1 Introduction¹

For the environmental community of North America, the 1990's began with great enthusiasm and energy, buttressed by a grave sense of urgency. In the post-Cold War world, sustainable development and conservation were widely embraced as pillars of a new world order. After being sidelined for much of the 1980's, the environment was restored to a position of primacy on the global agenda, and in short order elements of environmental rescue snapped into place like pieces of a global green jigsaw puzzle - *Our Common Future*, the Rio Earth Summit, Agenda 21, the Framework Convention on Climate Change, the Convention on Biological Diversity, the Global Environmental Facility, and so on. The *North American Free Trade Agreement* (NAFTA), which came into effect in 1994, included an environmental side agreement that promised to bridge the elusive gap between free trade and environmental protection.

The sceptical, obstructionist mindset of the Reagan and Bush I presidencies was swept away by the science-based environmentalism of Clinton and Gore. A heady mixture of capacity, resolve and opportunity wafted through Washington's corridors of power, sloshed across energy-hungry Canada, and spilled southwards into a Mexico seeking rapid economic development. The environment, the new American administration argued, could be saved without sacrificing human development, and the United States would lead this effort through the example of its own behaviour and through the authority attached to being the world's only remaining superpower.

While environmentalists in North America and around the world were rallying around sustainable development and *Agenda 21*, the North American secu-

rity community found itself at sea after five decades of unwavering focus on preventing a nuclear war with the Soviet Union. The process of rethinking security soon became intertwined with the process of environmental rescue.² The linkages were forged by many people, for many reasons. Some believed that in our degraded global environment, natural resource scarcity was rapidly becoming a significant contributor to violent conflict (Homer-Dixon 1991, 1999; Gleick 1993). Others looked at the sheer size of the world's militaries, and their ugly Cold War footprints, and concluded it was time for these powerful entities to be greened and harnessed to an environmental agenda (Butts 1999). Still others sought to integrate environmental issues into the larger project of complementing - or replacing - the concept of national security with the concept of human security (Lonergan 1999).

While a plethora of initiatives in Canada and the United States explored often highly original ways of associating the environment with security, these initiatives triggered a sobering, cautionary response literature. How would such a linkage be viewed in the developing world (Dalby 1992)? Could it lead to the securitization of the environment (Käkonen 1994)? Could the cultures of environmentalism and security be reconciled enough to ensure the effort produced more good than bad (Deudney 1990)?

In this chapter we examine several of these initiatives, focusing on North American scholars and giving a fair amount of attention to the behaviour of the Clinton-Gore administration, which sought to lead on this new policy agenda.³ We conclude that efforts to

3 We do not include Mexico that is partly covered in chap. 90 by Oswald Spring.

link environment and security have had mixed results. For example, some practitioners have reasoned that if natural resources are becoming so scarce that countries will fight over them, then we need to lower the bar for development at home in resource-rich protected areas such as Alaska and the Arctic – hardly the outcome sought by scholars and environmentalists. On the other hand, the environment has been fused successfully to the burgeoning paradigm of human security, which is emerging as the foreign policy focus of middle powers such as Canada and Japan. Most problematically, we argue that popularizing the concept of environmental change as a complex, global threat marked by much uncertainty established a discursive model that the current Bush II administration has adapted for explaining terrorism to its public, and for justifying enormous expenditures and pre-emptive action through reference to a formulation of the precautionary principle. The zeal with which some scholars acted to establish the policy relevance of their work has had some unintended, and negative, consequences. At the same time, however, Al Gore has done much to reframe climate change as a global and human security issue, integrating natural and social science research into a powerful presentation for practitioners, and compelling all North Americans to think in the often unfamiliar terms of global connectedness and interdependence.

60.2 Origins of Environmental Security in North America

Efforts to link environment and security have not in any sense been confined to North America, and, in fact, much of the most important, influential and inspiring analysis has been conducted by scholars in Scandinavia, Germany, Australia and many parts of the developing world, such as Pakistan and India. The brief history we provide here, focused mainly on events and writings in North America, should be understood as part of a larger story, to which North America contributed and with which it has interacted in many ways.

Responding to global concerns about the impact of human behaviour on the natural world, the contemporary formulation of the environmental movement emerged in North America in the 1960's, building on an earlier era of conservation identified with individuals such as John Muir and associated with achievements such as the founding of the Sierra Club and the establishment of a national park system. Envi-

ronmental historian John McCormick (1989) points to several factors that converged in the 1960's to promote the transformation of earlier conservation movements into modern environmentalism. The proliferation of nuclear weapons, the post-World War II continuation of wartime levels of military spending, and the rapid pace of economic development raised general concerns about the high-consumption character of advanced industrial society. Scientific evidence began to record and explain the magnitude and variety of human-generated environmental change with great – and disquieting – precision. Environmental accidents, such as oil spills, increased in number and captured public attention. In North America, as in Europe, baby boomers entered a period of intense social critique and activism that engendered, among others, civil rights movements, women's movements, antiwar movements, and back-to-nature movements. In 1962, Rachel Carson wrote an impassioned account of the human recklessness evident in gratifying immediate needs by spraying the planet with poisonous pesticides such as DDT, which gave rise to new forms of birth defect and social criticism.

Concern about the environment gathered critical mass throughout the 1960's and 1970's. Throughout much of this period, however, environmental concerns seemed of little relevance to national security analysis and planning. Defence institutions were generally regarded as an intractable part of the problem. From an environmentalist perspective, they were irresponsible entities that resisted the regulatory constraints emerging around the Clean Air and Clean Water Acts; dumped and abandoned enormous quantities of solid and toxic waste on land and at sea; secretly tested nuclear and other environmentally destructive weapons, exposing humankind to radioactive contamination and other health threats; and were willing to destroy nature when preparing for or engaged in war. But they had to be tolerated in an anarchic world dominated by superpower rivalry and ever vulnerable to the threat of all-out nuclear Armageddon.

Nonetheless, evidence of the harmful effects of using defoliants in Southeast Asia during the Vietnam War (Neilands/Orians/Pfeiffer/Vennema/Westing 1972; Westing 1976) did lead in 1977 to two important international agreements: the Additional Protocol I to the 1949 Geneva Convention on the Protection of Victims of International Armed Conflicts and the Convention on the Prohibition of Military or Any Other Hostile Use of Environmental Modification Techniques (Brauch 2003c).

The ‘limits to growth’ thesis propounded by Meadows, Meadows, Randers and Behrens (1972) and the first OPEC oil crisis in 1973 stimulated some fear about how resource scarcity might endanger economic growth in the North and create competitive conditions ripe for armed conflict. The Carter Doctrine, affirming the strategic value of the oil-rich Middle East, was in part a response to these concerns.⁴ But discussions of energy self-sufficiency garnered little support. After all, through trade, arms, and ingenuity one could gain access to anything as long as the real threat to the United States was held in check: the threat of Soviet expansion.

But while the structure and character of the Cold War shaped security thinking in much of the Western world, the elaboration of broader concepts of security did gain some attention. The environmentalist Lester Brown (1977), described by the *Washington Post* as “one of the world’s most influential thinkers,” wrote an exploratory piece on *Redefining National Security*. In 1982 the Independent Commission on Disarmament and Security Issues, chaired by the Swedish socialist Olof Palme, released a report on *Common Security*. The authors of this report distinguished between ‘collective security’ (security against armed force provided to its members by NATO) and ‘common security’, which focused on non-military threats such as those posed by environmental degradation and poverty. This conceptual trajectory was pushed further in Richard Ullman’s 1983 article “Redefining Security,” in which he sought to broaden the concept of national security to include non-military threats to a state’s range of policy options or the quality of life of its citizens. In the mid-1980’s, former Soviet President Mikhail Gorbachev expressed a similar perspective through the notion of ‘comprehensive security’, and in his speech to the UNGA in 1989 he promoted the concept of ‘ecological security’.

In 1986 the Chernobyl nuclear facility experienced a meltdown that caused widespread harm and even wider spread anxiety. Arguments about environmental threats to human welfare and security seemed suddenly very persuasive. The *World Commission on Environment and Development* chaired by former Nor-

wegian Prime Minister Gro Harlem Brundtland (1987), issued its report: *Our Common Future* that focused on the interlocking processes of population growth, food production, ecosystem protection, energy use, industrialization, and urbanization, the authors argued for a global commitment to sustainable development. To fail to make this commitment, they contended, would place the future of much, perhaps all, of humankind in jeopardy.

By the late 1980’s, as the Cold War approached absolute zero and environmental awareness rose to unprecedented levels, and as some of the more threatening implications of rapid technological change were being worked out by researchers, articles began to appear making explicit linkages between environmental change and security. Influential writings by Jessica Mathews (1989, 1997), Norman Myers (1989), and others began to be widely circulated in policy circles. Arguments varied enormously, but the basic idea that environmental change was serious enough to be considered a security issue made sense to many analysts, activists, and practitioners.

60.3 Environment and Security during the Clinton-Gore Era

Perhaps in response to the articles on rethinking national security published at the end of the Cold War, former President George Bush added threats posed by environmental change to the *National Security Strategy of the United States* in 1991.⁵ The following year the Clinton administration was installed in Washington. Vice President Al Gore and others took seriously the claim that the health of the environment was a matter of utmost importance to the long-term interests of the United States and the world.

The level of interest in Washington increased notably when the journalist Robert Kaplan published an article in *The Atlantic Monthly* in which he described environmental change as “the national security issue

4 During his 1980 “State of the Union Address”, President Carter declared: “Let our position be absolutely clear: an attempt by any outside force to gain control of the Persian Gulf region will be regarded as an assault on the vital interests of the United States of America, and such an assault will be repelled by any means necessary, including military force.”

5 “Global environmental concerns include such diverse but interrelated issues as stratospheric ozone depletion, climate change, food security, water supply, deforestation, biodiversity and treatment of wastes. A common ingredient in each is that they respect no international boundaries. The stress from these environmental challenges is already contributing to political conflict. Recognizing a shared responsibility for global stewardship is a necessary step for global progress. Our partners will find the United States a ready and active participant in this effort” (Bush 1991).

of the early 21st century” (Kaplan 1994: 61). Kaplan's thesis in *The Coming Anarchy* was simple and, for many policymakers searching for a new security paradigm, compelling: combine weak political systems, burgeoning urban populations, grinding poverty, environmental degradation and scarcity, and a flood of cheap weapons, and societies could become highly volatile. This lethal mixture, Kaplan suggested, already was generating high levels of violence in West Africa; soon it would affect the rest of the planet. This was likely to happen because at the very root of the social collapse evident throughout West Africa was extensive environmental degradation—a problem the entire world was experiencing. The pathways to violent anarchy might differ from one place to the next, but all of humankind was being pushed along one of them. The state of the environment, Kaplan concluded, had become a matter of national security. This analysis intrigued both Clinton and Gore who were searching for an explanation of the tragedies unfolding in Haiti, Somalia and Rwanda.

Often working behind the scenes and in a context of stiff resistance from other senior White House officials, Gore used a variety of strategies to introduce environmental concerns into key agencies and policy areas.⁶ So successful was Gore in rallying support in the foreign policy arena that in 1996 Secretary of State Warren Christopher (1998), an individual who until then had seemed scarcely aware of environmental problems, made a corner-turning speech at Stanford University that caught the attention of both environmentalists and foreign policy-makers around the world. According to Christopher (1998):

The environment has a profound impact on our national interests in two ways: First, environmental forces transcend borders and oceans to threaten directly the health, prosperity and jobs of American citizens. Second, addressing natural resource issues is frequently critical to achieving political and economic stability, and to pursuing our strategic goals around the world.

Indeed, “Environmental initiatives can be important, low-cost, high-impact tools in promoting our national security interests.” What sort of environmental initia-

6 Gore proved especially adept at restructuring in situ policies and institutions and at using environmental initiatives as a basis for advancing diplomatic goals. The so-called ‘Gore bilateral,’ forged with his counterparts in Russia, South Africa, and elsewhere, are a series of high-level agreements to cooperate on shared environmental problems that are typical of Gore's resourcefulness. For a sense of his perspective on environmental issues, see Al Gore (1992).

tives? Christopher outlined an ambitious four-part programme for his Department:

- Produce an annual report to assess global environmental trends and identify American priorities, beginning in 1997;
- Establish a dozen Environmental Opportunity Hubs to involve American embassies in assessing and addressing regional environmental issues worldwide;
- Host an international conference on treaty compliance and enforcement within two years;
- Promote an array of partnerships with business, and bilateral, regional and global initiatives to channel environmental problems into the social settings that have the resources and will to solve them.

Unfortunately, within a few years budget constraints and other obstacles had largely erased everything from the State Department's far-reaching and even visionary agenda. Internal opposition, deeply ingrained and hard-to-change behavioural patterns, lack of congressional support, and the inability of anyone to articulate a clear set of foreign environmental policy goals help explain the mixed results of these efforts (Hopgood 1998).

Problems within the State Department, however, did not put the brakes on efforts to integrate environmental concerns and national security. In July 1996, John Deutsch, then director of the *Central Intelligence Agency* (CIA), discussed the relationship between intelligence and the environment in a speech to the World Affairs Council. According to Deutsch, the potential for using CIA capabilities and archives to provide useful environmental intelligence at a low cost is great.⁷ Another support was outlined in a speech by Deputy Under Secretary of Defense for Environmental Security, Sherri Goodman (1996), who signalled her office's desire:

to understand where and under what circumstances environmental degradation and scarcity may contribute to instability and conflict, and to address those conditions early enough to make a difference, [and] to determine where military environmental cooperation can contribute significantly to building democracy, trust and understanding.

The flurry of policy statements in 1996 capped several years of diverse and relentless efforts to integrate en-

7 In fact, as discussed below, several initiatives were well advanced by 1996, although problems associated with concerns about declassification criteria persisted.

environmental concerns into national security policy. Attention focused primarily on ways in which environmental change could threaten national interests and hence become relevant to the traditional mandates of military and intelligence institutions. But U.S. environmentalists and security specialists also considered ways in which security institutions and practices can and do affect the environment adversely, as well as ways in which security assets could be applied to restore the environment and support domestic and foreign environmental policies.

60.4 The U.S. Discourse: Environmental Threats to 'National Security'

One can discern in the considerable academic and policy activity that took place from 1990 to 2005 in the U.S. at least eight ways of linking environment to security. This list is not intended to be definitive, nor is it a typological list with a clear ordering logic. Instead it is an attempt to capture the principal areas of research and policy, together with some of the criticisms they triggered, evident in the U.S. during this time period.⁸

60.4.1 Tension, Instability, Conflict and Violence Affecting U.S. Interests Caused, Amplified, or Triggered by Environmental Problems

According to researchers such as Peter Gleick (1991, 1993), Michael Klare and Thomas Homer-Dixon (1994, 1999; Homer-Dixon/Blitt 1998) the potential for environmentally escalated violence is significant and growing. Gleick (1993b), for example, has written extensively on the possibility of 'water wars'. Throughout the world, the demand for fresh water is increasing due to population growth and economic development. Many states rely heavily on sources that serve other countries as well. Pollution, depletion, and natural limits affect the availability of water. As demand grows beyond supply, which UNEP FI (2005) predicts could be the case in fifty-two countries by 2025, tension could grow as well, especially if animosity already exists. This may be especially true in places like the Middle East, where several states compete for the already stressed waters of the Jordan, Nile, Tigris, and

Euphrates. Klare (2001) extends Gleick's concern about water to consideration of other resources such as oil, timber, gems and minerals. While other researchers point out that, historically, states have almost always found ways to cooperate over shared water systems (Wolf 1997) and others raise important questions about this type of analysis (Lowi 2003); many acknowledge that acute need may overwhelm regional cooperation in the years ahead, leading to tension and perhaps armed violence.

Homer-Dixon (1994, 1999) has argued that environmental factors could have a far greater impact on intrastate violence. He contends that the prospects for environmentally induced or amplified state institutional failure, ethnic conflict, urban violence, and mass migration are high and likely to increase. Through a series of globe-spanning case studies, his team of researchers paints a foreboding image of a future in which environmental scarcity plays a growing role in generating violent outcomes, especially in developing countries already straining under the burdens of poverty, inefficient and corrupt governments, ethnic hatred, and renegade militaries. Work on the scarcity-conflict thesis has received a great deal of criticism. Some critiques focus on the recommendations and predictions resulting from the research, rather than on the underlying theoretical notion that environmental degradation can indirectly contribute to security threats (Deudney 1990; Peluso/Watts 2001). Other critiques emphasize serious methodological flaws in the research (Levy 1995). Compelling arguments also have been developed by mainly European scholars suggesting that careful quantitative analysis does not support the conflict-scarcity thesis, but uncovers instead a strong link between abundant, lootable natural resources and violent conflict (Collier/Hoeffler 1999; Collier/Hoeffler/Soderbom 2001; Hauge/Ellingsen 1998; Gleditsch 1997).

60.4.2 Activities Affecting U.S. Access to Environmental Goods Abroad

The cornucopian thesis (Gleditsch 2003) promoted by writers such as Julian Simon and Herman Kahn (1984) suggests that under conditions of resource scarcity, innovation accelerates and technology often can be used to develop substitutes. Where this is not possible, others note that trade will often prove an economical approach to meeting shortfalls (Deudney 1990). But some analysts contend that substitution and trade will not always succeed. The easy access the

⁸ For a European perception of 'environmental security' as a US national defence goal, see Brauch 2003: 89–90.

U.S. has enjoyed to the world's natural resources may diminish.

Recently numerous conflicts have taken place over access to fisheries (Porter 1995). Popular discussions of the Gulf War (1990) and the Iraq War (2003) suggest that U.S. desire to protect access to cheap oil played a major role in the decisions to use force. It is conceivable that states will one day consider using force to protect environmental goods such as rain forests - which regulate climate, serve as important carbon banks, and contain high levels of biodiversity - if diplomatic solutions prove unsuccessful. In short, factors such as resource depletion, population growth, and economic development in the South could affect U.S. access to or enjoyment of some natural resources.

60.4.3 Terrorist Activities Responding to Environmental Degradation, Targeting the U.S. Environment, or Using Ecological Systems as a Medium for Spreading Terror

In the wake of the 11 September 2001 terrorist attacks and the anthrax incidents of October 2001, one of the great doomsday scenarios that has seized the imagination of the American public and policymakers is that of a group of terrorists contaminating the water, food, or air supply of one or more major American cities with some dangerous substance such as plutonium or a virulent pathogen. Recent studies suggest that the country is vulnerable to this sort of attack and unprepared to respond. In April 1998, following the 'anthrax scare' in Las Vegas, FBI Director Louis Freeh described chemical and biological terrorism as "the greatest vulnerability we have right now."⁹ At the same time, Attorney General Janet Reno stated: "We need to make sure we have a significant stockpile - and I don't think we do - of vaccines and other medications."¹⁰ Numerous researchers have suggested that there is a growing risk of a major chemical or biological attack on the U.S. Small incidents have already been identified, such as in 1985, when members of a religious cult contaminated several restaurant salad bars with salmonella, causing 751 people in Oregon to become seriously ill (Torok et al. 1997). A growing

concern in the U.S. is the steady stream of attacks on targets such as commercial logging, government facilities, bio-engineering companies and land developers by groups such as the Earth Liberation Front and the Animal Liberation Front.¹¹ These network-structured organizations are difficult to neutralize and have demonstrated a willingness to engage in violence.

60.4.4 Greening the Military

While many environmentalists promote deep structural changes that would tend to render the military obsolete, some are more pragmatic, aware that throughout the world militaries are highly trained, well-organized, and well-funded social institutions. Moreover, in a world that regularly produces a vast array of threats - including the threat of armed aggression - militaries are not likely to be dismantled in the near future. One must ask whether they can be made less environmentally destructive than they have been in the past. For in the past militaries throughout the world - and especially in the United States and the former Soviet Union - have been reckless and cavalier, devouring energy, treading carelessly over vast tracts of territory, experimenting with lethal weapons, and generally creating and disposing of huge quantities of toxic chemical and solid waste (Feshbach 1995).

According to Kent Butts (1994 1996), in the 1990's the Department of Defense decreased toxic waste by fifty per cent. In cooperation with Sweden, it developed guidelines for environmental standards for military training and operations. It worked with Russia and other Arctic nations to reduce radioactive contamination of the Arctic region. The Australia-Canada-U.S. trilateral commission is another example of an attempt to address environmental problems cooperatively. Base cleanup was somewhat less successful, and anecdotal evidence suggests that throughout the world militaries continued to treat the environment in a reckless manner. Nonetheless, environmental awareness appears to have penetrated this historically single-minded and independent entity, and even generated more sustainable forms of behaviour. Even as the American military became more focused on fighting wars in Afghanistan, Iraq and the global war on terror, it continues to address environmental issues.¹² Further research needs to be done, however, to fully

assess the ecological modernization process still under way in the defence sector.

60.4.5 Using Military and Intelligence Assets to Support Environmental Initiatives

Intelligence and defence possess highly sophisticated resources that can assist in environmental assessment and monitoring and in developing 'green' technologies. This issue received considerable attention in the United States in the 1990's. Under the aegis of Vice President Gore, the CIA permitted civilian scientists to examine archived material that might be useful in assessing environmental degradation. The 'Medea Group', set up by the *National Intelligence Council* (NIC) in 1992, determined that archived satellite imagery was of great scientific value. Moreover, current intelligence technology is so sophisticated that satellite imagery could be used to diagnose the health of forests as well as monitor deforestation. It can penetrate water well enough to assist in evaluating the condition of fisheries. It already has been used to track and help fight forest fires. In view of this, the NIC began exploring ways to make the CIA's data gathering and analysis capabilities available to environmental consumers, including foreign and nongovernmental organizations. In 1997 the *Director of Central Intelligence (DCI) Environmental Center* was created partly for this purpose.

Some observers are sceptical of this initiative, on the grounds that the CIA's penchant for secrecy and other responsibilities might corrupt its public offerings. Critics advocate the development of commercial satellite systems. But the technological sophistication of intelligence assets may not be achievable in the private sector for many years, although the private-sector demand for surveillance technologies seems strong. Thus efforts to build bridges between the CIA and new consumers could remain important.

The U.S. military also possesses extensive resources that might be detailed to environmental policy initiatives, including technology-driving programmes, land restoration projects, treaty monitoring, and, possibly, treaty enforcement. Experiments in the 1990's with recycling technologies and ecosystem res-

toration, by different branches of the U.S. military, may serve as models for future endeavours. Discussions on using the U.S. military (or NATO or UN forces) to monitor compliance with international environmental law remain at a preliminary stage and face stiff opposition.

One of the more fascinating features of these various activities is the notable expansion of interagency communication and cooperation. It seems inevitable that addressing environmental problems will be most successful if the different types of expertise and experience spread throughout the American government are coordinated. Government departments and agencies have a history of being less than forthcoming with each other and of zealously trying to protect and expand their jurisdictions and budgets regardless of how resources might be most efficiently deployed. Concern about the environment may be breaking down some of this hostility and distrust. Intelligence agencies have signalled their intention to be more accessible to agencies that never consulted them in the past. The Departments of Energy (DoE) and Defense (DoD), together with the *Environmental Protection Agency* (EPA), signed a Memorandum of Understanding in 1996 stating that they would try to cooperate in this area.¹³ Of special importance, through the Environmental Change and Security Project, the Woodrow Wilson Centre has hosted regular meetings since 1994 that bring together diverse government officials, scholars, and representatives of environmental NGOs to discuss different aspects of environmental security.

60.4.6 Promoting Dialogue, Building Confidence, and Transferring Technology

Within American military circles there is much informal talk about the value of face-to-face encounters to relieve tensions, address fears, and improve transparency. In the 1990's, this desire created another promising approach to linking environment and security. Conferences on environmental security have provided a new context for dialogue. These can have collateral benefits insofar as they create greater awareness of the concerns, incentives, and beliefs of other countries. Throughout the 1990's, the U.S. hosted or par-

12 See for example the websites of the Office of the Deputy Undersecretary of Defense for Installations and the Environment; at: <<http://www.acq.osd.mil/ie/>> and: Defense Environmental Network & Information eXchange (DENIX); at: <<https://www.denix.osd.mil/denix/denix.html>>.

participated in conferences and workshops on environmental themes, such as those organized by the Army War College, the Asia-Pacific Centre for Security Studies, and NATO through its Partnership for Peace programme.

60.4.7 Providing Disaster and Humanitarian Assistance

In recent years the U.S. military has been called upon to assist in natural and humanitarian disasters. The suitability of military forces for such roles has been demonstrated during responses to the 2004 South Asian Tsunami, Hurricanes Katrina and Rita in 2005, and the October 2005 Northern Pakistan earthquake. For example, in response to the December 2004 tsunami, the U.S. deployed over 18,000 military personnel to assist with search and rescue, disaster assessment and recovery operations. In times of crisis and disaster, the U.S. military will likely continue to find itself involved in helping with water and food distribution, managing population flows, and combating disease outbreaks. If it is to succeed, it will clearly require more focused training and a more robust mandate than have been the case in the past.

On this issue, it is important to remember that in many smaller countries the military is the only state resource that can be called upon to help implement and monitor state-wide policies and assist in managing disasters and other crises. Because these often have an important environmental component, some training in environmental factors may be crucial to success.

60.4.8 Environmental Peacebuilding

A new and related focus is emerging through the work of a network of U.S. scholars that includes Erika Weinthal (2002), and Ken Conca and Geoff Dabelko (2002).¹⁴ Their current research objectives are to clarify the role of environmental considerations in post-conflict peacebuilding; to define the current state of our knowledge about environment-peace linkages; to identify both the benefits and challenges of incorporating environment, sustainability, and human security into post-conflict reconstruction and development in-

itiatives; to identify environmental management strategies as a tactic for building confidence between former parties in conflict; and to identify the most pressing research and policy agendas around these questions. The principal goal is to identify the environmental conditions necessary for sustainable peace and the circumstances under which environmental initiatives can help to facilitate that goal.

To date, conventional approaches to post-conflict peacebuilding have concentrated on United Nations peacekeeper operations and civilian missions that include economic reconstruction, institutional reform and election oversight. Too often lost in this approach is a focus on efforts to foster human security and sustainability. Ignoring environmental management in post-conflict peacebuilding ignores another potential strategy for building trust and cooperation as steps towards broader peace. The core premise of this new research project and the starting point for inquiry is that overlooking considerations of environmental quality, ecosystem health, and the natural resource base from which people extract their livelihoods risks undermining any gains that may be made in the political sphere and through development-assistance initiatives. If this is correct, then it becomes necessary to explore environment-peace linkages in a deeper, more specific, and targeted way than has been done to date.

60.5 Canadian Discourse on Environmental Change and 'Human Security'

While it was a Canadian scholar, Thomas Homer-Dixon, who caught the attention of the U.S. administration in the early 1990's and whose central arguments are described above, the Canadian experience in this arena has differed significantly from that of the United States. As in the U.S., Canadian scholars fiercely debated the scarcity-conflict thesis, and this debate will not be reiterated here. Concerns about Canadian access to natural resources, environment and terrorism, greening the military, using military and intelligence assets to support environmental initiatives, and promoting dialogue by focusing on shared environmental threats have all been expressed in Canada, but with far less fanfare and intensity than in the U.S. for obvious reasons. Canada has a small military and intelligence capacity, and a much more modest role on the world stage. It is a resource rich country with a natural resource based economy, and far less concerned about its access to foreign resources.

¹⁴ The text for this subsection is based on the unpublished description of a workshop on environmental peacebuilding that was written by Ken Conca, Geoff Dabelko, Richard Matthew and Erika Weinthal. The workshop was held at Duke University on 29–30 November 2006.

Perhaps the most vibrant development in Canada during the time period under discussion has been the growing effort to link global environmental change to the concept of human security, which has moved into a central position in Canadian foreign policy and scholarship. Canadians have also made a significant contribution to the resource curse debate, and are involved in the emerging issue of environmental peacebuilding.

60.5.1 Global Environmental Change and Human Security

Canadian research on global environmental change and human security is covered in detail by Jon Barnett, Richard Matthew and Karen O'Brien (2008). Therefore, we limit ourselves to very brief comments. The concept of human security became popular with the 1994 United Nations Development Programme's Annual Report. In this report, human security "was said to have two main aspects. It means, first, safety from such chronic threats as hunger, disease and repression. And second, it means protection from sudden and harmful disruptions in the patterns of daily life" (UNDP 1994: 23). The report also emphasizes four key dimensions of human security: it is universal, its components are interdependent, it is easier to protect through prevention than intervention, and it is people-centred (UNDP 1994: 22). In the past 14 years, the term human security has been redefined in numerous ways and it has become central to the foreign policy paradigms of several countries, including Canada and Japan. The Canadian formulation is well-covered by the Government of Canada (<<http://www.humansecurity.gc.ca/menu-en.asp>>). The Canadian approach stresses 'freedom from fear' and its work is centred on six areas of activity: protection of civilians; conflict protection; peace operations; governance and accountability; public safety; and new policy development. In this context, the environment is scarcely mentioned let alone focal. However, during the same period that the Government of Canada developed human security as its foreign policy focus, several Canadian scholars were prominent in establishing an international project to explore linkages between global environmental change and human security. A highlight of this work was the development of a new definition of human security "as something that is achieved when and where individuals and communities have the options necessary to end, mitigate or adapt to threats to their human, environmental and social rights; have the capacity and freedom to exer-

cise these options; and actively participate in pursuing these options (GECHS Science Plan 1999). In other words, human security is a variable condition where people and communities have the capacity to manage stresses to their needs, rights, and values" (Barnett/Matthew/O'Brien 2008).

The issue, however, is a part of the focus of Liu Center for Global Issues established at the University of British Columbia and initially directed by Senator Lloyd Axworthy. One of the Center's research areas is "the connections between environmental change and human security, defined in terms of wellbeing."¹⁵

60.5.2 Environmental Peacebuilding

Canadian researchers are participating in the environmental peacebuilding initiative described above. Earlier work in this area includes the edited volume *Conserving the Peace* (Halle/Matthew/Switzer 2002), produced by the International Institute for Sustainable Development in Winnipeg.

60.5.3 The Resource Curse

Important work examining linkages among natural resource exploitation, human rights abuses and violent conflict has been carried out by Philippe LeBillon (2001, 2002, 2003a, 2003b; LeBillon/Addison/Murshed 2003; LeBillon/Khatib 2004). This work has been well-received as more empirically defended than the scarcity-conflict thesis discussed above (see chap. 83 Swatuck/Black).

60.6 Conclusion

In the U.S., research, debate and policy focused on integrating environmental concerns into 'national security' have been a small part of a larger global effort to explore linkages between various conceptions of environmental change and national well-being. It is also a rather small part of national security thinking and policy in the U.S. itself. In both contexts, it is a controversial undertaking, freighted with rhetorical and analytical tension that has mobilized scepticism and resistance from security specialists and environmentalists alike. The former fear obscuring national security planning and preparedness (Levy 1995); the latter a degradation of environmental policy and of the envi-

15 See at: <<http://www.ligi.ubc.ca/Programs/index.cfm?fuseaction=Environment>>.

ronmental movement (Deudney 1990). It is a small piece of a large picture, but a piece that has come into focus quickly, that has attracted billions of US\$ in the U.S. alone, that has garnered attention throughout the world, and that has mobilized many critics as well as supporters.

There are good reasons to be concerned with the real world effects of linking environmental change to national security. The first is the problem of blow-back. Having persuaded many security practitioners and other senior policymakers that environmental change is a serious threat, environmentalists now find themselves having to defend the value of protecting wilderness in remote, resource-rich environments such as Alaska and the Arctic Circle. For example, in 2003 and again in 2005 President Bush presented a plan for developing the *Arctic National Wildlife Refuge* (ANWR) that was rejected by a slim majority in the Senate. As of February 2007 Bush has lifted restrictions on oil and gas development in Alaska's Bristol Bay.¹⁶ The danger of framing something as a national security issue is that, once this is accepted in the U.S., it has the potential to trump any other way of framing the issue. Placed side by side, protecting the U.S. is always going to trump protecting wilderness if Congress and the public can be persuaded that such a choice needs to be made. And while this trade-off has yet to be fully accepted, incremental moves within this logic have already been taken.

A second reason for concern is that the more extreme variants of the neo-Malthusian conflict-scarcity thesis – such as the violent and anarchic world expressed by Robert Kaplan (1994) and tied to the research of Thomas Homer-Dixon (1991, 1994; chap. 20 by Homer-Dixon/Delingiannis) – may have created a perception of complex global threat that politicians and the security community can exploit. In the days after the 11 September 2001 terrorist attacks against the U.S., President Bush noted that in crafting their response his administration would not distinguish between terrorists and those who harbour them. By 2002, the Bush administration had developed a doctrine justifying the pre-emptive use of force in the war on terrorism, which was first publicly announced during the President's commencement address at West Point Academy:

For much of the last century, America's defence relied on the Cold War doctrines of deterrence and containment. In some cases, those strategies still ap-

ply. But new threats also require new thinking. Deterrence – the promise of massive retaliation against nations – means nothing against shadowy terrorist networks with no nation or citizens to defend. Containment is not possible when unbalanced dictators with weapons of mass destruction can deliver those weapons on missiles or secretly provide them to terrorist allies. We cannot defend America and our friends by hoping for the best. We cannot put our faith in the word of tyrants, who solemnly sign non-proliferation treaties, and then systemically break them. If we wait for threats to fully materialize, we will have waited too long. Homeland defence and missile defence are part of stronger security, and they're essential priorities for America. Yet the war on terror will not be won on the defensive. We must take the battle to the enemy, disrupt his plans, and confront the worst threats before they emerge. In the world we have entered, the only path to safety is the path of action. And this nation will act. Our security will require the best intelligence, to reveal threats hidden in caves and growing in laboratories. Our security will require modernizing domestic agencies such as the FBI, so they're prepared to act, and act quickly, against danger. Our security will require transforming the military you will lead – a military that must be ready to strike at a moment's notice in any dark corner of the world. And our security will require all Americans to be forward-looking and resolute, to be ready for pre-emptive action when necessary to defend our liberty and to defend our lives.¹⁷

The justification for a pre-emptive strike is similar to that provided by environmentalists for the precautionary principle – “a willingness to take action in advance of scientific proof [or] evidence of the need for the proposed action on the grounds that further delay will prove ultimately most costly to society and nature, and, in the longer term, selfish and unfair to future generations.”¹⁸

A third concern is that it is certainly not clear that linking the environment and national security has resulted in more investment in ecologically sustainable behaviour and green research. At the Earth Summit in Johannesburg there were numerous reports suggesting that progress was slower than expected or needed. It does not seem credible to even suggest

16 Announcement of this available at: <<http://www.peopleandplanet.net/doc.php?id=2947>>.

17 See at: <<http://www.whitehouse.gov/news/releases/2002/06/20020601-3.html>>.

18 Taken from the Wikipedia entry at: <http://en.wikipedia.org/wiki/Precautionary_principle>.

that, so far, linking the environment to this strand of high politics has paid a measurable dividend.

There are, however, also several reasons to be encouraged by the academic and policy activity in Canada and the United States over the past fifteen years. First, elements of the U.S. military, including the Marines and National Guard, have gradually accepted that they will have to play major roles in addressing humanitarian and natural disasters such as Hurricanes Rita and Katrina, the Indonesian tsunami and the earthquake in Kashmir, and that their efforts will be more productive if they are prepared for these types of events and able to work effectively with entities such as human rights and environmental NGOs that have expertise but cannot be forced into a traditional command hierarchy.¹⁹

Second, the direction taken by the Bush-Cheney administration has run counter to the aspirations of its predecessor, but it has opened a political space in which former Vice-President Al Gore has been able to operate with a high level of success. His documentary and book *An Inconvenient Truth*, have educated millions of Americans and others about the science of climate change, and the threat it is posing to human security.

Third, linking environmental change to national security was disturbing to many environmentalists. But one of the outgrowths of this activity has been the new research agenda examining links between the environment and peacebuilding. This is likely to be a far more comfortable association for many, as peacebuilding is not a primarily military activity but rather one that fully encompasses the human rights and development communities

Finally, the work on global environmental change and human security is creating a platform for influencing the foreign policy direction being charted by Canada and other countries such as Norway and Japan.

Ultimately, one must conclude that research and policy activities in North America have generated mixed results, but that there is great promise evident in many of the elements of this programme that have emerged recently and shifted the centre of attention towards human security and peacebuilding, and away from framing the environment as a national security issue on the grounds that it has or will become a significant cause of violent conflict.

19 These comments are based on Matthew's direct experience working with U.S. Marine Forces Pacific on planning for humanitarian and natural disasters.

61 The Debate on Ecological Security in Russia, Belarus and Ukraine

Alexander Sergunin

61.1 Introduction

Ecological security was nearly a taboo in the Soviet era. Only during the Gorbachev period environmental issues reached the national agenda when Gorbachev (1987) introduced the idea of ecological security in his book on *perestroika* and New Political Thinking. However, on the practical level the debate was mostly devoted to the implications of the Chernobyl catastrophe (1986). The broader debate on numerous environmental problems was at an embryonic phase, public attention was preoccupied with the political cataclysms of the early 1990's. Only in the 1990's the environmental security debate emerged.

This chapter explores how environmental problems have affected the CIS security discourse, including threat perceptions and national security doctrines and it examines how different national schools (Russian, Belorussian and Ukrainian) identify their approaches to the solution of the ecological problems.¹

61.2 CIS Security Thinking in the Post-Cold War Period: Changing Perceptions

The political and academic communities in the *Commonwealth of Independent States* (CIS)² were surprised by the post-Cold War dynamics that did not come overnight. But it took almost a decade to redefining the national security concepts of Russia, the

Ukraine and Belarus and to produce thorough academic analyses. Several fundamental changes in the CIS security thinking were caused by the post-Cold War environment.

First, in contrast with the traditional security thinking that emphasized 'narrow' (military) security, the CIS countries accepted a broader security concept. According to the Russian Law on Security (1992), not only military but also economic, social, information, and ecological aspects of security are important. According to this law, "security is a freedom from internal and external threats to vital interests of the individual, society and state" (Yeltsin 1992: 5). The same principles were developed in the Russian Ecological Doctrine (2002).

Second, in addition to a new definition of security, there is a growing understanding among CIS strategic planners that in the age of globalization the focus of national and world politics is gradually shifting from the 'hard' (military) to the 'soft' (non-military) security domain. This was unusual for the Soviet security policy. The Soviet Union had always emphasized the development of full-fledged armed forces (both nuclear and conventional) and the military had a major saying in the decision-making. In the post-Cold War period 'hard' security lost its former importance, a new agenda was de-securitized, 'normal', non-security issues became objects of global co-operation. 'Grand' policy retreated to the shadow and 'low politics' (economy, societal issues, ecology, migration, etc.) dominated the scene.

Third, there was a dramatic change of threat perceptions. For instance, Russian and Ukrainian national security doctrines³ asserted that these two countries faced no immediate danger of large-scale aggression, and that, because the countries were beset with a myriad of debilitating domestic problems, the greatest threat to their security was now an internal

1 This study covers only three Slavic CIS states – Belarus, Russia and Ukraine because both the approaches and the agenda are different in other post-Soviet countries.

2 The CIS is the international organization, or alliance, established in late 1991 after the dissolution of the USSR and consists of 11 former Soviet Republics: Armenia, Azerbaijan, Belarus, Georgia, Kazakhstan, Kyrgyzstan, Moldova, Russia, Tajikistan, Ukraine, and Uzbekistan. Turkmenistan discontinued permanent membership as of 26 August 2005 and is now an associate member.

3 Belarus still maintains a more traditional (military-oriented) approach to national security.

Figure 61.1: Map of the Russian Federation. **Source:** Map 3840, Rev. 2, January 2004. United Nations, Department of Peacekeeping Operations, Cartographic Section. Reprinted with permission.

one. For example, the national security concept of the Russian Federation (1997) stated:

An analysis of the threats to the national security of the Russian Federation shows that the main threats at present and in the foreseeable future will not be military, but predominantly internal in character and will focus in the internal political, economic, social, ecological, information and spiritual spheres (Yeltsin 1997: 4).

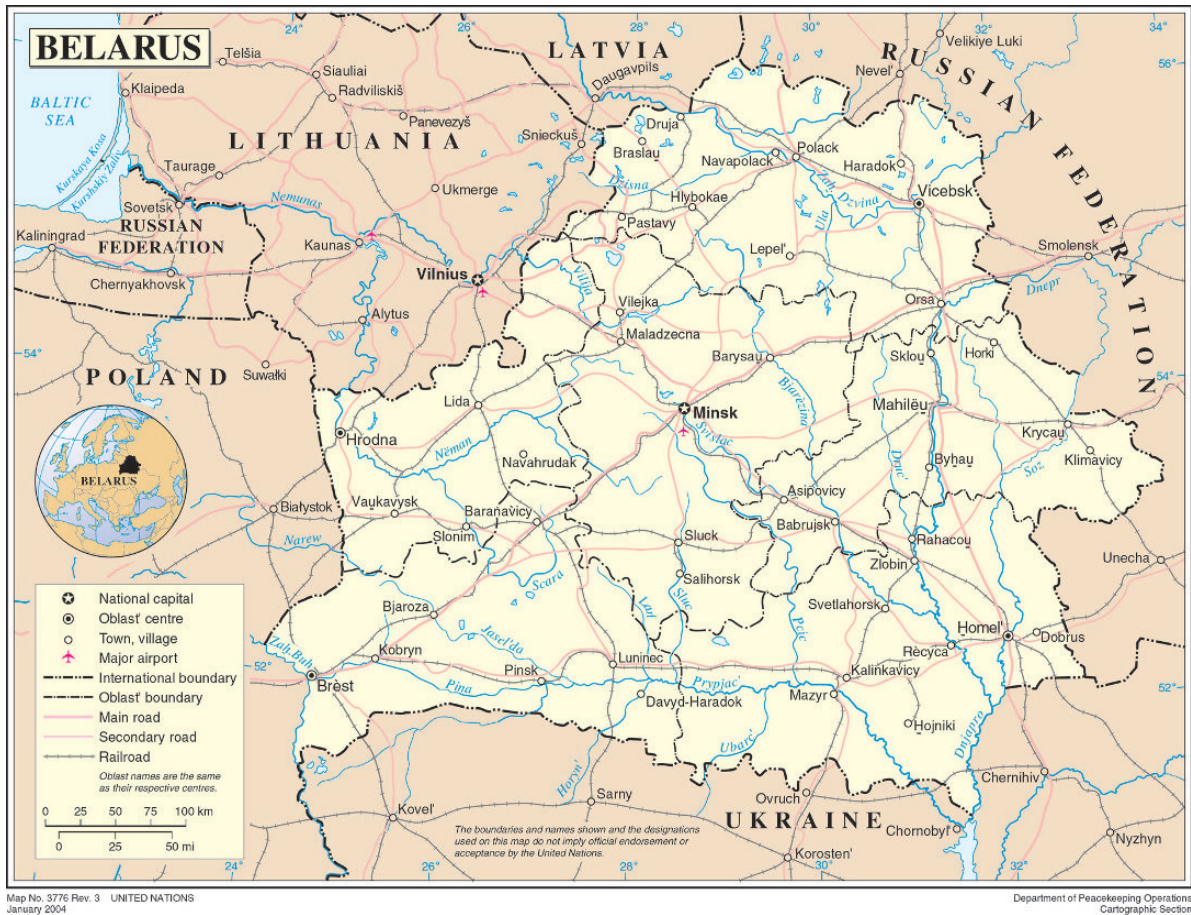

This is a distinct departure from previous doctrines. For example, the military doctrine of 1993 were based on the assumption that the main threat to Russia's security was posed by external factors such as local conflicts, territorial claims or violations of the rights of Russian-speaking minorities in the former Soviet republics (Yeltsin 1994).

Fourth, the predominance of the 'soft' security agenda has questioned the role and capabilities of the old actors (NATO, OSCE, etc.) in dealing with a new set of challenges. Several new institutions, such as the *Council of the Baltic Sea States* (CBSS), the *Barents-Euro-Arctic Council* (BEAC), and the *Arctic Council*

(AC) were set up to better cope with new problems rather than traditional actors. Among the 'old' multilateral institutions, especially the European Union (EU), the Council of Europe, the *Nordic Council* (NC), the *Nordic Council of Ministers* (NCM) and international financial institutions (IFIs) were more responsive to the 'soft' security problematic. It took the CIS foreign and security policies some time to adjust to this new reality.

Fifth, the post-Cold War period brought a new pattern of the globalization and regionalization relationship. It became a commonplace to ascertain that globalization and regionalization are the two sides of the same coin and different words (e.g., glocalization) are used to denote this complex phenomenon. The world faces the erosion of the nation state and of national sovereignty, the shift of power from the national level to supranational and sub-national institutions. The CIS is a part of this global dynamics and cannot ignore the rules dictated by it (although the

Figure 61.2: Political Map of Belarus (1997). **Source:** Map 3776, Rev. 3, January 2004. United Nations, Department of Peacekeeping Operations, Cartographic Section. Reprinted with permission.

Belarusian President Alexander Lukashenko tries to challenge this point from time to time).

The CIS is particularly affected by the regionalization in the transatlantic space due to the enlargement of NATO and the EU, Baltic and Nordic sub-regional co-operation, Eurasia (*Shanghai Co-operation Organization*), and Asia-Pacific (APEC (*Asia-Pacific Economic Co-operation*), and the ASEAN (*Association of South-East Asian Nations*) Regional Forum).

Initially, many CIS countries underestimated the role of regionalism in 'soft' security co-operation. They saw regional co-operation as either as a low priority (compared to 'grand policy') or a room for diplomatic manoeuvring (if 'grand strategy' failed). For this reason the CIS countries were quite suspicious about the regionalist nature of a number of sub-national and international initiatives (e.g. the EU's Northern dimension or Euroregions). These countries were afraid of strengthening separatist tendencies in a number of regions (e.g. Kaliningrad, Karelia

and the Russian Far East in Russia; Eastern and Western Ukraine and Crimea in Ukraine) as a result of their deep involvement in regional co-operation. Only with time the CIS states realized that regionalism brings more positive than negative results and started to think of its border areas as 'pilot' regions (Sergounin 1999). In addition, many environmental problems (e.g. Chernobyl catastrophe, water pollution in Neman, Don and Dnepr, etc.) have a trans-boundary effects and call for concerted efforts by several actors. As part of a new strategy CIS countries paid a serious attention to joining appropriate regional and sub-regional institutions.

For example, Russia concluded a *Partnership and Co-operation Agreement* with the EU (1994) and now takes part in various EU programmes on cross- and trans-border co-operation. Moscow participates in the activities of various sub-regional organizations such as the CBSS, BEAC, AC and the *Black Sea Economic Co-operation* (BSEC) (including on environment protec-

Figure 61.3: Political Map of Ukraine (1993). **Source:** Map 3773, Rev. 4, January 2005. UN, Department of Peacekeeping Operations, Cartographic Section. Reprinted with permission.

tion). In addition, Russia joined as a full member the ASEAN Regional Forum (1996) and the APEC (1998) organizations which are also involved in discussions of ecological issues. The Ukraine takes part in the BSEC and in a Euroregion in the Carpathian area. Belarus (regardless its xenophobic attitude to Western institutions participates in the Neman Euroregion (together with municipalities in Kaliningrad, Poland and Lithuania).

However, many elements of traditional security thinking still prevail and current CIS security thinking represents a mixture of different schools and approaches.

61.3 IR Schools and Environmental Security of CIS Member States

Ecological security has been a highly debated issue in the CIS International Relations (IR). It should be noted that all three alternative perspectives of IR - *state-centric* (realist), *multi-centric* (idealist or liberal),

and *global-centric* approaches to international politics (Rosenau 1982: 1-7) - exist in the CIS countries. Each school developed its own vision of environmental security.

61.3.1 Realism

Currently, realism is a dominant paradigm in the CIS countries. This group of theories regards the states as a key unit of analysis. Realists are rather reluctant to see ecological issues as a part of a global security agenda and believe that the implications of these problems for international relations are overestimated. 'Power politics', 'balance of power', and 'national interests' are still most valuable theoretical categories for them. Realists view globalization mostly as the emergence of the patterns of political control and domination which extend beyond borders (such as hegemonic control or spheres of influence), but they reject the argument that the idea of globalization is ac-

accompanied by a deepening sense of community (Klyuchnik 2002; Sekatskiy 2002). They believe that each country should solve its ecological problems by efforts of its own (or with a minimal international assistance) to avoid external control.

The realists are also sceptical about global governance, a product of globalization. They prefer to speak of world power distribution, world leadership, and 'concert of powers', alliances, etc. In their opinion, multilateral institutions are little more than vehicles for powerful states to establish rules and norms of action that are in their interest. Participation in an international institution does not mitigate the anarchic nature of world politics; the states are interested in survival at the very least, and in pursuing power at the most. Even those neo-realists who understand in principle the need for managing global problems believe that such governance is possible only when it is exercised by a superpower or by a coalition of the most powerful states (Klyuchnik 2002; Kozhinov 2001).

The greatest fear of realists about globalization and global governance is that countries might be unable in the future to control their own development. In this sense globalization means the denationalization of politics, markets and law (Klyuchnik 2002). The fear of external intervention to solve domestic ecological problems is also used by CIS realists as an argument for government protection of domestic markets and national industries. They claim that transnational corporations erode the ability of nation states to regulate their own economies and often use environmental issues as an excuse to intervene into the internal affairs of the CIS countries and they refer to the unfair competition with local business. For example, the Russian conservatives blamed the local branch of Greenpeace for helping multinationals to compete with Russian forestry and atomic energy industries.

In response to global challenges the realists suggest that the CIS political leadership should be more assertive in ensuring national security interests (Klyuchnik 2002; Zadokhin 2001). They articulate several alternatives to the global leadership in ecological security, including a greater reliance on bilateral and regional security co-operation and organizations, such as the Russian-Belarus Union Treaty, the Tashkent collective security system (CIS countries), the Shanghai Organization for Co-operation, etc. (Klyuchnik 2002). They warn the CIS leaders that ecological security co-operation with Western countries should be taken with a grain of salt and should strictly correspond to national interests and be of a short term and non-binding nature.

61.3.2 Liberalism

For the CIS multi-centric IR theories, non state actors are important entities in international relations that cannot be ignored; in addition, the state is not a unitary and often not a rational actor. This group of theories views multilateral institutions, along with the states, as crucial actors in world politics. Moreover, liberals believe that international institutions and law can be safeguards against anarchy in international relations and bring order and justice to world politics. For this reason, some versions of liberalism have been labelled as 'liberal institutionalism' or 'liberal transnationalism'.

The CIS liberalism emphasizes globalization trends in world politics, which strengthen the trend toward a global management of various developments (including ecological problems) and generally increases the relevance of international legal frameworks, thus reducing global anarchy. Although the trend toward a multipolar world is not neglected within the liberal perspective, it argues that the future development of the international system is no longer predominantly determined by the shape and outcome of rivalries among the major centres of power, but increasingly by the dynamics of their common development and interdependence (Bazhanov 2002; Khrustalev 1992; Zagorski/Zlobin/Solodovnik/Khrustalev 1992: 5-13). The liberals argue that the geopolitical drive for control over territories does not matter anymore, and suggest that it should be replaced by global thinking (Zagorski 1995: 5-8).

The CIS liberals view globalization and global governance as both an objective process that is impossible to resist and, at the same time, an opportunity for the CIS countries (Bazhanov 2002; Znachkov 2001). They believe that globalization is a chance for the CIS states to join the most developed part of the world and to reform their economy and socio-political systems with the help of the international community.

61.3.3 Globalism

Contrary to the realist and liberal schools, the CIS globalists depart from the assumption that the global context within which states and other entities interact and supranational structures are more important than nation states. Some globalists question the very existence of the nation state in today's world. National governments are unable to resist global processes and have to submit to universal laws dictated by the global dynamics.

The CIS globalist paradigm is not monolithic and consists of several sub-schools. The environmentalism is one of them. The environmentalist version of the CIS globalism was one of the first to re-define the concept of security in the post-Soviet period. According to Academician Yablokov (1992: 98), one of the leading Russian environmentalists, "National security is no longer purely military. I am sure that Russia's national security is environmental by at least one-third". Contrary to geopolitical threats which are mainly hypothetical, ecology directly affects the nation's economy, health, climate, etc.

Under the pressure of environmental concerns, nearly all CIS foreign policy schools included an ecological dimension in their security concepts. The environmentalists believe that traditional diplomatic methods are not sufficient for resolving ecological problems which have now tended to become global rather than national or regional. They believe that their countries, along with the entire world, should develop a 'new thinking' based on a common interest in survival (Pli-mak 1996; Shirokov 2003).

The concept of sustainable development is a key goal of environmentalists. As one Belarussian expert suggests, this concept aims to introduce a new, optimized, system of international division of labour, energy savings, development of alternative energy sources, environmentally clean agriculture, etc. (Shirokov 2003). Under the pressure of the environmentalists all three countries took part in the Pan-European Ecological Partnership "East-West" that has been launched by 12 post-Soviet countries and some European states in April 2002. This partnership is solidly based on the sustainable development approach (see at: <<http://www.priroda.org/docs/bul-rus-IL.doc>>).

Some environmentalists are quite radical in their policy recommendations. They recommend the dissolution of political boundaries and a de-ideologization of international relations. In order to cope with ecological problems, humankind should be able to forecast both the near and distant future and should consider all components of these problems in their historical and physical developments. Since only scientists are able to make good forecasts, this stratum should be charged with political management. National and international economies should be based on new technologies targeted at the rational exploitation of natural resources. Contrary to public and private properties, co-operative property would be the best form of ownership to deal with environmental issues. Trans-national rather than national bodies should be

in charge of global problems as nation-states are unable to cope with them any longer (Burlak 1992).

To sum up, the entire picture of the CIS debate on ecological security is very diverse and fragmented. This has hampered the formulation of a single national or CIS policy in the sphere of environment protection. None of the countries has a clear environmental strategy although on paper all of them have relevant legislation. Which environmental problems do the CIS countries presently face?

61.4 Problems and Solutions

Specialists identified several key environmental problems facing the CIS Slavic space (figure 61.4): pollution (61.4.1), terrestrial pollution (61.4.2), forest destruction (61.4.3), climate change (61.4.4), fisheries and marine environment (61.4.5), and nuclear safety (61.4.6).

61.4.1 Pollution

All three Slavic states suffer from heavy industrial pollution. The main source of industrial pollution is sectors, such as metallurgy (Russia and Ukraine), chemical industry (all three states), cellulose and paper-producing plants (Russia and Belarus) and nuclear industry (Russia). For example, in 2005 22 Russian cities with population of 14,3 million were indicated as areas with the level of air pollution that exceeded norms more than 10 to 50 times (The Russian Ministry of Natural Resources 2006).

All three republics also face soil pollution from pesticide use although a discussion on the preference of organic fertilizers has recently started. One more problem which is especially salient for Russia and Ukraine is the pollution of the surrounding seas. For example, the Baltic, Barents and Black Seas suffer from heavy water and air pollution because they are located in highly industrialized areas.

The Baltic Sea is one of the world's most polluted seas. Wastewater and sewage often goes untreated straight into the sea. Agricultural chemicals are destroying marine eco-systems. Over-fishing is threatening bio-diversity. Moreover, illegal oil spills from shipping are detrimental to the region's environment. St. Petersburg remains the main source of pollution: it contributes 2/3 of pollution generated by the Russian north-western regions (The Russian Ministry of Natural Resources 2006). Already the daily waste of local industries in the St. Petersburg area amounts to 120

Figure 61.4: Key Environmental Problem Areas in Russia. **Source:** University of Texas at Austin, Perry-Castañeda Library Map Collection; at: <http://www.lib.utexas.edu/maps/commonwealth/russia_environmental98.pdf> from the *Handbook of International Economic Statistics* (1996). This map is in the public domain.

tons of ammonium, 40 tons of nitric anhydride, 132 tons of oil products, 36 tons of phosphor, 50 tons of iron, and 2 tons of phenol (Kukk/Jervell/ Joenniemi 1992: 114; Roundtable discussion 2006). Barely two third of industrial wastewater in the area is purified. The sediment that is created after the cleaning is usually thrown into the Neva River or the Gulf of Finland. Resulting from a dam near St. Petersburg, coastal water pollution (industrial and agricultural) has increased one and a half times in early 1990's (now being 1500 mm/m^3).

Not only the Baltic Sea but also the Arctic zone became a subject of concern. According to some data, Russian oil companies pour some 20 to 30 million tons of oil into the Siberian forests and rivers (Yablokov 1992: 96). The Kola Peninsula has also been in trouble. According to the hydro-meteorological service in the Murmansk Region, one third of water samples taken in the region were classified as containing a high degree of industrial and agricultural pollution,

and of these, a further one third contained an extremely high degree of pollution (International Challenges 12.4: 36; The Russian Ministry of National Resources 2006).

To counter this situation, some experts maintain that international agreements on the marine environment of the Baltic Sea and the Arctic Ocean should be fully implemented.⁴ Forceful action must be taken on sustainable production techniques and investment in clean technology. For example, the Helsinki Commission (HELCOM) addresses the region's ecological problems. The HELCOM elaborated an extensive *Baltic Sea Joint Comprehensive Environment Action*

4 As far as other forms of pollution are concerned all three Slavic countries are the parties to international agreements on air pollution, air pollution-nitrogen oxides, air pollution-sulfur 85, biodiversity, climate change, desertification, endangered species, environmental modification, hazardous wastes, marine dumping, ozone layer protection, ship pollution, wetlands, etc.

Programme which identified 132 ecological hot-spots, most of which are in the eastern part of the Baltic Sea. However, because of the lack of resources, the programme has not been accomplished. Now the HELCOM concentrates on the development of the Action Plan on the Baltic Sea (The Russian Ministry of Natural Resources 2006).

The EU-Russian co-operation is the most crucial venue for the success of various regional endeavours. Priorities of a future common EU-Russian environmental policy in the Baltic and Arctic regions include: (a) keeping the Baltic Sea and the Arctic Ocean clean and reducing the release of pollutants to marine and fresh waters; (b) protecting biological diversity and ensuring sustainable use of natural resources, and (c) reducing emissions of greenhouse gases (Commission of the European Communities 2000, 2001, 2003; Vollebaek 2000: 59).

According to the Northern Dimension Action Plans 2000 (2001-03) and 2003 (2004-06), the EU supported investment projects in major 'hot spots' to reduce the pollution of the Baltic Sea, particularly in the Kaliningrad, St. Petersburg and the River Neva catchments areas (Commission of the European Communities 2000, 2003). The EU also supported a monitoring system on the environmental problems of the region in co-operation with the European Environment Agency.

It is also suggested to establish a link not only between the CBSS and BEAC but also with the AC (Ásgrímsson 2000: 54). The Council has a well-developed environmental programme that heavily focuses on the *Northern Dimension Initiative* (NDI) area and could be a very valuable addition to existing arrangements in this field. For example, the Council has an Arctic Monitoring and Assessment Programme that aims at monitoring pollution on the Russian coast of the Arctic Ocean (Forster 2000: 96; see chap. 73 by Hoogenesen).

It should be noted that not only the EU and sub-regional organizations but also some IFIs played a major role in the new environmental strategy, such as the *International Bank for Reconstruction and Development* (IBRD), *European Bank for Reconstruction and Development* (EBRD), *European Investment Bank* (EIB), etc. (Commission of the European Communities 2003; Eliasson 2000: 69). For example, their support was crucial in initiating the idea of the *Northern Dimension Environmental Partnership* (NDEP) in 2001. The IFIs were also quite helpful in funding specific projects in Russia's north-western regions.

The Nordic multilateral institutions also contributed to the regional process. In 1990, the NCM created the *Nordic Environmental Finance Corporation* (NEFCO), a risk capital institution with a total capitalization of ECU 80 million. The purpose of this corporation has been to facilitate the implementation of environmentally beneficial projects in the Nordic region. NEFCO invested ECU 245,000 in waste treatment and recycling in St. Petersburg, provided the St. Petersburg local government with a ECU 1,2 million loan for a municipal waste water treatment, and provided the Kostamuksha iron pellet plant (Karelia) with a ECU 1,8 million loan to carry out a modernization programme (Sawhill 1998: 66-67).

In 1996, the NC established a special environmental lending facility within the *Nordic Investment Bank* (NIB), with an initial capitalization of ECU 100 million. This facility aims to reduce the trans-boundary pollution in the *Barents-Euro-Arctic Region* (BEAR) and the Baltic Sea area by providing long-term loans and loan guarantees for public and private projects. Particularly, the NIB funded a number of projects on wastewater treatment in Kaliningrad, St. Petersburg and on the Kola Peninsula.

Country-to-country or bilateral co-operation is also important for solving Russia's environmental problems. For example, Finland and Karelia jointly monitor the ecological situation on their common border. Finnish consultants assisted in implementing a district heating system project (\$50 million cost) in the Murmansk Region (Council of the European Union 2001a).

Norway helped with the modernization of the Pechenganikel metallurgical combine to reduce trans-boundary pollution (Sigurdsson 1997: 133-134; Sawhill 1998: 66). A Russian-Norwegian agreement on co-operation in combating oil pollution in the Barents Sea was adopted in 1994, introducing notification commitments in emergency situations (Stokke 1997: 170). The UK set up a programme worth £2 million a year that focuses on air and water pollution, waste management, cleaner production, and sustainable forest management in Russia (Vaz 2000: 56).

The main threats to the Black Sea environment are polluted water, heavy metal, organic compounds, and oil-related pollutants. Waste water containing phosphorus and nitrogen-related elements is especially dangerous. The water supply in some areas of Ukraine contains toxic industrial chemicals up to 10 times the concentration considered to be within safety limits (see at: <<http://www.nationsencyclopedia.com/Europe/Ukraine-environment.html>>). The pollution of the na-

tion's water has resulted in a large-scale elimination of the fish population, not only in the Black Sea but also in the Sea of Azov (The Russian Ministry of Natural Resources 2006).

Air pollution is also a significant environmental problem in Ukraine. In 1992, Ukraine had the world's seventh-highest level of industrial carbon dioxide emissions, which totalled 611.3 million metric tons, a per capita level of 11.72. In 1996, the total had dropped significantly to 397 million metric tons and has so far remained at the same level.

It should be noted that these problems are generated not only by coastal regions of six countries (Bulgaria, Georgia, Moldova, Romania, Russia and Ukraine) with a population of 16 million but also by quite remote territories (ranging from Germany to Belarus and inner areas of Russia) via the big rivers, such as the Danube, Dniester, Dnieper and Don. The whole population of this area is about 165 million (Ryaboi 2006).

To cope with the environmental problems of the region the *Black Sea Commission* (BSC), the inter-governmental organ of the six coastal states, has adopted a Black Sea Protection and Recovery Strategic Plan (1996). The BSC budget in year was rather modest (US\$ 300,000) and allowed only limited monitoring activities. The BSC co-operates with OECD (*Organization for Economic Co-operation and Development*) and the EU (TACIS programme).

A concerted effort of these organizations forced the coastal states to tighten their environmental standards. In addition, there industrial activities in five of six littoral countries declined. This also contributed to a certain decrease of pollution. According to the international ecological expedition that examined the north-western (most polluted) part of the Black Sea in 2006, there is some modest progress towards a decreasing pollution and increasing bio-diversity in this area (Ryaboi 2006).

61.4.2 Terrestrial Pollution

This problem is especially important for Russia. Major mineral and metallurgy exploitation activities in Siberia and on the Kola Peninsula have disrupted the landscape in many places. Exploration for oil and gas, the development of new fields and other activities connected with petroleum affect heavily the interests of reindeer herding. Military exercises and transport were very damaging to the environment as well.

61.4.3 Forest Destruction

As Russian forests make up 25 per cent of the entire world's forestry, they play a crucial role in the functioning of the global biosphere and the climate of the planet. The Siberian taiga absorbs as much, or even more, carbon dioxide as the globe's rain forests, thereby stabilizing the atmosphere (Yablokov 1992: 96). Industrial and agricultural activities destroying forests in Siberia and on the Kola Peninsula, forest degradation through encroachment and over-exploitation violate the regional ecosystem balance; deteriorate animal and human living conditions (Heininen/Käkönen 1991). Scientists also point out that an additional effect of deforestation consists of the soil releasing more methane into the atmosphere than before. Methane is a powerful gas, which alters the atmosphere to a far greater extent than carbon dioxide, thus speeding up the greenhouse effect.

The international community has also been concerned about this problem. Reflecting these concerns, a parliamentary conference on deforestation was held in 1992 in Washington, DC. At the initiative of EU representatives, a special resolution on the Siberian forests was adopted. In March 1999 the BEAC also launched the Barents Region Forest Sector Initiative that aims at improving sustainable forest management and conservation, human resource development and socio-economic sustainability of the Barents region (Commission of the European Communities 2000: 12).

Again, the EU is the most important Russia's partner in this area. A number of EU initiatives were oriented to protect forests against atmospheric pollution (Council Regulation EEC No. 3528/86), to prevent forest fires (Council Regulation EEC No. 2158/92) and to protect forests from dangerous agricultural activities (Council Regulation EC No. 1268/99).

In the context of the *Baltic Sea Agenda 21* process, an *Action Plan on Forests* was adopted in 1998. The following problems were identified as key areas for priority action within the NDI: (1) promotion of sustainable forest management and efficiency in private forestry within the Baltic Sea region through the establishment of organizational structures or networks of forest owners and exchange of information on advisory services; (2) a gap analysis on forest conservation areas; (3) establishment of demonstration areas to illustrate forest management practices; (4) setting up a regional group for exchanging experiences and technological know-how, and promoting the use of wood-based energy; (5) promotion of the use of wood and wood-based products; (6) exchange of informa-

tion and national experiences on criteria and indicators for sustainable forest management; and (7) increasing networking and expertise in the forest sector through human resource development (Commission of the European Communities 2000: 14).

Since 2000 the Joint Research Centre's (JRC) *Global Vegetation Monitoring Unit* (GVMU) has been running a project called Sib-TREES (*Siberian Taiga Resources and Environmental Monitoring by Satellites*). This pilot project highlights the applications of earth observation with satellites for determining baseline inventories of forest resources and for forest monitoring (logging operations, fires, etc.) in northern regions (see, at: <<http://ies.jrc.ec.europa.eu/gem.html>>).

A 'Forest Sector Programme for the Northern Dimension' was presented to the Luxembourg ministerial conference on the NDI (April 2001) by the BEAC. The programme provided a good basis for further work in the areas of sustainable forest management, environmental conservation, and development of the forestry sector (Council of the European Union 2001b).

61.4.4 Climate Change

The deforestation and intensive use of fossil fuels are two major sources of the greenhouse effect. According to the report *Environment in the European Union at the turn of the Century* (1999), the world-wide increase in the use of fossil fuels will lead to a 3°C increase in the mean temperature in Finland and Northwest Russia between 1990 and 2050, this being one of the highest temperature increase expected in Europe (Commission of the European Communities 2000: 12). The greenhouse effect may result in a long-range climatic change. Because of the greenhouse effect, biologists predict that tundra areas will shrink and forests will creep north along coasts, up mountain slopes, and into former tundra areas. These processes would likewise change the composition of plant and animal communities. This warming trend has major implications for human activities in the North (offshore and onshore oil drilling, hydroelectric projects, and agriculture). In order to combat climate change, the EU and Russia aim at launching a regional pilot scheme for climate change joint implementation projects and projects to improve energy efficiency and better monitoring emissions (Commission of the European Communities 2000: 13).

61.4.5 Fisheries and the Marine Environment

The Black, Baltic and Barents seas severely suffer from water pollution. The stocks of some species such as cod and salmon are under pressure due to over-exploitation and water quality problems. In the Baltic Sea the fisheries sector is covered by the Agenda 21 Action Programme aiming at sustainable fisheries by harvesting within safe biological limits. This should be done by applying a precautionary approach and by gradually achieving a balance between the harvesting capacity of fleets and the target reference points for stocks based on long-term management strategies for all the fish stocks regulated by the *International Baltic Sea Fishery Commission* (IBSFC). A resolution on the long-term management strategy for the cod stocks was adopted in 1999 and the *Salmon Action Plan* (SAP) was adopted in 1997 (Council of the European Union 2000).

To protect the marine environment Brussels and Moscow adopted an EU-Russia Fisheries Co-operation Agreement in July 2006 (<http://www.delrus.ec.europa.eu/en/news_848.htm>). Russia and Norway have already made an arrangement pertaining to the fisheries of the Barents Sea. The EU-Russian co-operation on protection of bio-resources includes the following priorities:

- Equipping fishing boats with EU-mandated satellite-based *vessel monitoring systems* (VMS);
- Co-operation in the field of research, scientific work and fisheries management;
- Implementation of SAP to support restoration of damaged habitats, development of fishing surveys and monitoring in salmon index rivers;
- Achievement of sustainable aquaculture – action to minimize the environmental impact of aquaculture (Council of the European Union 2001a).

61.4.6 Nuclear Safety

For all three Slavic CIS countries the consequences of the 1986 Chernobyl catastrophe had many ecological, economic, social and political implications (figure 61.5). The northern part of Ukraine, the southern section of Belarus and the south-western part of Russia were affected by the fallout from the Chernobyl *nuclear power plant* (NPP). Belarus and Ukraine have especially suffered from the catastrophe. 23 per cent of the Belarussian territory with 1,3 million population were contaminated by the fallout (Office of Communications of the President of the Republic of Belarus 2006). Over three million Ukrainians live in danger-

ously radioactive areas and 12 per cent of arable land is contaminated.⁵

Fortunately, over the last decade the level of radiation in all contaminated areas has remained stable. For example, in 2006 the average radiation level was for: Kyiv - 0,012 mR/hr, the Kyiv Region - 0,009-0,017 mR/hr (the standard level is 0,050 mR/hr) and Chernobyl - 0,035 mR/hr (the acceptable threshold is 0,080 mR/hr) (Ukrainian Ministry of Emergency Situations 2006). The same was true for the Russian regions of Bryansk and Tula that also suffered from the Chernobyl catastrophe (The Russian Ministry of Natural Resources 2006).

In addition, Northern Russia has the largest concentration of military and civilian nuclear installations in the world. More than 80 nuclear submarines are located there, with over 200 nuclear reactors stored within them (Ahunov 2000: 73).⁶ According to some assessments, the operational risks of the 10 reactors in NPPs located in north-western Russia and Lithuania (6 of which are of the same type as at Chernobyl) also present a serious threat to the population and a large area of Europe (Commission of the European Communities 1998; Patten 2000: 12). Spent nuclear fuel and radioactive waste in Russia is also an extensive and worrying problem.

The Russian environmentalists believe that the northern part of Russia and Arctic Ocean are most vulnerable to nuclear contamination. Tens of thousands of cubic metres of seriously contaminated nuclear waste have been gathered here (Ahunov 2000: 73). Radiation emanating from nuclear munitions factories in Krasnoyarsk, Tomsk, Chelyabinsk used to float into the Arctic Ocean down the great Siberian rivers. From 1964 to 1991, fluid and solid radioactive waste has been dumped into the Barents and Kara seas. According to the Yablokov Commission's report (1992), the USSR dumped 16 nuclear reactors into the Kara Sea (including 6 with nuclear fuel). Also, a container with nuclear waste from the ice-breaker 'Lenin' has been dumped in a similar fashion. General radioactive waste amounts to 319.000 curie in the Barents Sea and 2.419.000 curie in the Kara Sea.⁷

The European multilateral institutions have given particular attention to nuclear safety in north-western Russia. The Nuclear Safety Account (NSA), as a special grant facility within the EBRD, has been established to serve as a mechanism to finance operational and near-term technical safety improvements for Soviet-designed reactors in the former socialist countries. The NSA is capitalized at ECU 257.2 million, provided by fourteen donor states (including the Nordic countries, above all Finland, Norway, and Sweden) and the EU. The NSA provided grants for safety upgrades in the Kola and Leningrad NPPs, amounting to 45 and 30 million ECU, respectively (Sawhill 1998: 66-67).

In 1995 the Nordic countries initiated an international Contact Expert Group (CEG) under the aegis of the International Atomic Energy Agency (IAEA). The group is made up of representatives of twelve countries and three international organizations. It meets regularly at least twice a year and co-ordinates a number of projects on nuclear waste and nuclear submarines, particularly in north-western Russia (Ahunov 2000: 73-74).

The Russian Federation signed several quite promising agreements with Sweden and Norway on handling nuclear waste and nuclear safety issues. According to these documents priority should be given to the following concrete projects: NEFCO to remove hazardous nuclear waste stored on board of the vessel *Lepse* in Murmansk; the Arctic Military Environmental Co-operation which also aims at the treatment of radioactive waste in Murmansk; the joint Norwegian-Russian arrangements on environmental co-operation in connection with the dismantling of nuclear submarines; and multilateral energy efficiency projects under the BEAC, *International Energy Agency* (IEA), *Economic Commission for Europe* (ECE) and Energy Charter auspices.⁸ The Netherlands contributed 0,5 ml guilders to the *Lepse* project (Forster 2000: 96). UK provided £ 5 million for the nuclear clean up in the Kola Peninsula (Vaz 2000: 56). A special project was signed between the ministers of defence of Russia, the U.S. and Norway to construct a concrete container for long-term storage of spent nuclear waste fuel (Ahunov 2000: 74).

The nuclear challenges in north-western Russia are of such a magnitude that a concerted international action was necessary. This is why in Bodø in March 1999

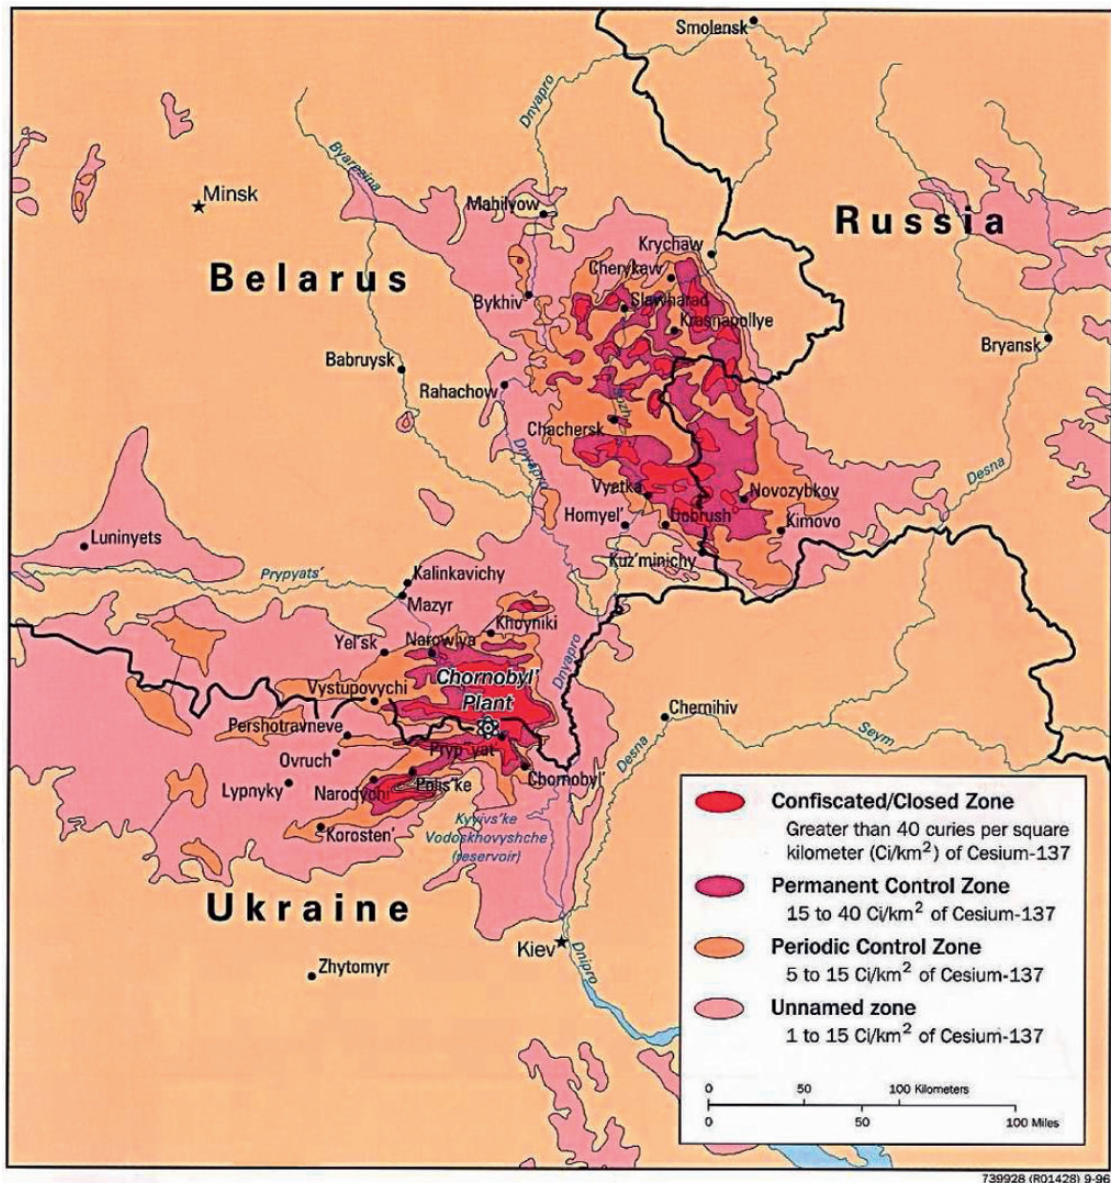

5 See e.g. at: <<http://dev.prenhall.com/divisions/hss/worldreference/UA/environment.html>>. There is an extensive scientific literature on the assessment of this nuclear accident.

6 According to the EU sources, there are approximately 300 nuclear reactors (20 per cent of the world's total) in the region (Commission of the European Communities 2000: 14).

7 See: *Izvestiya*, 20 April 1993; *International Herald Tribune*, 28 April 1993; Gizewski (1995: 25-41).

8 See: *Rossiyskaya Gazeta*, 13 March 1997.

This map is in the public domain.

the BEAC recommended that the interested nations and the EU should negotiate with Russia a *Multilateral Nuclear Environmental Programme in the Russian Federation* (MNEPR). This international agreement could serve as an umbrella for all projects on nuclear waste and spent fuel in Russia. It was planned that the agreement could contain a set of obligations for Russia and could establish a mechanism for better co-ordination. Such a programme could greatly facilitate planning and implementation of nuclear projects

in North-western Russia. But the negotiations were quite difficult and took almost four years. The most difficult questions consisted of tax and customs exemption, including liability, access and auditing (Eliasson 2000: 69; Vollebaek 2000: 59). The MNEPR agreement was signed on 21 May 2003 in Stockholm.

The EU strategy for Russia in the pre-MNEPR period explicitly linked nuclear safety programmes to two basic conditions: (a) the existence of Russia's strategy for radioactive waste and spent fuel manage-

ment, and (b) the conclusion of the MNEPR framework agreement. This strategy was quite successful and both objectives were achieved. Prior to the signing of the MNEPR the financial support given by the EU to the nuclear safety-related projects in north-western Russia totalled more than € 66 million (Commission of the European Communities 2001).

After the MNEPR entered into force, the EU-Russia co-operation on nuclear safety has aimed at:

- obtaining a commitment from the Russian government that the design lifetime of the Leningrad and Kola NPPs will not be extended;
- enhancing operational safety actions and supply of equipment for these NPPs, including additional training of personnel, upgrading the control room panels, creation of alternative shutdown systems, construction of a radioactive waste cementation facilities, development and construction of a treatment facility for radioactive liquid waste, development of leak detection and fire detection systems, etc.;
- developing exploratory projects, such as assessment of necessary improvements at the Russian submarines' unloading facilities at Iokanga and Gremikha; feasibility study for the rehabilitation of the Andreev Bay technical base (Murmansk region) that was initially built for storage of spent fuel and radioactive waste from nuclear submarines (reportedly there are over 20,000 spent fuel elements on the site); the environmental impact assessment for de-fuelling activities of laid-up nuclear submarines at Zvezdochka (Severodvinsk, Archangel region); the removal of damaged spent nuclear fuel from the Lepse service ship; the design, licensing and construction of a 80-tonne Murmansk storage cask for damaged spent nuclear fuel assemblies; the assessment of the safety of storage of radioactive waste in several important facilities located in the Murmansk and Archangel regions; the optimization of the transport schemes for spent nuclear fuel - removed from service ships, ice-breakers and laid-up nuclear submarines - from Northwest Russia to the Southern Urals (Mayak plant); the storage of spent nuclear fuel in Mayak; the assessment of several potential disposal sites and concepts for short-lived radioactive waste in North-western Russia, etc.

As far as the financial side of the EU-Russia co-operation is concerned, under the MNEPR funds are to considerably increase. At the same time, both Brussels and Moscow increasingly emphasized the need to

make such a co-operation more equal in financial terms (especially given the current recovery of the Russian economy).

The problem of nuclear waste has also been a topical issue for the Ukraine. The nuclear industry is the key component of the Ukrainian energy sector. Its 15 nuclear reactors provide 52 percent of the total Ukrainian energy supply (more than gas, oil, coal or hydro-energy). Currently, the Ukraine has to spend tens of million dollars to remove the spent fuel from NPPs to Russia. Experts suggested to construct nuclear waste storage sites on the Ukrainian territory to save money for other energy projects (see at: <<http://www.rainbow.gov.ua/action/>>).

61.5 Conclusion

Globalization has dramatically changed the CIS security thinking. New and broader definitions of 'national' and 'international security' were adopted. The top priority were 'soft' security issues. Environmental protection is one of the most important priorities on the CIS security agenda. The role of various international security organizations has been reassessed. Newly created regional institutions came afore to address non-traditional security challenges. A new strategy on regional ecological co-operation has been developed.

The CIS countries had also to adjust the centre-periphery balance in order to cope with new challenges for the sub-national level of their security. The era of globalization has required new approaches to national sovereignty and necessitated a combination of national and multilateral solutions to environmental security problems. At the same time, it should be noted that the CIS debate on environmental security still represents a mixture of traditional (realist) and more advanced (liberal, globalist) approaches. While in Russia and Ukraine the trend is in favour of the second group of theories, in Belarus the realist approach still prevails.

Although major environmental problems are still pertinent, some progress has been achieved in all three countries. Among the positive changes the following trends could be noted:

- A better legal basis for international co-operation (especially with the EU) has been achieved. In addition to specific EU-Russia, EU-Ukraine bilateral agreements, environmental issues have been placed into a better conceptual and legal framework. For example, the Ukraine has become part

of the European Neighbourhood Policy with a concrete Action Plan. Russia develops its co-operation with Brussels under the aegis of the 'EU-Russia Common Spaces' concept. Belarus is involved in the sub-regional environmental co-operation in an indirect manner (via the Neman Euroregion).

- Some institutional framework for ecological co-operation has been established - EU programmes (TACIS, INTERREG), sub-regional organizations (CBSS, BEAC, AC, BSEC, etc.), IFIs (NEFCO, NSA), umbrella-type projects (NEDAP, MNEPR), etc.
- The level of air and water pollution has declined for major pollutants, such as metallurgy, chemical, cellulose/paper-producing and nuclear industries after stricter ecological standards were established and cleaner technologies were introduced.
- A number of joint EU-Russian projects to prevent deforestation of North-western Russia were successfully completed.
- The situation in the areas that were contaminated by the Chernobyl nuclear accident has remained stable and there was even some progress in terms of decreasing the level of radiation.
- Some European-Russian nuclear safety projects (modernization of NPPs, improvement of storage and treatment of nuclear waste, etc.) have been successfully implemented (albeit most of them were of limited or exploratory nature).

To sum up, the constructive dialogue between Europe and the CIS countries on environmental problems (both on the inter-governmental and non-governmental levels) is very important to support the positive changes in the environmental strategies of the CIS countries.

62 Linking Knowledge Systems for Socio-ecological Security

P.S. Ramakrishnan

62.1 Introduction

With increasing awareness about the state of our environment, concerns about over-exploitation of resources and issues, not only just biophysical but also socio-economic and cultural dimensions relevant to rehabilitation of degraded ecosystems are now gaining importance.¹ These concerns for a socio-ecological systems approach for dealing with rehabilitation of degraded systems are largely arising from policy formulations and a whole range of market pressures on natural resources to fuel rapid industrialization of the developing and the developed world (key drivers), which gets exacerbated by pressures exerted locally by communities (proximal drivers) leading to changing or degrading landscapes.²

Recently recognized human-induced ecological drift collectively termed 'global change' (inclusive of climate change, land use dynamics, land degradation and desertification, biological invasion by exotics and the linked biodiversity depletion), and the market driven 'globalization' of economies have added another set of dimensions to biodiversity conservation and management.³ The results emerging from these

global analyses that the adverse impacts are likely to be more in the developing than in the developed world, and even in the developing world, the vast majority of the marginalized rural poor are likely to be impacted much more than others are confirmed through a few location-specific studies (Ramakrishnan 1992, 2001).

In particular, are a large section of 'traditional societies' (those living close to nature and natural resources around, in biodiversity rich areas), depending upon them for a whole range of non-timber forest products (Patnaik 2002), and also managing a whole range of biodiversity-dependant traditional agroecosystems (Swift/Ingram 1996; Swift/Vandermeer/Ramakrishnan/Anderson/Ong/Hawkins 1994).

With depleting natural resources leading to breakdown of traditional agroecosystems, we are also losing much of the relevant traditional knowledge available with local communities, particularly those determining ecological processes linked to social processes, traditional ecological knowledge (TEK) determining ecosystem or landscape level functions (water, soil fertility and nutrient cycling), on which these traditional societies depend for their survival (Ramakrishnan/Das/Saxena 1996). With a great economic divide arising from all this between the developing and developed world, and that between the rich and the poorer sections within the developing itself, global human security is under threat (Dragun/Tisdell 1999; Steffen/Jaeger/Carson/Bradshaw 2001). Viewed in the context of emerging concerns, it is appropriate that Brauch (2003b) suggests a new phase of research on *human and environmental security and peace* (HESP) that should combine ecological concerns (climate change, water, soil) and human dimensions (population growth, urbanization, pollution, agriculture and food) based on the expertise from both the natural and social sciences.

In a developing country context, as in India for example, about 25 per cent of the over a billion people are traditional societies living in biodiversity rich re-

1 See: Ramakrishnan (1992); Ramakrishnan/Campbell/Demieire/Gyi/Malhotra/Mehndiratta/Rai/Sashidharan (1994).

gions being dependant upon biodiversity linked TEK for meeting with their livelihood needs (Ramakrishnan 2001). These traditional societies remain highly marginalized for reasons that we have not been able to provide a developmental pathway based upon their own value systems based on the TEK that they possess. Further, arising from our studies on socio-ecological systems of north-eastern hill regions of India (Ramakrishnan 1992), we realized that TEK forms an important basis for linking biophysical ecological systems with equally complex social systems, a linkage which Brauch (2003b) sees as critical to understand outcomes and conflict constellations. It is in this context, an understanding of 'knowledge systems' - 'traditional' available with traditional societies and the formal that is text-book based, and the connectivity that could be established between the two, for an integrated view of socio-ecological systems assume significance (Ramakrishnan/Boojh/Saxena/Chandrashekara/Depommier/Patnaik/Toky/Gangawar/Gangwar 2005). Indeed, there is now this increasing concern amongst all to get close to nature, based on the concept of a 'cultural landscape' that they are already on the verge of losing (Ramakrishnan/Boojh/Saxena/Chandrashekara/Depommier/Patnaik/Toky/Gangawar/Gangwar 2005), or that they have already lost and wish to rediscover to the extent possible, based on the available knowledge base in the given natural situation (Maurer/Holl 2003) or even construct urban cultural landscapes (Shutkin 2000; Burel/Baudry 2003), with emphasis upon democratic renewal through a process of community participatory regional planning and environmental justice. This is the context in which the following discussion on the role of knowledge systems for environmental and linked human security has to be seen.

Starting with a discussion on our present state of understanding of 'knowledge systems', with emphasis on TEK, two case studies are used as illustrative examples of the role of knowledge systems for linking ecological conservation with sustainable livelihood/development of traditional mountain societies - one from the north-eastern hill region of India which happens to be an extension of the Himalayan mountain ranges on that end, and another from the Garhwal and Kumaon region of the Central Himalayan mountain region. This review concludes with a brief discussion on such an approach to empower these marginalized sections of mountain societies by providing them with a better quality of life, as part of a short-term developmental strategy. This approach is critical for 'environmental security' linked with 'human security'.

62.2 Knowledge Systems?

The knowledge systems that we are concerned with here are: (i) the text-book based 'formal knowledge' that are based on biophysical principles divorced from the human dimensions of the knowledge system; and (ii) the empirical knowledge, being derived through an experiential process has a strong human dimension linked to it, the communities who still have this in the tropical world tend to see both intangible (with social, cultural and spiritual values) and tangible (in the area of biodiversity conservation and economic benefits) accruing to the society. Extending into ecological, social, economic, cultural and institutional dimensions, a mix of these two knowledge systems can be seen to be of value to society, depending upon socio-ecological levels in which a given society operates. In this scale, industrialized societies who are largely divorced from nature can be seen to be on one extreme, being largely dependant upon 'formal knowledge' based technologies, whilst traditional societies living in biodiversity-rich areas can be seen to be on the other extreme, still being largely concerned with traditional knowledge that they have been able to conserve to a larger or lesser degree until the present. Both these knowledge systems, therefore, are trans-disciplinary in that they touch upon the more tangible biophysical, and socio-economic, and the linked institutional dimensions, and the intangible cultural and spiritual dimensions too. Therefore, knowledge systems, with appropriate linkages between the two, is being seen here as a powerful tool to related to a value system that a given society understands and appreciate, and therefore being able to contribute to a participatory developmental process with concerns for ecological conservation, particularly in the context of the developing tropics.

62.2.1 Formal Knowledge

'Formal' knowledge derived through an 'hypothetical-deductive' process arising from a biophysical understanding of ecosystem landscape processes has been well studied and elaborated over a century ago, and refined over a period of time (Odum 1971). This knowledge base that deals with biophysical attributes of ecosystems has been used to extensively address a whole range of ecosystem management, and often has worked well in the context of the industrialized world. Applying biophysical dimensions of ecology has caused problems in effective management of ecosystems. To this context this chapter will contribute.

62.2.2 Traditional Knowledge

There is now an increasing realization that the formal knowledge base alone is not adequate to address community participatory natural resource management issues, rather this knowledge should be linked with traditional knowledge and societal perceptions (Ramakrishnan 1984; Berkes/Colding/Folke 2003), which must also be related to the formal knowledge base of the given system (Ramakrishnan 1992). Ecosystem management issues are impinging on socio-economic and cultural dimensions of many traditional societies deriving not only tangible but also intangible benefits from natural resources around them (Ramakrishnan 1996; Ramakrishnan/Saxena/Chandrasekhara 1998). This traditional wisdom is based on the intrinsic realization that man and nature form part of an indivisible whole and therefore should live in partnership with each other. This ecocentric view of traditional societies is widely reflected in their attitudes towards plants, animals, rivers, and the earth (Ramakrishnan 2003a; Ramakrishnan/Saxena/Chandrasekhara 1998). *Traditional ecological knowledge* (TEK) based on an experiential 'trial and error' process must be analysed and integrated with the 'formal' knowledge to arrive at community participatory solutions to ecosystem management with sustainable livelihood and developmental concerns integrated into it.

Pre-Columbian societies in the Americas held the widespread view that the Earth and all her creatures are sacred, and therefore permission had to be sought before the resources could be used, or else the spirits guarding them would seek revenge (Hughes 1996; Ramakrishnan/Saxena/Chandrasekhara 1998). For these subsistence societies, which met a variety of their needs through the use of local resources, impermanence, transience and renewal formed central themes of life itself, for symbolic, spiritual and even functional reasons (Hay-Edie/Hadley 1998). For the enlightened sages of the eastern tradition, the forest is a world of wisdom, peace and spirituality (Saraswati 1998); being so, a strong feeling of human participation in the universal order pervades the 'Vedas', the ancient scriptures of the Hindu religion, suggested to be at least 5000 years old. This implies that humans are inseparable from their environment; sacredness begins with the five elements of existence - the earth, water, air, fire and 'Akasa' (void or non-existence, the opposite of matter), being worthy of worship (Vanucci 1993). The concept of the 'Cosmic Tree' ('Tree of Life') represents the centre of the Universe, in the

eastern culture and is part of the traditional belief system.

Even today, the highest and most rugged features of the mountain landscape, relatively inaccessible and rich in nature's endowments, evoke a sense of overwhelming sanctity amongst many societies around the world (Berbaum 1997), being seen as the abode of the Gods. Certain mountains are singled out as sacred, Himalayas in the Indian subcontinent, Mount Everest and Mount Kailas in the Himalayas for the Hindus and Buddhists, Mount Fuji and Koyasan in Japan, and Xishuangbanna in Yunnan province of China, for the Buddhists; the people in Bali, in Indonesia seeing the mountain, Gunung Agung representing the axis around which the Universe is organized. All these traditional beliefs and identities of the people can be seen in the light of shared territory, common rights and similar lifestyles (Kaushal 2001).

Indeed, regions of ecological prudence exhibit a symbiotic relationship between biophysical ecosystems and social systems, with strong cultural interconnections between the two. Thus, culture and environment are complementary, even in various stages of evolution, being a product of animistic religious belief system, fine-tuned subsequently (Ramakrishnan 1996, 2003a). Such belief systems are a fundamental aspect of a people's culture and strongly conditions their use of natural resources.

The benefits accruing from this TEK-based belief system are of three kinds: (i) *economic* - traditional crop varieties and lesser known plants and animals of food value, medicinal plants, etc. harvested from the wild; (ii) *ecological/social* - manipulation of biodiversity, at varied scalar dimensions; ecologically at the species and sub-specific levels, going up to ecosystem and landscape levels; socially touching upon individual decision-making going through the family, village and ethnic group levels for coping with uncertainties in the environment and global change for controlling; (iii) *ethical* - cultural, spiritual and religious belief systems centred around the concept of the sacred species, sacred groves and sacred landscapes (Ramakrishnan 1996, 2001).

The whole body of knowledge centred on direct economic benefits derived from plant and animal species is part of ethno biology, and has potential value for the society at large. Whilst knowledge centred around traditional uses of species for food, medicine, etc. are well documented (National Academy of Sciences 1975, 1979; Hladik/Hladik/Linares/Pagezy/Semple/Hadley 1993; Parrotta 2001), their sustainable extraction from the wild is still an issue, and the re-

sults on this front are only patchy, an area that needs to be further explored (Peters 1994).

TEK dealing with ecological functions at varied scalar dimensions, species, ecosystems and landscapes is an emerging area that connects ecological with social processes, with tangible benefits such as manipulating soil-water regimes and hydrology, soil fertility and nutrient cycling through appropriate organic residue, etc., with implications for natural management, an area of research initiated by this author way back in the early 1970's, and now widely recognized as relevant to natural and human-managed ecosystem rehabilitation and management (Ramakrishnan 1992). At another level looking into the intangible values attached to species, ecosystems and landscapes, the focus has moved to ethical dimensions (Ramakrishnan 1996; Ramakrishnan/Saxena/Chandrasekhara 1998) by looking into socio-culturally valued species, ecosystems (sacred groves) and landscapes (sacred/cultural landscapes), which are dealt with below.

62.2.2.1 Sacred Groves

The concept of 'sacred grove', a small patch of the natural ecosystem, devoid of human habitation and protected by human societies is a good example of the impulse to protect nature in a relatively undisturbed state, and is seen as an area for religious rituals to propitiate their Nature-linked deities, Wind, water, fire, sun, etc., as well as a site for the worship of their ancestral spirits an expression of the spirituality associated with nature (Ramakrishnan/Saxena/Chandrasekhara 1998), and could be viewed as symbolic of 'nature-human' interconnections; being the earliest expression of this cultural linkage, this could be seen as the earliest appearance of the 'sacred' in the evolutionary scale of socio-ecological systems.

Widely distributed in Africa, Asia, the Austro-Pacific region and the Americas, many of these groves still exist, though modern civilization has taken its toll. Europe had sacred groves in ancient times, but now most of them have disappeared; the ones like that at Kozmin Copse in the Kanin Tundra, with sacred birch and fir trees, is a notable exception, where offerings in cash and kind are still made (Hughes/Chandran 1998). Widely distributed in India, but rapidly dwindling, this traditional method of social fencing of ecosystem types as conservation patches is now being rediscovered, as repositories of germ plasma in an otherwise a highly degraded landscape (Ramakrishnan 2001). Indeed, sacred groves have now been identified as an important pathway for biodiversity conservation (Ramakrishnan/Boojh/

Saxena/Chandrashekara/Depommier/Patnaik/Toky/Gangawar/Gangwar 2005).

One such striking example is the Mawsmi sacred grove located in an otherwise highly degraded landscape, being maintained and protected by the Khasi tribe for animistic religious and cultural reasons, in the Cherrapunji region in the State of Meghalaya in the north-eastern hill region of India, bordering Bangladesh (Khiewtam/Ramakrishnan 1993). The ecological situation here is particularly dramatic in that this area is geographically significant, being one of the areas of highest rainfall in the world. This grove itself is a relict rain forest ecosystem, containing climax vegetation which was once widespread in the area. With a high annual rainfall of 12 m. on the average, which may go up to 24 m. in an exceptional year, as in 1974, such a high rainfall combined with human disturbance of the ecosystem, act as a major stress on the fragile rain forest system in the region; once cut down by the humans, the forest has not come back in most of the region, except for this protected forest.

This fragility is exacerbated by highly acidic and leached soils developed over limestone formations that have extensive underground tunnels with many stalactites and stalagmites (karst topography). Therefore, the soils themselves have few nutrients to support the large biomass of the sacred grove. However, a thick, fine root mat, developed on the surface layers of the soil, ensures tight cycling of nutrients released from litter decomposition, before it is lost from the system. The soil itself has little physiological role, except that of providing anchorage, and storing water in the interstices and some mineralization. We have shown that the forest, which is developed over hundreds of years, once destroyed often does not regenerate; and the fragile and tight nutrient cycling gets disrupted (Khiewtan/Ramakrishnan 1993). The nutrients that are released through deforestation get washed away by the intense rainfall. It is not surprising then that the landscape of Cherrapunji, except for the relict sacred grove, has been largely eroded. The Cherrapunji ecosystem that now stands deserted due to deforestation inflicted sometime in the past is now unable to recover to its original state as represented by the relic sacred grove. The community itself has banned the still prevalent major land use practice of the region, namely shifting agriculture (Ramakrishnan 1992), in and around the Cherrapunji area through their own traditional tribal institutions. However, it is too late to set in motion the natural recovery process of the forest ecosystem.

Linked with the drastic loss in biodiversity is the human suffering which now is immense. Water is a scarce commodity during the dry months in this high rainfall spot of the world, a contender for being the wettest spot on earth. The water flows away to the plains of Bangladesh down below, as in Cherrapunji, there is no vegetation to hold the water and the soil, and there is no soil to enable forest recovery. It is a vicious circle! For fuel wood, the tribal villager has to trek long distances. The ruins of villages all around remind one of the past and its out-migrations. The tribesman who is traditionally bound to the land and forests has been forced to seek other avenues for survival. No wonder the British, who tried to govern the north-east from Cherrapunji, because it reminded them of the Scottish highlands of the British Isles, had to abandon it because of too much rain. It is too late to rehabilitate what is already lost, because of the high cost of recovering this extremely fragile ecosystem. The surface mining of coal, which is the only option left for the local people, has created its own environmental problems, such as deeply scarred landscapes, polluted drinking water, etc. adversely impacting the quality of life itself.

Though Cherrapunji represents an extreme case, hundreds of sacred groves spread all over the Indian sub-continent virtually form islands of biodiversity in a highly degraded landscape, many of them are being lost rapidly to modernization (Ramakrishnan 1992). Not so long ago, the Khasi tribe, of Meghalaya in north-east India, who inhabits the Cherrapunji area, also had one sacred grove for each village. With the advent of Christianity in the region, the motivation for conservation has gradually been lost (Khiewtam/Ramakrishnan 1989). It is in such a context that an understanding of the sacred grove ecosystem functioning becomes even more significant as a source for biodiversity and as an ecosystem model on the basis of which a site-specific rehabilitation strategy of the degraded landscape could be designed, with peoples' participation.

62.2.2.2 Sacred and Cultural Landscapes

The concept of 'sacred landscape' (often referred to as cultural landscape) *represents* an elaboration of the sacred grove concept. Here again, the concept of a '*spatially diffused sacred landscape*' represents an earlier stage in social evolution, as seen by us on the basis of extensive analysis done in this area (Ramakrishnan 1996; Ramakrishnan/Saxena/Chandrasekhara 1998) where a given landscape (a set of interconnected ecosystems) often occupy a large area, are linked to a be-

lief system, but have no specified institutional arrangements to control resource use. The later stage in this socio-ecological evolutionary sequence would lead to '*spatially specified sacred landscape*', which often is a watershed unit, with more precise restrictions imposed on natural resource use. The guiding principles that regulate the use of natural resources are embedded in the codified and often non-codified institutions that have evolved. The social institutions linked to biological resource management are often linked also to religious or spiritual myths and socio-cultural belief systems. These sacred institutions were originally intended to boost social solidarity rather than promoting environmental consciousness *per se*. While religious norms explicitly foster social solidarity, the conservation values, *ipso-facto*, also get fulfilled.

Sacred landscapes (diffused and spatially specified landscapes) have traditional societies living within, as a part of the landscape unit. Here, therefore, traditional societies have co-evolved with their environment, modifying nature but actively maintaining it in a diverse and productive state, based upon TEK, socio-cultural practices and/or religious beliefs. From a socio-ecological viewpoint, these interconnections are significant for ensuring a sustainable livelihood for traditional societies, e.g., the shifting agricultural societies in India and elsewhere in the tropics (Ramakrishnan, 1992, 2001; Ramakrishnan/Saxena/Chandrasekhara 1998).

Spatially diffused landscape. One of the striking examples of a spatially diffused sacred landscape, with few codified norms and practices but covering a large zone of human influence, is the notional sacred landscape traced by the Ganga river system (Ramakrishnan 2003a). Starting from the higher reaches of the origin of this river in the north, at Gaumukh in the central Himalayan region, passing through the alpine, temperate and sub-tropical mountain ranges (with many small tributaries joining in the Garwahl in the Uttaranchal State of the Central Himalayan mountain region), and tracing its way through the large geographical region of the Indo-Gangetic alluvial plains, the river system eventually ends up in the Bay of Bengal, in the east. Human-managed ecosystems range from the terraced agroforestry systems of the mountain slopes, valley land agriculture between the hills, and expansive and agricultural lands of the Indo-Gangetic plains. All are nurtured by the sacred river system in a variety of ways through flooding and silt deposition. This biodiversity-rich natural landscape has many religious institutions dotted along the course of the river - Gangotri, Jannotri, Badrinath, Kedarnath,

Figure 62.1: Demojong, the land of hidden treasures: Pictorial depiction of holy sites in West Sikkim, Eastern Himalayas.
Source: Ramakrishnan (1996).

Rishikesh and Haridwar, all in the mountains; *Sanggam*, the sacred confluence of Ganga, Yamuna and the mythological Saraswati rivers at Allahabad, and *Varanasi* further down, and many smaller temples all

along, in the Indo-Gangetic plains before the Ganga river meets the Bay of Bengal.

In the east Asian Japanese Kii mountain region of *Koyasan*, *Kumano Sanzan*, *Yoshino* and *Omine* is

another 'spatially diffused' sacred landscape, rich in biologically diverse temperate forests, Buddhist temples and monasteries (UNESCO World Heritage Centre 2001) Being a hub for cultural and religious interactions since ancient times, the region represents a blend of the indigenous Shinto religion, based on nature worship, and Buddhism that came in subsequently. *Koyasan*, which is the location for the Kongobu-ji temple of the Shingon sect of Buddhism brought from China, is a major sacred landmark for the Japanese, and is part of the great pilgrimage route running through the Kii mountain range. At the root of this belief system is the religious belief that mountains, forests, lakes, ponds and other elements of nature are sacred places where deities live, that mountains are the home of the Gods of wealth and prosperity, and that a dead person climbs a mountain on his/her way to heaven; and that rivers and sea are holy entry points to paradise. Here in this landscape, the natural merges with the cultural heritage, to form a complex but integrated whole.

Spatially defined landscape. An example of a spatially defined landscape is the 'Demajong', a cultural landscape, extending from Khangchendzonga to sub-tropical rain forests down below (figure 62.1) in west Sikkim in the eastern Himalayas. The sacred nature of the landscapes is defined by Tibetan Buddhist philosophy; the landscape with well defined sacred boundaries is conserved through institutional norms and well specified institutional arrangements that are often codified to delimit human usage. The air, soil, water and biota are all sacred. Any alteration of the landscape is restricted and circumscribed by cultural norms. The guiding principles for natural resource use are strictly enforced through social institutions designed to allow small alterations, whilst larger alterations to ecosystems that destabilize them are prohibited, because the sacred treasures ('ter') hidden by the incarnate of Buddha, to be discovered slowly by enlightened Lamas at appropriate times will get destroyed, with adverse impacts on human welfare. With a variety of rituals linked to the diverse communities living within the landscape boundary, who have their own pre-determined rights for natural resource use, larger community participation is ensured. Though, these and many other spatially defined sacred landscapes have usage restrictions, traditional societies live as an integral part of it, being involved in a variety of agriculture and animal husbandry practices, and extraction of *non-timber forest products* (NTFPs). It is in this context that there was a strong social reaction when the governmental agencies attempted to have a

hydro-electric project initiated within the 'Demajong' landscape region, which was finally abandoned under pressure.

The concept of a sacred landscape as a whole could be viewed as a dynamic and evolving one (Ramakrishnan/Saxena/Chandrasekhara 1998; Ramakrishnan/Boojh/Saxena/Chandrashekhara/Depommier/Patnaik/Toky/Gangawar/Gangwar 2005). For example, a sect called 'Bishnois' founded about 500 years ago in the north-western Rajasthan desert region in India, practiced the absolute protection of all life, with the landscape itself being viewed as sacred. Founded by a spiritual leader saint Jambeshwarji, among many other well laid out rules that they have to adhere to, non-violence is an important one. The sacred groves with the dominant tree 'Khejri' (*Prosopis cineraria*) which is a sacred species too, within a cluster of Bishnoi villages form an integrated natural-cultural landscape. The sacred groves of the Bishnois called 'Orans', are widely known in the Indian region for their conservation ethos of protecting the tree - 'Khejri', and the associated wildlife - Blackbuck (*Antelope cervicapra*); in this process all the associated biodiversity also is protected. This tradition of protecting nature arose in the year 1730, when 363 Bishnoi men, women and children of the village Peepsar laid down their lives to protect the Khejri trees, when the then Prince of Jodhpur tried to fell the trees for firing his lime kilns; this was the beginning of this new sect under their spiritual leader.

The Khejri tree itself is not only an economically important species, specially revered and valued for its pods as food, leaves as fodder and manure, and branches as fuel wood and construction materials, by the local people; it is also an ecologically significant keystone species, supporting rich associated biodiversity - an example of the intangible with tangible benefits (sacred species discussed below). This value system of the 'Bishnois' resulted in islands of biodiversity being established wherever the Bishnoi village/village clusters were located. Thus in this case, a village cluster of the Bishnois with the protected sacred groves and the wildlife associated with it could be viewed as a sacred landscape unit rich in biodiversity, with institutions that determine resource use, based on their belief system. Indeed, these islands of biodiversity exist in an otherwise largely desert landscape where non-Bishnois live.

62.2.2.3 Sacred Species

At the lowest level in the hierarchical organization of the concept of sacred in many parts of the developing

tropics, but at a higher level in social evolution, is the concept of 'sacred species'. These socially selected species are valued for cultural/spiritual reasons (Ramakrishnan/Saxena/ Chandrasekhara 1998). For example, the sacred Basil (*Ocimum sanctum*), Neem (*Azadirachta indica*) became sacred as part of a conscious decision by the Hindu society that linked the intangible to the tangible value for its multipurpose use and medicinal properties. A whole range of spiritual taboos are too attached to the extraction of NTFPs from the wild, with possible implications for sustainable extraction from the wild, an area which awaits analysis.

A variety of socially valued species that are also ecologically important keystone species often determine ecosystem level processes – soil moisture regimes, soil fertility and nutrient cycling – thus contributing to the build-up of associated biodiversity.⁴ We have shown this as a generality through our research results from the Asian, African tropics, and remnants of this knowledge still existing in the Mediterranean Europe where sacred species are now largely confined to Christian monasteries (Ramakrishnan/Saxena/Chandrasekhara 1998) Indeed, many species/set of species may be common to different regions of the world - *Ficus* spp. for the Asian and African region; *Quercus* spp. mountain regions of the Asian and African tropics. Others may be location specific – e.g. *Alnus nepalensis* in north-eastern hill regions and *Prosopis cineraria* in the Rajasthan desert in India; *P. africana* in Cameroon, etc.

62.3 Linking Conservation with Participatory Sustainable Development

In an extensive review we have looked at the big divide that exists between the way biosphere reserves are currently managed by the reserve managers in the south and central Asian context who tend to offer rather simplistic solutions to complex socio-ecological problems on the one hand, and on the other hand the 'ideal' with a key role for TEK, as perceived by a section of the scientific community, so that community participation could be ensured (Ramakrishnan/Rai/Katwal/Mehndiratta 2002). Indeed, these are the

kind of dilemmas that marginalized traditional societies, being totally dependent upon nature and natural resources for meeting with their livelihood needs, face elsewhere too, whilst reconciling ecological conservation with sustainable livelihood/development concerns that they face (Ramakrishnan 1992; Hanna/Folke/Maler 1996; Gyasi/Kranjac-Berisavljevic/Blay/Oduro 2004; UNDP 2004a). The following two case studies are illustrative of the kind of problems in dealing with conservation linked to sustainable development.

62.3.1 The Shifting Agricultural Landscape in North-east India

Traditional societies in north-east India, comprising of the seven States of Arunachal Pradesh, Assam, Manipur, Meghalaya, Nagaland, Mizoram and Tripura (figure 62.2), with subsistence farming, operate a whole range of customary multi-species complex ecosystems, ranging low-intensity management-based shifting agriculture on one extreme, through middle-intensity management oriented agro-forestry systems, in which crop and associated biodiversity play a key role in determining the ability of the multi-species agro-ecosystems to cope up with environmental uncertainties (figure 62.3). In managing these agro-ecosystems, resource cycling occurs between them and the linked natural ecosystems (forests, grasslands, wetlands, etc.), forming part of a unique culture-specific landscape. Being linked to the biodiversity around them, it is not difficult to see that biodiversity in all its scalar dimensions forming the fundamental building blocks for sustainability of these agroecosystems, the associated TEK playing a key role in their agro-forestry system based redevelopment models; the objective is towards combining productivity with system resilience (Ramakrishnan 1992, 2001; Swift/Ingram 1996).

With TEK playing a key role, is an important basis for designing a variety of agro-forestry system models that combine productivity with resilience; the pathways could vary depending upon the socio-ecological status of the communities' concerned (Swift/Vandermeyer/Ramakrishnan/Anderson/Ong/Hawkins 1994; Ramakrishnan 2001). In the early successional forest fallow forests arising from shifting agriculture (locally called jhum) of north-eastern hills of India, a socially valued species like Nepalese alder (*Alnus nepalensis*) is a significant keystone species, fixing up to 125 kg ha⁻¹ yr⁻¹ N, and therefore could improve crop yield substantially, under shorter shifting agricultural cycles,

Figure 62.2: Two case study sites in India: shifting agricultural landscape, north-eastern hill region of India (dot and arrow on the right top); the central Himalayan Garhwal region (dot and arrow on top left); and the Demajong sacred landscape in Sikkim Himalayas (dot and arrow in the middle) of the Himalayan range of mountains in India. **Source:** University of Texas at Austin, Perry-Castañeda Library Map Collection; at: <http://www.lib.utexas.edu/maps/middle_east_and_asia/india_pol01.jpg>. This map is in the public domain.

and thus contributing to system sustainability. Many bamboo species like *Dendrocalamus hamiltoni*, *Neohozua dulloa*, *Bambusa tulda*, and *B. khasiana* also fall in this category due to their ability to conserve ni-

trogen, phosphorus and potassium in the early successional fallows, as these species are abundant in early successional jhum fallows (Rao/Ramkrishnan 1987, 1989).

and human-managed biodiversity; (iii) carbon sequestration to mitigate 'global change'; (iii) redevelop a 'cultural landscape' based on their own value systems.

Figure 62.4: Interdisciplinary interactions called for in tropical forest management and conservation.
Source: Ramakrishnan (2001).

62.3.2 Redeveloping the Central Himalayan Landscape

To take another example from a mountain region with settled agriculture, oaks (*Quercus* spp.) in the central Indian Himalayan region of Garhwal (lat. 29°26'N - long. and 31° 28' N; 77°49'E - 80°6'E) are socially valued with a lot of music, dance forms, poetry and folk-tales linked with them (Ramakrishnan/Saxena/Chandrasekhara 1998; Ramakrishnan/Chandrashekhara/Elouard/Guilmoto/Maikhuri/Rao/Sankar/Saxena 2000). They are also important fodder and fuel wood species, apart from performing not so obvious functions such as maintenance of soil fertility through efficient nutrient cycling, soil moisture conservation through extensive root system, both within the natural and human-managed agro-ecosystems, thereby supporting associated biodiversity too. In fact these oak species have been consistently removed by the timber extractors over the last more than 100 years, and the foresters have replaced them with fast growing Pines (*Pinus roxburghii*), which are of no socio-ecological value to the locals and therefore resented by them. During the 1970's when the women in the region went and hugged trees when the timber extractors went to fell trees in these mountains, the causative factor was attributed to mere sharing of benefit by the locals from timber extracted; indeed, the

real reason being large-scale forest conversions adversely impacting upon depleted water resources, declining soil fertility and breakdown of both agriculture and forest based rural economy. Indeed, oak in the Central Himalayan region could be seen as a powerful tool to trigger community participation, because of the cascading impacts it has on ecosystem/landscape level processes, which in turn have implications for sustainable livelihood/development concerns of mountain societies in the Central Himalayan region of India (figure 62.5).

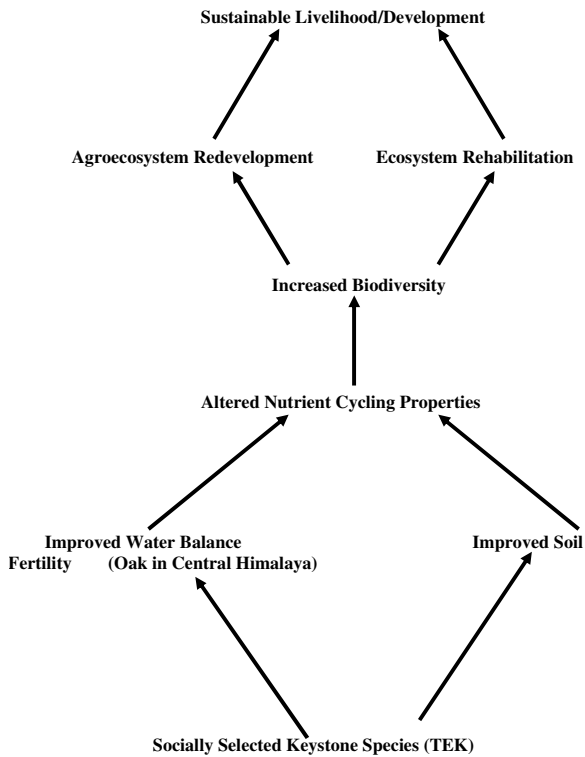

In short, this set of species could be seen as modulating landscape functions at mid-elevations of the Central Himalayas, impacting upon both the tangible and intangible benefits that communities seek from the biodiversity around (Ramakrishnan/Boojh/Saxena/Chandrashekhara/Depommier/Patnaik/Toky/Gangwar/Gangwar 2005).

62.4 Conclusions

If one looks at the ecological history of a country like India, right from the colonial period until recent times, the natural resources in the resource-rich mountain regions of the country where traditional societies live, have always been exploited by outsiders, with little benefits accruing to the local communities. Having degraded the landscape and thus adversely impacting upon their land use based livelihood activities, the suggested developmental pathways for these societies have always been alien to traditional value systems of these people, and have always relied on text-book based technologies, which time and again have been rejected by these societies. This alienation of traditional societies has posed serious human security issues arising from continued marginalization of these people.

Sabur (2003, also chapter in this volume) saw, a major rethinking of human security in the south Asian region since 1990, where it is now being seen more and more centred around, human dignity and human development and humane governance. Chari and Gupta (2003) go a step further and view that human security is under greater threat in the south Asian region, in the context of globalization of economies and global change, contributing to accelerated degradation of water, forests, farmlands, and fisheries. To sum up, Brauch (2005) sees the need to study and document, economic and social vulnerabilities with implications for environmental human security, and this he suggests can be achieved only through a dy-

Figure 62.5: TEK centred on the socially selected keystone species, *Quercus* spp., acting as a trigger for rehabilitation of the mountain landscape in the Central Himalaya. **Source:** Ramakrishnan (2001).

dynamic equilibrium between humankind and its surroundings. We have tried here to take this a step forward, with implications for traditional societies of the Asian region, by taking an approach towards the integrity of socio-ecological systems that these communities value, using knowledge systems as a powerful tool.

What emerges from the above discussions is that there is an urgent need to integrate 'traditional' knowledge available with them with the formal knowledge, and evolve 'hybrid' technologies based on a value system that they understand and appreciate and therefore participate in the process of conservation linked sustainable development; this assumes greater significance in the context of uncertainties arising from ecological 'global change' and economic 'globalization'. Linking cultural diversity with biological diversity (Ramakrishnan 2003b, 2003c) as the basis for sustainable management of natural resources, leading towards a sustainable livelihood is seen as the way out to ensure human security for these marginalized and neglected societies, including those who often are referred to as 'indigenous' or 'tribal' socie-

ties. Sustainability means different things to different people; what we should be aiming for as far as traditional societies are concerned to take care of the immediate short-term developmental needs (Ramakrishnan 1993, 1995), allowing such empowered communities to determine for themselves the direction/s that they wish to take for a long-term sustainable developmental plan.

In short, in many developing countries of the tropics, problems of rebellion and insurgency by marginalized sections of the minority traditional societies often arise from the lack of understanding of their value system linked with traditional knowledge; this has often lead to unsuccessful attempts towards a developmental pathway, de-linked from the human dimensions. This in a larger context acts as a trigger against global human security. The ultimate objective is to ensure global human security, by enabling different sections of society to have 'cultural landscapes' that are dynamic, based on a value system that they can relate with, both in space and time (Ramakrishnan/Boojh/Saxena/Chandrashekar/Depommier 2005a).

The two case studies discussed here indicate that a community participatory land use developmental initiatives have been shown to happen through small-scale model initiatives as in the Central Himalayan region, and through a larger regional initiative in the State of Nagaland in north-eastern hill regions of India. This is something which has not happened over the last more than 100 years in spite of governmental efforts. This linkage of ecological conservation linked with sustainable development, I believe, in the ultimate analysis is a step towards global human security.

63 Environmental Security in Northeast Asia

Miranda A. Schreurs

63.1 Introduction

This chapter addresses environmental security in Northeast Asia, focusing primary attention on China, Japan, the Korean Peninsula, Mongolia, and the Russian Far East. Reflecting the low status accorded to environmental protection in much of Northeast Asia prior to the 1990's, 'environmental security' as a concept is relatively new to both the scholarly and political debate in the region. Rapid industrialization, however, has resulted in such serious pollution and natural resource degradation that governments are being forced to pay more attention. This has especially been the case since the 1992 *United Nations Conference on Environment and Development* (UNCED). Increasingly, linkages are being made by scholars and practitioners between environmental protection and the concepts of 'human security', 'ecological security', and 'environmental security'.

This chapter suggests that while not often couched explicitly in the language of 'environmental security', there is growing awareness among policy makers that the region's environmental degradation is causing human health problems, worsening the quality of life, threatening long-term economic growth potential, contributing to political instability, and in some cases contributing to regional frictions and even deadly conflict. This is leading to changes in environmental laws and programmes throughout the region and greater discussion of environmental degradation as a threat to national well-being.

The chapter considers the nature of the environmental challenges confronting Northeast Asia and the ways these have been linked to environmental security debates. The prospects for greater domestic political attention to environmental conservation and the formation of regional cooperative mechanisms for addressing environmental security challenges are also considered.

After a brief review of the environmental security debates (63.2), and of the growing environmental

awareness and its implications for the environmental security debates (63.3), the role of NGOs and environmental scientific communities (63.4) and the implications for environmental security debates is considered for this diverse region (63.5) and specified for China (63.6). Furthermore the chapter addresses the international dimensions of Northeast Asia's environmental security problems as well as the regional cooperation for environmental security (63.7), linking environmental and human security concerns to official development assistance (63.8), assessing the regionalization of environmental protection (63.9) and drawing general conclusions (63.10).

63.2 Environmental Security Debates

Traditionally, international relations scholars of East and Northeast Asia (figure 63.1) have treated security as a matter of the protection of national borders from external threats and the state from domestic insurgencies. They have looked at the security alliances, military structures, and threat perceptions of states in the region. In recent years, however, there has been a growing move to treat security in more comprehensive ways. This has resulted in a focus on the implications of 'non-traditional security' threats, including disease, poverty, and pollution, to the economic, social, and environmental stability of individual states and the region more generally (e.g. Radtke/Feddema 2000; Theranian 2000; Thakur/Newman 2004; Igarashi/Sasaki/Takahara 2005).

Slowly, new security paradigms are coming to be accepted in the region. It is becoming increasingly well-understood that in both the short- and the long-term, many of the largest threats to the populations, economies, and governments of the region are not strictly military, but are tied to poverty, disease, migration, pollution, and natural resource degradation.

Within the scholarly community, in the past decade, there has been a push to examine what the growing demand for energy in the region means for re-

Figure 63.1: Map of East Asia (political), 2004. **Source:** University of Texas, Austin, PLC map collection. The map is in the public domain.

gional and economic security (e.g. Calder 1996, 1997; Manning 2000; Stares 2000; Wesley 2006). There has been considerable attention paid to the link between the region's growing energy consumption and its vast array of environmental problems, including air pollution, acid rain, and global climate change that threaten human health and long-term sustainability (e.g. Drifte 2003; OECD 2007a; Hyun/Schreurs 2007; Brettell 2007).

While East Asia has done far better than Africa in reducing poverty, the number of people living in poverty in East Asia is still in the hundreds of millions. This has led scholars to look into the links among poverty, migration, and human security (e.g. Akaha/Vassilieva 2006; Caballero-Anthony/Emmers/Acharya

2006). The international scare caused by SARS and the recurring incidents of Avian flu have opened eyes to the potential for epidemics that could threaten large numbers of people. There is also growing concern that global warming could increase the occurrence of diseases largely considered to be under control in the region, such as malaria (e.g. Schreurs/Pirages 1998; Dupont 1998, 2002; Caballero-Anthony/Emmers/Acharya 2006). With growing awareness of the deteriorating state of the natural environment and the severe pollution problems in many parts of East Asia, scholars, governments, and international organizations have started to explore the implications of pollution, resource depletion and environmental degradation on human health, sustainability, domestic po-

litical stability, and regional relations (e.g. World Bank 2001c; Harris 2005; Worldwatch Institute 2006; Hyun/Schreurs 2007).

In Northeast Asia environmental degradation and competition over scarce resources have the potential to contribute to political instability in a region that still has many remaining territorial disputes and where distrust among neighbours is still an issue. At the same time, the need to address common environmental problems opens the door to greater cooperation among states of the region. Joint environmental projects, cooperative research, and harmonization of standards and processes can serve the dual function of strengthening environmental capacity and improving ties among nations which for historical reasons have little experience with regional cooperation. Ken Conca and Geoffrey Dabelko (2002) have argued that while environmental degradation and pollution can pose real challenges for a state both internally and in its foreign relations, it can also provide a seed for the development of cooperation. Precisely because environment is a matter of 'low politics' this makes it a challenge through which inter-state contact and communication can be built up. Over time the development of networks among individuals, organizations, and states for addressing pollution and resource degradation can help to develop trust and mutual understanding. In the long run, cooperative problem-solving can contribute to an improved security environment. Mark Valentia and James P. Dorian (1998) have similarly argued that the region's energy problems could lead to competition, but also provide the potential for multilateral cooperation. Whether or not this line of reasoning will take hold in Northeast Asia remains to be seen.

Comparatively speaking, the Northeast Asia region suffers from what Gilbert Rozman (2004) has dubbed a case of "stunted regionalism." Still, there are signs that to at least some extent a sense of regionalism may be developing as economic, investment, cultural, and other ties deepen (Pempel 2005). Geun Lee (2007) suggests that in most issue areas, the states of Northeast Asia have yet to develop a shared understanding of common problems or what he calls a "regional inter-subjective community." Instead, he argues, that in most issues areas it is still only expert communities who share a common perception of environmental threats. Still, this kind of common perception among expert communities provides the basis for a deepening of cooperation as more and more actors gain awareness of environmental threats and begin to seek out ways of initiating change. Growing coopera-

tion among the governments of China, Japan, South Korea and the Association of Southeast Asian Nations in addressing economic, natural disaster, and environmental issues could work to strengthen prospects for some form of loose regime building in the future (Tan/Boutin 2001; Curley/Thomas 2006).

63.3 Growing Environmental Awareness: Implications for Environmental Security Debates

It can be argued that environmental security debates, which largely developed in the West, would have had a far more difficult time taking root in East Asia had it not been for the end of the Cold War. The collapse of the Soviet Union and the subsequent political and economic transitions in Russia altered significantly the meaning of the Russian presence in Northeast Asia. No longer was the Soviet Union considered the dominant security threat in the region. Although relations between Japan and Russia remain somewhat strained as a result of the territorial disputes involving the Northern Territories, the importance of engaging Russia in regional dialogue became increasingly accepted. The collapse of the Soviet Union also coincided with important political transformations in the region. Both Taiwan and South Korea transitioned from authoritarianism to democracy beginning in the late 1980's. Moreover, by this time the economic transformations initiated by Deng Xiaoping had led to growth rates in China that were among the highest in the world, and that were making China an integral part of the regional and global economy. Japan, South Korea, and Taiwan are now among the largest investors in China and trade relations among them have made the region highly economically interdependent. Japan also began to seek a new role for itself in the region (Maswood 2000).

While the North Korea situation remains a major security dilemma for the region, the otherwise altered security situation has encouraged the shift in scholarly and political debate to a wider range of issues, including human and environmental security.

63.4 NGOs and Environmental Scientific Communities

Important political and economic transformations in the states of the region have brought new actors into the environmental policy making arena. The end of

the Cold War coincided with the democratization of South Korea and Taiwan. It also eased China's entry into the world economy. A major outcome of the democratization of South Korea and Taiwan and the economic opening and shift toward capitalism in China has been the opening of political space to a larger number of actors. In the environmental realm, this has meant that many new players have been permitted on the scene. They have applied soft (and sometimes hard) pressure on governments to take environmental degradation more seriously.

In South Korea and Taiwan prior to the late 1980's, environmental protest was largely suppressed by authoritarian regimes. With democratization, several powerful environmental networks and groups formed, including *Green Korea*, the *Korean Federation of Environmental Movements*, *Greenpeace Taiwan*, and the *Taiwan Environmental Protection Union*. These groups have pressured the Korean and Taiwanese governments to strengthen environmental laws and have helped to stimulate environmental debate in local and national politics. Several of their leaders have acquired powerful political positions and helped introduce new environmental perspectives into political debates.

In Japan too, there have been important changes to the environmental movement since the beginning of the 1990's. While Japan as the oldest democracy in the region has long had environmental groups and movements, few operated at the national level or were concerned with international or regional environmental issues. This began to change in the 1990's as the Japanese state took on a larger global environmental role. With growing public interest in environmental protection, numerous new environmental groups emerged, including some with an interest in East Asia's pollution problems. Political institutional barriers to the creation and functioning of environmental groups were also addressed, so that it has become easier to form non profit organizations (Hasegawa 2004). Although still weak in the policy making process, these groups now have greater access to policy makers and have used their new positions to push the government to address global warming and nature conservation issues more aggressively.

In China there has been a rise of environmental movements as well. While many of these groups are similar to the kinds of environmental groups that were sanctioned by the former Communist states of Europe – that is, groups that assist the state in establishing an image of the state as a protector of nature or that aid the state in fulfilling its policy goals – there

are also a growing number of instances of environmental activists in China that are challenging environmentally destructive projects (Wu 2003; Yang 2005). Pollution levels are so bad in China that it has become difficult for China's leadership to ignore the health problems the pollution is causing or the impact it is having on China's economy. The leadership is starting to admit that if China is to sustain its economic growth, it will have to confront its very low energy efficiency levels and establish new energy sources without contributing to the already health-threatening pollution levels of many of China's urban regions. It has also started to recognize that it is incapable of implementing the vast array of environmental laws and programmes needed to deal with the country's pollution nightmare without the assistance of the public. Thus, the government has allowed some environmental groups to open their doors.

The first environmental NGO to register in China was the *Academy for Green Culture* (now called *Friends of Nature*) in 1994. *Global Village Beijing* and *Green Home* were then set up in 1996. In 2006, the Chinese State Environmental Protection Administration announced that there were 2,700 registered environmental groups in the country. Through their interaction with the State Environmental Protection Administration, groups such as *Environment Defense* have had some limited success in broadening debate about environmental problems in China. Environmental groups, however, tend to take on the language used to describe environmental problems by the state. This is done in part to show that they are working along side policy makers, and not against them.

Numerous new environmental scientific groups and research and policy think tanks have been set up as well in the various countries of the region. These institutions have been important to the provision of much needed scientific information regarding the extent of environmental problems and the effects of pollution on human health, agriculture, climatic systems, ecological systems, and the like. Prior to the 1980's, Northeast Asia lacked not only a vibrant environmental movement, but also the basic scientific institutions that are needed to adequately understand the causes and consequences of environmental degradation.

While there is no explicit regional institution focused on environmental security in Northeast Asia along the model of the Institute for Environmental Security in Europe, various academics and researchers, such as those at Korea University, the Institute of Defense and Strategic Studies in Singapore, and the *United Nations University* (UNU) have worked to es-

establish networks of researchers working on environmental security issues and to inject environmental security perspectives into policy debates. It should be noted that international foundations, like the Ford Foundation and the *United Nations Environment Programme* (UNEP) have been critical to this process.

63.5 A Diverse Region: Implications for Environmental Security Debates

Northeast Asia is a very diverse region, economically, politically, ethnically, and in terms of population density and natural resource endowments and constraints. This diversity significantly influences environmental security perspectives, the nature of environmental security problems, pollution control capacities, and the potential for cooperative-problem solving in the region. The range of environmental problems afflicting the region is vast, but also differentiated by country and region.

At one extreme is Mongolia, with just 2.79 million people, a population density of only 1.78 persons per square kilometre, and a per capita *gross domestic product* (GDP) measured on a *purchasing power parity* (PPP) basis of just \$ 1900 (CIA 2006). Many parts of Mongolia are still pristine and on the whole, environmental conditions are relatively good. Yet, Mongolia has suffered from sustained droughts and desertification. The Mongolian government has identified land degradation, desertification, deforestation, loss of biodiversity, and urban air pollution as its most serious 'ecological security' concerns. The first four of these are closely inter-related. Land degradation due to both natural and man-made causes, including the rapid development of farm land, overgrazing, mining activities, and settlement near the country's limited water resources, has contributed to the degradation of an estimated 70 per cent of Mongolia's pastureland. Land degradation is exacerbated by desertification, which according to some estimates, threatens as much as 90 per cent of the country. Approximately 40 per cent of Mongolia's territory is already arid or desert, and between the early 1960's and the beginning of the 2000's, the area covered by sand increased by an estimated 8.7 per cent (UNEP 2002b).

Notably, environment and sustainable development were included as one of the eleven priority areas of the Government of Mongolia's Good Governance for Human Security Programme, which was an-

nounced in 2001. There is growing awareness that protection of the fragile Mongolian environment is critical to the future of the country, and especially to the quasi-nomadic life-style of a significant part of the population. Mongolia has taken various steps to strengthen its environmental capacity since the UNCED. The 1992 Constitution guarantees Mongolian citizens the right to a healthy and safe environment and to be protected against pollution and ecological imbalance.

A Ministry of Nature and Environment was established, an extensive array of environmental laws was introduced, and Mongolia joined major international environmental agreements. Yet, the country's environmental problems are growing worse and environmental capacity and coordination remain insufficient to meet the country's needs.

At the other extreme is Japan, with a population of 127.5 million, a population density of 337 persons per square kilometre, and a per capita GDP (PPP basis) of \$ 31,600 (CIA 2006). Japan is one of the most densely populated and highly urbanized countries in the world. It also has among the most developed environmental regulatory systems in the world. At one time considered one of the most polluted countries on the planet, in the late 1960's and early 1970's Japan introduced an extensive and sophisticated pollution control regime (Gresser/Fujikura/Morishima 1981; Broadbent 1998). By the end of the 1970's, Japan had become a global leader in the production of certain types of pollution control technology, energy efficient production systems, and mass transport systems, and had done much to reduce air and water pollution levels (Moore/Miller 1994; Imura/Schreurs 2005). Despite remaining problems, including the loss of natural ecological systems and urban air pollution (including dioxin and nitrogen oxides), in Japan the dominant framing of the region's environmental problems are in relation to the lessons other states can take from the Japanese experience with pollution control. In the 1990's the Japanese government revamped its environmental regulatory regime, strengthening its focus on sustainability. In the 2000's, environmental conservation efforts in Japan began to be linked more explicitly to the concept of 'human security' (see chap. 84 by Shinoda) and the United Nations' *Millennium Development Goals*' (MDG) focus on poverty alleviation.

63.6 The Case of China

China's deteriorating environmental situation has become a matter of grave concern to policy makers domestically and internationally. Although seldom described explicitly in environmental security terms, there are growing references in public speeches to the country's grave pollution problems. The Chinese government announced that in 2005 there were 76 environmental emergencies and 536 people were poisoned by dangerous chemicals.¹

The current population of 1.3 billion will continue to grow reaching and most likely exceeding 1.4 billion around 2020 to 2030 before finally levelling off and then decreasing (assuming no inward migration) (UN, DESA 2006). Although on a per capita basis, Chinese use far fewer natural resources and emit far less pollution than do Japanese, South Koreans, or Americans, the sheer size of the Chinese population means that the society's footprint is very large and getting larger.

China's economy has been growing at astounding speeds since economic reform policies were introduced beginning around 1980. The number of Chinese living in poverty decreased from 250 million in 1978 (an estimated 30 per cent of the rural population) to 42 million in 1998 (4.6 per cent of the rural population) (UNDP 2001). In 2005, the number living in absolute poverty was down to 23.65 million.² In many ways, China has become the new economic miracle of East Asia. China's middle class is now estimated to be around 20 per cent of the population, and could grow to 40 per cent by 2020 if growth rates continue to be strong.³

China's rapid economic growth, however, has placed enormous strains on the environment. According to the *State Environmental Protection Administration* (SEPA 2006), pollution resulted in 511.8 billion yuan (US \$ 64 billion) in losses in 2004. SEPA Minister Zhou Shengxian noted in April 2006 that pollution was contributing to social instability and that there had been 51,000 environment-related disputes the previous year.⁴ Water pollution throughout much of China is severe. Rivers that run through major urban areas of China are of such poor quality that they

are not safe for human consumption (Economy 2004). Marine pollution has become so serious that fishing must be banned several months a year. In 2005, there were 82 red tides, which combined caused direct economic losses of 69 million yuan or US \$ 8.5 million.⁵

China's strong economic growth has been fuelled by coal, which produces sulphur dioxide, a precursor of acid rain, and carbon dioxide, a major greenhouse gas. Sulphur dioxide is believed to contribute to 400,000 premature deaths annually in China.⁶ Prime Minister Wen Jiabao noted that while China has surpassed its economic development targets in the 2000 to 2005 period, it had missed one of its key environmental targets: to cut sulphur dioxide emissions by 10 per cent. Instead, sulphur dioxide emissions rose by 27 per cent.⁷

Development, consumption, population pressures, and industrial pollution are taking their toll on natural resources and ecological systems. China has surpassed Japan as the world's largest catcher and harvester of fish. It is also now the world's second largest importer of forest products after the United States. China is among the countries in Asia with the largest number of plant, mammal, and bird species that are critically endangered, endangered, or vulnerable (UNDP/UNEP/WB/WRI 2005: 204-13; WRI 2006).

The scale of these problems and their substantial economic and health costs has pressured China's leadership to give a higher priority to environmental protection. At the China Council on International Cooperation on Environment and Development's annual meeting in November 2006, SEPA Minister Zhou announced to a group of international environmental experts that China's environmental situation was at a "critical point" and that "in some places, environmen-

tal problems have affected people's health and social stability, and damaged our international image."⁸ In response to the growing environmental crisis, the Chinese government has passed numerous environmental laws and begun a process of reorganizing its environmental administration. There are some signs of success; for instance, there has been improvement in the air quality of some major urban areas (Rock 2002).

Environmental conservation has been incorporated more centrally in the 11th Five-Year Plan (2006–2010). The plan calls for using a “scientific approach to development” and the building of a “harmonious socialist society” that is built on the principles of equity and justice. As described by the government of China, the plan reflects “a keener attention to the issues of humanity, society and the environment, as well as the economy.”⁹ The plan calls for cutting energy consumption per unit of GDP by 20 per cent and total discharge of carbon dioxide by 10 per cent by 2010 relative to the end of the 10th five-year plan (2005), and increasing forest cover from 18.2 per cent to 20 per cent.¹⁰ Both the *Organization for Economic Cooperation and Development*¹¹ and the *China Council for International Cooperation on Environment and Development*¹² independently recommended in November 2006 to the government of China that to deal with China's looming environmental problems, it should consider elevating the status of the State Environmental Protection Administration to that of a ministry, take measures to strengthen environmental capacity and enforcement at the local level, enhance public access to environmental information, and

strengthen international cooperation, among other recommendations.

63.7 The International Dimensions of Northeast Asia's Environmental Security Problems

Many of the environmental problems affecting the countries of Northeast Asia have international security dimensions to them (even though this is seldom how these problems are discussed). Here several illustrative examples are provided: environmental refugees from North Korea; transboundary acid rain and yellow sand; greenhouse gas emissions and global climate change; transboundary river and marine pollution; over fishing and fishing disputes; energy exploration and territorial disputes; and nuclear energy and nuclear waste disposal.

63.7.1 Humanitarian Crisis in North Korea

The Democratic People's Republic of Korea (hereafter, North Korea) is a unique case. According to its first ever State of the Environment Report, deforestation is among the country's most serious environmental problems. Deforestation, brought on in part by the country's severe energy shortage and the resultant demand for firewood, has led to wide-scale erosion, flooding, water degradation, and biodiversity loss (UNEP 2003e). These problems, in turn, have contributed to the malnutrition that affects over one-third of North Korea's population. In fact, nowhere in East Asia is there a humanitarian crisis as serious as that found in North Korea. North Koreans have had to endure a decade of wide-spread hunger, malnutrition, and starvation (Amnesty International 2004).¹³ The *United Nations' World Food Programme* (WFP) estimates that two million people died there during the 1990's from starvation and hunger remains widespread. Provision of humanitarian aid to the North, however, has become entangled in the politics surrounding North Korea's nuclear weapon's programme. The WFP has been hampered in its efforts to provide humanitarian assistance to the country, however, due to the unwillingness of donor states to

provide North Korea with aid after it conducted missile tests in July 2006 and a nuclear test in October. As of 30 November 2006, the *World Food Programme* (WFP) had only been able to obtain 13.2 per cent of the funds it had requested from donor states for recovery assistance for vulnerable groups in North Korea (UNWFP 2006). Hunger and starvation have, moreover, led many North Koreans to attempt to flee their impoverished state even at the risk of torture, imprisonment and possible execution if caught (Lee 2007).

63.7.2 Acid Rain, Yellow Sand, and Greenhouse Gas Emissions

Transboundary air pollution problems are also becoming increasingly serious threats to the region. An estimated one-third of China is affected by acid rain. Researchers at the Chinese Institute of Environmental Science and Qinghua University estimate that acid rain causes China 110 billion yuan (US \$ 13.3 billion) annually.¹⁴ Both Japan and South Korea are concerned that their domestic efforts to address air pollution and the pollutants that contribute to acid rain are being offset by acid deposition that has its origins in China.

The increasingly severe and frequent sand storms originating in the arid regions of China and Mongolia have become increasingly hard to ignore. Approximately 15.9 per cent of China's territory is desert (Hu Tao/Wu Yu-ping/Zhang Ling-yun 2006). While sand storms are a naturally occurring phenomena, there is concern that as a result of soil erosion, desertification, and overgrazing, the sand storms are getting worse (Brettell 2007). During particularly severe storms, sand fills the air in Beijing. It can also affect the Korean Peninsula and Japan (Wong 2001; Wilkening 2004). The dust and sandstorms are five times more common than they were in the 1950's. In one particularly bad storm in April 2002, dust levels in Seoul reached 2,070 micrograms per metre, double the level considered hazardous to human health. Scientists also warn that airborne pollutants, including heavy metals and carcinogens, are binding with the sand and dust as the storms travel over China's industrial areas. The sand and dust storms are dangerous to

respiratory health, damage croplands and livestock, damage equipment, and ground airplanes.¹⁵

As industrialization proceeds in China, demand for energy is expected to grow substantially. The International Energy Agency predicted that possibly as early as 2009, China would surpass the United States as the world's largest contributor to greenhouse gas emissions.¹⁶

These three atmospheric pollution issues are the ones receiving the greatest amount of attention from the international community. It appears to be widely understood that China's future will be the globe's future.

63.7.3 River Pollution

In November 2005, an explosion at a chemical plant in Jilin Province, China led to the release of 100 tons of a toxic mix of benzene, aniline and nitrobenzene into the Songhua River. The explosion killed five workers, injured 70 more, and required the evacuation of 42,000. The chemical disaster, one of the worst in China's history, was initially kept from the public, and the downstream city of Harbin, with a population of 4 million, was simply told that their water supply system would be shut down for routine maintenance. The scale of the disaster, however, eventually demanded that the government inform the population. Harbin's water supply was shut down for four days as the toxic slick slowly moved downstream. The Songhua River eventually joins the Heilongjiang River, which is named the Amur River once in Russia (Mao/Li 2006).¹⁷ The toxic spill became a matter of grave concern in neighbouring Russia and an embarrassment to the Chinese government. The government was forced to apologize to Russia and provide financial and technical assistance to deal with the spill. The crisis spurred the government to examine measures that could be taken to strengthen pollution control enforcement and emergency response measures. It

also led to the establishment of an International Rivers Commission with Russia.

63.7.4 Over-fishing, Territorial Disputes, and International Conflict

There is strong and growing demand for fish in East Asia. Over-fishing has led to losses of key species in coastal waters and this has forced fishing boats to move to more distant waters in search of their catch. There are still many unresolved territorial disputes in the waters of East Asia. Fishing disputes have erupted throughout East Asia when fishing vessels enter disputed territorial waters. There have been dozens of incidents involving the exchange of gun fire because of such fishing disputes.

In one particularly serious fishing dispute between North and South Korea, North Korean crabbers were accompanied by North Korean navy boats when they breached the Northern Limit Zone that was established by the United Nations in 1953 as a marine armistice border. The North Koreans were searching for crabs that they could sell for hard currency. South Korean patrol boats tried to force the North Korean boats out of the area. Tensions escalated and shooting erupted resulting in one of the bloodiest battles between the North and the South since the end of the Korean War. One of the North Korean torpedo boats was sunk along with its crew. The United States sent two warships to the region in response (Schreurs 2007). Fishing disputes have erupted between all of the nations of the region – between Japan and South Korea, Japan and Russia, China and South Korea, Russia and South Korea, and Russia and China.

Less dramatic, but still worrisome incidents occur on a yearly basis. Relations between Japan and South Korea have grown strained in recent years over fishing disputes near the Dokdo/Takeshima Islands. Problems between Japan and Russia have grown serious as well. In August 2006, one Japanese fisherman was fatally shot by the Russian Coast Guard after his fishing boat entered disputed waters and then allegedly tried to flee (Schreurs 2007). Until the territorial disputes in the region are resolved, it is unlikely that the fishing disputes will cease.

63.7.5 Energy Security and the Environment

Rising energy demand has raised a wide array of environmental and security concerns for the region. Japan, Taiwan, and South Korea are heavily dependent on imported oil to meet their domestic energy needs.

'Energy security' has long been a concern for these energy poor nations. More recently, China – a nation with abundant coal supplies as well as some oil reserves – is becoming concerned about its energy security as well. As a result of its rapid economic development, China's domestic energy production can not keep pace with demand. China became a net importer of oil early this decade, and has been intent on enhancing energy efficiency and securing oil reserves as a result (IEA 2007; box 63.1).

Concerns about energy security and the region's heavy dependence on foreign oil have pushed many countries in the region to search for oil and natural gas in regional seas. Competing territorial claims in areas that have or are suspected to have oil or natural gas reserves threatens competition and the heightening of tensions among regional states. Ownership of the oil-rich Spratly Islands is disputed by China, Taiwan, the Philippines, and Vietnam (Calder 1997). Similarly, Japan and China are in disagreement over the ownership of oil reserves in the East China Sea.¹⁸

The search for energy security has also been a major factor behind the push for nuclear energy. The governments of the region have promoted nuclear energy in an effort to diversify their energy supplies and improve their energy security. More recently, they are also justifying nuclear energy development as a 'clean energy' that does not contribute to greenhouse gas emissions. Nuclear energy development, however, has raised various environmental justice concerns pertaining to the citing of nuclear power plants and waste facilities. It has also raised concerns about nuclear proliferation.

The criticality accident at the Tokaimura uranium reprocessing facility in 1999 and other problems at nuclear facilities have made it very difficult for the Japanese Ministry of Economy, Trade, and Industry to continue with its plans for the development of additional nuclear facilities. The government has, nevertheless, pushed through with its development of a spent fuel reprocessing facility and interim high-level radioactive waste storage facility at Rokkasho mura in Aomori Prefecture.

Also problematic is that there is no permanent nuclear waste deposit site in East Asia for medium- and high-level radioactive waste. Efforts to develop a permanent waste depository for medium-level radioactive

18 Anthony Faiola: "Japan-China Oil Dispute Escalates: Relations Already Uneasy as Tokyo Accuses Beijing of Tapping Disputed Fields", in: *Washington Post* (22 October 2005): A17.

Box 63.1: "China's Share of World Energy Demand will Continue to Expand". Executive Summary. **Source:** IEA (2007: 6-7). Reprinted with permission.

China's energy needs will continue to grow to fuel its economic development. ... However, the rate of increase and how those needs are met are far from certain. ... In the Reference Scenario, China's primary energy demand is projected to more than double from 1742 million toe in 2005 to 3 819 Mtoe in 2030 - an average annual rate of growth of 3.2%. China, with four times as many people, overtakes the United States to become the world's largest energy consumer soon after 2010. In 2005, US demand was more than one third larger. In the period to 2015, China's demand grows by 5.1% per year, driven mainly by a continuing boom in heavy industry. In the longer term, demand slows, as the economy matures, the structure of output shifts towards less energy-intensive activities and more energy-efficient technologies are introduced. Oil demand for transport almost quadruples between 2005 and 2030, contributing more than two-thirds of the overall increase in Chinese oil demand. The vehicle fleet expands seven-fold, reaching almost 270 million. New vehicle sales in China exceed those of the United States by around 2015. Fuel economy regulations, adopted in 2006, nonetheless temper oil-demand growth. Rising incomes underpin strong growth in housing, the use of electric appliances and space heating and cooling. Increased fossil-fuel use pushes up emissions of CO₂ and local air pollutants, especially in the early years of the projection period: SO₂ emissions, for example, rise from 26 million tonnes in 2005 to 30 Mt by 2030.

China's energy resources - especially coal - are extensive, but will not meet all the growth in its energy needs. More than 90% of Chinese coal resources are located in inland provinces, but the biggest increase in demand is expected to occur in the coastal region. This adds to the pressure on internal coal transport and makes imports into coastal provinces more competitive.

China became a net coal importer in the first half of 2007. In the Reference Scenario, net imports reach 3% of its demand and 7% of global coal trade in 2030. Conventional oil production in China is set to peak at 3.9 mb/d early 7 in the next decade and then start to decline. Consequently, China's oil imports jump from 3.5 mb/d in 2006 to 13.1 mb/d in 2030, while the share of imports in demand rises from 50% to 80%. Natural gas imports also increase quickly, as production growth lags demand over

the projection period. China needs to add more than 1300 GW to its electricity-generating capacity, more than the total current installed capacity in the United States. Coal remains the dominant fuel in power generation. Projected cumulative investment in China's energy-supply infrastructure amounts to \$3.7 trillion (in year-2006 dollars) over the period 2006-2030, three-quarters of which goes to the power sector.

China is already making major efforts to address the causes and consequences of burgeoning energy use, but even stronger measures will be needed. China is seeking ways to enhance its energy-policy, regulatory and institutional framework to meet current and future challenges. In the Alternative Policy Scenario, a set of policies the government is currently considering would cut China's primary energy use in 2030 by about 15% relative to the Reference Scenario. Energy related emissions of CO₂ and local pollutants fall even more. Energy demand, nonetheless, increases by almost 90% between 2005 and 2030 in the Alternative Policy Scenario. Energy-efficiency improvements along the entire energy chain and fuel switching account for 60% of the energy saved. For example, policies that lead to more fuel-efficient vehicles produce big savings in consumption of oil-based fuels. Structural change in the economy accounts for all the other energy savings. Demand for coal and oil is reduced substantially. In contrast, demand for other fuels - natural gas, nuclear and renewables - increases. In this scenario, the government's goal of lowering energy intensity - the amount of energy consumed per unit of GDP - by 20% between 2005 and 2010 is achieved soon after. The majority of the measures analysed have very short payback periods. In addition, each dollar invested in more efficient electrical appliances saves \$3.50 of investment on the supply side. And China's efforts to improve the efficiency of vehicles and electrical appliances contribute to improved efficiency in the rest of the world, as the country is a net exporter of these products. Such policies would be all the more critical were China's economy to grow more quickly than assumed in the Reference and Alternative Policy Scenarios. China's primary energy demand is 23% higher in 2030, and coal use alone 21% higher, in the High Growth Scenario than in the Reference Scenario.

waste, which requires safe burial for decades (as opposed to tens of thousands of years for high-level radioactive waste), proved highly contentious in South Korea resulting in massive demonstrations until the government established a plan whereby the community which voted to house the storage facility would receive a huge compensation package (300 billion yuan or US \$ 288 million). Taiwan, which has also had trouble finding a suitable location for a medium-level radioactive waste depository is now adopting a strategy similar to that that was employed in South Korea

(Bae 2007). Still, neither country has a final site for their high-level radioactive waste.

Most dramatically, North Korea, which is suffering from a severe economic crisis and shortage of energy, decided to restart its moth-balled Yongbyon nuclear reactor. For many years, the international community believed that North Korea was using the Yongbyon reactor to mask its development of nuclear weapons. In 1994, the United States reached an agreement with North Korea to shut down the Yongbyon reactor, which produces plutonium, in exchange for

the development of two larger, light water reactors. Light water reactors are of a design that makes it difficult to convert their waste into nuclear weapons. The Yongbyon nuclear reactor's spent fuel rods, however, remained a source of concern because their plutonium could be converted for use in nuclear weapons. While under the early negotiations for the 1994 Agreed Framework North Korea was to ship its spent-fuel rods from the Yongbyon reactor to a third country, North Korea announced that it would hold onto the fuel rods until the completion of the building of the two light water reactors.

Soon after being elected, George W. Bush listed North Korea as a member of the 'Axis of Evil'. Then, in October 2002, the United States made public that it had intelligence that North Korea had a clandestine nuclear weapons programme. The U.S. stopped shipments of oil to North Korea in a bid to use sanctions to alter the North's behaviour. Instead, North Korea pulled out of the Agreed Framework as well as the Nuclear Non-Proliferation Treaty. In doing this it expelled the United Nations Atomic Energy Agency inspectors who were monitoring North Korea's compliance with the Agreed Framework. North Korea is now believed to have developed several nuclear weapons and is known to have conducted one nuclear test in 2006 (Shim/Schreurs 2007).

After several years of difficult Six Party Talks (negotiations that were held between North Korea and the five other major regional powers: the United States, China, Japan, South Korea and Russia), in February 2007, the North agreed to shut down the Yongbyong nuclear facility and give up the spent fuel rods it was using to manufacture nuclear weapons. This was done in exchange for oil, which the country desperately needs. The deal did not, however, solve the problem of the nuclear weapons which were already created. Whether or not the North can be persuaded to give up any nuclear weapons it possesses remains to be seen.

63.7.6 Regional Cooperation for Environmental Security

The kinds of transboundary and international environmental problems outlined above are becoming serious enough that governments in the region are slowly warming to the idea of bilateral and multilateral cooperation. Not all of the issues outlined above have made it to the table or receive equal policy attention. The humanitarian disaster of North Korea remains so entangled with traditional military security

concerns that the region has had trouble addressing the situation effectively. The territorial disputes that aggravate fishing and offshore energy disputes between countries have also not been given systematic or comprehensive attention.

Still, in recent years, growing attention has been turned to many of the environmental problems discussed above. This has been done through various bilateral and multilateral channels.

63.8 Linking Environmental and Human Security Concerns to Official Development Assistance

China, Japan, and the Republic of Korea are among the twelve largest economies in the world. China's case, however, is rather unusual. While ranking third in the world after the United States and the European Union in terms of its total gross domestic product (GDP) on a purchasing power parity (PPP) basis, this ranking masks its still relatively low per capita income levels and wide income disparity. While coastal areas boast considerable wealth, more rural communities are still impoverished. Due to China's huge population of over 1.3 billion people, per capita GDP (in PPP terms) in 2005 was still only \$6,800 compared to \$31,600 for Japan and \$22,600 for South Korea. Despite being one of the largest economies in the world, China remains a recipient of development assistance from Japan, South Korea, and Europe. Whereas in the past, much of this assistance was focused on infrastructure development, now much of it targets environmental pollution.

For Japan, the richest nation of the region, the end of the Cold War and the transformation of domestic political realities among its neighbours, has meant a rethinking of its role in regional affairs. Japan had long been pressured by the United States and European countries to contribute more to global problem solving. Japan's economic miracle had made Japan the second richest nation in the world, but in contrast with the United States, Great Britain, or France, one with limited international political influence. Japan's success with economic exports, moreover, had resulted in considerable trade frictions and a feeling that Japan was benefiting economically from its security relationship with the United States without in turn contributing sufficiently to global affairs. Japan's Constitution and domestic coalitions that supported a pacifist role for Japan, moreover, meant that there were still restrictions on the extent to which Ja-

pan could participate in international peace keeping operations.¹⁹ Thus, in the 1980's and into the 1990's, Japan began a search for other means to make such contributions, including official development assistance and environmental protection (Inoguchi/Jain 2000; Hirata 2002).

Overseas development assistance (ODA) became one channel for exerting soft power. In the 1980's, Japan emerged as one of the world's largest ODA providers. Japan's growing ODA loans and grants, while sought after by developing states, also came under considerable scrutiny. Japan found itself being criticized for tying ODA loans to Japanese corporate involvement and for supporting projects that were environmentally destructive or harmful to native populations.

The confluence of pressures on Japan to increase its global involvement, the end of the Cold War, and rising international concern with global environmental destruction provided Japan's ruling Liberal Democratic Party with a new possibility for carving out a niche for itself as a global environmental leader. In the 1990's, environmental protection became one of the pillars of Japan's foreign policy. This led to a greening of Japanese ODA as can be seen in Japan's first ODA Charter (1992), which outlines an aid philosophy that links environmental conservation to development assistance.²⁰ In 2003, there was a revision of Japan's ODA Charter and for the first time ODA disbursement was put in 'human security' terms. The revised charter maintains as its first principle that "environmental conservation and development should be pursued in tandem"; this is now considered, however, to be part of a larger strategic focus on 'human security' (Sunaga 2004; Fernandez 2006).²¹

China's pollution problems have become a big area of concern for Japan. China's pollution has the potential to offset environmental improvements made by Japan. Thus, it is not surprising that China was the single largest recipient of Japanese environmental ODA throughout the 1990's (Sderberg 2002). In 1996, Japanese grant aid was used to establish the Sino-Japanese Friendship Centre for Environmental Protection, which is affiliated to the State Environmental Protection Administration, and houses a variety of dif-

ferent environmental institutions, NGOs, monitoring centres, and research bodies. The Japanese government has also funded the Japan-China Comprehensive Forum on Environmental Cooperation (1996) to promote regular dialogue among private enterprises, local governments, academics, and NGOs. Beyond this form of capacity building, Japanese ODA has targeted problems ranging from desertification to air and water quality and flood control. A model city programme was established with the hope that by improving air quality and addressing acid rain in Guiyang, Dalian, and Chongqing, other cities would be able to learn by example.²² While China will continue to receive environmental ODA in the coming years, overall assistance to China is declining as public opinion in Japan becomes less favourable to providing aid to this increasingly rich and powerful economic competitor.

In the future, other countries in the broader East Asian region are likely to become the primary recipients of Japanese environmental ODA, including Mongolia, Vietnam, Indonesia, and the Philippines. Thailand, which has been another big recipient of Japanese environmental ODA, like China is likely to graduate out of the status of being an aid recipient in the coming years (Sunaga 2004: 23).

South Korea has also become a donor of environmental aid. South Korea went from being an aid recipient to an aid donor only quite recently, establishing an Economic Cooperation Fund in 1987 and the *Korea International Cooperation Agency* (KOICA; at: <<http://www.koica.go.kr>>) in 1991. The guiding principles of Korean ODA include relieving poverty and supporting sustainable development. China and Indonesia are South Korea's largest aid recipients. As the South Korean government becomes increasingly concerned about the implications of China's desertification and acid rain problems for environmental conditions on the Korean peninsula, South Korean aid is starting to be directed at addressing regional environmental problems although as Esook Yoon (2006) argues, currently there is a stronger focus on economic development projects, than environmental protection ones.

It should also be noted that at the same time that China is itself a recipient of ODA, it is has been providing aid to Africa for sometime and is beginning to

19 Since 1993, Japan has been participating in United Nations Peacekeeping operations.

20 Government of Japan, 1992: "Japan's Official Development Charter" (June 1992).

21 Government of Japan, 2003: "Japan's Official Development Charter" (29 August 2003).

22 Japan, Ministry of Foreign Affairs, 2001: "Japan's Environmental ODA for China: Pursuit for Sustainable Development"; at: <<http://www.mofa.go.jp/policy/oda/category/environment/pamph/2001/index.html>>.

do so for its poorer Asian neighbours as well. Chinese assistance tends, however, not to include the environmental conditionalities made by other aid providers (Perlez 2006). China has developed a form of internal aid dispersion as well, with eastern regions providing environmental and development assistance to western ones, under its 'Go West' campaign.²³

63.9 The Regionalization of Environmental Protection

There are now various channels through which multilateral environmental cooperation occurs. Since 1991 Japan has been hosting an annual meeting of the environmental ministers of regional countries known as the Environmental Congress for Asia and the Pacific (*EcoAsia*).²⁴ The idea of the workshop is to enhance networks, exchange information, and develop common priorities. Since 1999, there has been an annual *Tripartite Environmental Ministers Meeting* (TEMM) among the environmental ministers of Japan, South Korea, and the People's Republic of China.²⁵ Five prioritized areas for mutual cooperation were initially established under the TEMM: raising consciousness of a Northeast Asian environmental community; working towards fresh water pollution prevention; preventing land based marine pollution; promoting cooperation for environmental industries; and pursuing environmental conservation in Northwest China. There are now also regular TEMM working level meetings and numerous special projects, such as cooperative research being conducted on sandstorm control and climate change. TEMM also created a *Tripartite Environmental Education Network* (TEEN) to enhance cooperation among groups in the three countries working on environmental education.

A priority for the region has been to enhance monitoring capacities and basic environmental information. One of the first cooperative endeavours was the Acid Deposition Monitoring Network in Northeast Asia that was initiated by the Japan Environment Agency. Initial expert meetings were held in 1993 and the first inter-governmental meeting of the network

was in 1998. In the mid-1990's, an *Asia Pacific Network for Global Change Research* (APN) was formed to promote global change research and interaction between the science community and policy makers in the Asia-Pacific Region.²⁶

Most of these multilateral cooperation projects work on a voluntary basis. Due to the unwillingness of states in the region to give up any degree of sovereignty, these regional groups can do little more than work to build capacity, promote joint scientific research and information exchange, and initiate targeted pollution control projects. The fact that many of the problems affecting the region originate in China is also problematic. It means that downwind Japan and South Korea are left to foot the bill (Drifte 2003). This creates a certain wariness in Japan and South Korea related to the establishment of new cooperative projects and programmes. Still, these early steps at cooperative problem-solving are a much needed foundation for dealing with the region's pressing environmental security problems.

63.10 Conclusion

There has been a dramatic transformation of environmental policies and programmes in Northeast Asia. Environmental security is still not a widely understood concept in Northeast Asia. When environmental problems are put into 'security' language, it tends to be done in relation to 'human security'. As the pluralization of environmental communities in the region continues and regional and global environmental cooperation expands, however, it is likely that environmental security frames - particularly as linked to human security - will gain a stronger place in domestic political debates. Environmental cooperation is also likely to deepen in the coming years although it may be decades before the states of the region show themselves willing to commit to legally binding agreements that require emission reductions and penalize states for non-compliance.

64 Environmental Security in the Arab World

Mohammad El-Sayed Selim

64.1 Introduction

The concept of environmental security has emerged in the mid 1970's to reflect awareness of the threats posed by expanding environmental problems (Brauch 2000, 2003, 2005, 2005a). Since then, two major traditions of environmental security emerged. According to the first tradition, environmental security refers to that area where environmental concerns and security strategies interact. According to this definition, environmental issues are no longer pure technical issues to be handled by technocrats alone. They are part of the overall concept of 'national security', as they could pose more threats to that security than traditional military sources. This definition assumes the presence of a major link between environmental issues and national security concerns. Some advocates of this definition refer to four main types of linkages, (i) the impact of environmental problems on the likelihood of inter-state conflicts and wars, (ii) the impact of environmental problems on human survival in its broadest sense, (iii) the impact of wars on environmental degradation; (iv) the form of political interaction or institutional structure that can best protect against degradation of the environment (Winnefeld/Morris 1994; Dyer 2000; Foster 2001). This tradition tends to 'securitize' the concept and places it within the context of the traditional security strategy.

The second tradition views environmental security as 'securing the environment', which means taking a series of steps to ensure that the ecosystem will be preserved. It focuses on conceptualizing environment and security within the context of sustainable development rather than conflict and conflict resolution. The assumptions are that a secure ecosystem is fundamental to individual and community health and survival and that understanding environmental security in security terms rather than environmental ones diverts attention from the more immediate and real insecurity problems of environmental degradation and narrows policy options by focusing on symptoms than

causes. In this tradition the concept of environmental security is approached from a rather technical perspective and used interchangeably with the concept of the protection of the environment. Environmental security is viewed as a part of the overall concept of 'human security' (Teng 1999; Thakur 2000; Elliot 2000; Najam 2003).

Whereas the first tradition has dominated the primarily 'Northern' discourse on environmental security, some 'Southern' analysts and policy makers subscribe to the second tradition (Pachauri 2000). This is understandable given the fear in the South that environmental issues could be used to justify intervention in the domestic affairs of southern countries (Saad 1995).

In the Arab world, attention to environmental issues began in the early 1980's due to the global trend focusing on environmental threats and acute environmental problems. By the early 1990's, one can identify a new trend in the Arab world linking environmental issues with security which led to an emerging Arabic literature on environmental security. In 1992 King Saud University (Saudi Arabia) published: *Environmental Security* by Sadek, and in 1997 Al-Madani, a Bahraini scholar, published *Our Environment is in Danger*. Both authors employed the concept of environmental security adhering to the second tradition. With the environmental security concept they referred to technical strategies to 'protect' the environment, thus de-politicizing the environment. In fact, most Arab scholars approach the question of environmental security from a technical perspective (Al-Qasmi/Al-Ba'aini 1997). This reflects the Arab sense of vulnerability if environmental issues were approached from a political-security perspective, especially in relation to water.¹

This chapter reviews Arabs approaches of environmental security by assessing the extent to which this concept has been integrated into Arab discourses on environment and security (64.3), outlining the main environmental issues in the Arab world (64.4), evalu-

ating Arab performance in dealing with them, and determining the relationship between environmental and political issues (64.5). The key arguments are that the environmental question cannot be assessed in a purely Arab context; rather they must also be assessed in a Middle Eastern and African framework, as some of the most crucial environmental issues are quite linked to the wider Middle Eastern framework, especially with regard to water issues. These environmental questions are highly politicized and closely linked to security issues. This link has been articulated in the interaction between Middle Eastern conflicts and the deterioration of the environment in the region, and the emerging conflicts over environmental issues, and the fact major Arab rivers stem from non-Arab sources. When the Middle Eastern multilateral negotiations were launched in 1991, a special working group was earmarked for the environment. The deliberations of this group showed the extent to which environmental issues are politicized (Oka 2003). This will lead us to review the linkages between environment and security in the Arab world and the Middle East (64.6).

64.2 Profile of the Arab World

The Arab world comprises twenty two countries mostly located in North Africa and West Asia and extending from the Atlantic Ocean to the Arabian (Persian) Gulf and from the Mediterranean and the southern Anatolia in the North to the Victoria Lake in the heart of Africa (figure 64.1). The total area of the Arab countries is 14.1 million km². It has a total population of almost 304 millions according to 2003 estimates, and it is projected to rise to 386 millions in 2015. Whereas the world population has increased during the 1975–2003 era by 1.6 per cent, the Arabs

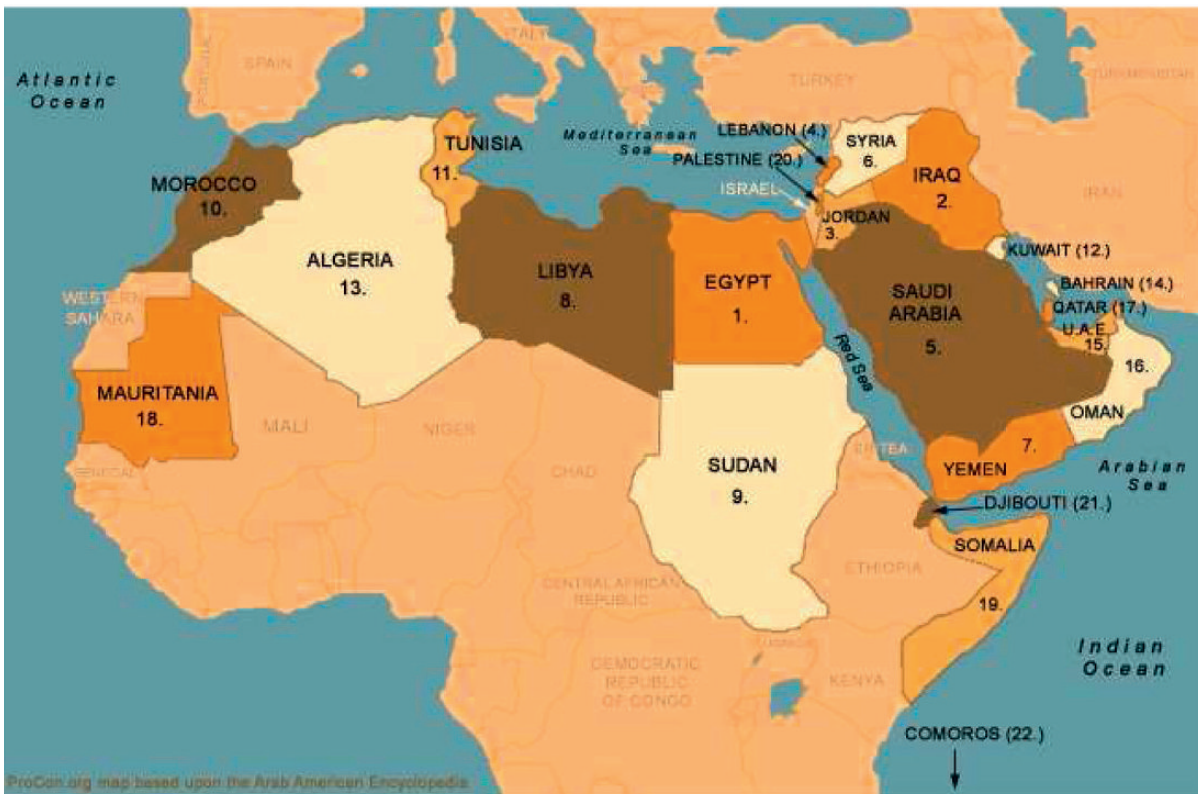

grew by almost 2.7 per cent. In 1975, almost 41.7 per cent of the Arabs lived in urban centres (compared to 37.2 per cent globally). This percentage increased to 54.7 per cent in 2003 (compared to 48.3 per cent globally). Population below the age of 15 years represent almost 36.3 per cent of Arab population) compared to 28.9 per cent at the global level (UNDP 2005a).

The Arab world is located in the Great Desert belt extending from northern Africa across the Red Sea to the Arabian Desert, an area which is characterized by its dry climate. Of the total area of the Arab world, 14.5 per cent is usable for agriculture with 4.2 per cent currently in use. This includes areas with rain-fed irrigation for cereals, and irrigated and natural grazing areas. In most Arabian Gulf states the desert represents almost 98 per cent of the total area. In Egypt, desert represents almost 94 per cent of the total area. All Arab countries are coastal at the Atlantic Ocean (Mauritania, Morocco), the Mediterranean (North African countries, Syria and Lebanon), the Red Sea (Egypt, Jordan, Saudi Arabia, Yemen), the Indian Ocean (Somalia, Djibouti, Comoro Islands), and the Arabian Gulf (Iraq, Gulf Cooperation Council States). As this has facilitated intraregional maritime transportation, it also created maritime pollution problems. The sources of the main rivers in the Arab world, the Nile, Tigris, and the Euphrates are located outside the Arab world, which is a source of conflicts between upstream and downstream countries.

Despite their oil wealth, and with the exception of Bahrain, Qatar, Kuwait, and the United Arab Emirates (which comprise only 2 per cent of the total Arab population) Arab countries belong to medium and low human development categories in the Human Development Index of the United Nations Development Programme (UNDP), ranging between the ranks of 58 and 71 (Libya and Oman respectively) till the ranks of 151 and 152 (Yemen and Mauritania respectively). According to the 2003 statistics, the total GNP of Arab countries is US\$ 773.4 billions. The GNP per capita is almost US\$ 2611 compared to the global GNP per capita of US\$ 5801. Whereas Arab GNP grew by an average of 0.3 per cent in 1990–2003, global GNP grew by 1.4 per cent annually during the same period (UNDP 2005). These statistics show that the Arab world lags behind the global averages of development and that due to its location it faces major environmental problems. Its resources may not be sufficient to deal with these problems effectively.

1 In a review of the environmental paradigm of the Arab Human Development Report of 2002 this author found that there was no reference to the linkages between environmental and political issues in the Arab world, such as the destruction of the environment in Palestine and the Gulf region as a result of political decisions, or the political conflicts rooted in environmental issues such as the Turkish-Syrian conflict over the distribution of the water of the Euphrates (Selim 2004); see also Scheumann (2003) and chap. 44 by Aydin/Ereker on the Euphrates and Tigris; on the Jordan river: see Dombrowsky (2003); Haavisto (2003); chap. 45 by Hayek, chap. 46 by Selby, chap. 47 by Jägerskog; on the River Nile: see chap. 48 by Adly/Ahmed and chap. 49 by Kamari-Mbote/Kindiki.

The 22 Countries of the Arab League and the year of their admittance: 1. Egypt (1945), 2. Iraq (1945), 3. Jordan (1945), 4. Lebanon (1945), 5. Saudi Arabia (1945), 6. Syria (1945), 7. Yemen (1945), 8. Libya (1953), 9. Sudan (1956), 10. Morocco (1958), 11. Tunisia (1958), 12. Kuwait (1961), 13. Algeria (1962), 14. Bahrain (1971), 15. U.A.E. (1971), 16. Oman (1971), 17. Qatar (1971), 18. Mauritania (1973), 19. Somalia (1974), 20. Palestine (1976), 21. Djibouti (1977) and 22. Comoros (1993).

64.3 The Arab Discourse on Environmental Security

Arab concerns on environmental questions emerged in the early 1980's when Arab policy makers expressed concerns on the quality of the environment and various books were published on environmental protection. However, this environmental concern was not linked to national security. The concept of environmental security emerged in the Arab public discourse in the early 1990's in policy statements and academic writings referring explicitly to linkages between environmental concerns and security strategies.

One can categorize academic and public writings into sub-groups depending on exact environmental issues being dealt with and whether these writings have approached these issues from a security perspective. The list of the writings reviewed is not meant to be ex-

haustive of the Arab literature on environment, but rather representative of the main themes dealt with in the Arab world. The publications in Arabic are categorized below into nine general themes.

64.3.1 The Environment in General

These writings are introductions to environmental issues, and do not specifically refer to the Arab world or to environmental security. But as the first books in Arabic in this field, they alerted a generation of Arab policy makers and scholars to the centrality of attending to environmental issues. The first book by Al-Sharnouby (1976) on *Man and the Environment* was followed by Najm, Al-Banna, and Abou Ayash (1986), Abdel-Maksoud (1997) Al-Sharnouby (1999), Al-Zouka (2000) and Mousa (2000), and Sariya (2003).

64.3.2 The Relationship between Environment and Education

By the late 1980's, a group of Arab scholars developed high school curricula to alert students to the importance of the environment. The first book entitled *Environmental Education* was published by Al-Sharrah (1986) in Kuwait which was followed by Al-Demerdash (1988) in Cairo. While the first book presented a curriculum for secondary schools, the second focused on higher education. At least four more books were published later by Al-Sabarini and Al-Hamad (1994), Metawe (1995), Al-Jabban (1997), and Al-Lakkany and Mohammad (1999), in addition to dissertations submitted to faculties of education and environmental institutes.

64.3.3 The Relationship between Environment and Development

Several Arabic books established linkages between environmental and developmental issues proving that environmental degradation negatively influences development. In 1990, the United Arab Emirates University published proceedings of the international conference it held on the economic and environmental dimensions of development in the Gulf Cooperation Council countries (United Arab Emirates University 1990). This was followed by books by Al-Sayed (1992), Al-Kandary (1992), Al-Bayaty (1996), Kassem (1997), Al-Gallad (1998), Embaby (1998), Kishk (1998) Al-Sheikh (2002), and Al-Sara'wy and Masoud (2001). These writings alerted Arab readers to the developmental costs of neglecting environmental issues.

64.3.4 The Relationship between Environment and Mass Media

Mass media analysts have focused on proving that mass media could play a major role in creating public awareness of environmental issues and how to deal with them. The most important of these writings are those by Al-Killini and Madkour (2000) and Saleh (2003), both were published in Egypt.

64.3.5 The Social Dimension of the Environment

This is the least researched issue in the Arab environmental discourse. A group of Egyptian sociologists conducted field studies on social and anthropological issues of the relations between environment and soci-

ety (Al-Gohary/Shukry 1995). But this aspect was not followed up by other scholars or stressed by policy makers. Thus, awareness of the social dimensions of environmental issues is still in its infancy which reflects the technical nature of Arab conceptualization of the environment.

64.3.6 The Relationship between Environment and Psychology

Some Arab scholars have developed an interest in the question of the impact of environmental degradation on human psychology. Such interest has led to the emergence of the new discipline of "environmental psychology," in some Arab universities. In fact, two books were published under this title by Gaber, Mahfouz, and Al-Khalifi in 1992 and by Al-Sabwa in 1997. The last book looked at the psychological and cognitive changes in Egyptian workers as a result of their exposure to Carbon disulfide (CS₂). Recently, Abdel-Hady (2003) published a book analyzing the impact of environment and pollution on the intelligence and creativity of the children.

64.3.7 The Relationship between Environment and Islam

As a part of the rise of Islamism in the Arab world, Arab scholars paid special attention to the development of 'an Islamic' view on environmental issues. This trend was not restricted to the environment; rather it extended to all academic disciplines, including the natural sciences. The main argument is that Islam has articulated a view on environmental issues and that attending to this view is a part of the Muslim's approach to life. But none of the "Islamic" perspectives on the environment was necessarily different from other perspectives. But the emphasis was on rooting environmental issues in Islam. The first book was published by Al-Saidi (1994), to be followed by a number of books such as Abdel-Azim (1999), Abdel-Maksoud (1986), Al-Sheikh (2000), Al-Shirazi (2000), Zahran (2000) and Murad (2003). All of them attempted to prove that Islam had developed an environmental paradigm which persuades the believers to protect their environment.

64.3.8 Specific Environmental Issues in the Arab world

The most widely studied environmental issues are those related to water shortages, pollution, and deser-

tification. Water shortages are so acute that some analysts used the concept of 'water security', such as Algerian scholar Al-Makhadmy (1999). The most important of these writings are those by Farrag (1986), Mekhemr and Hegazy (1996), Al-Akkal (1996), Nahar (1997) and Bakr (1999). Other analysts focused on the issue of pollution. The pollution issue was tackled by other analysts such as Al-Sara'wy and Masoud (2001), Kassem (1997), and Mousa (2000). Less attention was given to the issue of desertification (Balba' and Nassim 1994; Hassan n.d).

64.3.9 Environmental Security

The only book in Arabic by Sadek (2000) addresses environmental security from a purely technical perspective focusing on environmental protection, even though it introduces the concept of 'general environmental security'. Sadek, a specialist in microbial environmental pollution, did not identify linkages between environment and national security. He referred to water security, security against microbial weapons, maritime pollution and electro-magnetic pollution.

The concept of environmental security was indirectly used in other publications. Al-Qasmi and Al-Ba'aini (1997) referred to environmental security in their book: *Securing and Protecting the Environment* and Al-Banna (2000), an Egyptian scholar, stressed the indirect link between environment and security through the intervening variable of development. His argument is that environment impinges on security through its impact on the developmental process. This approach is contained in another book by Al-Madani (1997) published by the Arab Gulf University in Bahrain that argued that environmental degradation is a national security threat. He referred to the impact of such degradation on the fall of Communist regimes in the early 1990's. But direct linkages between environment and security were not specified. Tolba (1992), the former head of the United Nations Environment Programme, also referred to the destructive impact of wars on the environment and that "environmental pressures are a result and an outcome of the political tensions and military conflicts." Tarraf (1998) also argued that environmental hazards call for a re-definition of the concept of security. However, there were no suggestions on the directions of such a redefinition.

What are the main characteristics of the Arab literature on the environment and environmental security? In answering this question, one may utilize Sunderlin's (2003) classification of the three paradigms on the en-

vironment where he distinguishes between: class, managerial, and individualist. The Arab literature falls under the category of the managerial paradigm. This paradigm views environmental issues as a primary result of processes of industrialization and modernization, and the lack of proper state control and governance, rather than from the capitalist mode of production as the proponents of the class paradigm argue, or from the aggregate individual values and preferences as the advocates of the individualist paradigm believe. It covers these issues at the organizational level focusing mainly on relations among various state organizations. The state is seen as the major reference point in dealing with the problem. The essential tools for addressing environmental concerns is improved state management and control, and better coordination between various state organizations. The Arabic literature on the environment is of a technocratic nature focusing mainly on technical issues related to the environment and does not frame them within its conceptualization of national security. This literature is mostly non-ideological, and not supportive of any ideological trend. In the Arab world environmentalists belong to different ideological traditions. In short, the Arab paradigm on the environment is mainly *non-ideological*, and *apolitical* although it approaches the issue from a state perspective. The emphasis is on the organizational aspects of the state rather than on political ones.

A minority group of Arab intellectuals articulates a discourse on the environment quite close to the main arguments of the class paradigm. They tend to view environmental issues in political terms and put the responsibility for environmental problems in developing countries on the shoulders of developed countries. They refer to the emergence of a 'new global environmental system' characterized by the dominance of a 'new environmental imperialism'. This system is the main source of most environmental problems of developing countries such as nuclear waste disposal in developing countries, ozone depletion and global warming. This trend is best represented by the Bahraini scholar Ismael Al-Madany (1997).

64.4 Main Environmental Threats to Arab Security

The two major environmental threats perceived in the Arab world are those related to water scarcity, desertification and land degradation.

64.4.1 Water Scarcity and Arab Security

Water Scarcity is the most serious environmental threat to Arab security, as virtually all Arab countries are well below the line of 'water stress'. The World Bank has classified 22 countries as below the water poverty line where per capita water availability in cubic meters/year is below 1000. Among them fifteen are Arab countries. The annual per capita water in Qatar, Kuwait, Libya, and Bahrain is 91, 95, 111 and 112 m³/year. In Saudi Arabia, Jordan, Yemen, Tunisia, Algeria, and Oman the figures are 241, 318, 340, 434, 517 and 874 respectively. If this is the case today, one can imagine the water famines, the Arabs will be confronted with in ten years given present levels of population growth. Due to poor agricultural technologies, agriculture remains the major user of water sources in most Arab countries. A low level of efficiency is noted in the utilization of water in all sectors. This has generated many problems such as water logging, salinity, low productivity and infertility of soil and deterioration of the quality of ground water. Further water governance remains fragmented among various institutions, which generates problems for the rationalization of water use. The problem is further aggravated by high population increase, the geographical location of Arab countries in the Great Desert belt, the lack of national programmes to rationalize water consumption; and almost 60 per cent of water resources in the Arab world originate from outside the region which gives rise to tensions in using jointly-shared water. This is acutely clear in the cases of the Nile, the Euphrates and Tigris. These cases are a source of present and potential conflicts and will be reviewed later (Issa 1994): Al-Tamimi.

64.4.2 Desertification and Land Degradation

Deserts cover most of the Arab world. Almost 14.3 per cent of Arab lands are suitable for agriculture (with rainfall up to 400 mm). About 89 per cent of Arab land receives a rainfall below 100 mm. Most of these areas are deserts or desertified sand suitable only for grazing. Most Arab lands are threatened by desertification due to anthropogenic activities including overgrazing that is responsible for almost a quarter of the desertification. About one fifth of the total area is threatened by desertification due to forest/shrub clearing operations, compared to 2 per cent and 1 per cent of the total area lost annually due to salinization and urban expansion (UNEP 2003a).

64.4.3 Other Environmental Hazards in the Arab World

There are other environmental hazards in the Arab world, such as the degradation of the marine environment, biodiversity losses, decline of the quality of the atmosphere and climate change, and the impact of sea-level rise on land especially on the Nile Delta. Coastal zones in the Arab world are under stress as a result of demographic shifts from rural to urban areas, landfills and dumping of untreated waste. The marine environment is increasingly threatened by land-based sources of pollution, and by the heavy ship traffic in the region. Out of the world's exported oil, 60 per cent is transported through the Straits of Hormuz. The charged water could cause irreversible damage to marine ecosystems. The coasts of some Arab countries have been increasingly shrinking as a result of the sea-level rise. This issue has particularly threatened the Egyptian Nile Delta which has been eroding during the last quarter of a century. Further, the unique biodiversity of the Arab world is at serious risk from increased human activities. The main issues are the degradation and/or destruction of habitats and loss of species. This is mainly the result of population growth, agricultural and urban expansion into ecologically sensitive areas, poverty and unsustainable use of biota, and industrial pollution. Finally, urban air pollution is emerging as a serious threat facing most cities. Cities are experiencing air pollution with gases and particulates and lead at levels often-exceeding global standards.

The main sources of air pollution are energy and industrial production and transportation. The last factor accounts for almost 90 per cent of air pollution in urban centres which is mainly due to poor maintenance, aged cars, low quality fuel, and poor traffic management. Stationary sources, such as outdated power generation stations, are another major source. Finally, the region is also experiencing climate change as a result of burning of fossil fuel (UNEP 2003a).

64.4.4 Climate Change as a Security Challenge

Finally, it seems that global warming and climate change has begun to impact upon Arab countries (IPCC 2007, 2007a, 2007b; Brauch 2002, 2007j, 2007k, 2009). In May 2007, British Foreign Secretary Margaret Beckett said that the Middle East is the most vulnerable to the negative consequences of global warming as this area comprise 5 per cent of world population and only 1 per cent of its water resources.

She added that climate change will result in the loss of almost 80 per cent of Nile water resources, and the loss of main parts of the Nile Delta which could make 2 million people homeless, which will result into major conflicts between the riparian states. However, these forecasts were disputed by Mahmoud Abu-Zeid, Egypt's Minister of Water Resources.²

64.5 Arab Strategies to Deal with Environmental Threats

There is an increasing awareness in the Arab world at the governmental and non-governmental levels of the urgency of the environmental problems the Arabs are facing. Thus, most Arab countries have established national institutions (ministries, or public corporations) on issues related to the environment³, issued national strategies for environmental protection⁴, developed NGOs to support the work of the governmental institutions⁵, issued various journals to deal with the environmental issues⁶, and established academic institutions to major into the study of environmental issues.⁷ Arab countries have also signed and ratified over 64

international and regional governmental conventions and agreements on the protection of the environment. Among the most important are the three Rio conventions with sustainable development focus, the *United Nations Convention to Combat Desertification*, the *Convention on Biological Diversity*, the *UN Framework Convention on Climate Change*, and the *Montreal Ozone* convention. Implementation of some of these conventions has been rather modest for many countries due to lack of adequate resources. The Montreal Ozone convention has achieved the most successful level of implementation in the Arab world.

At the Arab regional level, there has been a concerted effort within the framework of the *League of Arab States* (LAS) to co-ordinate Arab environmental strategies. LAS has established a Department of Environment and Sustainable Development responsible for coordinating Arab environmental projects. A *Council for Arab Ministers Responsible for the Environment* (CAMRE) was also established in 1989. CAMRE meets annually to review common environmental issues. It elects an Executive Bureau of seven members for a term of two years and a chairman and it presented to the *World Summit on Sustainable Development* in Johannesburg (September 2002), an Assessment Report on the progress made towards achieving sustainable development. CAMRE also launched the *Arab Initiative on Sustainable Development* to be implemented in the region in cooperation with UN agencies such as UNEP. In its session in Benghazi, Libya in December 2003 it adopted "The Arab Environmental Work Programme of CAMRE for 2004 and 2005" (CAMRE 2003). This CAMRE document dealt with programmes such as desertification and increasing the green land, industry and the environment, education and environmental mass communication, capacity-building in the area of environmental legislation, follow-up of international environmental treaties, and completion of statistical data bases on the environment. There have also been various regional initiatives to combat desertification such as the *Sub-Regional Action Programme* (SRAP) for West Asia and the Arab Maghreb Union.

2 Mahmoud Abu-Zeid, Press interview with Al-Masry Al-Youm, in: *Al-Masry Al-Youm*, Cairo, 12 and 14 May 2007.

3 For example, in Egypt, Lebanon, Palestine, and Tunisia ministries for the environment were established. In Kuwait, United Arab Emirates, Saudi Arabia and Libya public corporations on the environment were created.

4 Such as *The Strategy and National Work Program to Combat Desertification in the United Arab Emirates*, issued in 2004 and *The Environmental Strategy of Kuwait* issued in 2000.

5 Such as the *Friends of the Environment Association in the United Arab Emirates* established in 1992.

6 Such as *Muntada Al-Bee'a*, a non-periodical review issued by the Arab Network for the Environment and Development in Egypt, *Al-Bee'a wa Al-Tanmiya*, a monthly journal issued by Technical Publications Ltd in cooperation the Middle East Center for the Transfer of Appropriate Technology in Lebanon, *Al-Emirate Wa Al-Bee'a*, a quarterly issued by the Federal Corporation for the Environment in the United Arab Emirates, *Shu'un Bee'iya*, a monthly issued by the Association of the Friends of the Environment in the United Arab Emirates, *Al-Bee'a*, a monthly issued by the Kuwait Foundation for the Protection of the Environment, *Minbar Al-Bee'a*, a monthly magazine issued by the UN Program for the Environment in Bahrain, *Assuit University Bulletin for Environmental Research*, a quarterly issued by Assuit University in Egypt, and *Bee'atona*, a monthly issued by the Kuwaiti Public Corporation on the Environment.

7 Such as the *Institute of Environmental Studies and Research* in Cairo and Ain Shams universities in Egypt, the *Center for Environmental Studies and Research* in Sultan Qabos University in Oman, and the *Center for Environmental Development for the Arab Region and Europe* in Egypt.

The Gulf Cooperation Council (GCC) has also initiated the Prize of the GCC for Best Environmental Works.

At the level of NGOs the *Arab Network for Environment and Development* (RAED) was formed in 1990. It comprises NGOs in Arab countries majoring in environmental issues. In 1995, RAED was granted an observer status in meetings of CAMRE, and it participates in its meetings and secretariat. It also sponsors various activities at the Arab, Mediterranean, and regional levels for the protection of the environment.⁸ These strategies have been helpful in creating public awareness of environmental hazards in the Arab world. Environmental problems in the Arab world still pose a major security threat. According to Mustafa Tolba, the leading Arab environmental specialist, “environmental problems have begun to impact upon the health of present generation, and threaten the future ones.”⁹ This is due to the prevalent paradigm in the Arab world that environmental issues are residual ones, which results in limited financial allocations to deal with them. It is a result of inefficient government bureaucracies, inadequate legislation, and most importantly of the tendency to view environmental issues as purely technical ones that do not pose immediate security threats.

64.6 Linkages between Environment and Security

With regard to the Arab environmental paradigm and environmental issues in the Arab region, a high level of asymmetry exists between them. Whereas the Arabs subscribe to a managerial-technical paradigm, environmental issues have strong political dimensions. These dimensions are reflected in the two-way relationship between environmental issues and political conflicts. Environmental issues have been the sources of conflicts especially between Arabs and non-Arabs of the Middle East, and in Africa. This is clearly reflected in water issues especially in the Nile, Euphrates, and Tigris. The Nile flows through ten countries until it reaches its destination in Egypt (Peichert 2003; see chap. 48 by Adly/Ahmed and chap. 49 by Kameri-Mbote/Kindiki). Egypt is dependent on the Nile for the survival of its 70 million people. According to a 1959 agreement with Sudan, the Egyptians are entitled to 55 billion cubic meters of Nile water a year, while Sudan gets 18.5 billion. But with the population

growth, this quota is increasingly falling below the needs as demand for water in Egypt increased to 68 billion cubic metres in 1998. Upstream countries are beginning to engage in agricultural projects utilizing water, which will mean a reduction of the Egyptian quota. They claim that they were not part of the Egyptian-Sudanese agreement are not bound by the treaties signed on their behalf by Britain and Italy during the colonial eras (see chap. 49 by Kameri-Mbote/Kindiki). Recently, Tanzania has announced it will build a 150 km long pipeline to divert Nile water originating from its land. Ethiopia is also beginning to launch similar projects. The Egyptians suspect that foreign influences are playing a role in persuading riparian states to launch these projects in order to pressure Egypt. Egyptian president Anwar Sadat threatened to go to war against Ethiopia if it tampered with the Nile water.

The same potentially conflictual relationship characterizes relations between Syrians, Iraqis, and Turks over the use of the water resources of the Euphrates and Tigris, which originate from Turkey (Scheumann 2003). Turkey argued that these rivers are not international rivers, and that it has the right to use their water resources with no obligations towards Syria and Iraq. It argued that Turkey has not claimed that it shares with Iraq its oil, and Iraq is not entitled to share the water resources of the two rivers with Turkey. Turkey has built a huge complex of dams (GAP: *Great Anatolia Project*) which reduced the annual average flow of the Euphrates within Syria from 32 billion cubic meters to 20 billion (chap. 44 by Aydin/Ereker). Syria depends on the Euphrates for almost 80 per cent of its water needs and is already plagued by shortage of water, with an annual water availability of almost 1,000 cubic meters per capita. The water that passes to Syria from Turkey is also laden with agrochemicals and pesticides which poses serious health threats. Turkey also threatened to impound the Euphrates water if Syria did not strain the Kurdish militia operating from its territory. At present, Turkey and Syria have been able to contain this emerging conflict over the distribution of the water resources of the Euphrates. This is essentially because Syria does not have many options to deal with Turkey. A flare up of conflict may be possible if present political alignments in the region change. In 1987 Turkey suggested to build the ‘Peace Pipeline Project’ to sell water to Middle Eastern countries through pipelines. The Arab countries were reluctant to accept the Turkish suggestion because it would give Turkey a leverage over their survival. The idea seems to have been accepted

8 See the report of RAED submitted to CAMRE in December 2003 which outlines its projects (Council of Arab Ministers Responsible for the Environment 2003).

9 Interview in: *Minbar Al-Bee'a*, 5,3 (September 1992): 9.

by Israel. The problems of the Euphrates and Tigris have also influenced Syrian-Iraqi relations. In 1974, both countries were on the brink of war when Syria established the 'Revolution dam' on the Euphrates which reduced the flow of the Euphrates to Iraq by 25 per cent. The Saudi mediation averted war. In 1990, Syria and Iraq signed an agreement to share the water resources of the Euphrates (42 per cent for Syria and 58 per cent for Iraq),

The Jordan River has been a source of conflict between Jordan and Israel (Dombrowsky 2003; chap. 45-47 above). The Jordan basin (Jordan and Yarmuk rivers) is Jordan's sole source of surface water. Jordan tried to build storage systems on the Yarmuk, but these were destroyed by the Israelis in 1967. Israel also objected to Jordan's building of a dam at Markarin on the Yarmuk near the Syrian border in the 1970's, and the Al-Wahda dam on the upper Yarmuk in 1990 because both project would affect its water shares. The 1994 Jordanian-Israeli peace treaty dealt with the water issue in a way that gave Israel a larger share of the water resources of the Yarmuk River (Gann 2001).

Wars and conflicts have also contributed to the destruction of the environment in the Arab world. The prime targets of such impact were the Arabian Gulf region (Westing 2003) and Palestine (Haavisto 2003; UNEP 2003c, 2006a). The 1991 Iraqi invasion of Kuwait, the 1991-2003 UN blockade against Iraq, and the 2003 Anglo-American invasion of Iraq have resulted in major environmental damages in the Gulf region (UNEP 2003, 2003a, 2003d). The attack on Iraqi industrial facilities in January-February 1991, led to the loss of electrical production firms which had a negative impact on water supply, sanitation and refrigeration. The loss of electricity disrupted systems of pumping saline water from irrigated lands in the southern floodplain, leading to widespread water logging and salinization. Bombing of chemical and industrial plants led to the release of numerous toxic chemical compounds into the atmosphere, soil, and local waterways. The livestock and agriculture in Iraq were devastated by disease and epidemics due to lack of vaccines caused by the destruction of production plants, and by the lack of pesticides and fertilizers as a result of the bombing of chemical plants (UNEP 2003b).

The American forces also used depleted uranium ordnance which had seriously affected the Iraqis and the Kuwaitis as well. It is estimated that around 290 metric tons of depleted uranium were fired by the Western forces during the war (UNEP 2003a). During their retreat from Kuwait in February 1991, Iraqi

forces uncapped seventy-six oil wells and allowed oil to flow freely into land. Another 99 wells were deliberately damaged. Approximately 60 million barrels were released. Over 246 pools were formed, covering an estimated area of 49 km². Estimates of total quantity of oil accumulated in the pools ranged from 25 to 50 million barrels. More than 600 Kuwaiti oil wells were set on fire by retreating Iraqi troops, burning between 2.5 and 6 million barrels of oil per day from the end of February till the beginning of April 1991. The environmental damage in Kuwait was estimated at US\$ 40 billion (Abdulraheem 2000; Austin/Bruch 2000; Omar/Briskey/Misak/Asem 2000; UNEP 2003).

The economic sanctions imposed on Iraq after the war constrained its ability to deal with these environmental hazards, which led to the decline of the quality of the Iraqi environment. The 2003 Anglo-American invasion of Iraq has also witnessed the extensive use of depleted uranium munitions against civilian targets. Today, the Iraq environment is in shambles as a result of almost 12 years of wars and blockades (UNEP 2003, 2003a).

Likewise, the Israeli-Palestinian conflict had major negative impacts on the Palestinian environment, especially after the Second Intifada (Uprising) of September 2000. The environment was used as a tool to crush the Intifada, as the Israeli army destroyed trees, filled in wells, and damaged water infrastructure. The Israelis have also disposed of hazardous waste in Palestinian controlled area, and destroyed greenhouses and crops. Water tankers are frequently attacked and most of the water is controlled by the Israelis to be used inside Israel and for the settlers, which had resulted in major water shortage (Twite 2003; see chapters by Twite and Dajani in this volume). The building of the 'settlements' and of the 'Separation Wall' has destroyed thousands of agricultural lands and made it impossible for many Palestinians to reach their farms (chap. 67 by Dajani; chap. 66 by Twite). The environmental consequences of the Israeli settlements have been documented by Amnesty International report issued in 2003 (Amnesty International 2003; Whitson 2005). The Advisory Opinion of the International Court of Justice issued on 9 July 2004 regarding the Separation Wall also referred to the impact of the Wall, built on occupied Palestinian territories on the life of the Palestinians (International Court of Justice 2004).

The 2006 war between Israel and Hezbollah also had major consequences for the environment of Lebanon. During the war, Lebanese oil storages and their pipelines were destroyed which resulted in 15,000

tons of oil pouring into the Lebanese coast of the Mediterranean Sea thereby causing major environmental damages (Khuraybit 2006).

The political character the environmental issues in the Arab world was reflected in the deliberations of the Middle Eastern Working Group on the Environment which was formed within the multilateral track resulting from the Madrid peace conference of October 1991. The deliberations of this group that was chaired by Japan witnessed major disagreements on the relationship between environmental and political issues and the strategies for dealing with environmental hazards (Oka 2003).

The Israelis suggested to give priority to environmental questions and to establish a regional framework for cooperation with joint teams to deal with the environmental issues. It also suggested giving priority to the uses of air pollution, climate change, and maritime pollution of the Mediterranean. Egypt advocated linking the progress of regional cooperation on the question of the environment to the settlement of the Arab-Israeli conflict arguing cooperation on the question of the environment should be a part of an overall regional cooperation, and suggested engaging the United Nations Environment Programme in regional projects for cooperation. It also contended that priority should be given to issues such as desertification, marine environment, air pollution, and natural disasters, and demanded that the point of beginning in establishing a regional system for cooperation was to determine the parties that caused the environmental damage and holding them responsible for it. The Egyptians rationalized their approach on grounds that Israel has caused tremendous damage to the Palestinian environment by building settlements on agricultural lands and removing trees. They also wanted banning anti-environment military activities, and committing all regional powers to get rid of radioactive materials within their territories in an indirect reference to the Israeli nuclear programme (Goma'a 1994).

The Israelis and the Egyptians agreed on one point, that is, the need to engage outside powers in building a regional system for cooperation in the field of the environment. However, whereas the Israelis preferred an engagement by Japan, the U.S., and the European Union, the Egyptians wanted also the UN to be involved. Also, whereas the Egyptians preferred to begin by dealing with grand issues such as nuclear and chemical weapons and their impact on the environment, the Israelis preferred to deal with purely technical issues. It is obvious that the Egyptians advocated the politicization of environmental issues. This

is not because they adhere to a politicization paradigm, but mainly because they wanted to use the card of environmental cooperation to accelerate the peace process. The Egyptians wanted to safeguard against creating a precedent of regional cooperation and normalization without progress on the political issues. Further, despite its technical character, the Israeli approach had major political objectives, that is, to establish an Arab-Israeli regime for cooperation, a regime which will have political implications.

With the collapse of the peace process in 1996, the meetings of the Environment Working Group were suspended. Understandably, such collapse led to a further worsening of the regional environment especially in the occupied territories after the Second Intifada of September 2000. Recently, a joint Jordanian-Israeli research centre was established under American sponsorship to major in the study of the ecosystem of the Dead Sea area. It remains to be seen if this experience will survive the political upheavals of the Middle East.

64.7 Conclusion

Since the 1990's there has been an increase in Arab interest in and concern about environmental issues. This was reflected in a general trend to establish institutions, formulate strategies, issue academic and policy-oriented books and literature, and develop NGOs which major in the field of environment. There has been a trend to coordinate environmental policies among Arab countries within the framework of CAMRE and to coordinate policies with the UNEP. The Arab environmental paradigm is characterized by its emphasis on the managerial-technical character of environmental issues. It tends to de-politicize these issues and deal with them outside the main thrust of the national security strategy. Perhaps the only exception is the Arab approach to environmental issues in the Middle Eastern framework. The Arabs also tend to view environmental issues as residual issues compared with statehood, sovereignty, and territory. This has resulted in limited resource allocations to environmental issues and the tendency to rely on foreign support.

In the meantime, environmental issues in the Arab world have strong political components by virtue of their linkages with the larger Middle Eastern and African frameworks. This is reflected in the two way relationship between regional conflicts and wars as was reflected in Palestine and the Arabian Gulf region.

There are conflicts over environmental issues and such issues were the main causes of conflicts and wars in the region. The linkage was also articulated in the deliberations of the Environment Working Group of the Middle Eastern talks in the 1990's. It was clear that the sides have different views of the strategies to deal with environmental hazards and the relationship between regional environmental cooperation and the Middle East peace process.

As the deterioration of environmental issues in the Arab world were noted despite the increased interest in these issues. The Arabs must change their environmental paradigm towards integrating the environment into their overall national security strategy that is, 'securitizing' their concept of the environment. This will result in more allocations to deal with environmental issues, but it will also require more bureaucratic efficiency. Perhaps, they should think of establishing a regional environmental agency to deal with the common issues as is the case in Europe. There is no shortage of suggestions to deal with environmental issues in the Arab world. The UNEP and CAMRE studies and the *Arab Human Development Reports* are full of proposals on how to deal with environmental issues. The heart of the problem lies in the commitment, the paradigm, and in enhanced bureaucratic efficiency.

65 In the Name of Security: In the Name of Peace – Environmental Schizophrenia and the Security Discourse in Israel / Palestine

David Newman

65.1 Introduction

This chapter focuses on the relationship between the military and environmental dimensions of the security discourse in Israel and Palestine. The issue of environmental and human security in Israel and Palestine lags behind the environmental discourse in most parts of the industrialized world. The reconceptualization of the security debate in recent years to include many issues over and beyond the traditional discourse of military security has not impacted Israel and Palestine in a major way. While the traditional military, territorial, and demographic dimensions of the security discourse have continued to play centre stage in the political agenda of the country, the latter – along with a host of other civil society issues – has largely been ignored as constituting a sort of ‘luxury’ issue, subsumed by the ongoing concern with the perceived existential and physical threats of the political conflict. For Israelis, security means safety from suicide bombers (for the individual) and from an existential threat to the State as a whole (for the collective), while for Palestinians, security is safety from Israeli soldiers and roadblocks (for the individual) and from the ongoing process of Occupation (for the collective). The fact that the environment in this region is undergoing a constant process of degradation is, at the most, of concern to aware citizens but is not defined in terms of security. For both Israelis and Palestinians, ‘security’ still belongs to another realm of discourse.

This chapter will address the notion of environmental security in Israel/Palestine from two, inter-linked, perspectives. In the *first* place we will address the wider issues of environmental and ecological threat faced by societies who do not undertake actions aimed at preserving and replenishing scarce resources within the context of a growing population and a semi-arid and arid environment. We identify a form of environmental ‘schizophrenia’ where the so-

ciety and its institutions are aware of the ecological problems, discuss them in great detail, but fail to act accordingly in an effort to prevent further environmental degradation. *Secondly*, we will examine the way in which the existence of the political and military conflict impacts, both directly and indirectly, on environmental management, resulting in an even more serious problem of resource scarcity and degradation than would otherwise have been the case. There are direct and indirect impacts of the conflict on the way that the physical environment is managed, often making use of the securitization discourse as an excuse for bypassing the normal planning and statutory authorities. The chapter concludes with a brief discussion of the implications of conflict resolution and a peace agreement on the environment. While peace is obviously a positive development, the hasty implementation of development projects ‘in the name of peace’ without due recourse to the necessary environmental checks and balances, could result in substantial and irreversible damage to the environment.

65.2 The Traditional Securitization Discourse in Israel

The nature of the Israeli security discourse is closely tied to the perceived existential threat facing the State from its Arab neighbours, the need to maintain a strong military deterrent and the desire to retain control of territories which provide the State with a security/strategic advantage. Contextually, the Israeli security discourse centres on the need for physical security against invasion or terrorism, while the Palestinian need for security is more firmly rooted in the need for economic wellbeing and national self-determination. As such, each views the other as constituting the main threat through which their own human security is threatened and denied. Despite the events

of the past two decades, including peace agreements with both Egypt and Jordan, as well as the (failed) beginnings of dialogue with the Palestinians aimed at finding a political solution to the conflict, the nature of the security discourse has not changed substantially throughout this period.

The traditional notions of military and political security in Israel-Palestine have been the subject of much academic research. This can be typologized in three broad categories:

65.2.1 Military Security

Israel has been in a state of perpetual conflict since its inception over fifty years ago. The main issue on the public agenda throughout that period has been the issue of military security, as defined through the role of the IDF (Israel Defence Forces) and the notion of the “people’s army”. Security is defined at the collective level in terms of the perceived existential threat facing the country from the wider Middle East region and the need to maintain strategic superiority. At the individual level, security is defined through the need to fight terrorist activities and, most recently, the growth in suicide bombings inside Israel’s civilian centres. Kam (2003) defines three major categories of threat facing the country, namely the conventional military capabilities of the Arab states, the non-conventional ballistic and chemical weapons, and the threat of terrorism and guerrilla warfare, the latter two having gained prominence in recent years, as the conventional threat has largely been removed (Kam 2003). This has resulted in the recent construction of the ‘separation fence’ between Israel and parts of the West Bank,¹ the Israeli government proposal to ‘disengage’ from the Gaza Strip,² and the prevention of Palestinians from entering into Israel. Military deterrence is also defined through Israel’s nuclear weapons programme which, despite

the surrounding secrecy, is widely assumed to be the most advanced in the region (Cohen 1998).

65.2.2 Territorial Security

Territory is perceived as constituting a central plank in the Israeli understanding of security. Given the small area of the country (20,000 sq. kms excluding the Occupied Territories) and the fact that in the pre-1967 territorial configuration, the country’s population was concentrated in a narrow coastal strip located between the sea in the west and the West Bank in the east, many Israelis perceive the need for territorial expansion as a guarantee of greater security (Newman 2002). During the 1967 Six Day War, Israel extended its territorial control through the conquest of the Sinai Peninsula, the Golan Heights and the West Bank. These areas were seen as providing a territorial buffer between Israel and her neighbours, although the major buffer – the Sinai Peninsula – was returned to Egypt as part of the Camp David Peace Accords. Successive Israeli governments have argued for the retention of the Golan Heights and the Jordan valley as a guarantee to future security and the creation of “defensible” borders (Horowitz 1975; Al-lon 1976; Cohen 1986). In reality, the peace agreement with Egypt and the introduction of a multinational peace force into the Sinai Peninsula (to the south), the peace agreement with Jordan and the American conquest of Iraq (to the east), and the military superiority with respect to both Lebanon and Syria (to the north and north east) have all but rendered micro-territories increasingly irrelevant to the contemporary security discourse (Newman 1998a). Notwithstanding, Israel continues to use the territorial pawn as a key factor in its negotiations aimed at achieving conflict resolution.

65.2.3 Demographic Security

For many countries, the notion of demographic security relates to the pressures of rapid population growth on a limited resource base, the former outstripping the capabilities of the latter to provide the basic existential resources necessary for the increased population. In Israel and Palestine, notions of demographic security concern the demographic ratios between Jews and Arabs, Israelis and Palestinians, and the respective aspirations of each group to reach demographic majority and thus strengthen the political claims to territory and sovereignty. Israel is self defined as constituting a Jewish state in which eighty

Jerusalem: David Newman: “Barriers or bridges? On Borders, fences and Walls”, in: *Tikkun Magazine*, 18,6.

2 David Newman: “Boxing in Palestinians”, in: *Los Angeles Times*, 4 August 2004: The World Bank Report: *Disengagement, the Palestinian Economy and the Settlements*, 23 June 2004.

percent of the population are Jewish. Together with the Occupied Territories, the Jewish population constitute only 60 percent of the population, while the gap between the two national groups is rapidly closing, given the much faster natural growth rates of the Arab-Palestinian population. For many Israelis, it is the supreme desire to maintain Jewish demographic hegemony which results in their support of territorial separation and a two state solution to the conflict, rather than any altruistic belief in the rights of Palestinian self government and independence. Israeli governments have always supported policies which have encouraged natural growth amongst the Jewish population, as well as policies aimed at encouraging Jewish immigration from throughout the world as a means of retaining demographic superiority (Newman 1998b). The immigration of approximately one million people from the former Soviet Union during the 1990's (increasing the country's population by one fifth in a short space of time) is seen as a major contribution to the demographic notion of security. Israeli government opposition to the right of Palestinian refugee return to Israel is also seen as a central plank in the demography security discourse, even though the respective Israeli - Palestinian population ratios inside pre-1967 (sovereign) Israel are approximately 80:20 and have remained relatively stable (given rapid Arab population growth on the one hand, countered by waves of Jewish immigration on the other) throughout the fifty five years of the existence of the State of Israel.

65.3 Environmental Security in Israel and Palestine

Environmental issues have not occupied a prominent place in the Israeli public agenda. The redefinition of notions of security which have taken place throughout the world, to include energy, food, health, livelihood, rights or global environmental change (Brauch 2003, 2004, 2004a), are not considered part of the "security" discourse as such inside Israel, where the term 'security' retains a narrow and highly focused interpretation. Even in recent years when a new environmental lobby has begun to take shape, their concerns are not considered as being of major national importance.³ This is surprising given the amount of attention given to 'land' related issues in the public

discourse. But, as will be discussed below, this is due to the political, rather than the environmental, significance of land within collective thinking. In the words of Parag (2002) Israel remains an environmental laggard in comparison to most western countries.

65.3.1 The Public Discourse: Environmental Schizophrenia

Israelis could best be described as suffering from a form of environmental schizophrenia, in the sense that there is a large gap between the amount of environmental awareness and socialization instilled into the country's population (especially the younger generation) and that of actual environmental preservation practices. At the level of high school, notions of environment are considered to be of great importance. It is common practice in Israeli schools for children to go on annual school trips and hikes throughout the length and breadth of the country as part of a process of geographic and political socialization, as well as an educational process aimed at increasing environmental awareness.

But when it comes to practice, when these children grow up, they show scant regard for any form of environmental preservation. Despite the problem of water scarcity, Israelis continue to hose their cars in the middle of the summer, irrigate water consuming lawns in the middle of the desert, and to generally waste water as though there was no scarcity.

It is not just at the level of children that notions of environment and ecology are disseminated. Israel boasts some of the world's leading research institutes dealing with issues of arid environments, water scarcity, and climatic change. The Desert Research Institute at Sdeh Boker in the Negev Desert has become one of the leading centres of global research in this field, while the Israeli Water Commission is a global leader in developing and implementing plans for desalination. The country clearly does not lack the necessary expertise or knowledge in dealing with the human security constraints imposed by the environmental realities.

On the face of it, Israel has many environmental agencies and environmental conflicts are gradually becoming part of the public discourse (De Shalit/Talias 1994; Vogel 1998). The Environmental Protection Service (EPS) was created in 1973 which, in turn, eventually gave birth to the Ministry of the Environment in 1988. To date, there are 142 designated nature reserves and 44 national parks spanning some 3,500 square kilometres, including sites of natural her-

3 For a list of Israeli environmental agencies and NGOs at: <http://www.israelemb.org/envlist.htm>.

itage, Mediterranean forests, marine landscapes, sand dunes, freshwater landscapes, desert and crater landscapes, oases, as well as sites of historical and archaeological heritage (Gabbay 2002).

But despite their formal status, the environmental and green lobby in Israel is relatively weak. With the exception of the Public and State Institutions (such as the Society for the Protection of Nature or the Jewish National Fund - both of which also have clear political agendas aimed at land reclamation and control, justifying policies of afforestation and fencing) real grass roots environmental lobby groups have only been founded since the 1990's.⁴ These are relatively small and their effective influence is very limited. The Ministry of Environment is a small, resource starved ministry. The Minister is usually appointed from amongst the junior members of the government. Ministers appointed to this position often see it as no more than a jumping point to a more 'senior' job in the future and, with few exceptions, have little expertise or interest in the particular job.⁵

The Ministry of Environment does have a seat on the regional and national planning commissions and often raises objections to planned developments on environmental grounds. All major infrastructural and regional planning proposals must be accompanied by an environmental impact survey. In most cases however, and despite the raising of objections on the part of the environmental lobby, the development agencies and other economic interests create the sort of coalitions with other government ministry representatives which enables them to go ahead with projects despite the damage that may be caused to the environment. The environmental agencies do not have any veto power in the planning commissions - they have a single vote like all other public Ministries and Agencies and, as such, are normally outvoted by development oriented agencies.

A good example of the environment - development dilemma in Israel has been the construction of the new north to south Trans-Israel highway. From the moment that the plans were announced in the early 1990's, the environmental agencies joined forces in an attempt to prevent its construction. They argued that the construction of this major highway would destroy some of Israel's few remaining areas of open space and cause ecological havoc to localized nature and water resources.⁶ The environmental

lobby further argued that rather than relieve congestion on the existing roads, the construction of the new road would bring in its wake an even further increase in the number of cars on the road. Despite these objections, the government and its associated planning agencies approved the project, albeit with some minor modifications taking into account some of the major environmental issues.

Another recent example has been the construction of Israel's new national airport, 'Natbag 2000'. This major infrastructural project was the subject of a number of environmental impact surveys. In 2002, the airport development agency was obligated to construct a new sewage purification and treatment plant to go into operation once the airport was opened, as a means of dealing with all the additional environmental hazards and wastes which would result from the operation of this facility, but this had not been completed by the time of opening (in November 2004). Despite the objections from the environmental agencies, the opening of this major facility went ahead with a vague promise that the sewage system would be developed.⁷

How do we explain this gap between environmental socialization and awareness on the one hand, and the lack of good environmental practices on the other? On the one hand (as we will discuss below) notions of security are related to military and strategic issues. As such, notions of threat, as contrasted with notions of aesthetics, are not associated with the environment. Moreover, this is an increasingly laissez faire capitalist society in which notions of the common good are gradually taking second place to the objectives of economic development and venture capital. The latter agencies and private firms have much more, in terms of finance and power, to offer the decision makers than do the relatively young and inexperienced environmental lobbies and, as such, the latter groups are often unsuccessful in their attempts to prevent harmful construction projects from taking place.

65.4 Geopolitics and Discourses of Water Security

Issues of environmental and military strategic security are interlinked through the water geopolitics of the region. Since the establishment of Israel in 1948, the country's population has grown tenfold from approximately six hundred thousand to over six million inhabitants. Moreover, the existing population has increasingly adopted western water consumption patterns, with more washing machines and dish washers, more cars to wash, more lawns to irrigate, while former traditional societies, such as the Bedouin communities who learnt to live within a framework of stringent water limitations for thousands of years, have also begun to adopt western consumption patterns. Against this backdrop of a huge increase in demand for water, the region has suffered a growing number of drought years, significantly reducing the available supply of water for domestic consumption purposes. The growing gap between supply and demand has brought the country to extreme crisis situations on a number of occasions during the past decade, with the Kineret reservoir falling below its red line, beyond which no more water is meant to be pumped out of the lake for fear of salinity and irreversible damage, while similar situations have been reported in each of the country's main underground water aquifers.

Given the nature of the political relations between Israel and her neighbours, the lack of sufficient water resources for basic consumption needs is perceived as constituting a major geopolitical source of tension and friction. In the eyes of some analysts, the struggle for water is as likely to cause regional conflict during the next decade as are the contentious issues of oil and/or religious fundamentalism (Allan 1992; Kliot 1994; Stauffer, 1996). Within the specific context of the Arab-Israel and the Israel-Palestine conflict, water has figured prominently as a source of geopolitical contention (Shapland 1997). With the exception of Egypt, water has been a source of friction and conflict between Israel and all of her neighbours, including Jordan, Syria, Lebanon, and the Palestinian Authority.

In the case of Jordan, issues related to water and the environment figures prominently in the peace treaty between the two countries.⁸ Israel agreed, despite its own water shortage, to transfer 50 million cubic metres of water per annum to Jordan, as well as

developing joint projects for research into the more efficient usage of scarce water resources in this region. In the case of Syria, the Yarmouk River, flowing into the Jordan River, has - in the past - constituted an issue of friction between riparian States. In 1965, Syria began a dam construction project on the Yarmouk which would effectively have completely ceased the flow of water over the border into the Jordan River. Israel responded by bombing the dam and stating that any attempt to interfere in the free flow of water would be interpreted as a legitimate *casus belli*. Israel's occupation of the Golan Heights in the June 1967 War enabled it to control some important water sources such as the Banias Springs, as well as other melt flow from Mount Hermon. Much of the informal negotiations which have taken place between Israeli and Syrian representatives over potential peace agreements in the future have dealt with the issue of water as a major topic, second only in importance to the military security arrangements.⁹

In the case of Lebanon, Israel's invasion of that country in 1982 was originally intended only to reach as far as the river Litani (although, in effect, the invasion went as far as Beirut). Following Israel's pull back from Beirut to the Litani, there were suggestions on the part of both Lebanon and Syria that Israel was planning to exploit the free flowing waters from this river and to divert some of them southwards through channels to Israel (Amery 1993). In the early twentieth century (1919-1920), when power in this region was transferred from the defeated Ottoman Empire to the British and French mandate authorities, the British government attempted to demarcate the boundary between the two along the River Litani so that they too would have access to these critical water resources - in a period when the nature of water scarcity vis-à-vis a relatively small local population was nowhere near as critical as it is today.

Control of water is also central to the Israeli-Palestinian negotiations over future territorial configurations and has been the subject of numerous publications (Elmusa 1993; Shuval 1996; Shapland 1997; Amery/Wolf 2000; Newman 2000; Allan 2003d; Dombrowski 2003). Numerous discussions have been held since the signing of the Oslo Accords in 1993 and 1995 in an attempt to reach an acceptable solution concerning the distribution of water resources

9 Some anti-withdrawal groups use the strategic importance of water to persuade the Israeli public and the government not to withdraw from this region. See at: <<http://www.golan.org.il/water.html>>.

8 See Israel-Jordan Peace Treaty, Annex IV - Environment.

between Israel and a future independent Palestinian State. These talks, held under the international auspices of the Canadian government as part of the multilateral peace talks (Kaye 2001), focused on the quotas which each side would be allowed to exploit from the underground water aquifers which underlie both Israel and parts of the West Bank. In the past, these underground water sources have proved to be a major point of contention, as Palestinians have accused the Israeli Administration of using this water for the purposes of settlement construction while, at the same time, refusing to allow them to drill new wells for the basic subsistence needs of their own growing towns and village.¹⁰ The international partners to the water negotiations attempted, unsuccessfully, to persuade both sides to develop joint control and management of this important trans-boundary resource in such a way that they would derive mutual benefit from the arrangement, coupled with the more efficient exploitation of this valuable scarce resource. The two sides would become inter-dependent on each other and thus less likely to enter into renewed conflict in the future, given the danger of destroying their own water infrastructure and not just that of the other side.

During the past two decades, there have been proposals aimed at importing water from the major water surplus country in the region, Turkey.¹¹ While the possibility of a land pipeline has been ruled out because it would have to run through Syria, the laying of a pipeline along the floor of the Mediterranean Sea was considered. This too was rejected on political grounds when it became clear at one stage that the Turkish government insisted on having a transit station for the transfer of water in the occupied zone of Northern Cyprus. Originally, it was assumed that the import of water would be cheaper for the consumer than the construction of desalination plants in Israel. However, given the improved and cheaper technology for powering the desalination plants, the Israeli government eventually authorized their con-

struction assuming a similar price per cubic metre of water as that of the imported water. But given their desire not to worsen relations with Turkey who had become an important regional and strategic ally, the Israeli government agreed to sign an agreement for the import of a limited amount of water at an undefined date in the future.

The politics of water inside Israel also plays a major role in the way that this resource is managed. Given the major focus on agriculture in the first decades of Statehood (partly due to the national expression of the “return to the ancient land” and partly because of the desire to be totally self-sufficient), water was provided to the agricultural sector at a greatly reduced cost. During the past decade, Israel has moved out of agricultural branches of production which require high water inputs, although the agricultural sector continues to lobby, quite effectively, for lower costs, resulting in some cases in considerable water wastage. Notwithstanding, the siege mentality which led Israel to insist on water and agricultural independence fifty years ago is no longer relevant in a globalized world with easy access to most markets and, as such, is becoming less prominent in the Israeli security discourse. This is particularly the case with respect to water heavy products, such as cotton and even the famous Israeli-Jaffa citrus orchards, a product which is now becoming less prominent throughout the world. At the same time, Israel was the pioneer in the development of trickle irrigation techniques which greatly reduced the amount of water necessary for agricultural production, as well as the use of brackish water for certain crops.

65.5 Environmental Security and the Israel-Palestine Conflict

The Israel-Palestine conflict impacts the environment both directly and indirectly. This is as true of the conflict itself as it is of the many attempts to bring about conflict resolution and move towards a lasting peace in the region. Peace and conflict resolution brings with it the opportunity to deal with a host of social, educational, and environmental issues which have largely been pushed aside in previous periods due to the priority given to the physical and military dimensions of the security discourse. However, the supremacy of the security and conflict as well as the peace and cooperation discourses means that large-scale developmental and infrastructural projects which are put forward as a means of either ensuring security or

10 For a full analysis of the geopolitics of the West Bank waters, see the United Nations University project: *Hydropolitics along the Jordan River: Scarce water and its impact on the Arab-Israeli conflict*, at: <<http://www.unu.edu/unupress/unupbooks/80859e/80859E01.htm>>.

promoting peace will have a strong chance of overriding any environment or ecological related objections which may arise as a result of their implementation.

65.5.1 Securitization Discourses and the 'National Interest'

One area in which the conflict plays an important role in either degrading or preserving the environment is the virtual monopoly of the defence and military establishment in determining land use and land zoning. According to Oren and Newman (2005) almost 50% of the land surface inside Israel (not including the Occupied Territories) is influenced, directly or indirectly, by the demands and priorities of the defence establishment. This ability to use the defence-securitization discourse as a 'national' discourse overriding all other civilian and economic development interests means that the defence establishment maintains a monopoly over almost all spatial development throughout the country (Baumer 1997; Yanai 2000; Oren 2002). The role of the army and the defence establishment in determining land use zoning and development in the 'name of security', or the role of investors and development agencies in promoting large-scale infrastructural projects in the 'name of peace', can have major impacts upon the local environment, some positive but many negative (Blacksell/Reynolds 1987; Soffer/Minghi 1986). Such plans are often pushed through at great speed, in certain instances even bypassing the normal planning and legislative processes as they are portrayed as serving national objectives. In certain cases, the reverse may be true.

In some cases, the military use of land - for the purposes of military camps, or the construction of the separation fence between Israel and the West Bank - can have a serious detrimental effect on the physical landscape and the ecological balance, and will automatically be opposed by the environmental lobby. In other cases, the army insistence on leaving land untouched for training purposes (especially non-vegetated open areas in the southern coastal sand dunes), prevents its alternative use and despoliation by economic developers.

The securitization discourse is also linked with a broader discourse of 'national interest', even where the specific purpose is not always directly related to matters of military security or defence. Two of the largest projects of the past decade which have been promoted by Israeli governments have been, respectively, the mass construction of housing in the 1990's

for the one million new immigrants from the former Soviet Union, and the construction of the separation fence separating Israel from the West Bank. In both cases, the use of the 'national imperative' and 'securitization' needs of the country, as well as the immediacy of the projects, have enabled the government to undertake emergency procedures which have bypassed the civilian Planning Authorities. This has had major implications with respect to the conversion of land uses between functions (particularly from rural and agricultural to housing, developmental and commercial), which otherwise would have taken a great deal of time, discussion, and bureaucracy within the statutory planning authorities.

The implementation of both national projects has had an immediate impact on the country's fragile environmental resources. In the case of the mass construction for the Russian immigrants, the then Minister of National Infrastructure (currently Prime Minister), Ariel Sharon, succeeded in gaining emergency powers for the construction of new housing developments without the need to get normal planning authorization from either the Israel Lands Authority or the statutory planning commissions on the grounds of 'national emergency requirements' - opening the door for land privatization in Israel (in a country where, for political reasons of land control, over 90 percent of the land has been State owned - a fact which may have prevented even greater environmental degradation in the past) (Alterman 2002). In the case of the rapid construction of the Separation fence, a large swathe of land was cleared of all previous usages, including the destruction of orchards and the conversion of agricultural lands into a brutal defensive landscape consisting of barbed wire fences, concrete walls, and patrol roads. The military and defence authorities are thus able to use the argument of 'national interest' as a means of promoting or opposing many projects relating to infrastructural development or land use, a power which is not possessed by any of the civilian planning agencies.

Despite the fact that the army is such a major user of land, there is no national masterplan, even taking into account different security and strategic scenarios ranging from conflict to peace, for the security land uses in their broadest sense. The Defence establishment works on an ad hoc basis, depending on specific needs (as self-defined within the system).

In most cases, any area of land deemed as necessary for defensive purposes - however defined - is not subject to the normal scrutiny or veto power of the civilian planning authorities. But in cases of civil-

ian development, planning permission has to be coordinated with the defence authorities and they have a veto power over all civilian related development if, as they often argue, such development is detrimental to the security interests of the State, without the need to elaborate precisely what these interests are. At the same time, all regional and national plans have to be submitted to the Defence Authorities prior to their being tabled before the relevant committees. At the local and regional levels, the Defence Ministry has automatic power of veto, while at the national level it is rare for decisions to be made which negate the Defence establishment position, with agreement over major developmental issues being reached at ministerial and cabinet level.

65.5.2 The Environmental Impact of Occupation

For as long as Israel continues to occupy the West Bank and Gaza Strip, she is responsible for the management of all civilian affairs, including the economic, social, governance, and environmental issues. But given the fact that even inside Israel proper, the environmental issues are largely neglected, the Civil Administration of the Military Government (the responsible authority for the Occupied Territories) paid scant attention to such matters. For their part, the Palestinian Authority which replaced the Military Government in parts of the region following the implementation of the Oslo Accords and partial transfer of power in the mid-1990's, was too involved in creating a new administration for any serious attention to be given to what was, and continues to be, perceived as issues of secondary importance, given the continued struggle for independence and self governance. Neither does the Palestinian Authority have the necessary expertise to deal with a host of environmental issues, ranging from landscape preservation, efficient use and conservation of scarce resources, particularly water, or the preparation of environmental and ecological surveys relevant to future development and construction plans for a new State which will have to improve housing conditions and absorb tens of thousands of returning refugees.

In their report on environmental degradation, Isaac and Ghanyem (2004) lay the blame for the extremely poor situation of the local environment directly on Israeli colonization policies.¹² The report attributes the depletion of water resources, continued desertification, deforestation and the uprooting of trees, and general pollution within the West Bank, as

a direct outcome of Israeli government policies aimed at ensuring physical security (through the construction of bypass roads or the uprooting of orchards along existing roads) or furthering settlement activity (through the transfer of green areas into construction sites, the exploitation of limited local water resources, and the disposal of industrial and domestic wastage without proper treatment facilities) (Foundation for Middle East Peace 1998).

The construction of Israeli settlements throughout the region has had a major impact on the local environment (Newman 1989; Isaac/Selby, 1996; Qumsieh 1998). In the first place, the settlements have taken up a large amount of open land. Given the western suburban nature of the Israeli settlements, population densities are much lower than amongst the neighbouring Palestinian villages and towns and, as such, the amount of land consumed per family for settlement purposes is exponentially greater than in the neighbouring communities (Newman 1996). This is accompanied by the preparation of access roads, security fences, and additional infrastructural capacity which eats into the available open land resources. There has also been much dispute over the water rights of the new settlements, in many cases tapping into local water sources which are already depleted and, ironically, from which some of the neighbouring Palestinian communities are forbidden the drilling of new wells because of the 'dangers to the aquifer' which will result from over exploitation of a scarce resource.

Israel has also used afforestation as an important political means of land control. The "return to the land" dimension of the state formation process has resulted in a great deal of reforestation throughout Israel and Palestine. But in many cases, the objective of turning the brown arid desert into a green landscape has been accompanied by a political objective of asserting control over land, or preventing the use of land by Arab settlements in empty or vacant areas. Cohen (1993) has shown how the politics of planting has also been implemented in frontier and border regions, both as a territorial demarcator and also as a means of preventing the use of this land by groups whom the State deems as undesirable. Ironically, much of the afforestation, especially in the southern and more arid parts of the country, has caused some

12 For an analysis of the environmental problems in Palestine (West Bank and Gaza Strip), see: PENA (Palestinian Environmental Authority): *Environmental Strategy Plan*, Ramallah/Gaza, October 1998.

long-term ecological damage, given the non-suitability of some of the tree types used for this purpose. The same happened in the Hula swamp lands in the north of Israel. A century of over-fertilization and over-working of this small area, for many years shown to visitors as a miracle of reclamation, has now reverted to its original swamp characteristics through restoration activities.¹³

65.5.3 The Environmental Threat of Peace

It is often assumed that the transition of a region from conflict to peace will, somehow automatically, have a positive spill over effect on a host of civilian issues, including greater attention to environmental protection and conservation. Conca and Dabelko (2002) note that the issue of environmental cooperation has gone almost unexplored as a means of peacemaking, even though it opens several effective channels, such as: enhancing trust, establishing habits of cooperation, lengthening the time horizons of decision makers, forging cooperative trans-societal linkages, and creating shared regional norms and identities. Post-conflict situations are often accompanied by a desire to undertake major construction and investment projects 'in the name of peace', replacing what was done in the past 'in the name of security', despite the fact that their rapid implementation does not always take into account the negative impact on the already depleted environmental resources.

The experience of Israel and Palestine in the first decade following the implementation of the Oslo Accords is a good example of these problems. The lack of coordination between the Israeli and Palestinian authorities, when many civilian authorities and functions were handed over from the Israeli military administration to the Palestinian Authority, even resulted in the exacerbation of some environmental problems. One would have assumed that in those areas which affect the quality of life of both peoples and which have no direct implications for the political process per se, such as the joint preservation of the local environment, it would have been easiest to create new modes of cooperation. Environmental spill over from those areas under control of the Palestinian Authority should have been an obvious area of cooperation.¹⁴ But here too, the nature and extent of

cooperation is seen by each side as part of a political one-upmanship. Complaints by one side to the other are couched in political terms, blaming the other side for negatively impacting the quality of life of their own citizens, and demanding, rather than suggesting, that solutions be found immediately. What could have been a focus for new cooperative modes of activity are transformed into part of the conflict, instead of being used as a means of overcoming bridges of animosity and mutual suspicions.

Of greatest significance has been the flow of untreated domestic and industrial waste from the West Bank into Israel. This brings problems of noxious elements and provides the breeding places for mosquitoes and other human irritants. The Israeli authorities accuse the Palestinian authorities of not dealing adequately with problems of waste disposal and treatment, using this as an example of the "inability" of the PA to manage its own affairs.¹⁵ For their part, the PA points to the interference of the Israeli military authorities in their attempts to create new infrastructural projects as well as the fact that they lack the necessary economic resources for putting such programmes into effect. The PA requests the assistance of international environmental agencies to deal with these problems, arguing that they do not have the expertise or the necessary resources.

Environmentalists are particularly concerned with the expected economic effects of a peace agreement. The short period following the signing of the Oslo Accords was enough to demonstrate the large number of capital venture projects - from both local and international investors - waiting to get through the door once a situation of political stability was to emerge. In particular, one can expect major housing and construction projects, as well as investment in large tourism resorts. These will be implemented in haste, with the full backing of both Israeli and Palestinian governments eager to reap the economic dividends of peace and with little, if any, environmental checks and balances. Thus the coming of peace will prove to be a major challenge for the environmental security of the inhabitants of the region who may find that one security threat (the military and the

14 At the time of writing, this author is directing a project on behalf of USIP (the United States Institute of Peace) examining the potential role of future Israel-Palestine borders as bridges and points of contact, with a particular focus on trans-boundary environmental cooperation.

15 David Newman: "The politics of mosquitos", in: *Jerusalem Post*, 3 July 1998.

defensive) has simply been replaced with a new one (the environmental and the ecological).

Most recently, the plans for the relocation of the evacuated Gaza Strip settlers has also run into environmental problems. The government has announced its plans to construct alternative housing on the Nizana sand dunes near the coastal town of Ashqelon. But this is opposed by the environmental lobbies which argue that this will result in the destruction of one of the last remaining open sand dune areas in the country. In this case too, the government is using arguments of 'political and national need' to dismiss these valid environmental arguments.¹⁶

Finally, there has also been concern with the attempts of some Israeli companies to move their development projects to neighbouring countries and thus bypass Israeli environmental laws. It was suggested that the much touted Red Sea - Dead Sea Canal be built entirely within Jordan as a means of avoiding any potential environmental opposition on the Israeli side of the border (Bromberg/Twite 2002)

Clearly there is a need for both the Israeli and the Palestinian populations to become more aware of the security dimensions of the environmental and ecological threat facing both populations on an equal basis. The discourse needs to be transformed from that of a 'problem' to that of a 'threat', from a mundane quality of life issue to one which, if not dealt with, can cause harm to the existing population. The move towards conflict resolution and an eventual peace agreement can be used as a means of changing the environmental security discourse, but only if it is a joint effort on the part of both populations, probably with the assistance of international environmental agencies and foreign governments who are actively involved in attempting to reach a lasting political solution. The peace discourse requires that basic perceptions of what constitutes "security" in this troubled region still have to undergo structural change.

65.6 Concluding Comments

This chapter has focused on the notions of environmental security facing Israeli and Palestinian populations. Other issues of 'soft' security, such as economic livelihood, access to health and housing etc; have not been addressed in this chapter although

they, too, suffer from the hegemonic discourse given to the military and defensive securitization discourse in Israel and Palestine. Notwithstanding, Israel's welfare state policies (although these are being threatened under the current move towards a *laissez faire* economy with a great deal of privatization along Thatcherist lines) posits these issues as constituting no more than a social or economic problem rather than a threat to the security and livelihood of the people. This is particularly the case with regard to the first world socio-economic conditions of the Israeli population, although less so with regard to the third world (and worsening) conditions of the Palestinian population. The latter problems are, in turn, directly related to the political conflict, the extent to which the Palestinians are able to exercise self government, find places of employment inside Israel (or are cut off from this market place due to separation barriers and security fears on the part of Israel) and are enabled to create their own civil society institutions. The human security issues facing the Palestinian population constitute basic needs and are much more directly related to the outcome of the political conflict than are those facing the Israeli population. That does not mean to say that there is no connection between "hard" and "soft" security issues for the Israeli population. There is a constant discourse concerning the distribution of the national budget between defence related and civil society (education, health, welfare) related issues in the public discourse, but this is a question of degree and quality of life for Israelis, while for Palestinians it is increasingly becoming a basic existential and hard core security issue. These non-environmental, but nevertheless 'soft', security issues also need to be addressed as part of the ongoing security debate in Israel and Palestine. Notwithstanding, the growing economic gap between the 'haves' and 'have-nots' in Israeli society, along with a significant increase in the public discourse concerning environmental issues, is creating public awareness to the severity of these problems. But they will never replace the 'hard core' military and defensive issue for as long as the Israel-Palestine conflict (and peace process) continues to determine the public agenda.

66 Security and Environment and the Israel-Palestine Conflict

Robin Twite¹

66.1 The Environment as a Political Issue

The long conflict between Israelis and Palestinians is fuelled by many different factors: the memory of past violence, disputes over land, opposing historical narratives, religious dogmatism, demographic fears about the increasing number of the 'other' (more especially on the Israeli side), to name but a few.

At the heart of the conflict is the struggle over land, which in its turn relates to security since each community wishes to ensure its safety by ensuring that it controls a viable geographic area and has access to natural assets such as water. On each side are those who believe that only by controlling as much land as possible can their future be secure. This attitude was neatly summed up in a car sticker which appeared in the late nineties when the Israeli government was about to hand over Hebron, aside from the enclave occupied by settlers in the centre of the city, to Palestinian control. It read, in Hebrew of course, 'Hebron is Tel Aviv' - and was meant to imply that if

Israel gave up voluntarily its control of any part of the 'Holy Land' it would not be long before the Palestinians would claim that they had a right to the whole of Israel. Israeli security, according to this view, depends upon holding on to as large an area of the land between the Jordan and the Mediterranean as is possible.

From the Palestinian side similar extreme views can be heard from the leadership of Hamas, denying the right of Israel to prevent the return of refugees who fled in 1948 and rejecting the recognition of Israel which had been agreed by Chairman Yasser Arafat and the PLO in the peace accords. According to such views the Land of Palestine is seen as being an integral part of the Moslem world, inalienable, and not to be negotiated whatever the realities on the ground.

In their on-going conflict extremists on both sides have made use of the environmental argument to persuade the wider public that they must avoid compromise and that their security, their very existence, is threatened by making concessions. Mutual suspicion is at the heart of these arguments and conflicting claims are purposely fuelled by statements in the media which serve to promote fear and hostility. In the minds of the more extreme on both sides 'they', the other party, the enemy, aim only to "destroy us, to take our land, to limit and corrupt our supply of fresh water, to deliberately poison the very air we 'breathe', as a correspondent observed in 2002 in the *Jerusalem Post*. The Israeli public, suffering as it does from the traumas imposed upon it by the history of the Jewish people and the many wars fought since the establishment of the State of Israel in 1948, is particularly susceptible to such reasoning.

There is no doubt that in Israel and in Palestine perceived threats to environmental security are exploited for political reasons. Exaggeration of the dangers which each side poses to the other's long-term environmental well-being is deliberately practised in order to secure short-term political gain. Just as in the

1 This article is based primarily upon personal experience as director of the environment and water programme at the Israel Palestine Center for Research and Information (IPCRI) in Jerusalem. The programme is designed to promote understanding and cooperation between Israelis and Palestinians on environmental issues and has been in existence for over a decade. It is financed by grants from the international community and private foundations and has involved organizing many seminars and conferences on specific issues as well as promoting joint research projects. In October 2004 a major academic conference on water problems in the region held in Turkey attracted about 200 participants from Israel, Jordan, Palestine, Turkey and the international community. The proceedings were published in 2005 by IPCRI and by *Springer* in a peer reviewed book edited by Shual and Dweik (2007). Working on these activities over a sustained period has given the author the chance to assess the causes of conflict and the opportunities for future cooperation.

world wide context, the threats of terrorist action is used to obtain public approval in the USA and elsewhere for actions which would not normally be accepted without demure since they diminish individual freedom. Making a bogeyman to frighten people can be a significant and powerful tool for political manipulation. This is not to say that there are not genuine threats to environmental security in the region, but that these can be, and sometimes are, deliberately over-emphasized by groups who care not so much about the environment as about seeing their cause succeed. It is worthwhile looking at the question of how real these fears are, where there is real cause for concern, and where there is not.²

66.2 Perceptions of Regional Dangers to Environmental Security

Both Israelis and Palestinians are afraid that their environment and quality of life is being, or could be, compromised by the action of the 'other'. There are certain concerns which are especially important for both sides. The two most evident today relate to water and the ways in which solid and hazardous waste are disposed of. In the last two years an additional adverse element has been added to the situation in the construction by Israel of the new 'separation fence' as it is known in Israel official terminology, or wall (as it is popularly known among Palestinians), being built between Israel and the Palestinian areas in the West Bank. The fact that the fence is largely built on Palestinian land has added yet more fear and suspicion to the relationship between the two communities. It is viewed quite differently by the two parties. It is seen as improving the security of the State by most Israelis, and by Palestinians as harmful to their quality of life, affecting the livelihood of those living near it, and damaging the environment for no good reason.

66.2.1 Water

The idea that a perceived enemy can control the supply of water to your home or to your farm, is deeply

worrying. This fear affects both Israelis and Palestinians. The fear of being deprived of water is an atavistic one. Israel has always been concerned that if it did not have control over its water sources, neighbouring states might cut the supply. These fears are given added point by the fact that so much of Israel's surface water reaches the country from sources in Syria and Lebanon, and its ground water from aquifers which it shares with the Palestinians. Israel's policies are designed to protect the status quo. The violence of the Israeli reaction when in 2002 the Lebanese government sought to divert for their own purposes part of the present flow of water from their country into the Jordan, showed how strong the drive to maintain control over water is. Fears of water contamination by terrorists are also taken very seriously. A special unit within the Israeli Defence establishment exists solely to guard against any attempt to introduce toxins into the water system or otherwise interfere with water supply. The work of this unit includes pioneering research designed to ensure that systems which have been attacked can be detoxified within a short period of time. Some Israeli experts undoubtedly believe that the failure of the Palestinian authorities to treat urban waste water (Israel treats over 65% of its urban waste water and plans to increase this figure dramatically over the next two years) derives not only from the difficulties experienced as a result of the on-going conflict, but from a deliberate intention to use the fact that untreated waste water can pollute the shared aquifer as a bargaining card. This contention is disputed by the Palestinians who claim they have done their best, but that violence and political tension have made it impossible to deal with the problem effectively. Whatever the truth of this, raw sewage still flows into the wadis of the West Bank and into the Mediterranean Sea from Gaza. This dispute about what is the real state of affairs is derives directly from the atmosphere of suspicion which exists between the two sides.

On the Palestinian side, fears that Israel will use its control over water supply to control them in the event of an emergency are always evident. This was demonstrated recently when an Israeli offer to build a desalination plant and supply water to the north of the West Bank was greeted suspiciously by Palestinians who were concerned that if such a plant operated under Israeli control, the Israelis might be able to "turn off the tap" if a confrontational situation should arise.

Palestinian suspicions about Israeli intentions are fed by their feeling that Israel is taking far too large a

2 This chapter is based on both personal observations of the author and the following scientific sources: Bulloch/Darwish, 1993; Curtin/Charrier 2004; Daibes 2003; Haavisto 2003: 535-562; Jägerskog 2003; National Research Council 1999; Twite 2003: 563-572; UNEP 2003c.

share of the water from the mountain aquifer which runs beneath the land upon which they live, as well as beneath Israel. They claim their human rights to the water are being infringed upon and though international law on this point is by no means clear, the fact is that there is among them an abiding sense of having been cheated out of something that belongs to them by right (see Dajani's chapter in this volume).

However, in spite of this somewhat forbidding situation, professionals in the field from both Israel and Palestine have recognised that they need to cooperate. While Israel has maintained control, the Israeli Water Authority has sought to ensure that water supply to the Palestinians is maintained, and allegations that cutting off water supply to Palestinian communities in order to bring them to heel has been a practice of the Israeli authorities have not been easy to prove. Though of course the violent conflict of the past five years has damaged infrastructure in the Palestinian areas (chap. 67 by Dajani).

The Joint Israeli/Palestinian Water Committee established after the Oslo Peace Accord still functions and handles day-to-day business of water supply and quality control. Mekorot, the Israeli company which acts as the executive arm of the Water Commission in supplying water to Palestinians, services water networks in many parts of Palestine in collaboration with Palestinian local authorities. These are positive realities on the ground.

Another encouraging fact is that though the Multilateral Initiative relating to environment which was initiated after Madrid has largely collapsed, the part of it which relates to water concerns is still active. The Multilateral Initiative was designed to provide a forum where representatives of the international community met with Israelis and Palestinians to undertake action which would help improve the situation with the help of outside donors. In the field of water management some useful, though relatively minor, things have been done (notably in the fields of training and the sharing of data)³.

It is also worth noting that shortly after the second intifada broke out in 2000, both the Israeli Water Commissioner and the Head of the Palestinian Water Authority signed a joint declaration asking all concerned in the violence to try to avoid damage to water installations. Plans outlined by the Israeli Water Commissioner at a conference in Stockholm in

August 2004 include the supply of desalinated water to the Palestinian Authority and encouraging the Authority to treat waste water from Palestinian towns to a level where it can be used to replace fresh water in order to meet almost all agricultural needs.

To sum up the reasons for conflict in the area of water rights, water supply and distribution are clear but there are some encouraging facts also in evidence. These, in effect, constitute a recognition that both sides have to work together whether they want to or not. But suspicion between the two sides runs deep. While professionals on both sides appear reasonably optimistic, the general public and politicians are sceptical and easily lend an ear to voices which warn against the intentions of the other side.

66.2.2 Solid and Hazardous Waste

All advanced societies today are concerned with the amount of waste they generate and what to do with it. Israel and Palestine, though at different stages of development, both face considerable problems in this area. In Israel the problem of solid waste disposal has been tackled with resolution over the last decade; almost all small dumps have been closed and replaced by large 'state-of-the-art' sites and a central facility for the disposal of hazardous waste created at Ramat Hovav in the Negev. But there remain problems. Not all hazardous waste reaches the central facility and little has been done to clear up the sites that are now closed, some of which are highly toxic. .

In the West Bank and Gaza the situation is deplorable. Of over two hundred and fifty unlicensed dumps in operation, many are a hazard to health. The Palestinian Authority, with the support of the World Bank, attempted to deal with this problem by planning for the construction of two large state-of-the-art facilities for storing waste, one near Jenin in the North of the West Bank and one near Hebron in the south. These were to have collected waste from large areas and in effect solved the problems of the north and south of the West Bank (though not of Jerusalem and its environs). In the event, the facility at Jenin was almost completed but its utilization has been prevented by the Intifada since 2000, while the one in Hebron was never even started because of disputes about finding a suitable site. Israeli interventions in this area have not been helpful since the proliferation of road blocks, limitations on the movement of trucks, and other factors of this kind have made it still more difficult for waste to be disposed of effectively.

3 Jacob Keidar: "Israeli/Palestinian Water Issues", paper for seminar of water problems in Israel and Palestine delivered at the Stockholm Water Week, August 2004.

In addition, hazardous waste is not properly recovered and dealt with. While all hazardous materials entering both Israel and the Palestinian Authority areas are monitored by Israel and the Palestinian Authority when they come into country and certificates issued, the ultimate fate of the hazardous material going to Palestinian recipients is not monitored. Arrangements envisaged under the Oslo Agreements for the treatment of waste material resulting from the use of such hazardous materials have not been carried out. Fortunately, the amount of hazardous material used by Palestinian factories and hospitals is relatively small, but failure to treat it poses an environmental threat both to water quality and to public health.

Palestinians also regularly claim that Israel has secretly buried some of its hazardous waste in the West Bank (chap. 67 by Dajani). It is undoubtedly true that there have been incidents in the last few years in which hazardous waste was transferred to West Bank locations, but there is no proof that this is government policy. It seems that this is the work of contractors anxious to avoid the costs of having the

waste destroyed at the Ramat Hovav facility, which is high.

Over and above the question of hazardous substances used in industrial processes or in hospitals, there remains the question never discussed openly in Israel but raised from time to time in Palestinian and other Arab media: the disposal of waste from the atomic facility at Dimona. Palestinians claim that there is a threat to their security and rumours circulate to the effect that such wastes have been buried secretly in the West Bank by Israeli contractors. There is, however, no way of knowing what the facts are in this case.

What is not in doubt is that the failure of the Israelis and Palestinians to work together on these issues regarding waste constitutes a threat to public health and to the quality of life of both communities, since diseases and noxious insects can readily travel from a Palestinian waste disposal site to Israeli communities, and practices like burning waste simply because there is nowhere to store it are harmful not only to the Palestinians living nearby but also to the wider community of both Palestinians and Israelis.

While in relation to water there are encouraging signs of cooperation, no such positive features can be currently perceived in relation to more far-reaching environmental cooperation, though there is talk of reviving the Environmental Technical Committee which was established as part of the Oslo agreements to help work on environmental problems and which ceased to function in 1998.

66.2.3 The Security Fence and its Environmental Implications

The security “fence” (only a small proportion of the “fence” is an actual wall and the rest a three meter high chain link barrier protected by ditches) is undoubtedly environmentally detrimental. There seems little doubt that it will adversely affect the flow of surface water, it takes up a great deal of land and it is visually repulsive. In addition large numbers of Palestinian farmers are cut off from their land by the wall and their freedom of movement to their land restricted... Arguments for its construction derive, of course, from the Israeli belief that it will help to prevent suicide bombers from crossing into Israel, and it

has to be remembered that about 1,000 Israelis have been killed by suicide bombers or other violence in the period from 2000 to 2004.

These arguments would be more convincing if the wall had not been built almost entirely on land which was part of the West Bank before 1967, so that it appears to be designed as a ‘land grab’. Israeli official sources claim that water supply has been maintained to Palestinian villages affected by the fence and that only 4 per cent of the wells supplying the West Bank will be cut off from the West Bank by the fence. They also claim that provisions have been made for farmers cut off from their land by the wall to cross the fence at special checkpoints (something Palestinians dispute), and that discussion taking place in January 2005 may result in substantial readjustments to the route to be taken by the fence so as to take account of Palestinian objections. Palestinian sources dispute most of this and more especially the account of the number of wells affected (see Dajani, *op.cit.*).

From an environmental point of view, the fence has nothing to recommend it. But from a security point of view Israel may well feel that it has already cut the number of attacks on its citizens by Palestini-

Figure 66.3: The Security Fence Separating Israel and the West Bank. Photo © Gershon Baskin. Publication permission was granted.

ans. There have been far fewer attacks in those areas where the fence is already completed. Israel has also shown a limited willingness to change the route in order to accommodate particular objections by specific Palestinian communities. But this is a case where the claims of security (as far as Israel is concerned) and the claims of the environment are in head-on collision. No effective solution to this problem is even remotely on the horizon at the time of writing, though a dramatic improvement in the general political climate could in the long run render the wall superfluous.

66.2.4 Mitigating the Adverse Effect of Potential or Actual Environmental Conflict in Israel and Palestine

While it is clear that environmental issues are adversarial in the region, opinions differ as to how far they might become the source of actual violent conflict. A variety of opinions have been expressed, but the majority opinion holds that it is not likely that the countries of the region would actually become involved in prolonged armed conflict because of dis-

putes over such things as water rights, and distribution, or the adverse effect of the security fence. There might be occasional incidents, but not more. However, whether or not actual violence results from environmental concerns and their perceived relationship to security, more can, and should be done to provide mechanisms for the diffusion of potentially dangerous disputes.

66.2.5 New Mechanisms for Conflict Management and Resolution

Given the amount of suspicion there is between Israelis and Palestinians, there is an acute need for mechanisms which will help the two sides work together on their problems. They need to have the feeling that their environmental interests are recognized by the other side as being of importance and are being given attention. It goes without saying that mechanisms alone will not be enough, an atmosphere of trust and cooperation has to be created, but structures and innovative ideas have their place in creating such an atmosphere.

66.2.6 Role of Non-Governmental Organizations (NGOs)

Given that official channels are rather limited in their ability to foster cooperation as a result of the overpowering nature of political dispute, NGOs in the region have a role to play in creating a more positive atmosphere. Effective NGO actions will foster cooperation and thus by easy stages to a greater sense of security among all those concerned. Over the period since the Oslo Agreements were signed, the work of NGOs such as FOEME (Friends of the Earth Middle East) and of IPCRI (the Israel Palestine Centre for Research and Information) which are directed jointly by Israelis and Palestinians (and in the case of FOEME, Jordanians) has had a positive effect on dialogue over environment between the two communities.

Friends of the Earth has stimulated a dialogue between regional stakeholders on the future of the Dead Sea which has done much to illustrate what the problems are in relation to the future of the Sea itself and the surrounding region. An innovative project on promoting water awareness among Palestinian and Israeli rural communities has also had some success. IPCRI has sought to supplement the work of the Joint Water Committee by creating a whole series of seminars and other activities involving water professionals, culminating in a four day academic conference on *Water for Life in the Middle East*, attended by some 180 participants from the region and outside it.⁴ In addition, IPCRI (in collaboration with the Consensus Building Institute in Boston, USA) has trained some twenty Israelis and Palestinians in the techniques of environmental mediation. Many of these are now working in the field. Such efforts cannot resolve problems or give security to the peoples of the region, but they can help create an atmosphere where concerns about security are talked about in a logical way, in a positive atmosphere, and without hysteria or extremist bias.

Just as significant as the work of these two organizations are collaborative research projects involving academics from both sides. These have been initiated by both Israeli and Palestinian NGOs and institutions of higher education, among them the Palestinian Hydrology Group, the Applied Research Institute in Bethlehem, the Truman Institute for Peace at the Hebrew University, and the Israeli based Arava Insti-

tute. All these have at various times brought together scientists and researchers from both Israel and Palestine in a framework which permits of genuine cooperation.

66.2.7 Involvement of Third Parties – Providing Appropriate Mechanisms to Facilitate Cooperation

The effective and long-term involvement of third parties could do much to ease tensions in the region. In 2002, the United Nations Environmental Programme (UNEP) undertook a study of the environmental problems of the West Bank and Gaza which it wished to serve as a basis for dialogue between the two sides. It included a long series of recommendations directed both at the Israeli government and the Palestinian Authority, designed to improve the effectiveness of their environmental policies and their ability to cooperate effectively with one another. Unhappily, this report fell on stony ground. Neither party has, as yet, taken any significant steps to implement its recommendations.

However, this report did serve as an example as to how, if both parties agree, an outside player can have potential significance. Other donors with influence in the region have also from time to time played a significant part in promoting cooperation. The 'behind the scenes' role of the U.S. Agency for International Development (USAID) in supporting the work of the Joint Water Committee is an instance of this.

In the long term the provision of a mechanism whereby representatives of United Nations (UN) organizations, donors, and international organizations such as the World Health Organization can serve on joint Israeli/Palestinian committees and help to find solutions to thorny problems, would be very advantageous to the long-term environmental security of the region.

Various ideas currently being discussed in environmental circles about creating an international body with the ability to adjudicate environmental disputes are also relevant in this context, though it is doubtful if at this time either side would be interested in outside mediation. This, however, could change if the general political climate were to improve. In a situation where lack of trust is perhaps the main obstacle to general security and environmental security, since neither side can change its attitudes because of deep-rooted distrust, third parties have much to offer.

4 See proceedings of the Conference published by IPCRI in 2005; Shuval/Dweik (2007).

The establishment of frameworks within which Israelis and Palestinians can meet on a regular basis to discuss problems and deal with them (perhaps with the participation of a third party as suggested above) would seem to be a necessary step. Joint bodies representing government, local authorities, and other stakeholders should be established to deal with such matters as hazardous waste disposal, management of shared aquifers, or protection of nature reserves, which are important to both societies. These would report to the appropriate ministries in the two countries and help to maintain a network of contacts and ensure that both sides were fully informed of the other's concerns.

It might also be worth considering the establishment of an Israeli/Palestinian Advisory Committee made up of individuals serving in their private capacities nominated by government and other stakeholders. The Advisory Committee could be provided with a small secretariat to monitor the progress of joint agreements and draw attention to issues which needed the intervention of both governments, if they are to be dealt with effectively. Such a body should be supported by an outside donor in order that it has a degree of independence from either government.

Another interesting suggestion is that the management of all the water resources of the region should be entrusted to an independent organization or even a private company which would include in its management structure both Israelis and Palestinians together with outside experts. Difficult as it is at present to see either side agreeing to something of this kind, the idea warrants further consideration.

Altogether the present situation where contacts between the two entities, Israel and Palestine, are so limited, demands an imaginative effort to break down barriers and introduce new mechanisms for thinking together about both immediate problems such as those posed by the security fence and long-term developments, such as global warming, which threaten all the people of the region.

66.3 Conclusion

Environmental security is a necessity for Israel, Palestine, and the neighbouring countries. This can only be achieved if they work together through appropriate mechanism on a long-term basis. These should permit both sides to express their views, share in decision-making, and help to implement them. They should also in due course allow for the participation

of Jordan representatives and those of other neighbouring countries. The region is too small for the environment to be managed on a strictly national basis with each national entity making its own decisions irrespective of what is being done elsewhere. Obtaining environmental security implies trust and can probably only be reached once the general political climate has somewhat improved, but planning should be done in advance so that when the situation permits action can be taken. All those involved should try to make sure that those who live in the region are provided with facts, not alarmist speculations designed to fuel conflict and serve direct political ends. The main outlines of the Israeli/Palestinian environmental conflict itself, the reasons for it, and the difficulty of dealing with it, are all clear. What is needed now is an equally clear concept as to what needs to be done in order to secure security and trust for the peoples of the region.

67 Conceptualization and Debate on Environmental and Human Security in Palestine

Mohammed S. Dajani Daoudi

67.1 Introduction

There has been an impressive range of academic studies on environment in Palestine as well as military, political, and economic security. However, the issue of environment and security has not been sufficiently seriously addressed by scholars and experts in the field. Although this chapter will focus primarily on the environmental security challenge, it will also analyse the related political environmental concerns. The Palestine National Authority (PNA) maintains that Palestinian environmental problems are primarily “due to violent Israeli occupation practices on the ground, including the confiscation of land, illegal settlement activities, the uprooting of trees, the destruction of Palestinian agricultural land, the use of Palestinian occupied lands by Israel as dumping ground for poisonous industrial waste, and the exhausting of water resources and the polluting of the water ground reservoirs by settlements”. This chapter argues that the PNA also bears a heavy responsibility for the poor environmental conditions in the Palestinian Territories. So far, not much has been done to link PNA environmental policy to security and environmental reconstruction¹.

In Rio in June 1992, the United Nations Conference on Environmental Development (UNCED) drew world attention to the need for regional as well as global cooperation to achieve sustainable development by stressing the inevitable link between national security and the environment. To bolster this link, governments are faced with the challenge of formulating proper policies and laws that would balance security with environmental concerns as called for in Agenda 21: “Integration of environmental and developmental

concerns and greater attention to them will lead to the fulfilment of basic needs, improved living standards for all, better protected and managed ecosystems and a safer, more prosperous future.”

As a result of the escalation of violence in Palestine and Iraq, the Middle East region is now experiencing one of the most disturbing environmental turbulences in its modern history. As expected, the negative impact of those two conflicts on the environment is causing profound regional concern. Attracting wide public attention by the early 2000's, environmental security unmistakably has become a principal regional issue (UNEP 2003c).

67.2 Overview and Basic Data on Palestine

Palestine is located on the east coast of the Mediterranean Sea, west of Jordan and south of Lebanon. The territory of Palestine covers around 10,435 square miles of which 10,163 square miles is covered by land, and the rest is water: half of the Dead Sea, Huleh Lake which was dried by Israel, and the Lake of Tiberias or the Sea of Galilee. The 1967 Israeli occupation has divided Palestine into the West Bank and the Gaza Strip. The total area of the West Bank covers 5,820 km², while the Gaza Strip covers 365 km².

The West Bank is characterized by a great variation in elevations ranging between 1,020 metres above and 375 metres below sea level. The highest point is near Kherbet Khillan north of Hebron City and the lowest point is at the north-eastern tip of the Dead Sea. The West Bank is divided into four major regions: Nablus Mountains, Jerusalem Mountains, Hebron Mountains, and the Jordan Valley. The mountains extend over the length of the central part of the West Bank from Jenin in the north to Hebron in the south. The drainage and valley systems originate from

1 The chapter is also based on the following references: Bashir/Winkelstein 2004; Haavisto 2003; IPCRI 2001; MENA 1999, 2000; Oka 2003; PASSIA 2003; PEC DAR 2001, 2004; PWA 1996, 1999.

the mountain range and extend either eastwards or westwards (ARIJ 2001).

- The *Nablus Mountains* extend from Marj Ben Amer in the north to the Jerusalem Mountains in the south. The water divide separating the western and the eastern basins coincide with the summits of these two mountains. The elevation range between 750 and 800 metres, with Mount Ebal reaching 918 metres above sea level.
- The *Jerusalem Mountains* consist of three main groups, the hills of the eastern slopes (100 to 250 metres), central mountain crests (750 to 880 metres), and the hills of the western slopes (250 to 300 metres). The highest point is located between Deir Jarir and Silwad.
- The *Ramallah Mountains* include the eastern slopes, the mountain crests, and the western slopes (250 to 500 metres). The mountain crests from the watershed line separate the eastern and western slopes. Elevation ranges between 750 and 800 metres. The highest point in Ramallah district is 1,022 metres at Tel A'sour and the lowest elevation is 24 metres below sea level at the southeast corner of the district.
- The *Hebron Mountains* on the southern rim of the West Bank are located south of Jerusalem and extend to the Negev. They are 850 metres above sea level near Kherbit Khellan north of Hebron City, and the highest elevation of 1,011 metres is in the Halhul area. The eastern slopes where elevation drops from 1,011 to 100 metres characterize the eastern part of the district. Here, most built-up areas are located between 600 and 1,000 metres.
- On the eastern boundary of Palestine the *Jordan valley* is part of a long and deep depression of the earth's crust (Jordan Rift). The Jordan valley has a semi-tropical climate characterized by hot summers and warm winters. However, without access to water this region is desert-like.

The Gaza Strip is a foreshore plain gradually sloping westwards. In the north there are four ridges: the coastal ridge, the Gaza ridge, the el Muntar ridge and the Beit Hanoun ridge with elevations ranging between 20 to 90 metres (ARIJ 2001).

The political structure of Palestine is still in the process of development. Following the signing of the Declaration of Principles in 1993, the Palestinian Authority (PA) was established. According to the 1995 Oslo II Agreement, the control over the Palestinian areas is divided into three sectors: Sector A remains under Israeli control, Sector B falls under Palestinian

control, and Sector C is under joint control. This division has left its effect on the environmental security situation.

67.2.1 Environmental Strains, Threats, and Problems

Palestine has been suffering from severe environmental strains, threats and problems, among them the deterioration and pollution of groundwater resources, scarcity of water resources, the smallness of the land, rapid population growth, contamination of the aquifers from waste water, industrial and medical waste, landfills and hazardous waste, shortcomings in environmental legislation, soil erosion, and low level of public services on waste water and solid waste management (UNEP 2003c; Twite 2003).

Furthermore, Palestinian environmental protection and development has been subjected to two different, conflicting and incompatible practices and strategies - i.e. Israeli and Palestinian - that have resulted in further environmental deterioration. The persistent Israeli occupation had undermined to a great extent Palestinian efforts to tackle domestic environmental problems, at times creating new ones such as those caused by Israeli military action, building new or expanding old settlements, or those created by what the Israelis call the Separation Security Wall and the Palestinian vocabulary refers to as the Apartheid Wall. An advisory opinion was rendered on 9 July 2004 by the International Court of Justice on the "Legal Consequences of the Construction of a Wall in the Occupied Palestinian Territory." The Assembly noted the detrimental impact on Palestinian natural resources being caused by the unlawful construction of the wall by Israel inside the occupied Palestinian territory, including in and around East Jerusalem, and of its grave effect on the economic and social conditions of the Palestinian people. The outbreak of the *Al-Aqsa Intifada* in September 2000 and the subsequent Israeli re-occupation of the West Bank and the continued military operations in the Gaza Strip led to a serious deterioration in the political and economic conditions, leaving devastating effects on the environment.

The continuing violence and conflict in the Palestinian territories threaten the lives and livelihoods of the population. The United Nations World Food Programme conducted a vulnerability assessment in which it reported that an estimated 38 per cent of the population lacks sufficient food, while a further 26 per cent are at risk. In the Gaza Strip alone, food in-

security rates reached as high as 66 per cent in Rafah, 56 per cent in Jabalia, and 40 per cent in Khan Younis.

67.2.2 The Peace Process and the Environment

The Oslo I Accord of 1993 contains in Annex III a provision that both parties agree to establish an Israeli-Palestinian Committee on Economic Cooperation focusing, among other matters, on environmental issues such as water, energy, and industry. The two parties also agreed to develop an environmental protection plan, providing for joint and/or coordinated measures. According to the Oslo II Accord of 28 September 1995, issues related to water rights were to be negotiated in the permanent status negotiations. The Israeli-Palestinian Interim Agreement on the West Bank and the Gaza Strip, Appendix I, Article 40, Principle I, stipulates that "Israel recognizes the Palestinian water rights in the West Bank. These will be negotiated in the permanent status negotiations and settled in the Permanent Status Agreement relating to the various water sources." Under Article 12 of Annex I to the Accord, which deals specifically with environmental protection, the Israelis transferred powers and responsibilities to the Palestinian side to undertake limited environmental management activities in the West Bank and Gaza Strip.

The Oslo Accord divided the West Bank and Gaza Strip into three types of areas; A, B, and C. Areas A are under Palestinian control, areas B are under joint Palestinian and Israeli control, and areas C are under Israeli control. Israelis and Palestinians agreed to cooperate on the basis of mutual understanding and shared responsibility in virtually all areas of environmental protection. Both parties agreed, pursuant to their environmental and developmental policies, to the following;

- Prevent damage to the environment and take measures to ensure that activities in areas controlled or managed by one party do not cause environmental damage to areas controlled or managed by the other;
- Adopt, apply, and comply with internationally recognized environmental standards concerning emissions and effluents;
- Prevent uncontrolled discharge of waste water and effluents to water bodies and promote proper treatment of waste water, solid, and hazardous wastes;
- Ensure that a comprehensive environmental impact assessment (EIA) is conducted for all major

development programmers specified in the Accord;

- Take precautions to prevent water and soil pollution as well as other environmental safety hazards;
- Take measures to prevent noise, dust, and other disturbances from quarries.

To ensure effective collaboration on the environmental issues identified, the parties established a Joint Environmental Experts Committee (JEEC). However, the outbreak of the Al-Aqsa Intifada in September 2000 resulted in the suspension of all Palestinian-Israeli cooperation on environmental security. Since its establishment in 1994, the PNA gave little attention to the management of the environment and other similar issues such as waste water, domestic solid waste, industrial waste, hazardous waste, and noise and air pollution. Reports and studies on environmental protection funded by donors and prepared by international consultants assisted by local experts remained unfulfilled. In 1996, the Ministry of Planning and International Cooperation (MOPIC 1996, 1996a, 1996b, 1998, 1999), the agency then responsible for environmental planning within the Palestine National Authority (PNA), took the initiative to prepare an Emergency Natural Resources Protection Plan. This plan was the first step towards the protection of the natural and cultural environment in Palestine from environmentally harmful development projects and programmes. In October 1999, the Palestinian Ministry of Environmental Affairs published the Palestinian Environmental Strategy (PES). Its objective was "to identify and analyse the main environmental problems and their causes in Palestine, define environmental objectives and to introduce a series of prioritized measures that will lead to reaching these objectives." The study was intended to be "a first step towards establishing [a] healthy and clean environment for present and future generations." The PES distinguished nine environmental themes to be addressed in the coming decade:

1. Depletion of Water Resources;
2. Deterioration of Water Quality;
3. Depletion of Natural Resources;
4. Land Degradation;
5. Air and Noise Pollution;
6. Marine and Coastal Pollution;
7. Deterioration of Nature and Biodiversity;
8. Landscape and Aesthetic Distortion;
9. Threats to Cultural Heritage. In April 2000, the Ministerial Council approved the Palestinian Envi-

ronmental Assessment Policy as proposed by the Ministry of Environmental Affairs.

Article 1 lists the definitions of 18 major terms used in this policy, but not included among them is the term Environmental Security. The Palestinian Environmental National Authority (PENA), a centralized environmental authority responsible for environmental management in Palestine which succeeded the Ministry of Environmental Affairs, has been entrusted with the following tasks:

1. Preparing a national environmental policy and plan;
2. Setting environmental protection standards for air, water, and land;
3. Cooperating with other ministries and NGOs in the field of environmental protection;
4. Conducting international environmental linkages;
5. Setting environmental legislation and overseeing the enforcement of the legislation;
6. Establishing adequate monitoring networks (laboratories and monitoring stations) to collect information and to present this information to the public;
7. Conducting environmental impact assessment (EIA) studies for proposed projects before licensing;
8. Promoting environmental education and public awareness.

67.3 Environmental Threats to Palestinian National Security

In Palestine, environmental threats to national security may be classified in two major categories: a) as *domestic environmental security challenges*, such as water, solid waste mismanagement, waste water pollution, air and noise pollution, land misuse and land degradation; lack of environmental legislation and enforcement; and b) *External Environmental Security Threats*, including: i) Israeli military occupation, ii) Israeli settlements, iii) Israeli separation/apartheid wall, iv) uncontrolled chemical imports from Israel and releases of hazardous materials in Palestine, and v) illegal dumping of hazardous waste imported from Israel.

67.3.1 Domestic Environmental Security Threats

The West Bank and Gaza Strip are poor in natural resources. The only known natural resources are rocks,

sand, and minerals of the Dead Sea. The mineral resources in the West Bank and Gaza Strip are still undetermined. Only a few geological studies have been conducted. These resources are being exploited by the following activities:

1. Sand in Gaza is currently overexploited for building purposes.
2. Palestinians and Israelis in the West Bank carry out rock quarrying.
3. The Israelis are extracting the minerals of the Dead Sea extensively.

Palestinians cannot benefit from these natural resources due to restrictions imposed by Israel. The Dead Sea includes high concentrations of KCl, NaCl, MgCl₂, and Br₂. The diversion of water at the upper part of the Jordan River through the Israeli national carrier system has resulted in a drastic drop in the sea level by 15 metres since 1955 (Ecopeace 1997). The natural resources of the West Bank remain negatively affected by the Israeli Occupation. The systemic uprooting of trees, destruction of agricultural land, and confiscation and destruction of the water supply is devastating. The building of the separation or apartheid wall intensifies these problems in the surrounding areas and poses immediate and long-term destruction and degradation to the Palestinian environment and natural resources. [See the report prepared by the UN Economic and Social Council, and presented to the General Assembly on 24 May 2005, on the economic and social repercussions of the Israeli occupation on the living conditions of the Palestinian people in the occupied Palestinian territory, including Jerusalem.]

67.3.1.1 Water

The Middle East is one of the world's most water-stressed regions. This made water a politically highly sensitive issue in the Arab-Israeli conflict. Since its 1967 occupation of the West Bank and the Gaza Strip (OPT: Occupied Palestinian Territories), Israel has almost completely controlled the water available to the Palestinian population. According to the Oslo II Interim Agreement (Annex III, Appendix 1, Article 40), Israel has recognized Palestinian water rights in the West Bank, however, it has not implemented that agreement and continues to deprive Palestinians of their fair share of water. The main sources of water available to Israelis and Palestinians are (i) the Jordan River and (ii) groundwater underlying the occupied West Bank and coastal areas.

The impact on the water supplies for the areas around the apartheid wall is a serious concern. Many water wells are lost for communities near the wall. In villages around Qalqiliya and Tulkarem the Palestinian Hydrology Group (PHG) has listed 30 wells lost in the first phase of the apartheid wall. Those 30 wells have a total discharge of 4 MCM/year. These groundwater wells are located in the Western Groundwater Basin and were drilled prior to 1967. As a result, Palestinians stand to lose nearly 18 per cent of their share of the Western Groundwater Basin (PENGON, 2002).

Water Consumption. The average (renewable) quantity of fresh water available in Israel and the OPT per year is slightly over 2.4 billion cubic metres. Israel allocates approximately 90 per cent of this amount to itself, leaving the Palestinian population just over 10 per cent. If water resources were divided into equal per capita shares, Palestinians would receive approximately 45 per cent. As a result of these severe Israeli restrictions on the Palestinian water supplies, each of the approximately 3.3 million Palestinians living in the OPT receives less than 100 litres per capita per day. This is far less than the 150 litres per day recommended by the World Health Organization as the minimum per capita water need. The average Israeli uses 353 litres of water per day, 3.5 times the water Israel allows the Palestinians. Israeli settlers living illegally in the OPT use up to nine times as much provided to Palestinians. This discrimination by Israel violates the human right to water as recognized by the United Nations. The low water consumption affects the sewage quality. This results in a strong waste water in terms of Biochemical Oxygen Demand (BOD) and suspended solids. The BOD of raw sewage in the West Bank averages 600 mg/l. Sewage networks serve approximately 25 per cent and 45 per cent of the population of the West Bank and Gaza Strip respectively (PWA 1999). Sewage networks are mainly found in major Palestinian cities, but parts of the networks are poorly designed and suffer from leakage.

Israeli Control of Water. For nearly four decades of its military occupation, Israel has assumed near complete control over all Palestinian water sources, thus depriving Palestinians of their right to control their own natural resources. Discriminatory measures adopted by the Israeli occupation authorities include:

a.) **Restricting Drilling of New Palestinian Water Wells or Pumping Existing Wells.** Israel's control over Palestinian water resources has resulted in the destruction or closure of hundreds of Palestinian

wells and sharp restrictions on pumping existing wells. According to the Palestinian Water Authority, Palestinians were allowed to dig only 13 wells between 1967 and 1996, less than the number of wells which dried up during the same period due to Israel's refusal to deepen or rehabilitate existing wells (B'Tselem 2000). Even the Oslo II Interim Agreement was insufficient to maintain the per capita water allocations to Palestinians, as the additional water was insufficient to keep pace with the growth of the Palestinian population.

b.) **Restricting Palestinian Access to Water Sources.** Lands adjacent to the Jordan River were declared 'closed military zones' and Palestinian farmers could no longer use the area for irrigation. Areas with freshwater springs were classified as 'nature reserves' where access is limited or requires payment (B'Tselem 2000). In addition, illegal Israeli settlements are provided running water by connecting the Israeli National Water Carrier, while Israel refuses to provide running water to many villages on whose land such settlements are built.

c.) **Palestinian Water Rights.** Under international laws relating to belligerent occupation, Israel as an occupier to the West Bank and Gaza Strip has an obligation to use Palestinian water resources only to the extent necessary for the maintenance of its military occupation. It is not permitted to appropriate the water of the occupied territory for the use of its own civilians, much less for illegal settlers. Israel has done precisely this, in violation of its obligations under international law.

67.3.1.2 Solid Waste Mismanagement

Solid waste includes waste from household, medical, and industrial activities that is the responsibility of municipalities, village councils, village communities or UNRWA in the refugee camps. Solid waste has accumulated inside Palestinian cities and towns due to the closure of many landfill sites serving cities and population centres, and the prevention of waste disposal teams from reaching these landfills. For example, the Northern Gaza landfill and Gaza City landfill were closed and access prohibited. The roads, highways, and fields are littered with uncollected garbage containers, plastic bags, empty bottles, paper tissues, and other refuse revealing a widespread lack of environmental awareness and concern. Solid waste is dumped everywhere, sewage streams are flowing in many areas and air pollution from burning of solid waste, quarries, and vehicles is evident. Due to the absence of efficient collection systems and lack of law

enforcement, solid waste is dumped everywhere. None of the dumping sites assigned by municipalities are fenced, lined or monitored. The violent conflict resulted in a stop of many solid waste projects especially of landfill construction projects, including the Ramallah and Bethlehem/Hebron landfill projects. In 2005, 25 per cent of the population of the West Bank has no solid waste collection or management programme. But all towns and villages in the Gaza Strip have storage and collection systems, and most of the solid excluding the Northern district, waste is disposed of in a satisfactory manner (Coad 1997).

Household Solid Waste. It is estimated that 2,600 tons of domestic waste is generated daily in the West Bank and Gaza Strip in addition to 450 tons of domestic waste generated by the 350,000 Israeli settlers living in the West Bank and in the Gaza Strip. Currently, dumping in open area and open burning are the most common methods of disposal. Evidence also shows that much of the solid waste generated by settlers is being disposed of on Palestinian land, in addition to the illegally transferring of toxic waste generated inside Israel into the West Bank (ARIJ 2001). Appraisal of waste from Palestinian communities has shown that the majority of waste is organic material, mostly food waste. Also, plastic bags are used and disposed of frequently. Paper makes up a relatively small portion, most is cardboard and newspaper. Most disposal sites are unplanned and unmanaged open dumps with little consideration being given to their proximity to people, agriculture, or water resources. Solid waste burned at these sites causes serious air pollution.

Medical Waste. Infectious waste, toxic chemicals, drugs, flammables, and sharp edged waste generated from hospitals and medical centres are disposed of along with municipal garbage in open dumps without treatment and burned in the open air. There has been a noticeable increase in the quantity of medical waste as a result of large numbers of dead and injured people in hospitals due to the increase in armed conflict.

Industrial Waste. The industrial sector in the West Bank and Gaza Strip is still undeveloped so the existing industries are mainly of small to medium scale. These industries are found within residential and agricultural areas, as well as in industrial areas. Environmental conditions in the existing industrial zones are poor. Several problems are associated with these areas such as improper disposal of solid waste. Industrial waste management programmes for hazardous waste do not exist in the West Bank. Industrial solid waste

is managed together with municipal waste. Open burning of solid waste is common, thus many dangerous materials, such as PVC, are burned and emissions, which may contain dioxins, are released into the air. In the Gaza City dumping site, a special section has been built to receive inorganic hazardous waste and biological hazards (Coad 1997).

Hazardous Waste. Several incidents of dumping hazardous waste in the OPT occurred:

- The dumping of unknown substances and wastes in underground trenches in area C under Israeli control similar to what happened near Gosh Qatif on the Palestinian beach and in Hebron. These substances and wastes could not have been identified as their sites lie within military controlled areas.
- The dumping of unknown waste in Palestinian landfill sites and the opening of random dump sites for settlements on Palestinian land on the beaches of Khan Younis and Deir Albalah in the Gaza Strip.

Many of these smuggled waste materials are various forms of paint waste and the containers have 'Fire' and 'Poison' signs on them. The waste contains cyanide compounds and after laboratory tests it was proven to have a high percentage of heavy metal content or was polluted with them (Environmental Quality Authority 2003).

Agricultural Waste. Various kinds of agro-chemicals (fertilizers, pesticides) are applied in the West Bank and in the Gaza Strip. The total quantity of pesticides used in agriculture in the West Bank and Gaza Strip in 95/96 growing season was 454 tons. Fertilizers also remain as a major source of groundwater contamination associated with agricultural practices. The total quantity of chemical fertilizers used in the West Bank and Gaza Strip is estimated to be 49,420 tons in the 1995/96 growing season (ARIJ 2001).

Recycling Solid Waste. Currently a small fraction of solid waste is recycled, mainly steel scrap and glass. Waste pickers can be found in the dumping sites, especially at locations where Israelis dump their waste (Coad 1997). Although the majority of the domestic solid waste is of organic origin, composting of waste is still not practised on a large scale.

67.3.1.3 Waste water Pollution

Waste water generated from Palestinian cities, villages, and Israeli settlements is a primary source of pollution. Such waste water is discharged untreated into

open areas or through cesspits. Israeli shelling of waste water collection and treatment stations in many Palestinian cities in the West Bank and Gaza has caused deterioration to those facilities. The waste water treatment station in Gaza has been subject to repeated shelling that caused drastic damage to the buildings and the carrier line. The electric control tableaux of the pumps have been damaged, and much effluent has run out, causing a decrease in the efficiency of the treatment station and an increase in the pollution of the effluent that consequently increases the pollution of sea water. Similarly, Beit Hanoun sewer station has been subject to bombardment and the sweeping away of its constructions.

Israeli siege and bombardment of Tul-Karem, Jenin in the West Bank, and Beit Hanoun in Gaza has resulted in the Palestinian inability to reach treatment stations to carry out the necessary maintenance. Israel also bans the entry of spare parts to Palestinian areas. Israelis also discharge dangerous waste water from Israel to Palestinian areas. On 26 March 2001, the eastern areas of Gaza and north governorates were flooded with huge quantities of waste water discharged from an Israeli waste water reservoir. Sample analysis has revealed the existence of microbiological pollution to agricultural land, and henceforth, the transmission of pollution to humans. The Ministry of Environmental Affairs has published a detailed report regarding this incident.

Israeli military operations have caused the cessation of waste water projects, especially of the waste water project in Khan Younis City in Gaza, in addition to the destruction of several local networks due to bombardments and sweeping away activities (Environmental Quality Authority 2003). There are six treatment plants in the West Bank and Gaza Strip, three of them are located in Ramallah, Jenin and Tulkarm, and the rest are found in Beit Lahia, Jabalia, Gaza and Rafah in the Gaza Strip. They are not functional, and most of them are overloaded, underdesigned, or suffer mechanical failure. One new waste water treatment plant is currently under construction in Salfit and another new one in Al-Bireh is operational now. The pressure from waste water on the West Bank is intensified by the large amount of raw waste water disposed by Israeli settlements in the West Bank. Waste water from settlements is either disposed through cesspits or collected in sewage networks which open into the surrounding Palestinian land.

Industrial and Hazardous Waste Water. According to Article 12 of the Oslo II Agreement of September 1995 all hazardous waste, if separated, should be exported

for treatment and disposal in Israel at costs ranging from US\$ 300 to US\$ 1,000 per cubic metre. Although the industrial sector is still undeveloped in the West Bank and Gaza Strip, leather tanning, metal finishing (including electroplating), chemicals, and olive oil pressing are major sources producing industrial and hazardous liquid waste. There are 19 leather tanneries in the West Bank, of which ten are located in the Hebron and the rest in the Nablus and Jerusalem districts. Waste water from tanneries includes heavy metals, such as chromium, arsenic, and sulphide. The generated waste water is discharged freely into the nearby valleys without treatment.

Waste water generated from the olive oil mills is also hazardous as it contains dangerous chemicals. There are around 300 olive mills located in the West Bank. These mills work only for a limited period of time and dispose of their waste without treatment. The quantity varies from year to year depending on the amount of olives produced (ARIJ 2001). Only one facility is built to accept hazardous waste from the whole West Bank and Gaza Strip. Due to the lack of proper infrastructure, incomplete regulations, standards, and enforcement, all types of wastes are released untreated into the environment.

Although Israel has signed the Basel Convention on control and transport of toxic and hazardous wastes and materials across borders, Israel does not abide by the provision of the Convention and smuggles these hazardous materials into the OPT. Many cases were reported in different places in the Gaza Strip and the West Bank where settlers were responsible for smuggling toxic and hazardous materials from settlements into the Palestinian Territories (PNA 2002).

67.3.1.4 Air and Noise Pollution

Air Pollution. The air quality in the Palestinian Territories is subjected to continuous deterioration. The increasing population in the West Bank and in the Gaza Strip, and the expansion of industrial activities, are key factors in the deterioration of the air quality. The main sources of air pollution are as follows:

- **Vehicle emissions:** Although the number of vehicles in the West Bank is low, approximately 60 per cent of the cars were made between 1980 and 1990, and only 10 per cent between 1990 and 1996 (ARIJ 1996). Unleaded gasoline is not used widely.
- **Quarries and stone cutting:** Large amounts of particulate materials and dust are produced from quarries and stone cutting facilities as many of

them are located near residential areas. Quarries are mainly located in the Bethlehem, Hebron, and Nablus districts. Particulate materials are harmful to human health, especially the respiratory system.

- **Burning of waste:** The unregulated burning of municipal solid waste in open fields or containers in local streets emits a variety of hazardous pollutants into the air.
- **Industry:** The industrial sector in the West Bank and the Gaza Strip is not developed. Yet some industries are polluting the air through their emissions, such as metal factories and bakeries which consume used motor oil as fuel, and the pottery industries mainly located in the Hebron district which use old tyres as a source of energy. Moreover, large amounts of toxic gases such as CO and CO₂ are emitted into the atmosphere from the charcoal industry, which is mainly found in the Jenin district.

Transboundary Air Pollution. Air pollution from Tel Aviv and other urban areas is carried to the West Bank by the western winds. Studies showed that NO_x generated from the traffic at Tel Aviv is found as ozone in Bethlehem, Jerusalem, and Nablus (ARIJ 2001).

Noise Pollution. Sources of noise in the West Bank and Gaza Strip are mainly traffic and motor vehicles, construction of roads, buildings, and industrial activities, in addition to the noise resulting from Israeli military aircraft and military training activities. Noise can become a significant nuisance, disturbing the normal daily activities of the people.

67.3.1.5 Land Misuse and Land Degradation

Land Misuse. Careful management of land use in the West Bank and Gaza Strip is critical. The limited natural resources and the Israeli measures of land confiscation and settlement construction impose a challenge to those working in this field. In the West Bank there are 580 Palestinian built-up areas, mainly located in the mountainous area while Israeli settlements occupy the Jordan Valley, near the Green Line, and around Jerusalem. In the Gaza Strip there are 42 Palestinian built-up areas spread over 4,694 hectares, along with 8 refugee camps hosting 250,604 refugees (PCBS 1997). Israeli settlements were located in the southwest and north of Gaza.

Land Degradation. Land degradation includes the deterioration of the soil quality by contamination, salinization, and erosion. Soils of the West Bank are exposed to many sources of pollution that deteriorate their quality. These sources include irrigation with

salty water, extensive use of pesticides and fertilizers, uncontrolled dumping of industrial and domestic solid waste and waste water. In addition, the lack of water for irrigation leads to an increase in soil salinity. These sources have detrimental effects on soil properties since they contain high concentrations of heavy metals, nitrates, phosphorus, and salts which accumulate in the exposed soil (UNEP 2003f).

Marble and Stone Cutting. The marble and stone cutting industry is a main pillar of the Palestinian national industries in the Palestinian Territories, particularly in the Hebron region where there are more than 360 plants, each representing an environmental hazard to both humans and wildlife. However, the environmental hazards have become more serious with time and thus threaten the lives of thousands, particularly of children.

67.3.1.6 Lack of Environmental Legislation and Enforcement

Although the Palestinian Environmental Law was finally approved on 18 December 1999, a month later, in January 2000, an Environmental Strategy was released. But in early 2005 still no effective implementation of any legislation or regulatory programme for environmental protection and security has existed in Palestine.

67.3.2 External Environmental Security Threats

67.3.2.1 Israeli Military Occupation

Since the Israeli military occupation of the West Bank and Gaza in June 1967, the Israeli government has adopted several acts that resulted in environmental security threats. Israeli military occupation activities have caused the death of thousands of birds and animals through the destruction of hedges and farms. The losses in livestock were:

- Destruction of 158 poultry farms;
- Destruction of 89 animal hedges;
- Killing of 1.5 million birds;
- Destruction of 7,000 beehives;
- Death of 3,990 sheep and goats, and 653 cows;
- Death of many domestic and wild birds in the cities and villages.

The other indirect negative effects have been:

- Difficulty of obtaining fodder, and medicine for animals;

- Difficulty of extending agricultural service such as the veterinary service and agricultural extension service (Environmental Quality Authority 2003).

The size of damage in livestock and in the agricultural sectors throughout the Palestinian Governorates has been severe. The reports of the Palestinian Ministry of Environmental Affairs indicate that the excessive use of weapons and dangerous chemicals has forced animals to leave Palestinian lands. Bird-watchers have noticed a remarkable disappearance or decline in the number of migratory birds passing the area. Municipalities have reported that Israeli army units have opened fire deliberately against domestic animals, leaving their corpses to rot, adding more disasters to the Palestinian environment.

67.3.2.2 Israeli Settlements

Israeli settlements destroy the territorial integrity of Palestine and limit the possibility for urban and economic development, by the seizure of land and by blocking the physical expansion of Palestinian villages and towns. They also undermine Palestinian economic development by restricting movement and impeding the flow of commerce and workers from one Palestinian area to another, and contribute to the increased rate of violence against Palestinians.

There are over 150 illegal Israeli settlements with more than 400,000 settlers in the West Bank, and until August 2005 in the Gaza Strip, and their expansion in the West Bank has been accelerating. In 2003 the Israeli Central Bureau of Statistics recorded a 35 per cent increase in new settlement building (Kay 2004). Some of the effects on environmental conditions are:

1. Precluding the Palestinian people from using their groundwater reservoir because these settlements are constructed on their land.
2. Contaminating groundwater by discharging waste water into the areas of sand dunes and valleys where the best quality water is available.
3. Burying the solid waste of these settlements unsafely, causing leakage of pollutant substances into the groundwater.
4. Erecting sewage-processing stations over the best quality groundwater reservoir.
5. Drawing the high quality water from the OPT to Israel through these settlements.

Some of the pollution sources relating to the Israeli settlements include:

Waste water. The partially processed waste water runs from the Israeli settlements into valleys and agricul-

tural lands. As a result, waste water leaks into the groundwater through soil causing contamination in groundwater and the environment (PNIC 2001).

Smuggling Hazardous Substances into the Palestinian Territories. The smuggling operations of hazardous substances are carried out across the borders and from settlements causing a real danger to the environment and public health in the West Bank and in the Gaza Strip. These hazardous substances include the following: fuel, diesel, bromine, hydrochloric acid, ammonia, chlorine, etc. Under any weather and with the help of winds, such substances can be easily transmitted to the Palestinian Territories.

Illegal Burial of Hazardous Wastes Smuggled from Israel. Israel buries a great deal of solid wastes coming from its settlements close to Arab villages. These solid wastes cause serious harm to the environment and public health (PNIC 2001).

67.3.2.3 Israeli Separation/Apartheid Wall

Construction of the wall uprooted tens of thousands of trees that play a major role in preserving the environment and ecological balance of the area. These trees, most notably the olive tree, are also a basic part of the Palestinian landscape, culture, and heritage.

The footprint (the area of the wall and the associated landmass on either side) is enormous. In the first phase of construction the area lost as a direct result of the wall is about 11,500 dunums. The footprint of the entire wall as proposed could reach about 35,000 dunums. Construction of such a massive structure and the disturbance of such a large land mass will have significant impact on the ecology of the area (PENGON 2002).

The wall will cause changes in the microclimate which will also have its affect on the flora and fauna in the area. Migratory patterns of some species are interrupted and flight patterns of certain bird species will be interrupted. The wall is interrupting surface water patterns and has continued affects on the surface water quantity and quality of the area as well as groundwater levels.

Furthermore, the presence of the wall will have severe long-term environmental effects. As a result of the habitat loss, the micro-ecology of the area is impacted and weeds, pests, and pathogens are expected to be thriving in the wall vicinity. These species then spread to adjacent areas becoming a problem for native species, and as a result diminish the native diversity of the ecosystem. The wall will create displacement factors that will affect animal distribution and

Table 67.1: Total agricultural areas in dunums, annual production in tons, and value in US\$ in the eastern part of Israel's segregation zone. **Source:** ARIJ, Agriculture & Biodiversity Research Unit, 2003.

Crops	Area (Dunum)			Production (Dunum)			Value in US\$
	Rain fed	Irrigated	Total	Rain fed	Irrigated	Total	
Fruit trees	47,611	3,402	51,013	10,261	6,820	17,081	4,125,653
Vegetables	7,468	14,341	21,809	3,831	58,510	62,341	80,770,142
Crops	198,274	1,585	199,858	51,551	4,496	56,047	7,208,169
Total (A)	253,353	19,327	272,680	65,644	69,826	135,470	92,103,963
West Bank (B)	1,544,877	114,978	1,659,855	377,447	755,605	1,133,051	487,237,000
% (A/B)	16.4	16.8	16.4	17.4	9.2	12.0	18.9

movement patterns, and some populations will be fragmented. Habitat fragmentation of both flora and fauna reduce genetic diversity. The remaining small populations are then vulnerable to all problems associated with rarity: genetic deterioration from inbreeding and random drift in gene frequencies, and environmental catastrophes.

As a result of the long-term existence of the wall populations of resident species and groundwater will be impacted. Groundwater and surface water quality and quantity will be reduced. Native flora and fauna populations will be reduced and some species are expected to disappear completely from the area of the wall.

The wall segregation zone endangers the agricultural sector as well as other Palestinian economical and natural resources. The Palestinian communities located inside the segregation zone are mainly agricultural communities. Agricultural activities comprise the main source of income for Palestinian citizens living in these communities.

Israel's segregation wall continues to devour and trap the Palestinian agricultural land; 224.87 km² of the West Bank lands were razed to construct phase one of the wall which extends from the village of Salem in the North of the West Bank to Al Qanna colony near Masha village in the Qalqilia district, whereas 869.74 km² of land were confiscated to continue the construction of the wall in the second phase. 81.17 km² of the Palestinian built-up areas are isolated inside *ghettos* by this segregation process. On the other hand, 99.53 km² of the land is reserved for the exclusive use of Jewish settlements.

The Israeli segregation zone entraps agricultural lands in different locations throughout the West Bank, extending to considerable depths at several points. The agricultural sector and the Palestinian food security situation suffer huge losses due to this segregation process, as the agricultural production

was sharply reduced. Meanwhile, many Palestinians are unable to reach their agricultural fields or market their agricultural products.

The eastern part of the Israeli segregation zone endangers the Palestinian lands located in the Jordan Valley agro-ecological region, as well as the eastern part of the eastern slopes agro-ecological region along the West Bank. The Jordan Valley agro-ecological region is a semitropical area, characterized by hot summers and warm winters. Irrigated agriculture is the dominant cropping pattern in the valley and prevails in the areas where water resources are available. The eastern slopes region is a semi-dry area characterized by dry-land cultivation. Approximately 80 per cent of the Palestinian range lands are located in the eastern slopes.

The total area of the endangered agricultural lands in the eastern part of the segregation zone is about 272,680 dunums. About 7.1 per cent of the endangered agriculture areas are irrigated, while 92.9 per cent are considered as rain-fed lands. The annual agricultural production reaches 135,470 tons. Accordingly, 12.0 per cent of the Palestinian agricultural production with an economic value of US\$ 92.1 million will be threatened due to this Israeli segregation zone. The following table illustrates the total agricultural areas threatened, annual production in tons and value in US\$ in the eastern part of the anticipated segregation zone.

67.3.2.4 Uncontrolled Chemical Imports from Israel and Release of Hazardous Materials in Palestine

Releases of hazardous materials in Palestine and across the border in Israel from industries and chemicals including: petroleum, hazardous waste, chlorine, paint, pesticides, foam, etc. pose risks to human health and the environment in Palestine. Release of hazardous material across the border in Israel em-

nates from the industrial areas of Haifa Bay, Ramat Hovav, Petah Tekva, Ashdod, and Ashkelon. Three of those industrial areas (all but Haifa Bay), plus the industrial area of Ashkelon, can be considered relatively close to the West Bank and/or the Gaza Strip.

67.3.2.5 Illegal Dumping of Hazardous Waste

Illegal dumping of hazardous waste imported from Israel has frequently occurred. It has proven difficult to return such imports to their source in Israel. Imported drums were found at different locations, including Jenin, Qalqilia, the north beach of Gaza, and in Hebron.

and the occupied Syrian Golan. In the resolution, the Assembly recognized the right of the Palestinian people to claim restitution as a result of any exploitation, damage, loss or depletion of, or endangerment to their natural resources, and expressed the hope that the issue would be dealt with in the framework of the final status negotiations between the Palestinian and Israeli sides.

67.4 Conclusions

Collecting, recording, and documenting data on environmental pollution in the Palestinian territories is extremely important for combating and overcoming such hazards. Considering the growing population and very scarce resources in Palestine, environmental security will be one of the most important key policies for formulating a future Palestinian national development strategy. The major problem facing the Palestinian Authority is the presence of many polluting industries in Palestinian regions which are neither subject to Israeli nor Palestinian jurisdiction. Thus, the Palestinian Authority has no control over them to limit the environmental dangers they represent. No doubt, without reaching a comprehensive, lasting peace between the Palestinians and the Israelis, it will be very hard for the tough environmental problems to be resolved and the challenges to be met.

Occupation, policies of closure and curfews, lack of awareness on the Palestinian side, and many other factors all have had significant negative environmental impacts. In the current phase of the conflict, the absence of even minimal cooperation is worsening the situation on a daily basis, with impacts not only on the environment but also on human health. Hence, both parties should pursue parallel attempts to address environmental protection along with reaching a peaceful resolution to the conflict.

In its resolution 59/251 of 22 December 2004, the General Assembly reaffirmed the inalienable rights of the Palestinian people and the population of the occupied Syrian Golan over their natural resources, including land and water; and called upon Israel, the occupying power, not to exploit, damage, cause loss or depletion of or endanger the natural resources in the occupied Palestinian Territory, including Jerusalem

68 Environmental Scarcity, Insecurity and Conflict: The Cases of Uganda, Rwanda, Ethiopia and Burundi

Mersie Ejigu¹

68.1 Introduction

Upon independence from colonialism about four decades ago, many Africans thought that the post colonial period would be a period of reconstruction and development; prosperity, peace and stability; and indeed a period of cooperation and mutual respect among various ethnic and religious groups. However, what we have witnessed and are witnessing today is an increase in the number of conflicts. Africa's conflicts have left a trail of destruction of life, property and most importantly 'hope'.

A change in the nature and characteristics of these violent conflicts can also be observed. As elsewhere, contemporary African conflicts, for example, Darfur in Sudan, Somalia, Cote d'Ivoire, Congo Democratic Republic, Liberia, Sierra Leone, Ethiopia, and Uganda are not interstate but intrastate. Some of these wars are fought in capital cities and are difficult to guess where and when they will erupt. Wide ranging groups including local communities, religious and other social groups, countries, United Nations organizations and international community, in general are involved and all have different interest.

Conflicts are driven by a variety of motives with a wide range of contributing factors: ideology, access to resources, deprivation, ethnicity, religion, greed, political power, etc. In natural resource dependent economies, like Africa, many of these conflicts are related to

the use and management of natural resources, in particular land.

Because land is the primary source of livelihoods for the majority of the population, land /environmental degradation easily threatens the people's socioeconomic existence. This in turn means more insecurity and more tension. Environmental insecurity arises not from the loss of extreme scarcity of environmental resources but more from the perceived and actual threat (individual and community levels) arising from that scarcity.

There is an emerging global consensus that there is significant positive correlation between environmental insecurity and armed conflict. Many scholars, however, caution that the link between environment and conflict is never direct, because wide ranging factors, for example, governance, socio-economic situation, culture, level of technology, and property rights impact heavily on the environment-conflict link. Governance has perhaps the most vital factor because government policies and institutions heavily influence the behavior of resource users and determines how, when, and why a natural resource is used. Further, as contemporary history shows it is rather unlikely for environmental insecurity to lead to conflict in countries where there is democratic and sound governance. Indeed, it is where there is governance deficit and state failure that there is prevalence of environment induced actual or potential violent conflict.

To contribute to the understanding of the environment and conflict link, the *Partnership for African Environmental Sustainability* (PAES), with funding from the European Union, launched the project, "Integrating environmental security concerns in national development policies." Its primary objective was to study the role of environmental insecurity in triggering, amplifying and causing armed conflicts through, among other things, capturing community perceptions, and thereby influence development policy decision-making and peace negotiation processes.

1 The author was team leader of the Partnership for African Environmental Sustainability (PAES) project cofunded by the European Commission: Project B7-6200/00-15/dev/env, Integrating Environmental Security Concerns in Development Policy in Africa that studies the link between environmental security and armed conflict in Burundi, Ethiopia, Rwanda, and Uganda. This chapter is a summary of the study: *Environmental Security and Conflict: The Quest for Sustainable Peace and Development in Africa*, March 2004.

The Study covered Uganda, Rwanda, Ethiopia and Burundi. These four countries represent countries with a recent history of internal conflicts and heightened environmental insecurity characterized by high population density, pervasive poverty, heavy dependence of the population on natural resources for livelihoods and survival; severe land degradation and a recent history of internal violent conflicts.

To discuss the findings of the study, PAES organized a symposium, "Environmental security, Poverty, and Conflict: Toward Sustainable Peace and Development" in September 2003 at the International Conference Centre in Kampala, Uganda where over fifty senior government officials, experts and media representatives participated. The ideas that transpired at the symposium have enriched the findings of the study.

68.2 Changing Nature and Characteristics of Conflicts: Environmental Security as a Paradigm for Understanding and Managing Conflicts

In the 1950's and 1960's, most wars in Africa were associated with the struggle against colonization. Since then, armed conflicts have increased in number and frequency (McNeely 1998; Myers 1996; Renner 2002), and have left a trail of mass destruction of life, property, and financial resources. Three times as many people - 110 million - fell victim to war in this century as in all the wars from the first century AD to 1899 (<<http://www.gsreport.com/articles/arto00167.html>>). Since World War II, more than 160 wars have been recorded (McNeely 1998). About 70 per cent of all war casualties since World War II have been civilians, rising to more than 90 per cent in the 1990's and Africa alone has experienced more than 30 wars since 1970 (Myers 1996) and some of these, including those in Somalia, Ethiopia, Eritrea, Sudan, Chad, Angola, Uganda, DRC, and Mozambique, have been prolonged. In addition, more than 200 coups or attempted coups have been experienced since 1950 (Renner 1996). In 2003, for example, some 17 of Africa's 53 countries were involved in armed conflicts that resulted in more than 3 million refugees and displaced people. "Only 2 out of 27 armed conflicts in 26 locations around the world were external conflicts" (SIPRI 2001). Today's armed conflicts are complex, unstructured, and difficult to predict, often fought by multiple actors with multiple interests, involve civilian population, and most victims are women

and children (SIPRI 2001; McNeely 1998; Myers 1996; Renner 1996). Timberlake (1988) went further and argued that "every civil war in Africa has had a 'drought' or a 'famine' as a cause or triggering factor." In many parts of Africa, there are cases of conflicts over natural resources covering wide-ranging ecological zones. For example, the conflict in Somalia, which made the country stateless, is the continuation of a 100-year-old movement of major Somali clans southward into agricultural areas from nomadic grazing areas that have been becoming more and more overpopulated (Hutchison 1991). The Rwandan genocide that claimed the lives of close to one million people is attributed to competition over declining farm holdings between Hutus and Tutsis. In Rwanda, the average farm size has declined from 2 ha to 0.7 ha per family over the past four decades, and this is believed to be the root cause of armed conflicts between the two groups, and hence the civil wars fought in Rwanda since 1959 (Bächler 1996). In Zimbabwe, at the time of independence in 1980, 45 per cent (mostly fertile soils) of the agricultural land were in the hands of white farmers, who were only 1 per cent of the country's population, leaving masses of the natives to cultivate the remaining largely infertile land. Faced with intense domestic political pressure, Zimbabwe's President Robert Mugabe instituted the Land Reform Policy that led the natives to illegally confiscate the whites' farms (Mukaro 2003), sparking off state-community and community-community conflicts in the country.

In most African countries, including Uganda, Rwanda, Ethiopia, and Burundi, which this study covered, land occupies a central place in the cultural and political history, social organization, and economics. Most grievances, family and societal disputes, court cases, and conflicts are associated with scarcity of arable land (Diamond 2005; Homer Dixon 1994; Ejigu 2004). But reversing environmental degradation or investing in natural resource management has seldom been in the centre of conflict prevention and resolution agenda of the international community.

On 15 July 1999, the BBC reported based on the findings of the Stockholm International Peace Research Institute (SIPRI): "large-scale trafficking in light weapons has been singled out as a major cause of the wars being waged in large parts of Africa." This large-scale trafficking of light weapons implies that there is an effective demand for such weapons. But the question is why do low-income societies invest in guns when they do not have sufficient resources to feed themselves? Why do people think that owning a gun

will give them a sense of security, not saving the money?

68.3 Conceptual Framework and Study Methodology

The notion of environmental security enables us to understand changes in the environment in light of their potential to trigger, amplify, and or cause violent conflict. It also helps us to understand how war impacts environmental change and also how we can use sound environmental management as a tool for conflict resolution and building enduring peace. Although we often come across terms like 'land conflicts,' 'timber or diamond conflicts,' it is important to note that neither the abundance nor the lack of access to nor the misuse of these two resources would automatically result in societal conflict. It is rather the perceived or actual feeling of threat, insecurity, and hopelessness arising from deprivation that could trigger and cause conflict. Even in this case, individuals and communities adopt complex strategies to cope with environmental stress. Conflict erupts after all coping strategies are exhausted and when public policy and institutions fail to make timely and substantive interventions to guarantee socioeconomic well-being, law and order, job opportunities, and hope.

When we talk about security or insecurity, our primary concern is the security of human beings² as individuals and communities. Individuals and communities are said to be secured when they are free from threats, conflict, hunger, disease, deprivation, and poverty. The attainment of security, or the lack of it, is a product of the interactions of many factors that affect us, for example, the biophysical situation, economic policies and conditions, population and settlement, political system and institutions, and culture. We can be secured, if the economic, social, political policies are right and are well functioning to guarantee our wellbeing. Effective governance, sound environmental policy, is critical to sustainable management of land and forests and to the attainment of political stability.

It is widely recognized that land/ environmental degradation is a result of individual and/or collective decisions made regarding land use in response to changes in public policy, markets conditions, and pop-

ulation growth. Responses at the individual level may take the form of changes in land use, management practices, and investment. At the community level, responses may include changing the size of commons, the rules governing uses and transfer of common resources, as well as the distribution of benefits. These changes in resource conditions affect productivity and livelihoods. Individuals, among other things, may respond through migrating either in search of cultivable land to other rural areas (rural-rural migration) or in search of income (rural-urban migration). Population migrations, often under conditions of weak governance, failed policies and states, lead to violent conflict (Homer-Dixon 1994, Homer-Dixon/Percival 1996; Percival/ Homer-Dixon 1996). A good public policy has the potential to avert impending conflicts through creating incentives to invest in land, promoting and enforcing sustainable use of resources, strengthening institutions to innovate, supplying new technologies, and in creating conditions for dialogue and participatory development. On the other hand, wrong policies create conditions for land and forest conflicts to erupt, and can subject a country to a period of political and socio-economic instability.

Social and economic instability and conflict in turn damage the environment causing insecurity. The two-way relationship between the environment and conflict is rather complex and non-linear influenced by a host of policy, institutional, cultural, and economic factors. Some scholars, for example, Gleick argues that environment related threats to human security are real and what is needed is not a redefinition of security, but rather a better understanding of the links between environmental and resource problems and international behavior and security (Gleick 1991).

Uganda, Rwanda, Ethiopia, and Burundi, share important common processes that help to link environment scarcity and insecurity to poverty and conflict. Population has significantly increased. The size of farmlands has become smaller. The quality of soils and fresh water has deteriorated. Degradation of natural resources, particularly renewable resources, is widespread as evident from loss of forest, soil, and water resources. These resources are increasingly scarce because of diminished supplies, increased population-induced demands, and inequality in distribution. The economic returns to these resources are low and falling as evident from diminishing productivity, declining livelihood, and impoverishment. Population mobility in response to scarcity and impoverishment is common. Policy, institutional, and technological deficiencies are prevalent in all countries.

2 The *Human Development Report* of UNDP (1994) listed seven main threats to human security; see the chapter by Abdus Sabur in this volume.

In studying the link between environmental insecurity and conflict (potential and actual) the four country study considered two ecosystems: agricultural land (farm and grazing) and fresh water. Agricultural land as a percentage of total land accounts in Ethiopia (31 per cent), Uganda (43 per cent), Rwanda (66 per cent), and Burundi (86 per cent). The recent estimates of ERS/USDA show that Ethiopia has nearly 20 per cent of its total land in the category of 'good soils and climate', which compares with 36 per cent for Rwanda. About 22 per cent of the land in Uganda is covered by fertile soils, 43 per cent with soil of fair productivity, and 33 per cent of soils are of low productivity (NEMA 2001).

The study commenced with the hypothesis that environmental insecurity potentially translates into environmentally-induced conflicts, and a transition from competition for scarce resources to environmentally induced conflicts occurs under unique sets of conditions: (i) population growth and pressure on resources; (ii) restricted mobility of labour or large-scale influx of population; (iii) socio-economic and ethnic heterogeneity related to inequality; (iv) distribution of finite resources or the wealth created from these resources; (v) low technological innovations to mitigate loss of productivity of resource; (vi) weak institutional arrangement to economize and allocate scarce resources; (v) environmental goods and services to competing claimants; (vi) failed state, democracy and public policy.

A simple conceptual framework was developed and a set of indicators identified. Data was obtained from three sources: literature review, data from governments, NGOs and international agencies; and primary (household surveys and community group-focused discussions). Field studies were designed and carried out to capture community perception and test the hypothesis that environmental insecurity causes, amplifies, and/or triggers armed conflict. The field surveys consisted of a rapid rural survey of 480 households in Ethiopia and Uganda; and 240 households in Burundi and Rwanda in selected conflict and land degradation affected provinces and districts. Community group discussions were also conducted to verify information collected at the household level. The field survey has been generally consistent with data at the national level obtained from secondary sources.

68.4 1.4 Key Findings of the Study

68.4.1 1.4.1 Pervasive Environmental Insecurity

The findings of the study highlighted the strong evidence of severe and significant environmental insecurity that exists in all the four countries. Key indicators included:

- a.) **Farm size is small and declining.** The overall trend in all case countries is towards declining farm size. In the case of Rwanda, there was little land available for agricultural expansion by the late 1980's, while the number of people placing demands on existing cropland increased. Hence, land scarcity is manifested both in declining farm-size and failure to produce enough food for subsistence.
- b.) **Incidence of land fragmentation:** The evidence from Uganda demonstrates intensity of land fragmentation, which tends to be high in land-scarce areas. At the root of the explanations are population concentration and agro-ecological conditions (nature of soils and rainfall regimes). Land fragmentation is practiced in areas where even small plots remain economical to operate in the eyes of the subsistence farmers.
- c.) **Increased cultivation intensity:** As land becomes scarce relative to labour, farmers use more labour per unit of land or cultivation intensity increases. Such practice is common in the densely populated highlands of Burundi, Rwanda, and Ethiopia.
- d.) **Growing landlessness:** Because of scarcity of land, there are a sizable number of farmers who seek but are unable to access land. For example, there are probably as many as 15 to 20 per cent of the farm population without 'official' landholdings in Ethiopia and Rwanda (Ejigu 2004).
- e.) **Grazing land is in short supply:** Grazing lands are overcrowded during the rainy season. Farmers respond to scarcity of grazing land by reducing the number of animals they keep and in some cases they change from cattle to smaller ruminants (sheep and goat) to enhance drought resistance, flexibility in grazing requirements, and ease of converting into cash. In Burundi, pasturelands are contracting because of conversion to crop farming. In Rwanda, shortage of grazing land is also acute with over 65 per cent of respondents reporting lack of land for grazing.
- f.) A new tenure arrangement is emerging with rising informal land transactions. Generally, customary

land tenure systems dominate in Burundi, Rwanda, and Uganda and inheritance is the primary means of acquiring land. In Uganda survey sites, the percentages of farmers with land through customary system range between 72 per cent in Sango Bay and 99 per cent in the Kabale and Ntungamo site. The evidence from Rwanda shows a shift in mode of land access in response to land scarcity with acquiring land through lease and purchases becoming more common. While administrative based land allocation is the principal venue for land acquisition in Ethiopia, access to land through informal land transactions, particularly rental land markets, are gaining importance. The current evidence indicates as many as 15–30 per cent of farm households in different parts of the country transact land through informal land markets. Because of growing scarcity of arable land, renting in land is tighter than renting out land. The evidence from Ethiopia points that land rental rate is on the rise. Second, farmers who lease out land also demand cash deposits or advance payment, which is beyond the reach of the majority of farmers. Third, access to land favours farmers with farm skills and experience.

68.4.2 Poverty, Environmental Degradation, and Conflict are linked: Burden of Coping Falls Heavily on the Poor

The evidence from these four countries shows that environment and poverty are closely linked. First, the majority of the population is dependent on natural resources for their livelihoods, particularly on agriculture. Second, the natural resource base is shrinking (i.e. forest cover, grazing land, arable agricultural land, and water resources). Third, incidence of poverty tends to be greater in ecologically fragile marginal agricultural areas with few routes to escape poverty. For example, mapping of poverty by geographical area for Ethiopia shows poverty to be lower in villages with adequate and stable rainfall, moderate population density, and high market access. Fourth, while in general rural households are constrained to protect downside fluctuations in food consumption by limited income substitutions, unfavourable terms of exchange in market place, and weak community and public support systems; the burden of coping is unequal and falls heavily on those with a low income and asset base. In Rwanda, a new category called 'very poor' has emerged, where the links between poverty, food insecurity, and land degradation have been

gravely exacerbated by war, as in the case of the 1994 civil war.

68.4.3 Water Stress and Scarcity is Increasing

The study countries are increasingly facing water stress since the demand for water is growing rapidly relative to supply of water resources. Getting access to water sources is more limited in rural than urban areas. This is partly due to the pattern of population settlement relative to water sources as population is largely settled in high-lying areas while the water sources are found in low-lying springs. On the other hand, demands for water are increasing due to population growth and development requirements. Scarcity of water poses potential threat of conflict among riparian countries without established enforceable institutional arrangement governing allocation and uses.

68.4.4 Households Often Fully Exhaust Their Coping Strategies Prior to Migration

Households have developed multiple coping strategies. For example, in Ethiopia, when subsistence farming fails them, households move into lower-return occupations: (i) sale of collected environmental goods such as firewood and charcoal; (ii) collection of dried dung; (iii) attaching child labour as herder with wealthy households or rearing animals for others in exchange for consuming their products such as milk; (iv) casual wage labour in rural towns; (v) petty trading; (vi) renting out land for lack of complementary inputs; and (vii) income transfers including relief aid. In Uganda, however, renting land is the key coping strategy. Migration is a coping strategy of a last resort.

68.4.5 Mobility of Population is a Major Mechanism for Easing Pressure on Land through Migrating to Areas with Low Population Density

Migration provides a way to mitigate climatic risk across space, which is a common practice among pastoral population in arid and semi-arid environments. Migration is also a common coping mechanism in time of food crisis. Most cases of migration in the four case countries are from rural to rural areas. In the 1994 population census in Ethiopia, for example, rural to rural migration accounted for 48.9 per cent of total migrants followed by rural-urban (24.8 per cent), urban-urban (18.9 per cent) and urban-rural (7.3 per cent). Migratory movements from overpopulated re-

gions to the fragile ecological areas are also noted in Rwanda and Burundi after independence, which is marked by considerable population mobility. The majority of rural households in Burundi do not live in their places of birth. In Uganda, five major migration streams (of at least 50,000 migrants) involving massive migration have been experienced: Bushenyi to Mbarara, Kabale to Kabarole, Kabale to Mbarara, Mpigi to Kampala, and Tororo to Iganga. Four of the five major streams of massive migrations in Uganda were from rural to rural areas, an indication of real or impending environmental insecurity at the source (Kabale, Tororo and Bushenyi).

68.5 Environmental Insecurity and Conflict: Key Evidence

Disputes and conflicts over scarce natural resources are highly prevalent in case countries. The evidence so far points that these disputes and conflicts, in the majority of cases, are related to competition over access, use, and transfer of scarce natural resources. For example, the majority of the land users in the Ethiopian sites relate to these conflicts to scarcity of land resources, particularly farmland scarcity in the upper elevation communities and grazing land in the low lying communities where farmers-cum-herders are more dependent on extensive livestock. Whilst armed conflicts do not figure prominent in the community-based rankings, there are cases of disputes and conflicts. And more than 77 per cent of conflicts and disputes in each of the five study areas were over land (both arable and pasture). In the four countries, different types of environment insecurity-induced conflicts exist, although a country may not experience all of them.

68.5.1 Cultivator-Cultivator Conflicts

These are associated with pressure on farmland and common property resources (grazing land, community forests, and water points). There are several cases of competition over agricultural land caused by inter-generational transfer, division of common pool resources, settlement of non-indigenous population, and claim on original land by returnee migrants.

- **Conflicts over inheritance:** This is the principal source of disputes between fathers and sons and between the young and the old that threatens the stability of rural communities in Ethiopia under existing land tenure system. In Uganda, the study

found that most court cases, both criminal and civil, to be land related disputes arising from children fighting over ownership of small land with their fathers. In cases where land is inherited, there is a greater likelihood of societal conflict as inherited land is more disputed than rented or purchased.

- **Conflicts over individualizing the commons:** Common lands such as hillsides and marginal areas are distributed to individuals in some regions of Ethiopia as a way to ease the problem of landlessness and promote regeneration of degraded lands, since each individual will be responsible for his/her plot. But the scheme has sparked conflict among users, and between the community and the local government.
- **Returnees and claims to original (or, ancestral) land:** After the fall of the military government in the early 1990's in Ethiopia, there were a great number of refugee returnees from neighbouring countries, demobilized soldiers, and returnees from the major resettlement programme of the 1980's to their places of origin in the northern highlands. The settlers returned to their homes in increasing waves; small in the early years and then increased appreciably towards the end of the decade, and grew to huge proportions by the time of the fall of the military government. Upon the return of these settlers, many of them found that their land was allocated to others and there was very little land to distribute. Some communities were forced to parcel up marginal, often grazing land to give to returnees, while in other communities returnees were left empty-handed. Many returnees did not have any means of livelihood and thus survived by 'harvesting' and marketing forest and common-property resources.

68.5.2 Herder-Cultivator Conflicts

These are conflicts between pastoralists and cultivators over access to pasture and water resources. Such conflicts are common in the 'cattle corridor' of Uganda, which extends from the southwest to Karamoja in the northeast including Mabarara, Rakai and Katakwi districts. A well-publicized example is the conflicts in the Katakwi-Karamoja region in North-east Uganda. There are also other current conflict spots in Uganda involving pastoralists and cultivators: The Nyabushoze pastoralists in Mbarara district face severe land degradation and scarcity, and those who move out to places like Teso face conflict with the lo-

cal population. The Bahiima and Banyarwanda pastoralists, who lost their traditional grazing land in former government ranches, have moved into the Teso region in pursuance of water and grazing land but face armed resistance by the Iteso people. The fear of violence necessitated the government to deploy soldiers to protect the safety of the migrant herders. The classic example of cultivator herder conflict is the historical and contemporary conflicts between agriculturalist Hutus and pastoral Tutsis in Rwanda and Burundi. Tutsi is not exactly the name of an ethnic group: historically it meant 'people who own cattle', and Hutu meant 'people who farm'. But these conflicts have taken over time multi-dimensions within the Lakes Region, explained in the main report and the country case studies.

68.5.3 Herder-Herder Conflicts

There are numerous cases of inter-community conflicts between different pastoralist societies living adjacent to each other. The most significant conflicts in the Ethiopian cases occur in the Awash River basin, which cuts across different ethnic groups. There have recently been frequent clashes between the Afar and the Issa Somali, between the Afar and the Kereyu, and the Issa and the Borana, to mention only the most significant. The Afar and Issa conflict may be taken as a good example of an ecological conflict driven by water. Within each herder community there are conflicts over access to resources, especially of grazing land and water.

68.5.4 State-Cultivator and Herder Conflicts

Conflicts between state and farmers including both cultivators and herders are pervasive in Ethiopia since the 1960's. During the Haile Selassie regime, such conflicts were triggered by the government's decision to individualize the commons. During the Dergue (1974-1991) and Woyane (1991-???) regimes, state-cultivator conflicts became more prevalent in the aftermath of the 1975 land reform that prohibited land transfer other than through the state functionaries. Land is state owned and qualified farmers have access through local state functionaries. Hence conflicts arise between these functionaries and farmers over access, use, and transfer of government-owned land. The conflicts over the water of the Awash basin in Ethiopia is partly the making of the successive governments' effort to develop large-scale commercial agriculture that by and large has failed to take into ac-

count the needs and interest of the pastoral communities inhabiting the Basin.

In Uganda, there are cases of conflicts arising from encroachment of government-controlled protected areas. For example, there was massive eviction of the Bakiga, who had settled in the Mpokya/Kibale Forest areas in Uganda in 1993; Mt. Elgon National Park in 2000, and other protected areas, which include Mgahinga, Mt. Rwenziri, and Queen Elizabeth National Parks. The Karamojong in Uganda are against the gazetting of most of their fertile land and, in response, they encroach on pasture and water in Teso and Lango. The Mbale conflict is due to the encroachment of public domain. The encroachers are not ready to leave the forest but negotiations are still ongoing. The Kibaale and Kyenjojo conflicts have become hot political issues and time bombs waiting to explode. The Bakiga community was settled by government due to land scarcity in Kabale in the 1960's and the growing economic and political power of the Bakiga has incensed the Banyoro. Violent clashes and loss of lives have been reported leading to deployment of the national army and other security agencies in the area.

68.6 Contributing Factors to Environmental Insecurity-Induced Armed Conflicts

The degree and intensity of environmental insecurity-induced conflicts are contingent on other contributing factors.

68.6.1 Failed State and Policy

A defining characteristic of weak governance is the inability of government to establish viable institutions that can address people's needs and minimize social conflicts. Competent judicial institutions can mitigate conflicts arising over scarce natural resources. Varieties of these arrangements exist in the country studies. In addition, there are regional based organizations designed to prevent conflict over shared resources such as shared river basins. The likelihood of armed conflict is enhanced where groups organized around social cleavage (e.g. ethnicity or religion) perceive or experience governance deficit. Environmental scarcities and loss of livelihoods provide an *opportunity* for opportunistic political forces to mobilize people into violent acts. Extremist forces were able to exploit the historical ethnic cleavages and animosities, for exam-

ple, in Rwanda to mobilize a very large part of the majority group of the population against the minority group in the 1994 civil war in Rwanda.

The likelihood of environmental insecurity-induced conflicts increases in countries where traditional institutions and systems are undermined. In all four countries, there are established indigenous institutional arrangements for managing conflicts in the study countries. These arrangements involve at the simplest level the intervention of elders, leaders of community-based support networks (e.g. *idir* or *qire* in Ethiopia and the *ubushingantabe* in Burundi, *gacaca* in Rwanda) religious leaders or prominent personalities. The decisions handed down by traditional peacemakers do not have the force of law but only the force of tradition and community sanction, and yet they are as binding as the formal decisions of the law.

68.6.2 Scarcity-induced Migration

Population mobility and settlement tend to raise a likelihood of resource conflicts in most of the study areas. For example, the conflicts between the Bakiga and indigenous Banyoro and Batooro in the Kibaale and Kyenjojo Districts, and the Bahima/Banyarwanda pastoralists in northeast Uganda are resisted by the recipient indigenous communities what has often caused ethnic tensions. The study found that there has been increased migration especially by the pastoralist communities in search of water and pasture (grazing land), which has often attracted hostile reactions from host communities. The latest case being the attempted migration of Bahiima herders to Teso (2002), which has attracted hostile reception threatening to result in violence if the migrants do not move.

The Rwanda and Burundi studies take a different perspective on environmental migration and conflict links. Resource scarcity in the Rwandan situation propels stronger groups/communities to resort to resource capture. Resource capture by powerful groups within communities has the effect of shifting resource distribution in their favour and thereby subjecting the remaining population to resource scarcity. In an environment whereby few privileged individuals and/or groups grab most of the environmental resources at the expense of the weak majority may lead to a situation that results in large migration of poorer and weaker groups into ecologically fragile regions that subsequently become degraded and causing serious pressures on livelihood security, thus creating room for conflict.

68.6.3 Societal Heterogeneity

Large-scale migration may lead to conflict more likely where there exists social cleavage between migrants and indigenous population. The Uganda study underscores that the major link between environmental insecurity and conflict occurs mainly through environmental-induced migration into communities with different ethnic makeup. Conflict arises between heterogeneous communities differentiated by ethnicity and at times by livelihood strategies (e.g. conflict between pastoralists and cultivators). In many cases, ethnicity was used as a cover for environmentally-induced conflicts. Conflict entrepreneurs have used ethnicity to gain and maintain political power and thereby access to scarce resources. In Rwanda and Burundi, the pre-colonial differences between the Hutu and Tutsi deepened during the colonial period. The post-colonial governments in both countries further polarized the ethnic divide to control political power and resources. The Burundi report highlighted that the conflicts in Burundi are not between the Hutu and Tutsi masses, but conflicts between elites from both ethnic groups in their competition for economic and political power.

68.6.4 Economic and Political Ascendancy

Societal heterogeneity as a contributing factor gains more strength where the migrant people assume economic and political power in their place of settlement. For example, the indigenous Oromo people in southwest Ethiopia resented the Wolloye migrants as the latter assumed local administrative and political powers and penetrated into the traditional settlement areas of the Oromo population.

The Uganda study underscores the fact that underlying resource conflicts are increasing the economic and political position of the immigrant population, such as the conflict between the Bakiga migrants and indigenous Banyoro and Batooro. It is indeed scarcity that induces conflict, particularly where it is fuelled by tribalism and quest for political power. These ethnic groups have been living together in peace since the 1950's. But, with decline in land availability, economic ascendancy of the Bakiga, and their quest for political power migrant, ethnic clashes are more pronounced now. The loss of political power by the indigenous Banyoro in the 2002 local election, for example, sparked ethnic conflict.

68.7 Conclusions

The evidence from the case studies, including community surveys gathered from the four country studies, confirms the widely held view that environmental insecurity plays a significant role in causing, triggering, and aggravating armed conflicts. There are clear indications that environmental scarcity in the context of high population pressure, low institutional and technology response, and poverty is bound to induce armed conflict between communities. The probability of conflict increases, where environmental insecurity induces population mobility particularly towards heterogeneous communities (e.g. ethnic, culture, etc.); and where these migrants tend to dominate economic and political spheres, the recipient communities become aggravated and propensity to conflict mounts. Conflicts are almost certain where a weak state fails to deliver law and order, provide transparent and accountable administration, implement unbiased and fair policy, and institute effective mechanisms to address and resolve grievances and disputes. On the other hand, nurturing of social ties and economic integration neutralizes forces that tend towards armed conflict.

Poverty, economic deprivation, and vulnerability create conditions of environmental insecurity to lead to violent conflict. It is not the general level of poverty that causes conflict, *per se*. Rather, it is the consequence of poverty and the control of scarce resources that results in increased economic deprivation, pushing the poor onto marginal areas, and heightened social despair and uncertainty of the future. To explain conflict, what matters is thus not being poor today but the perception of future threat of their livelihoods and growing poverty. When people are under threat of environmental insecurity, they are prone to manipulation by warlords or conflict entrepreneurs for engaging them into conflicts for political ends. Or, the poor may be pushed onto marginal areas by powerful groups.

The good news is that conflict prevention and resolution processes and programmes can bring sustainable peace if anchored in combating environmental degradation, increased investment in natural resource recovery, and sound environmental management. Therefore, integrating environmental security concerns in development policy is a vital tool for attaining sustainable peace and development that needs to be promoted at the national and regional levels.

There is a move towards decentralization in all four countries. This process means setting a process

of broadening participation of stakeholders, aligning development priorities to needs, greater control and management of resources including scarce natural resources, and mitigating conflicts. A distinct feature of the decentralization is the increasing space for participation of indigenous institutions and promotion of private sector investment. Regional sub-groupings and organizations have also been strengthened and the capacity to enforce agreed policies enhanced as seen in the incident in Togo in early 2005, where the military appointed interim leader was forced to resign. Africa, thus, can hope for economic recovery, growth, technological transformation, and sustainable peace.

69 Environmental Security in Sub-Sahara Africa: Global and Regional Environmental Security Concepts and Debates Revisited

Sam Moyo

69.1 Introduction¹

Environmental security is a major concern in world affairs. However, the concept has not yet been coherently defined, together with its threats, and policy responsibilities (Brauch 2005, 2005a). Few countries have an official definition of environmental security that unifies thought and action. Major international organizations (UNEP, WHO, UNDP) have no agreed definition to guide policy. However, other organizations, such as NATO list environmental security among their priorities. The definition of the term is clustered around two central concepts: repairing damage to environment for human life support and for the moral value of the environment itself; and preventing damage to the environment from attacks and other forms of human abuse. Environmental security threats often involve transborder and/or global impacts that would require international cooperation. Nation-states acting alone can not provide environmental security. International organizations lack the capacity to address the threats. The weight of decision power rests with national governments. As a result, national sovereignty can come in conflict with actions necessary to insure environmental security.

Environmental security is sometimes confused with sustainable development. Although both are mutually reinforcing concepts and directions for policy, they mean different things. Sustainable development focuses on environmentally sound socio-economic development, while environmental security focuses on preventing conflict related to environmental factors. Environmental insecurity generally occurs as a cumulative result of high population growth, decline in quantity and quality of renewable resources and the lack or unequal access to these resources. As popula-

tion grows, given existing technology, the available land per capita is reduced to smaller and smaller sizes. Community and household characteristics in addition to land use system dynamics condition the nature of these changes. Buzan (1983) defined environmental security as the capacity to live harmoniously with nature or to maintain a sustainable environment. Mohamed Salih (1994) put forward two perspectives on environmental security. The first one relates to the capacity of individuals and groups to meet their basic needs from a sustainable environment. According to the second perspective, environmental insecurity involves serious consequences for social, economic, political and physical security. Following these arguments, the traditional conception of security must be reconfigured to include non-military threats, such as human rights abuses, outbreaks of diseases, resource scarcity and environmental degradation (Moyo/Tevera 2000).

Environmental security is considered an integral part of human security. Human security refers to a state of human conditions free from threat of hunger, poverty, and armed conflict at the individual, group, community, country, region, and global levels. A society or community becomes environmentally insecure when severe environment scarcity arises and becomes a threat to national, community and individual welfare and survival under conditions of failed ecological stability, increased vulnerability to livelihood and survival, and heightened risk of armed conflict. Environmental insecurity is a collective expression of these manifestations (or, risks) that is particularly real where institutions and governance fail to prevent and resolve conflicts. Conflict here refers to disputes and clashes that arise from claims and command over agricultural land and fresh water resources, and the distribution of induced conflicts between two or more societal groups or communities as well as between states and sub-national groups that involve the use of arms. Conflict areas refer to places where there is potential (crisis stage) or actual conflict.

69.2 Social and Economic Dimensions of Environmental Security

Several studies have emphasized the high dependency on natural resources by most African economies.² Increasing demand for resources for both local and export markets, as well as escalating competition for the control of natural resources, have been a source of insecurity and have increased the incidence of environmental conflicts.

69.2.1 Water

Water stress and scarcity are widely felt in many sub-Saharan African countries, although only few cases of actual conflicts over water have been reported. Some studies have shown that countries are increasingly facing water stress since the demand for water is growing rapidly relative to supply of water resources. Getting access to water sources is more limited in rural than in urban areas. This is partly due to the pattern of population settlement relative to water sources as population is largely population settlement in high-lying areas while the water sources are found in low-lying springs. On the other hand, demand for water is increasing due to population growth and development requirements. Scarcity of water poses potential threat of conflict among riparian countries (Rwanda, Uganda, Sudan, DRC, Tanzania, Zambia, Mozambique and Zimbabwe) without established enforceable institutional arrangements governing allocation and uses. While states are more likely to fight over non-renewable than renewable resources, river water is more likely to stimulate an interstate resource war. Water is a critical resource for personal and national survival, and since river water flows from one area to another, one country's access can be affected by another country's actions (figure 69.1).

The boundaries of 11 southern African countries lie across fifteen river basins and straddle five lakes. It therefore follows that cooperation is built upon the mutual interest of the riparian states. Given that water is a shared resource, with most river systems, which constitute the biggest source of surface water flowing through more than one country, the resource is a constant source of potential tension. For example, coun-

tries upstream may not only pollute the water, but as a political measure may threaten to dam the river as a means of coercive diplomacy (see chap. 50 by: Ashton/Turton; chap. 51 by Kipping; chap. 52 by Borghese; and chap. 53 by Lindemann).

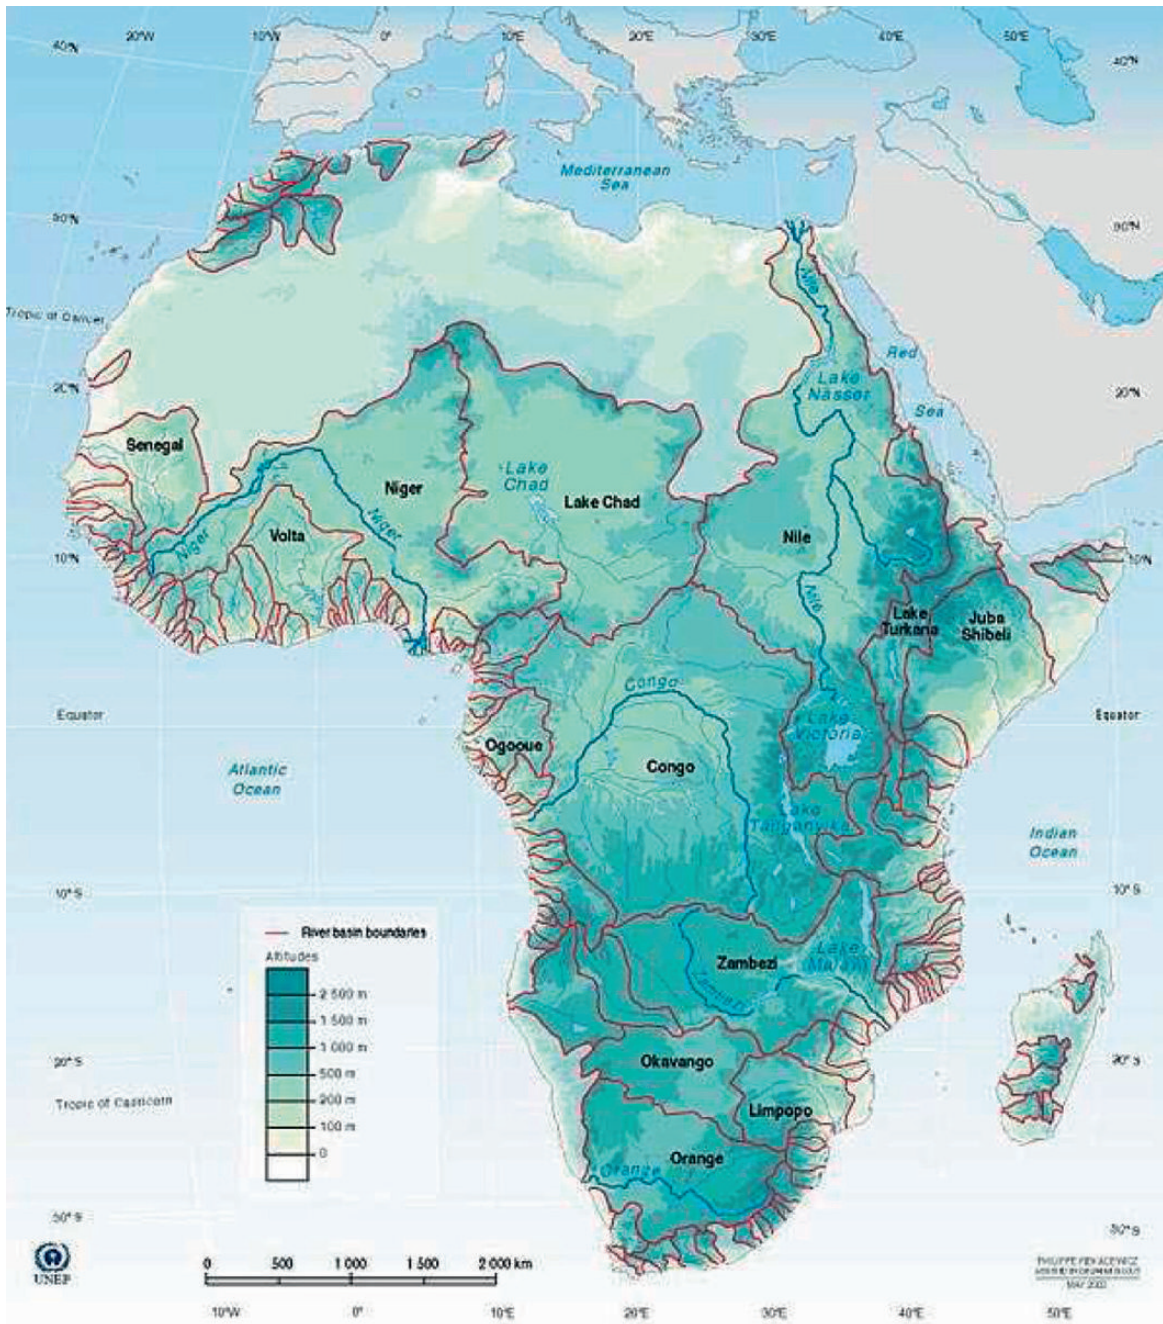

Water scarcity is increasingly being recognized throughout the world as a threat to human security. The growing water scarcity in Africa, mainly arising from unequal distribution of fresh water resources is a major issue of concern (figure 69.2). Thirty percent of the total runoff from Africa originates from a single river basin, the Congo (figure 69.1). As population increases and the amount of available water remain constant, the maximum per capita demand that a country supports obviously decreases correspondingly. Africa's population grows at 3.3 per cent per annum. With this phenomenal rise, water requirements for energy generation, domestic use, agricultural intensification and industrial production increases as well. The over exploitation of water by some privileged sectors might result in acute shortage. Increasing competition can potentially destroy the existing social arrangements and mutual tolerance and lead to ethnic and social dichotomies. Currently 14 of the 53 nations of Africa are subject to water stress or scarcity and by 2025 almost half (25) of the continent is expected to be under water stress or scarcity (UNEP 2002c, figure 69.3) The main conflicts in Africa during the next 25 years could be over water, as countries fight for access to scarce resources, and that potential 'water wars' are likely in areas where rivers and lakes are shared by more than one country. In this regard, the Nile (DRC, Ethiopia, Kenya, Rwanda, Sudan, Tanzania and Uganda), Niger, Volta and Zambezi basins (Mozambique, Zimbabwe, Zambia) could be cited as possible flashpoints

Environmental-induced conflicts occur between states arising over sharing common resources such as trans-boundary waters. Conflict in a country can also spill-over into neighbouring countries such as large refugee flows. As the case of the Nile basin shows, the upstream riparian countries do not benefit as much as Egypt and Sudan. As the Nile water becomes scarce and the capacity of the upstream countries (or, the needs) increases, conflict is bound to arise unless a mechanism is in place dealing with sharing water resources, utilization and management, and distribution of benefits (chap. 48 by Adly/Ahmed and chap. 49 by Kameri-Mbote/Kindiki).

There are eight riparian countries that share the waters of the Zambezi basin. The following are issues that are potential sources of conflict: (a) increasing

scarcity of water in the riparian countries and unequal demand for Zambezi waters; (b) declining water quality associated with pollution; (c) management of catchments areas and flows of water (e.g. low lying countries such as Mozambique are subject to flooding in time of good rain); (d) equitable sharing of benefits; and (e) threat from unequal economic and military strength between countries. SADC has consid-

ered how best to address these issues but it has to build confidence and trust among the countries (chap. 50 by Ashton/Turton and chap. 53 by Lindemann).

69.2.2 Land

Africa accounts for 20 per cent of the world's land mass (2,963,313,000 hectares), about 66 per cent of Africa is classified as arid or semi-arid, and the region experiences extreme variability in rainfall. Approximately 22 per cent of Africa's land area is under forests (650 million hectares), 43 per cent is classified as extreme deserts (1,274 million hectares), and only 21 per cent (630 million hectares) is suitable for cultivation (UNEP 2002). In 1999, it was estimated that about 200 million hectares (32 per cent of the suitable area) were under cultivation while some 30 per cent of the total land area (892 million hectares) was being used as permanent pasture (UNEP 2002c). Since the 1970's, Africa has seen massive soil erosion and degradation of other renewable resources that created millions of environmental refugees. According to a United Nations Environment Programme (UNEP 2000) report, an estimated 500 million ha of land, including some 65 per cent of agricultural land has been affected by soil degradation since the 1950's. Only in the last two decades, Africa has lost about 50 million ha of tropical forest. This in turn triggered large scale cross border migrations, an increased flow of rural migrants to cities, and a breakdown of the social, economic, and cultural fabric of rural societies.

Many ethnic conflicts over socio-economic dominance in Africa are structured by unequal control over land and natural resources, since they are key sources of livelihood and wealth, and of the means to pay for education and hence to attain non-agricultural employment. Land conflicts vary among countries depending on specific histories of land concentration, the farming systems and political economic structures that sustain resource inequalities. The land question as a source of ethnic and racial differences and dominance has tended to be underplayed in sub-Saharan Africa outside of former settler colonies (Zimbabwe, RSA, Namibia), even though it tends to be a common problem in many countries, including in relatively stable economies and democracies.

Colonial and post-independence land policies tended to partition national economies into ethno-regional enclaves of unequal growth, where land and resources concentration occurred alongside marginalized regions. Land conflicts take the shape of 'ethnic' struggles among pastoralist groups competing for the control of grazing lands and water supplies, especially during droughts (Flintan/Tamrat 2002). Such land conflicts (e.g. Ethiopia) escalated following the demarcation of boundaries which fragmented pastoral groups and impeded cross border movements which essentially undermined the viability of customary land

Figure 69.3: Water Availability and Water Stress in Africa in 2000 and 2005. **Source:** UNEP-GRIP, Vital Graphics, at: < <http://www.grida.no/climate/vitalafrica/english/15.htm>>. Permission was obtained from Philippe Rekacewicz, UNEP-Arendal.

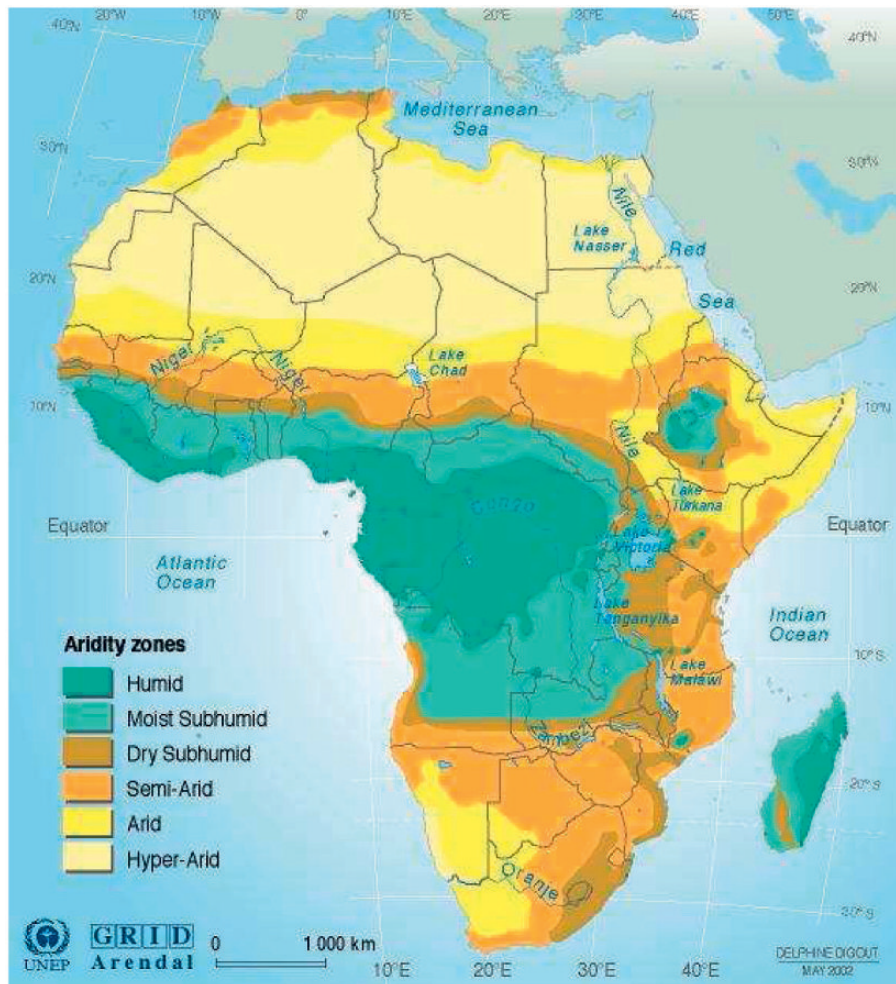

and resource-use systems (Flintan/Tamrat 2002). Territorially based ethnic clashes reign over local citizenship as conferring rights to such land (e.g. Ivory Coast). Minority groups have suffered substantially. Land distributional conflicts affecting some ethnic groups, especially minority ‘indigenous’ groups (such as the San/Bushmen in Botswana; Herero in Namibia) are common in some countries, especially where post-independence land expropriations by the

state have facilitated or led to the reallocation of land to local elites and foreign capital.

Land based ethnic conflicts in much of Africa are derived from increasing land concentration (Moyo 2004) among the elites (in Nigeria, Uganda, Kenya, Zambia, Mozambique, etc.) and the conflictual relationship over the power of the state vis-à-vis that of customary law authorities to allocate land. In formal law (in Ivory Coast and Burkina Faso) where the ‘tra-

ditional chiefs' are granted the right to mediate 'customary rights', this is most often limited solely to the right to cultivate (Delville 1999). This contradicts fundamental aspects of customary land tenure regimes, wherein the authorities responsible for land allocation also play a role in regulating local land-use systems (Delville 1999). But although the state has taken over the absolute right of land allocation, these local authorities usually remain legitimate in the eyes of the community and continue to enjoy considerable political power over land management systems (Delville 1999). The right of eminent domain and the power to allocate land rights are fundamental to customary systems and the power of local authorities, hence pre-colonial states using their right of conquest, tended to allocate land to their clients or servants (Delville 1999). Thus, territorially based ethnic clashes over land are common in various countries.

State control over land allocation and concession procedures by both the colonial and independent African governments, tends to be delegated to elected rural councils (in Senegal), through various forms of land allocation procedures (Delville 1999); leading to conflicts between formal law and customary land rights. This has especially afflicted French-speaking West Africa. Since the territorial distributions of local 'traditional' authorities are generally based upon lineage and clan social structures with particular ethnic identities, such land conflicts tend therefore to assume an explicit or implicit ethnic character.

But land conflicts also reflect wider resource based conflicts, including competition for grazing and water resources, as well as disputes over community territorial land and district borders, especially because in large parts of sub-Saharan Africa land use is dominated by pastoralism which is the only economic and

social livelihood in various countries. The causes of land conflict in non-settler Africa include: the grabbing and sale of communal land and favouritism in its allocation; partisan roles of security agents in mediating conflicts; the squatting in communal land; the commercialization of cattle rustling and competition over natural resources such as pastures, water and livestock; human and wildlife land use conflicts. Historical colonial alliances over the control of land underlie some of these conflicts, as the alliance between the British administrators and the Yao elite in Malawi, who were chosen as the instrument for indirect rule, demonstrates (Vail/White 1989). Land conflicts also have an international dimension which arises from the growing tendencies for land to be concessioned and sold to foreign companies, through investment agreements in agriculture, tourism, forestry and urban land investments.

The legacy of settler colonial land expropriation remains the source of extreme land conflicts in Africa. Racial inequality in the control of or access to land in Africa has been most extreme in Zimbabwe, Namibia, South Africa and Kenya, and led to radical land reforms in Mozambique (1976) and Zimbabwe (since 2000). The proportions of land held by racial minorities ranged from 87 per cent in South Africa in 1994 to 50 per cent and 30 per cent in Zimbabwe in 1980 and 1999. The Government of Zimbabwe (GoZ) resorted to compulsory land acquisition methods since 1997, but faced legal challenges from landowners, and failed to get British finance (on grounds of colonial responsibility) for speedier land acquisition. This radical approach was accompanied by violence and reduced agricultural production.

In spite of an orderly official land redistribution process in South Africa, land policy and conflict over land have been driven since the late 1980's by illegal land occupations which affected all its major cities and involved close to three million 'squatters' in shanty peri-urban township (Sihlongonyane 2005). The murder of 100's of white farmers each year reflects a deep-seated land conflict in South Africa, given that only 3 per cent of the land was redistributed by 2004, with a 40 per cent unemployment rate.

Recent attempts to confront the historical land expropriation and contemporary land-based inequities and discriminatory legislation and institutions, have generated renewed racial conflict. Land-related conflicts today increasingly arise from social initiatives to forcibly repossess rights to land and embedded natural resources. The greatest threat to security in SSA rests on unequal land ownership patterns in countries

where poor people's livelihoods depend on farming. Formal employment is unable to absorb the numerous unemployed, land-short, landless and homeless (Moyo 2004a; Tevera/Moyo 2000).

Land and natural resources conflicts revolve around five major issues. *First* among these is the general scarcity of land which forces villagers to occupy land perceived as vacant. *Secondly*, political issues have a tendency to encourage illegal settlements among villagers in return for political favours. *Thirdly*, communities also choose to dishonour boundaries in pursuit of their survival strategies. *Fourthly*, the marginalization of certain social groups forces them to defy certain rules and regulations. *Lastly*, armed conflict often results in the destruction of the environment. In addition, there are several types of environment induced conflicts in the countries in East Africa (Sudan, Rwanda, Uganda and Ethiopia). There are conflicts between farmer and pastoralist; among farmers; among pastoralists; between the state and pastoralists; between the state and cultivator and between different state cultivators.

In the majority of cases conflicts are related to competition over access, use and transfer of scarce natural resources. These conflicts arise over intergenerational transfer of land, sharing common resources (i.e., common grazing and water resources), migrants encroaching in indigenous land, and claims over ancestral land. Shrinkage of natural resources thus means less resource available for livelihood and survival, or less land available for intergenerational transfer, decreased likelihood of getting access to those who seek to acquire land or resource capture by powerful groups and marginalizing the weak or shrinkage of expansive territory necessary for extensive mobile pastoral population. These different conditions or manifestations of scarcity could lead to disputes and armed conflicts. The majority of land users relate conflicts to scarcity of agricultural land. Disputes and conflicts over scarce natural resources are highly prevalent in the East African countries (especially in Rwanda, Uganda, Burundi and Ethiopia; chap. 68 by Ejigu).

Conflicts have occurred or have the potential to occur where property rights are not responsive to scarcity of resources in a way that allows equitable access, efficient use and security of tenure. Inequitable distribution of resources where powerful groups marginalize the weak could in particular be a source of grievance and conflict. The cases of Rwanda and Burundi demonstrate issues of persistence, such as inequality in land ownership, squeezing of the poor onto marginal areas, and resettling the returnee refugees.

Also where governance deficit manifests itself in a variety of ways such as absence or weak central authority to enforce law and order, control by interest groups and biased policy, absence of transparent rules of law and enforcement, inadequate institutional and legal framework, and deficiency in capacity (i.e., manpower, finance and broad-based political support) conflicts are apparent. Environment induced conflicts become highly politicized over time, as shown in pastoral communities in the Awash Basin of Ethiopia, and the Hutu-Tutsi conflicts in the Great Lakes region. And, as in the case of Ethiopia in 1991-1992, environmental conflicts have a tendency to escalate during times of political or authority vacuum.

69.2.2.1 Land Tenure and Land Use

In Southern Africa, colonial policies on land tenure and access influenced patterns of land use and management in many ways. For example, legislation creating national parks and forest reserves was passed, leaving peasant farmers with little land and forcing them to turn to intensive production in either cultivated areas or grazing areas (Annersten 1989 cited by UNEP 2002c). Traditional communal land tenure was perceived as insecure and hence land was either leased from the state or privatized. The inequitable distribution of land in countries like Namibia, South Africa, Malawi and Zimbabwe has contributed to the declining state of resources in these countries, thereby creating the conditions that lead to food insecurity. Emerging informal land tenure arrangement is a key indicator of environmental insecurity. Informal land transactions, particularly, underground rental land markets are gaining importance (e.g. in Ethiopia).

Land tenure and land-use conflicts have the potential to undermine both environmental stability and food security. These forms of conflict are prevalent across and between land tenure categories. Whilst conflicts are normal in society (Widstrand 1980), their management is a major challenge. Investment in institutional development for local level conflict management is often the missing dimension in development policies. There are undoubtedly 'tenure hot spots' where, if the rights of the more vulnerable members of society are to be protected, change must not be allowed to take place in a legal and administrative vacuum (Adams/Sibanda/Turner 1999). For Zimbabwe Moyo (1995) describes how competing and ineffective attempts by both government and NGOs were frustrated by weak local administration and disingenuous central government interventions, and failed to resolve land tenure problems in the absence of constitu-

tional and legal principles governing land in the communal areas.

Studies in South Africa demonstrate the increasing breakdown of customary management arrangements and the often dysfunctional mixture of old and new institutions and practices (Adams/Sibanda/Turner 1999). People are often uncertain about the nature of their rights and confused about the extent to which institutions and laws affect them. Matters are further clouded by local and national political conflicts over land management roles in the communal areas and by continuing corruption.

At the micro level, peasants use various strategies to press for their land demands. Some of the main peasant strategies that have been used include 'poaching' of natural resources, fence cutting, illegal settlement/land occupations and resistance to development projects. Such strategies have tended to target various forms of state lands, particularly forests and national parks, and communal areas, as well as privately owned lands. In the case of Zimbabwe, land occupations have targeted various land tenure categories over the last two decades, including white owned 'commercial land' and state land (Moyo 2000, 2001).

Given the tendency for small-scale farmers or peasants to be largely concentrated in marginal land areas, and to have the least access to water infrastructures and investment finance, it is not surprising that their land uses are extremely vulnerable environmentally. It is in these peasant lands that land use regulation is coercive rather than based on incentives. Land-use patterns in Africa are very much restricted by the agro-ecological potentials of the land, as well as the underdevelopment of irrigation resources and the low levels of finance available for and applied to farm technologies. These land use patterns reflect environmental vulnerability and the technological backwardness of African farming, and the framework within which the peasantry is marginalized.

Smallholder agricultural development schemes are notorious for the coercive and discriminatory regulation of land uses applied to them. Since land held under freehold tenure systems and by the state tends to be the least regulated while customary tenure systems, under which most of the indigenous people in Africa live, attract numerous coercive and top-down land-use regulations (Shivji/Moyo/Ncube/Gunby 1998). However, since these customary tenure regimes are important electoral constituencies and they also tend to be physically remote from the reach of an increasingly withdrawing state, the direct regulation of their land uses cannot be extensively implemented. The coloni-

alists seem to have been able to enforce many such regulations with greater vigour than post independence governments have been able to do.

Land use patterns in Africa have tended to develop in close relationship with coercive land use regulations. Dirigiste land use regulations tend not only to determine which commodities are to be produced but also the timing and methods of production. In this respect, land use regulations themselves have been part of the problem of food insecurity at both national and household levels, given their promotion and prohibition of so-called 'cash' (and export) crops over domestic food crops, in keeping macro-economic incentives and agricultural support services directed at promoting these land use patterns.

The extension of these short term and external oriented land use regulations and policies on degradation, towards the more intensive extraction of forest, biodiversity and wildlife resources largely for export markets, has led to greater land use extensification in Sub-Saharan Africa, and led to a diminishing land and resource base available to the peasantry. Such processes have themselves not only extended the scale and scope of environmental degradation, but has also reinforced unequal patterns of access to land through the enclosure of vast tracts of lands by the state and elites. The effect here again has been the marginalizing large rural populations from access to natural resources for their basic consumption and livelihoods.

It is this inequality in access to land and natural resources, as well as misguided land use regulation, which underlies much of the land degradation in Sub-Saharan Africa, rather than the neo-Malthusian demographic determination thesis, in which increasing demographic pressures on land lead to natural resources degradation. Ineffective agricultural and economic policies entrenched by misguided short-term domestic elite interests and the external manipulation of global agricultural and financial markets structure the land question of distorted land use regulation and misguided production incentives.

In most of Sub-Saharan Africa, land use regulations and planning frameworks have been an ideological tool for maintaining the unequal distribution of land and inequitable security of tenure. The regulation of land use, usually rationalized on the basis of the need to protect legitimate public interest, is often unevenly applied to different tenure systems, and through this to different classes of landowners and land-use systems.

69.2.3 Natural Resources

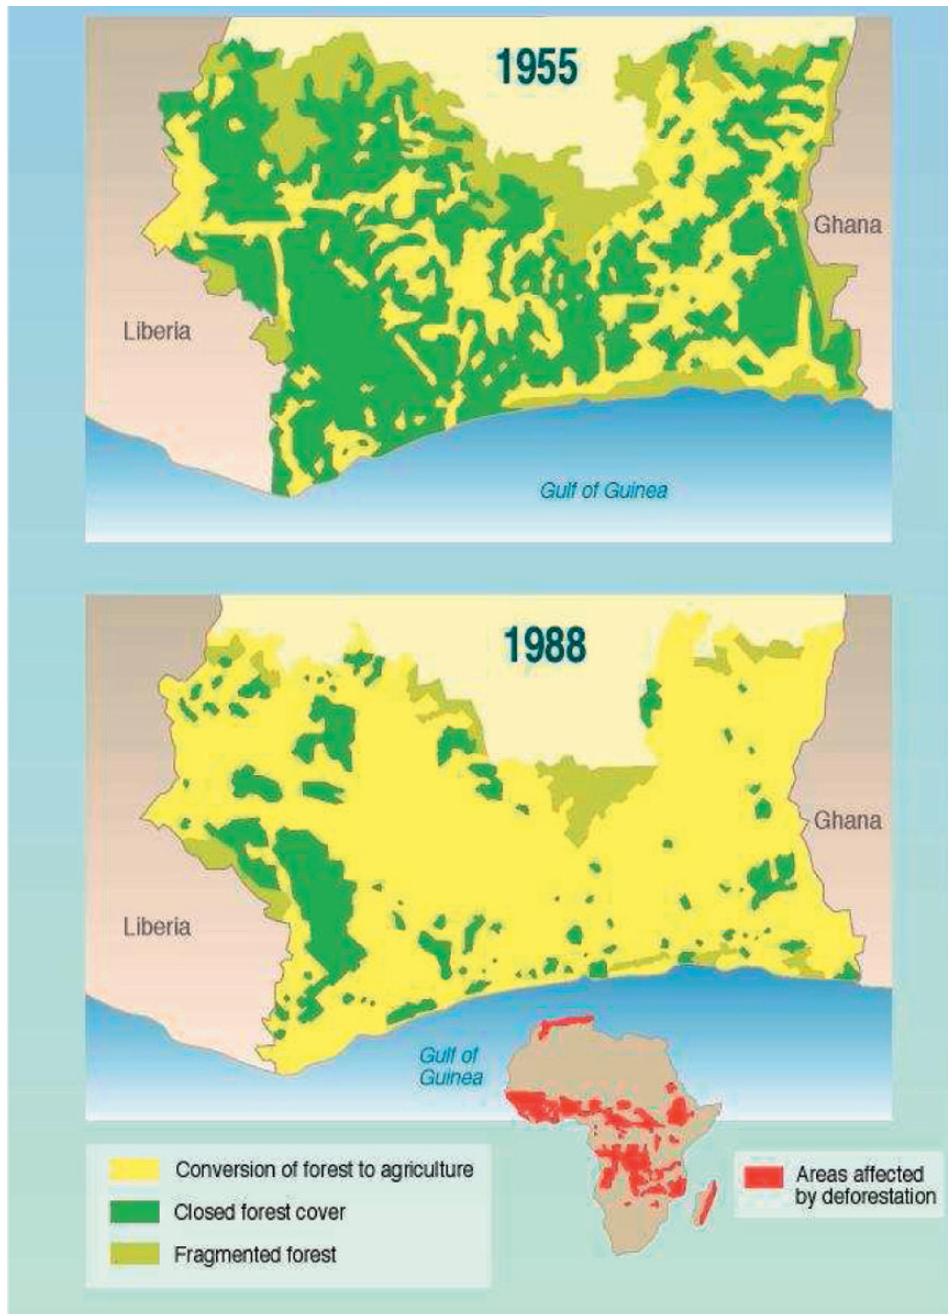

There are several processes that are contributing to the degradation of forests in Africa. Firstly, the international corporations undertaking commercial logging operations are a major cause of deforestation. Gabon, Cameroon, the Central African Republic, Congo Kinshasa, Congo-Brazzaville and Equatorial Guinea represent the main countries whetting the appetites of transnational forest companies, after almost all West African forests have been depleted.

The structural adjustment and other free market policies forced on African countries by the *International Monetary Fund* (IMF), *World Bank* (WB), and *World Trade Organization* (WTO) have provided greater incentives for unsustainable exploitation of natural resources. In Cameroon, state claims to property over all trees and plantations have provoked conflicts over land tenure between the government and local communities. Also, the establishment of large-scale oil palm plantations in Cameroon has often resulted in the expropriation of the land of neighbouring villages without adequate compensation. Cameroonian law states that peasants do not own the land by customary right, and hence expropriation by the state does not require compensation.

Settlement of game reserves and forest reserves is also extensive in a country like Uganda. In Côte d'Ivoire, conflicts also assume various dimensions (figure 69.5). The defining factors in the Ivorian situation include migrant labour, ethnic issues and the development of illegal land markets. The incidence of civil wars in countries like Angola, Rwanda, Burundi and Mozambique has also contributed to the destruction of forests. After the 1994 genocide in Rwanda, the massive return of refugees led to the destruction of existing woody areas, and the quasi-anarchical takeover of protected zones, namely the Akagera National Park and Gishwati Forest Reserve. Estimates are that 15,000 hectares of plantation were destroyed while another 35,000 hectares were damaged. The pressure on the existing forest resources also accelerated as the energy needs of orphanages, prisons, schools and tea factories had to be met.

The unsustainable exploitation of forests in most of Africa emanates from the fact that, after independence, governments maintained parts of the unjust provisions which had been imposed in legislation by colonial governments, including those referring to the appropriation of community forests by the state. Current governments can, therefore, still legally open up forests for exploitation by transnational companies in-

Figure 69.5: Deforestation in Africa. **Source:** UNEP-GRIP, Vital Graphics, at: <<http://www.grida.no/climate/vitalafrica/english/07.htm>>. Permission was obtained from Philippe Rekacewicz, UNEP-Arendal.

stead of making them available to local communities. Inappropriate land tenure policies have, therefore, resulted in various forms of economic, environmental and social impacts (Ouedraogo/Toulmin 1999). For example economic impacts involve loss of livelihoods and increasing poverty, environmental impacts include lack of investment in land improvement, while

social conflicts manifest themselves in deterioration of community cohesion and rising levels of conflict.

Most environmental resources tend to be transboundary in nature both in terms of distribution and demand, and as such the potential for inciting international conflicts over such resources is high. For example, the once ready international market for elephant products often led to armed conflicts between poach-

ers and wildlife patrol units, particularly within the Zambezi Basin. Despite brave fights by both state and private security agents to contain poaching, serious wildlife losses were incurred. For example, mainly Zambian poachers killed 380 black rhinos in Zimbabwe between 1980 and 1987; further endangering the already threatened species and spawning tension between the two neighbours.

Figure 69.6: Food Production in Africa and the World. Food Production Index, Net per Capita (PIN base 1989-1991). **Source:** UNEP-GRIP, Vital Graphics, at: <<http://www.grida.no/climate/vitalafrica/english/26.htm>>. Permission was obtained from Philippe Rekacewicz, UNEP-Arendal.

The net effect of land and natural resource conflicts is the destabilization of food production, degradation of the environment and, in the case of armed conflicts, creation of open access conditions for natural resources. Attainment of environmental security is never possible in the absence of appropriate conflict management strategies.

69.2.4 Minerals

Socio-economic dominance has also arisen from wider economic processes in which ethnicity has tended to be co-opted, if not institutionalized. Structural shifts in the livelihoods and occupations of Africans, during colonial and post-colonial periods arose from fundamental economic and resource policy interventions centred on land expropriation, the enclosure of mining and regional enclaves and the creation of corridors of transport infrastructures. These had

regional dimensions that served to segment opportunity along the geographic distribution of ethnic groups.

The expansion of colonial era trade, however, led to attempts by coastal inhabitants in West Africa in particular to mobilize themselves as privileged intermediaries between the Europeans and the African clientele of the hinterland. This led to a social differentiation of an ethno-regional character and to conflict between the ethnic communities in towns where individuals of different origins met, as well as between coastal and northern regions. Thus the West African coast divided the southern groups from northern savannah/pastoralist social formations. In Kenya where colonial land alienation deprived mainly the Kikuyu, some of them instead of opting for squatter settlement, became petty traders, and seeking new and better markets, spread throughout the country, especially in new urban centres and along the railway lines. This ethnic dispersal into business influence attracted resentment from local communities leading to the crystallization of ethnicity (Peacenet-Kenya 2001).

Efforts to transform agriculture in Nigeria since the mid 1970's focused on elites in various regional enclaves, to the exclusion of some ethno-regional populations, especially remote peasant social formations in general. Regional variations in natural resource and land endowments, infrastructures and social services fomented unequal ethnic distribution of socio-economic opportunity, creating ideological grounds for ethnic deterministic thought in explaining inclusion and exclusion in spite of the class and external factors (Egwu 1998).

The ethnic and racial basis of socio-economic dominance and conflict in Africa also derives from patterns of external control of minerals and commerce in Africa's uneven enclave economy. Africa has witnessed much more broadly based struggles between 'foreign' and indigenous elites and business people over wealth accumulation and dominance, through competition for land, minerals and commercial activity, during and after colonialization. After independence marginalized indigenous businessmen gained access to opportunities in national markets, which they rapidly monopolized (Egwu 1998), using ethnic mobilization strategies.

The struggle to control commerce in Africa has for long been predominantly a racially shaped conflict as indigenes compete with Asians, Lebanese, Whites and Arabs. The notable cases of such include, former settler colonies, Tanzania, Sierra Leone, Sudan and southern Africa. This has led to extreme measures to

bring balance. However, reverse racially based discrimination based upon a broad concept of affirmative action has been experienced in Africa. Extreme actions in Uganda, for instance resulted in the deportation of Asians and expropriation of their properties in 1972. Malawi practices racial discrimination in land tenure against the 'Asians'.

In a variety of African countries state based control and distribution of mineral resources and related rents and services have been a major strategy used to mobilize socio-economic and political dominance, and a key source of ethno-regional wealth differentials and struggles over resource control. Countries affected by this include: Nigeria, Cameroon, Angola, Sudan, DRC, Sierra Leone and South Africa. The exploitation of oil became the major source of post-independence conflict in Sudan, as the government controls the oilfields within a unitary state created against southerners (Goldsmith/Abura/Switzer 2002).

The worst ethnic conflicts over socio-economic dominance seem to occur in those African countries and within those regions of high mineral potential. For instance, in the DRC, Kivu province, "... which have been under rebel control during 1998–2002, ranks among the most productive regions in Africa. ... became the target of extensive, though illegal, natural resource exploitation within the framework of a wider conflict system involving a myriad of actors and interest" (Moyroud/Katunga 2002). Ethnic and interstate conflicts and war dominate this region. Nigeria's delta region is in this sense a key conflict zone.

Dominant discourses instead focus on 'internalist' perspectives, which argue that African ethnic primordial tendencies are central to the socio-political implosion and conflict in Africa. While internal mobilization of ethnic dominance has been critical, external resource extraction has been critical in countries such as the DRC, Liberia, Rhodesia, Nigeria, Sierra Leone, Mozambique and Angola. Whereas ethnic clashes (among Tutsi, Rwanda refugees, Hutus) were not new to the Kivus region of the DRC, sub-regional or neighbouring state interventions (by Rwanda and Uganda) have shaped ethnic dominance patterns there, using regional armed confrontation (Moyroud/Katunga 2002). Thus, internal-external alliances have provided a framework for the emergence of socio-economic dominance structures founded on ethno-regional politicization and foreign resource extraction and trade.

69.3 Other Resources Issues

Population growth is a major cause of environmental instability in Africa as a whole. More than 70 per cent of the population in Eastern Africa is rural, depending mostly on subsistence agriculture. In Ethiopia for example, 95 per cent of agricultural output is generated by small-scale farmers who use traditional farming practices (UNEP 2002c). High variability of rainfall, increasing population and the resultant high demand for food are forcing farmers to expand the area under cultivation into more and more marginal areas.

The need to increase food production to enable increased food consumption has become more desperate as the demands of an increasing population have failed to be met. As a result, marginal land has been brought into production (cultivation or grazing); commercial operations continue to use fertilizers and chemicals for increased productivity while fallow periods have been reduced. Although such activities are designed to increase productivity, they can result in exhaustion of production capacity of the land which manifests itself in declining yields of the land, vegetation and soil degradation and, in some cases, desertification. Climatic variability and change, and inappropriate land use or land tenure policies add to the pressures magnify the impact.

The high fragility of Africa's environment tends to compromise food production and leaves a majority of the poor vulnerable. For example, the mountainous and hilly area which covers much of Burundi, Rwanda, and Uganda leaves insufficient arable land to support the high population densities of these countries. There is some extensive cultivation in Burundi, Rwanda and Uganda, with the area cultivated standing at 42 per cent, 35 per cent and 45 per cent respectively.

In many cases, ethnicity was used as a cover for environment-induced conflicts. Conflict entrepreneurs have used ethnicity to gain and maintain political power and thereby access to scarce resources. In Rwanda and Burundi, for example, the differences between the Hutu and Tutsi deepened during the colonial period. The post-colonial governments in both countries further polarized the ethnic divide in order to control political power and resources. The Burundi study highlighted that the conflicts in Burundi are not between the Hutu and Tutsi masses, but between elites of the two ethnic groups in their competition for economic and political power (Musabe/Bikwemu 2004).

In all the cases where there is violent conflict, there is an element of population mobility. The examples from Ethiopia and Uganda demonstrate the cases where migrant population encroaches on scarce resources of indigenous inhabitants and thereby denying access to customary sources of livelihoods (e.g., access to hunting and forest resources). For example, the conflicts between the Bakiga and indigenous Banyoro and Batooro in Kibaale and Kyenjojo Districts, and Bahima/Banyarwanda pastoralists in northeast Uganda are resistance by the recipient indigenous communities, often causing some ethnic tensions. The Rwanda and Burundi studies (Musabe/Bikwemu 2004) take a different perspective on environment-migration and conflict links, where resource scarcity propels stronger groups/communities to resort to resource capture. Resource capture by powerful groups within communities has the effect of shifting resource distribution in their favour and thereby subjecting the remaining population to resource scarcity. This results in large migration of poorer and weaker groups into ecologically fragile regions that subsequently become degraded and causing serious pressures on livelihood security, thus creating opportunity for conflict.

Large-scale migration translates onto conflict more likely where there are social cleavage between migrants and indigenous population. The Uganda study (Mugisha 2004), in particular, underscores the major link between environmental insecurity and conflict occurs mainly through environmental induced migration into communities with different ethnic make-up. Conflict arises between heterogeneous communities differentiated by ethnicity and at times by livelihood strategies (e.g., conflict between pastoralists and cultivators). When migrants, for example, are perceived the source of deprivation and despair, particularly where there is societal heterogeneity, grievances give way to conflict. The Uganda study underscores the fact that underlying resource conflicts is increasing economic and political power of the immigrant population such as the conflict between the Bakiga migrants and indigenous Banyoro and Batooro.

Poverty, economic deprivation and vulnerability create conditions of environmental insecurity to lead to violent conflict. Poverty is widespread in all the case countries. Incidence of poverty tends to be greater in ecologically fragile marginal agricultural areas with few routes to escape poverty. For example, mapping of poverty by geographical area in Ethiopia shows poverty tends to be lower in villages with adequate and stable rainfall, moderate population den-

sity, and high market access. The worst villages are characterized by poor topography and soils, low and variable rainfall, high population density and poor market access.

As regards the link between poverty and conflict, it is not the general level of poverty that causes conflict, *per se*. Rather, it is the poverty consequence of control of scarce resources that results in increased economic deprivation, pushing the poor onto marginal areas, and heightened social despair and uncertainty of the future. What matters to explain conflict is thus not being poor today but the perception of future threat of their livelihoods and growing poverty. When people are under threat of environmental insecurity, they are prone to manipulation by warlords or conflict entrepreneurs for engaging them into conflicts for political end. Or, the poor maybe pushed onto marginal areas by powerful groups. Whilst recognizing poverty as a consequence of environmental degradation, it is also the cause of land degradation. The causality is not thus one way.

The poor often degrade their natural resources, which are their basic livelihoods. It is not, however, inherent in the poor to degrade their natural resources. The poor are bound to degrade natural resources, for example, under conditions of insecurity of tenure, lack of access to technology to improve productivity, perception of high risk and uncertainty over livelihoods and survival, and poor access to credit to smooth consumption. Or, the poor may be pushed onto marginal areas by powerful groups as the evidence from Rwanda and Zimbabwe indicates. When incentives are right and constraints are relaxed, the poor invest their own time and resources to conserve and improve their natural resources. Whether the land degrading behaviour of the poor is due to lack of knowledge or other factors needs to be understood for effective policy intervention.

The burden of poverty as a consequence of environment degradation falls heavily on women, who are dependent on natural resources to provide family subsistence. Addressing the poverty and environmental links eases the burden on women and consequently on welfare of families.

Focusing on sustained pro-poor development process is necessary to de-link the positive relation between poverty and environmental degradation. Broad based and diversified economic growth lessens the burden on natural resources through shifting population into other livelihoods. As the Ethiopia PRSP demonstrates, environment as a priority area is main-

streamed with strengthened regulatory and institutional capacity (Teklu/Tegene/Rahmato 2003).

Evidence is strong that environmental insecurity contributes to migrations, declining agricultural productivity, and weakening of the legitimacy of governments, hence serving as an underlying yet strong cause of intrastate conflicts. Some scholars argue that sub-national and persistent conflicts took the form of ethnic clashes due to environmentally induced population movements and civil strife stemming from environmental scarcity that affected economic productivity and therefore livelihoods, elite interests, and state capacity to confront these challenges. It is thus believed that the notion of environmental security may offer an alternative paradigm and analytical framework to address both the causes and consequences of political instability in Africa.

There is also wide recognition that the linkages between environmental factors and security are frequently indirect and difficult to identify with certainty. Studies that attempted to verify empirically the causal relationships between environmental variables and violent conflict have shown that environmental factors, while contributing to the likelihood of conflict, are extremely difficult to isolate as sole causal variables. Indeed, environmental and resource factors, though vital, cannot be considered in isolation from geography, history, and socioeconomic and cultural variables. Therefore, the issue of environmental change, security, and development must be dealt with holistically taking cognizance of the crucial role that economic, social, political and cultural policies play

69.4 Environmental Security in the SADC Regional Perspectives

Sustainable environmental management and nature resources trade are critical areas of regional cooperation towards achieving a balanced socio-economic development and security. The economies of the *sub-Saharan Africa* (SSA) region are extremely dependent on natural resources both through their international commodity exports orientation and because 70 per cent of their population's livelihood dependence on natural resource exploitation and consumption (Moyo/Tevera 2000). Increased demand for resource for both local and export markets as well as escalating competition for the control of natural resources have been a source of insecurity and have increased the incidence of environmental conflicts in the SSA. Environmental security problems in the region such as nat-

ural resource conflicts and environmental change arise from multiple processes which manifest at various spatial and sectoral levels. These include conflicts at the inter-state and intra-state levels, the class and racial levels and at the local level. The changing power relations driven largely by class and race based inequitable control over natural resources, which have a specific historical basis, govern the emerging patterns of environmental insecurity and conflict in the region.

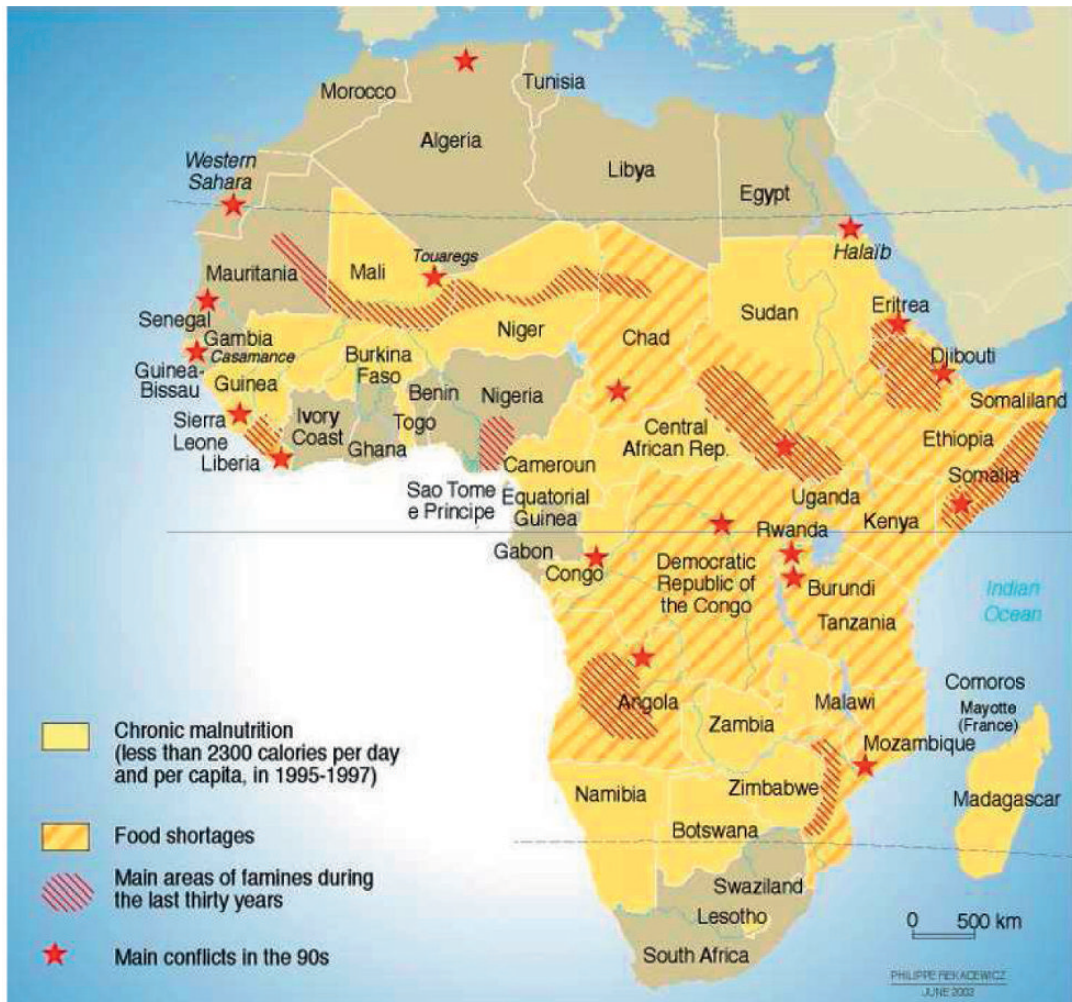

The key environmental problems which underlie and define environmental security in the SSA include:

- The resurgence of unresolved historical claims over national boundaries and land including the natural resources which are embedded in them;
- Conflict over the definition, security and realization of rights to land, water and other natural resources; and
- Conflicting authority and relations of governance between the state and civil society groupings.

These problems span the local, national and inter-state levels of governance. The issue of environmental security has become pivotal in regional co-operation. The legacy of regional destabilization and civil war and the recent market oriented development within a globalized framework has had several negative and positive environmental consequences in the SADC region. The region is experiencing various national and cross-border environmental problems such as natural resources degradation and pollution, growing inter-state and private competition and conflict over the control of and use of natural resources. National and regional struggles to control natural resources have become central to political stability, economic development and environmental sustainability. However, mainstream research in economic policy studies, international relations and environmental research have underplayed the emerging and potential regional conflicts over natural resources. A case in point is Angola where, during the past decades, there have been intrastate conflicts over a variety of natural resources, especially minerals.

For the semi-arid SADC region, the locus of growing struggles over natural resources is water. The exponential increase in current and future national and regional demand for water resources for domestic, urban, industrial and agricultural development has already created several conflicts (chap. 50 by Ashton/Turton; chap. 53 by Lindemann). The rapid expansion of the tourist industry and export markets based upon natural resources such as wildlife, forest products and consumptive biodiversity is a more recent arena of po-

Figure 69.7: Food Shortages, chronic malnutrition, famines and conflicts in Africa during the 1990's. **Source:** UNEP-GRIP, Vital Graphics, at: <<http://www.grida.no/climate/vitalafrica/english/27.htm>>. Permission was obtained from Philippe Rekacewicz, UNEP-Arendal.

tential trans-boundary source of conflict given the growing regional competition to capture global markets. Land resources, which in most countries were alienated from indigenous people during the colonial era, continue to be inequitably distributed and dominated by a few land owners, while the pressures for privatizing communal lands escalates. Even the exploitation of hydro and coal power for energy has been concentrated among a few industries, as have been the benefits of nature conservation and natural resources trade.

The movement of people in transborder areas generates environmental insecurity and conflict over natural resources. Involuntary migration of peoples across numerous SADC region borders (Malawi, South Africa, Zambia, Zimbabwe, Tanzania, Swaziland, and Botswana) due to conflicts in Angola, Mo-

zambique, Rhodesia and South Africa over decades not only dislocated peoples and local governance systems, but they also increased the damage to various fragile ecological systems, thereby causing environmental insecurity (Singh 1995). Economic depression and drought in some SADC regions have escalated migration to South Africa (Dateline Southern Africa 1996), causing the resurgence of xenophobic nationalism, as migrants claim shares of natural and socio-economic resources. Illegal cross-border poaching and trade in natural resources have now become crucial strategies for capital accumulation by the elites and for the survival of the poor, resulting in growing armed grabbing and protection of such resources.

SADC countries now openly compete for and appear prepared to wage war over, shared natural resources. Tapping the Zambezi waters is the dream of

most riparian states, although only a few of them can muster resources to tap this water for energy or large scale consumptive purposes. Some border resources, such as the Sidhudhu Island, are being fiercely contested by Botswana and Namibia. The attempt by some states to use natural resources which are wholly within their borders, such as the damming of key tributaries (e.g. in Botswana and Namibia), can be expected to have trans-boundary ecological and economical effects. During 1998/99 there were armed interventions in Lesotho and the Democratic Republic of Congo (DRC), partly over the control of water resources.

SADC states are increasingly experiencing various trans-boundary environmental processes such as river channel siltation and the pollution of water and air by cross-border industrial and agricultural activities. This raises critical intellectual and policy questions about the future of national sovereignty given that ecological systems transcend national boundaries. To what degree could SADC regional supra-state institutions assume custodianship of key natural resources and regulate the potential environmentally negative trans-boundary effects of trade and development, while expanding the benefits from their exploitation.

National sovereignty continues to be circumscribed by the increased globalization of natural resources management. Cross-border investments from abroad and within the SADC region, especially in sectors such as tourism, transport corridors, sea ports, agriculture and mining have increased the foreign control of land and natural resources. Given the limited local benefits of such land transfers and the increasing concentration of land ownership by a few national elites, there is growing nationalistic resentment against a trend often perceived as territorial and natural resources recolonization, especially where governments have facilitated such land transfers, through legislative change (Zambia, Mozambique and Tanzania) or through bilateral agreements to settle large scale white South African farmers (Zambia, Mozambique). South African capital has, for instance, moved towards the control of pristine land and other natural resources in several SADC countries, especially Zambia and Mozambique. Trans-boundary solid waste problems arising from increased trade, since the demise of apartheid and the launching of economic liberalization programmes in various countries in the region, are also a potential source of regional environmental security.

The proliferation of global conventions and aid conditionality also raises queries over national sovereignty in natural resources management, while bring-

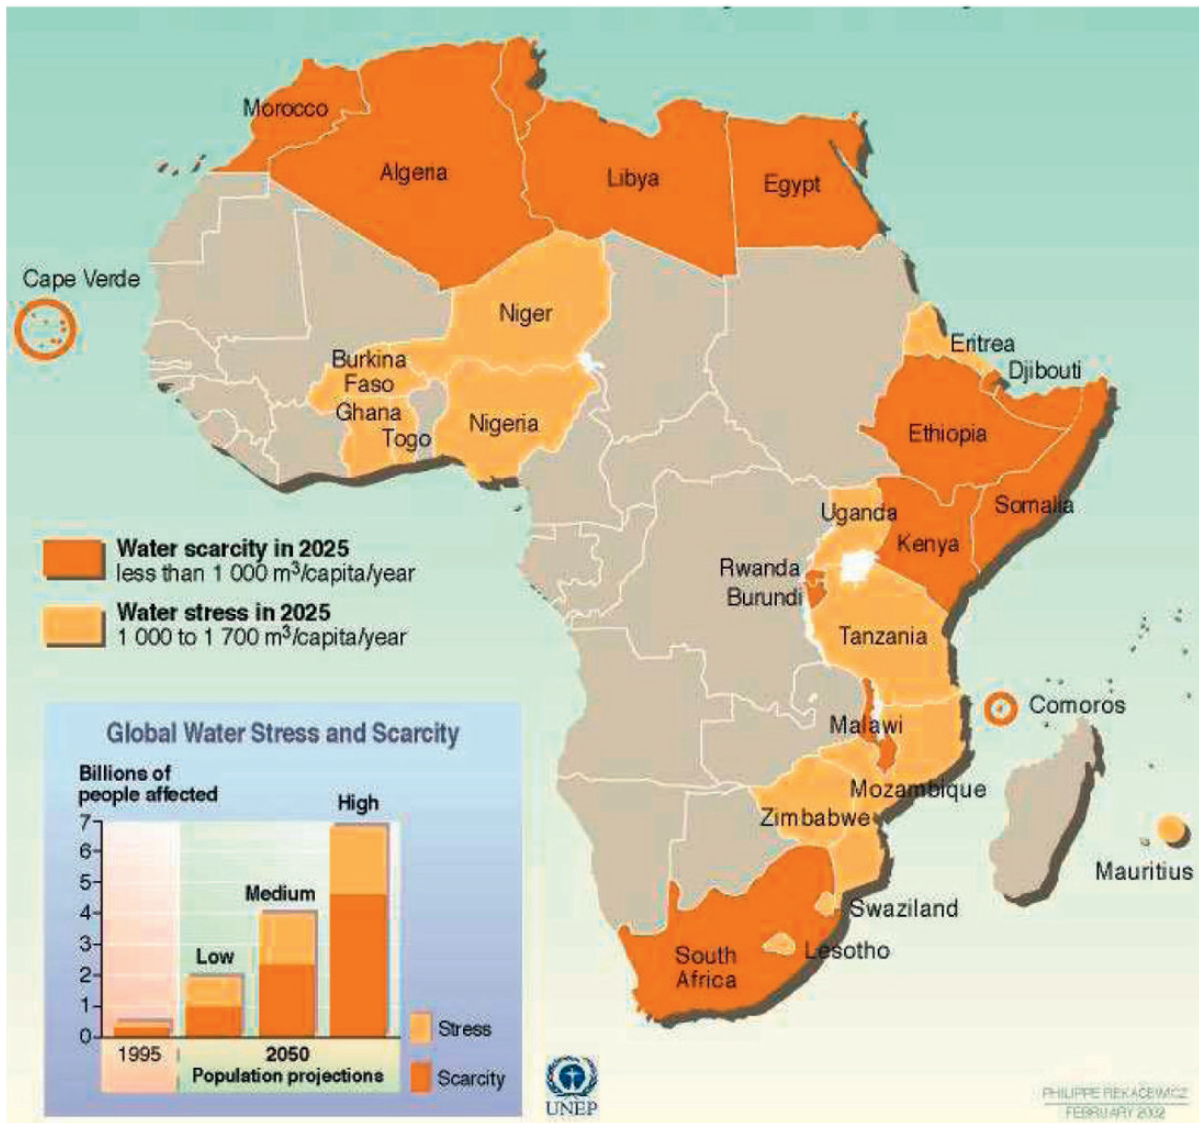

ing in new prospects for regional environmental policy co-ordination. For instance, the CITES which regulates the exploitation of elephants through the ivory trade ban, became a crucial rallying point for regional environmental policy formation in the SADC region. Similarly, the UNCED conventions on Climate Change, Biodiversity and Desertification resulted in increased forms of policy co-operation among SADC states, through struggles to influence global environmental planning and development assistance.

Multi-lateral and bilateral institutions have increased their funding of such regional co-operation efforts in recognition of their importance. Various environmental scientific exchanges and joint inter-state management of large-scale natural resources such as cross-border parks are being planned, as the SADC states seek economies of scale in natural resource management and market development. These efforts are perceived to bring both positive and unequal benefits among participating states, and are thus a potential source of conflict and environmental insecurity.

There is need to promote the development of regional approaches to regulate inter-state natural resources management, monitor and anticipate potential environmental insecurity and conflict. The potential for regional approaches is emphasized by the emerging treaty-making tradition. For instance, recent macro-economic reforms among the SADC have resulted in increased policy harmonization as well as the adoption of specific sectoral co-operation protocols such as the one on water resources. SADC treaty-making and policy co-ordination are, however, not yet adequately established, especially on the resolution of security matters and internal and internal conflict.

However, the emerging regional politics or international relations of environmental security, collective natural resources development and SADC level policy formation, and the evolving social forces which influence the diverse environmental interests in the region are not yet well researched. These need intensive examination from an integrative perspective addressing the environmental and socio-economic plight of the region's 185 million people. The current environmental research focus is on regional eco-tourism, cross-border formal trade in natural resources and large scale conservation strategies which affect the interests of the elite and state structures. An appropriate conceptual and methodological framework for understanding the SADC region's environmental security and development is essential for the achievement of balanced, equitable and sustainable development.

Figure 69.8: Freshwater Stress and Scarcity in Africa by 2025. **Source:** UNEP-GRIP, Vital Graphics, at: <http://www.unep.org/vitalwater/25-waterstress-africa.htm>. Permission was obtained from Philippe Rekacewicz, UNEP-Arendal.

69.5 External and Global Dimensions of Environmental Security in Africa

The external forces of concern in the genesis and reproduction of socio-economic dominance can be found in both 'Northern' state governance interventions and economic interactions with Africa as well as in Africa sub-regional or neighbouring states interventions in various African states. The latter process is most prominent in some countries such as the DRC, Liberia, Rhodesia, Nigeria, Mozambique, Angola etc

where inter-state conflict has been extreme, while the former is more generalized in Africa, albeit more prominent in the mineral resource rich African states. But different sets of issues, interest and events define the incidence and character of the external forces which shape the problems of ethnic dominance, exclusion and conflict.

For example, whereas ethnic clashes were not new to the Kivus region of the DRC, sub-regional or neighbouring state interventions prolonged the armed conflict (Moyroud/Katunga 2002). Thus, "during the early 1990's a number of clashes had occurred along

the eastern border between Zaire, Rwanda, Burundi and Uganda, primarily between communities of Tutsi origin (Banyamulenge) resident in the DRC and local communities of other ethnic origins but the DRC internal conflict dynamics were reinforced by the influx of the large number of Rwandan refugees and armed Hutus, exacerbating tension between Hutus and Tutsis of south of Kivu” (Moyroud/Katunga 2002). Many localized conflicts between various communities (such as Hema/Lendu/Ngiti in the Orientale province) also emerged, and the announced restrictions on the people of Tutsi descent – who had lived in the DRC for generations – acted as a major triggering event and provided the opportunity to recruit an armed rebel movement that galvanized the Tutsis and other groups in opposition to Mobutu’s unpopular government in Kinshasa (Moyroud/Katunga 2002).

Rwandan military forces prominently provided aid and direction to the rebellion that included Tutsis and other discontent groups, given that its primary objective was to enter the eastern DRC and eliminate Interharamwe and ex-FAR forces (Moyroud/Katunga 2002). While the conflict in the DRC was originally focused on the east, it developed into a national war which overthrew Mobutu and then in 1998 to fighting in the northern, eastern and western parts of the DRC, between the Congolese forces under Laurent Kabila and several rebel factions (Moyroud/Katunga 2002).

This escalation and regionalization of conflict and polarization in the Central Africa region became a source of ethnic and inter-state mobilization of dominance over access and use of mineral and other resources. The rebels’ stated case was corruption, cronyism and nepotism in Kabila’s regime, but the relation between Kabila and the governments of Rwanda and Uganda had turned sour over the ostensible persistence of Interharamwe rebel movements in the Eastern Congo, and the loss of entrenched resource exploitation opportunities by these neighbours and foreign Northern governments. By the late 1990, the DRC however had acquired a new balance of power divided into zones of external in military control and resource exploitations (Moyroud/Katunga 2002). Countries which supported the DRC (Angola and Zimbabwe in particular) became part of this national partition. This strategy of internal-external alliances provided a framework for a socio-economic dominance structure founded on ethno-regional politicization and foreign resource extraction and trade. The sources of the overall Great Lakes conflict are structural and relate to external interests.

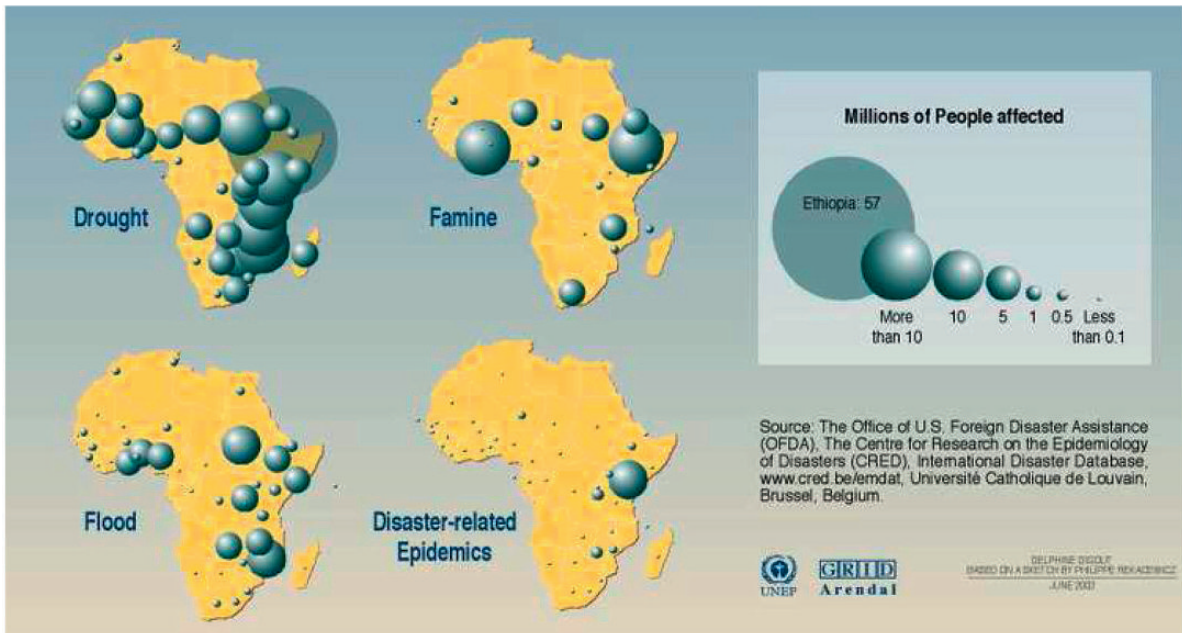

In particular the external demand for coltan – a combination of Columbium-tantalite, 80 per cent of the reserves of which are found in the DRC (which forms of the basis of high-tech global commodity chain) – has become one of the driving forces behind the war in the DRC and the presence of rival militias (Moyroud/Katunga 2002). Countries such as Angola, Sierra Leone and Liberia have seen the mobilization by ethnically based groups of rebellions, which have been financed by mineral and resources exploitation (diamonds, timber etc), and in which international trade has been critical.

69.6 NGO’s and Social Movements in Environmental Security

Repressive land use regulations are commonplace in Africa because these are driven by state and NGO-led environmental ideologies, which drive current eco-imperialist approaches to issues of environmental degradation, conservation and sustainability as eco-imperialism (Kirkby/Moyo 2001). In these frameworks global interests create the environmental regimes, under a project of ecological modernization labelled sustainable development. Nature is preserved as national parks and biosphere reserves or debt for nature carbon sinks created apparently for the benefit of the third world, but the benefits primarily accrue to first world interests, specifically elites and multinational corporations. This is achieved with and through the compliance of local elites and in many cases at the cost of excluded and dispossessed people. Many responses to deforestation, desertification, soil erosion and biodiversity loss are within this mode, characterized by top-down hierarchical, neo-colonial systems and in some cases these totalitarian systems are best described as eco-fascist (Kirkby/Moyo 2001).

Similarly, Southern African environmental discourses tend to regard land husbandry by blacks as intrinsically poor, implying that the environment will collapse if land is redistributed. The perception is that only whites value and nurture the environment, while agronomic practices of blacks, such as intercropping, are thought to destroy the soil. Thus the ‘conventional’ settler-introduced system of agriculture – planting crops in straight lines, and using advanced technology and chemicals, which again, the blacks are thought to be incapable of using – are considered superior systems. However, recent research has disproved these notions.

Figure 69.9: People Affected by Natural Disasters in Africa. **Source:** UNEP-GRIP, Vital Graphics, at: <<http://www.grida.no/climate/vitalafrica/english/08.htm>>. Permission was obtained from Philippe Rekacewicz, UNEP-Arendal.

Yet, indigenous technical knowledge promoted by liberal environmental non-governmental organizations (NGOs) seems to suffer from a lack of real agronomic alternatives that can take blacks in communal areas beyond current community-based natural resources projects that do not improve the standards of living of the majority. The common middle-class perception is that the poor degrade land while the white large-scale commercial sector uses land efficiently. This belief underlies the excessive focus of NGO schemes on 'protecting' land and 'educating' the peasantry on sustainable land use, rather than on advocacy for land redistribution.

Generally, NGOs have been and remain a reactionary force on land reform, rather than an agenda-setting movement. NGOs can be conceived as a new mechanism for promoting the so-called indirect rule system, in which they increasingly substitute for local state and traditional authority in organizing communities in the co-management of state and donor-initiated development projects. This tendency begs further questions in the debate on the nature of NGOs, and on their ability to champion the rights of indigenous people with regard to their land and with regard to improving standards of living (Mamdani 1996).

NGOs are at the root of the further alienation (transfer) of natural resources and monopolistic control of tourism by white minority companies in alli-

ance with regional and multinational corporations (Moyo 2000). In countries such as Mozambique, Namibia and South Africa, white individuals, companies and regional mega-tourism ventures have expropriated land at the coastal zones. In the past, racial discrimination meant that blacks could not have access to holiday resorts. More importantly, the cost of coastal prime land for tourism development was made artificially high to deny access to blacks. Fighting for access to beaches and fishing rights on oceans was therefore central to the liberation struggles in those countries that were not landlocked.

The project of subjugating blacks is underpinned by the discourses on environmental aestheticism (ecoculture, ecotourism), which now claim to preserve primordial black cultures as part of the image of the African wilderness. Thus, ecotourism allocates monies to trickle into landless black communities, while the bulk of the benefits of land control rest with external financiers and safari operators. Furthermore, through the so-called transboundary 'peace parks'³ involving two or more countries, global capital has found an avenue for land expropriation in the context of foreign direct investment.

In Namibia, Zimbabwe and South Africa many of the black, white and foreign elites tend to allocate to themselves large tracts of land for commercial farming or tourism and, in addition, lobby the state for fa-

vourable tourism policies (Moyo 2000). The marginalization of the majority of the people tends to create political conflicts with those minority groups who seek to control such benefits. The political and economic consequences of these problems in the region are broadly the same: poverty, enforced high population density in customary lands, land degradation, lack of resources to invest in adequate land management and political uncertainty.

69.7 Conclusions and Implications

Without greater measures to insure environmental security, continued population and economic growth will diminish natural life support systems leading to migration and conflict. With half the world clustering into urban environments, natural disasters and global environmental change affect greater numbers of people who are dependent on civil systems for water, power, transportation, food, and other manufactured systems.

Low cost and relatively simple methods - compared to nuclear weapons - for environmental destruction increase the opportunities for even small terrorist groups to destabilize large populations. Military operations and training also have environmental impacts that threaten their own troops as well as having potential long-term impacts on civilian populations. As a result, the environment is now considered in terms of human security and viewed much more urgent and important a future challenge than conventional and nuclear war.

69.7.1 Recommendations⁴

- Integrating environmental insecurity concerns in development policy (Putting in place an integrated management of environmental risks including con-

flicts, natural and man-made disasters and health risks; and putting in place a national sustainable development strategy);

- Strengthening and developing state capacity;
- Policies that promote equitable access to natural resources merit priority consideration;
- Outlawing ethnicization and promoting sound environmental management;
- Sound population policy;
- Putting in place supportive macroeconomic policies;
- Sound management of decentralization;
- Developing gender insightful natural resources management policies;
- Strengthening traditional or local level conflict management mechanisms;
- Development of internal migration policy and legal framework;
- Promoting the environmental security agenda at the level of NEPAD.

3 Since the late 1990's, environmental NGOs and private firms have promoted 'transboundary' natural resource conservancies involving large tracts of land within the borders of Zimbabwe, Mozambique and South Africa (10,000,000 hectares) To enhance large-scale tourism focusing on the freely roaming large mammals. This entails excising lands from local communities and state parks for private exploitation. Because most rebel movements (for example, the Resistencia Nacional Moçambicana/RENAMO, of Mozambique) had used these woodlands for armed incursions during the 1980's and 1990's, these new woodland conservancies were dubbed peace parks, and a foundation with that name was formed.

4 For more details on the recommendations: see Partnership for African Environmental Sustainability (PAES), the symposium on Environmental Insecurity, Poverty and Conflict: Towards Sustainable Peace and Development took place at the Nile Hotel International Conference Centre, Kampala, Uganda, 23-24 September 2003.

70 The Brazilian Amazon in an Environmental Security and Social Conflict Framework

Alexander López

70.1 Introduction: The Argument

This chapter offers an overview of the key historical factors influencing the contemporary Brazilian Amazon that responds to a dynamic that has emerged since the discovery and colonial period combining two myths of the richness of the Amazon basin, and of its open and unexploited space. This is essential for understanding the environmental security and social conflict approach to this region (70.2). Then this chapter analyses the dynamic link between environmental factors and security and social conflicts as a result of continuous interactions between systemic (Amazon) and supra-systemic factors (70.4). These interactions explain why environmental matters have been politicized (70.6) and to a certain extent militarized (70.7). This chapter attempts to explain why social conflicts are mainly a product of two systemic constraints of a misallocation of resources and of skewed land distribution (70.8). Thus, in most cases environmental change is no direct source of social conflicts, but an important aggravating factor through its side-effects. Finally, in the Brazilian Amazon in most situations environmental scarcity is no key factor for social conflicts, rather in the northern state of Roraima abundance is crucial (70.9). Thus, the environmental scarcity hypothesis¹ claiming the more natural resources are available in the system, the less likely conflicts are among its components must be revised.

1 This thesis was presented by Thomas Homer-Dixon (1999, 2000, 2001; Homer-Dixon/Blitt 1998; chap. 20 by Homer-Dixon/Deligiannis) who argues that environmental scarcities will have profound social consequences – contributing to insurrections, ethnic clashes, and other forms of civil violence, especially in the developing world. However, the claim that resource stress is a *necessary* cause of violence has been refuted with reference to cases of violence not preceded by resource stress (Bann/Collier 2003; Peluso/Watts 2001).

70.2 Discovery, Occupation and National Integration of the Amazon

The Amazon and its affluents is the largest river system on earth that transports one fifth of all fresh water to the oceans. The Brazilian Amazon covers almost 5 million km², or 55 per cent of Brazil's territory. It contains one third of the earth's remaining tropical forest and a very high biological diversity. It also has an outstanding cultural diversity with indigenous groups, peasant communities, Caboclos², miners, forest dwellers, etc. The Brazilian Amazon is not flat nor entirely covered by rainforest; many areas are grassland (*campo*), upland savannah (*cerrado*), and annually flooded wetlands (*várzea*).³ Its population is primarily urban.

The occupation of the Amazon by outsiders began in 1500 with the expedition by Vicente Yanez Pinzón who only reached the mouth of the Amazon, which he named Santa Maria de la Mar Dulce (freshwater sea). The European impact began at the end of the 15th century, with the interest of Spanish and Portuguese navigators to explore the New World. The first expedition (1541–1542) was by Francisco de Orellana and described by Gaspar De Carvajal in: *Do Novo Descobrimiento do Famoso Rio Grande das Amazonas*. Its purpose was to find the country of cinnamon what was then a lucrative commodity for trade.

The colonial period is marked by Portuguese domination and the impact of the Pombal era on its management, with the military, the merchant, and the mis-

2 They are the local people along the Amazon river, too often illiterate, and dependant on a hard exploitation of the natural resources to survive.

3 Approximately 60 per cent of the Brazilian Amazon are covered by tropical rain forest, grassland and savannahs occupy another 35 percent. Finally, a very small area is composed of flooded wetlands.

sionary as key actors. The military assured control over the area by building forts, the merchants integrated the region into the royal economy by exploiting some forest products, and the missionaries controlled the labour force (basically Indians).

With the treaty of Madrid, after 1750 a new period began aiming to preserve the area conquered by Spain and Portugal. Under the principle of *uti possedetis*⁴, Spain granted to Portugal the Amazon up to the mouth of the Madeira River. This period marked the beginning promotion of an agrarian rural class able to control social tensions in the region supporting the colonial powers. A first attempt to ‘modernize’ the Amazon was carried out during the so-called Pombalina era that began in 1750 with the appointment of José de Carvalho e Mello, Marquis de Pombal, as secretary of Foreign Affairs and War by King José I of Portugal (Messias 1995: 25).

This led to major modifications in Portuguese colonial policy for the Amazon that included taking control of social relations by expelling the Jesuits, and appointing lay directors responsible for allocating Amerindian labour to colonist and colonial authorities, the so-called directorates. This made Indian labour available to civil authorities in villages, thus replacing Jesuit missions, and promoted the economic expansion of the Amazon, using the crown as a sponsor. Pombal founded the *Companhia Grão Pará e Maranhão*, a semi-state company promoting foreign investment, giving incentives and offering military protection for investors, especially during the transport of products produced in the region (Messias 1995: 25). The economic integration concept emerged from the Pombal project, and was developed further almost 200 years later by the military governments when the *Superintendencia do Desenvolvimento da Amazonia* (SUDAM) was set up. Although widespread European contacts with the Amazon occurred during the 16th and 17th centuries, only in the late 19th century the exploitation of rubber reached significant levels and became a driver of the Amazonian economy.

The occupation and national integration of the Amazon has been a major objective of Brazilian governments since the 1930’s when the region was considered as an empty space started by the four times president Getúlio Vargas (1930–1934; 1934–1937; 1937–1945 and 1951–1954) who announced in 1940

that the Brazilian government was planning to open up and to occupy the Amazon region.⁵ As the first Brazilian president he travelled throughout the Amazon and established the *Estado Novo*.⁶ Vargas supported the ‘nationalist developmentalism’ based on concepts by the economists Prebisch and Celso Furtado of the *United Nations Commission for Latin America* (CEPAL). These ‘structuralists’ saw the state as the engine of development and argued that the formula of their conservative rivals would condemn the country to perpetual underdevelopment (Schneider 1989: 171). With Vargas the integration of the Amazon into the rest of Brazil started with a state-led development of its economy with road construction and economic incentives for investments. To implement this objective in 1953 the *Superintendencia for the Economic Valorization of the Amazon* (SPVEA) was set up.

The geopolitical interest to populate the Amazon was developed later under the military regime by General Golbery do Couto e Silva (1964). In his view Brazil needed “to inundate the Amazon forest with civilization” (cited by Schmink/Wood 1992, quoting Hecht/Cockburn 1989). A basic problem of its economy was the manpower shortage during the Pombal period and the rubber boom. While General Golbery responded to this concern there were other important issues, such as protecting Brazil’s international borders, and the need to promote immigration and colonization in those empty spaces.

70.3 Military Years: Security and Economic Growth

During the last decades the Amazon basin has been defined as a huge homogeneous flat region of humid tropical forest, as a demographic vacuum, a world’s reserved ‘El Dorado’, and as an empty space. Since the 1930’s most of programmes for the Amazon basin were based on these assumptions. Concerns for economic growth and national integration were very high during the military years, as reflected in the following

4 A concept of international law that defines borders of newly sovereign states on the basis of their previous administrative frontiers.

5 President Vargas defined the Amazon as an empty space in a speech in Manaus in 1940 when the Amazon was seen as a network of demographic islands connected by rivers running through an uninhabited forest.

6 The *Estado Novo* can be characterized by being highly centralized and authoritarian as well. Moreover, the state would use the powerful institution of patronage to effectively control the organized labour into a system of State tutelage and control.

activities: *Operation Amazônia* (1964); the first *Amazonian Development Plan* (1972); the second *Amazonian Development Plan* (1975) formulating *Polamazonia*; and the third *Amazonian Development Plan* (1980) including *Polonoroeste* and the *Great Carajás Programme* (PGC).

The military regime linked the economic approach with a geopolitical one by combining security (human occupation, extension of territorial control) with economic growth. As a matter of high priority they used the state apparatus to promote development and to assure control over the country. In 1964 president Castelo Branco stated that the “Amazonian occupation would proceed as though it was a strategically conducted war” (Hecht 1984: 370). The state should maintain a central role in promoting greater efficiency in regional planning by trying to improve the role of private enterprises in Amazonian development. The government would provide the infrastructure and funding for economic growth, while entrepreneurs would basically carry out the task of regional development. The main areas sponsored by the military were agriculture, livestock, mining and metallurgy.

The military government established the development agencies, among them the *Superintendência do Desenvolvimento da Amazônia* (SUDAM) that replaced SPVEA, and a regional Development Bank, named the Amazon Bank (BASA). “Operation Amazônia” was the first plan of SUDAM that was oriented at “establishing development poles, self-sustaining population groups especially in frontier areas, encouraging immigration, providing incentives to private capital, infrastructure development, and research on the potential of natural resources” (Mahar 1979: 11).

This strategy implemented developmentalist ideas whose core goals were capital accumulation, extra-regional investment, and large economic projects. Manaus and Araguaia-Tocantins were considered as basic areas for investment; the former for industry and a new free trade zone, and the latter for cattle ranching. This policy of promoting livestock, industry, and crops tried to free the Amazon from its dependence on extractive commerce.

Operation Amazônia introduced generous fiscal incentives basically through SUDAM and the Amazon Bank (BASA). According to Hall (1997) from 1971 to 1987, US\$ 5.15 billions were used for incentives and subsidies particularly for large ranchers. These fiscal incentives were described by several authors as the major force behind deforestation promoting the expansion of cattle ranching, which resulted in environ-

mental degradation. Due to these incentives the land became the main factor of dispute among social actors. Thus, the variable resource allocation is significant for understanding the frequency and intensity of social conflict in the Amazon.

For livestock in the Amazon, “between 1959 and 1973 the World Bank lent Brazil an estimated amount of US\$ 839.2 million, plus US\$ 1,004 million in counterpart funds, for small-scale livestock projects. The largest allocation of these funds occurred between 1966 and 1970” (McCleary 1990: 13). The subsidies for cattle ranching exceeded those for industry and agro-industry. While “there were only 4 ranches that received SUDAM incentives in 1966, the number had increased to 162 in 1969” (Hall 1989: 7). It was defended in the 1960s and 1970s that Brazil had the conditions to become a leading beef exporter. The World Bank endorsed this idea by giving a credit line for the sector. In the Amazon the economic advantages of investment in livestock were clear: land was perceived as promising, plentiful and inexpensive, subject to rapid capital gains, and requiring only a minimal workforce. Industrial development was hampered by shortages of skilled labour, limited local markets, lack of credits, and competition from extraregional industry.

This interrelationship between economic growth and security caused an incompatibility between two opposing priorities. On one hand, there was an emphasis on private property, incentives for capital accumulation, and promotion of livestock and agricultural projects. On the other hand, there were the provisions for state intervention to reduce poverty and to make land available to those who worked for it. This contradiction partially explains the so-called land question.

Here the expression ‘land question’ is used because land reform has been the hottest issue in contemporary Amazon. The military dealt with the land question by allocating plots of land to settlers in the Amazon as the immediate answer to poverty and unemployment in Brazil, above all in the north-east. Among the misconceptions that stopped land reform was the misunderstanding of the basic character of the extractive nature of its economy, which made it difficult to define property rights compatible with bureaucratic procedures.⁷ Land property was determined by the effective use, thus both large and small holders clear as much as they can to assure the principle of *uti posseditis*. This tradition of land rights comes from the pre-independence period, when small and large producers were permitted to establish legal access to land based on habitual occupation and/or

effective cultivation. There was a misallocation of land to small farmers in the sense that most of the Amazonian soils are not suitable for agriculture because of their deficiency in inorganic nutrients such as nitrogen and phosphorus. As in the Amazon basin land seems to be plentiful compared with capital and workforce, the bureaucratic structure tends to use land extensively as the cheapest production factor. This contradiction (leading to the agrarian question) contributed to social tension and conflicts, thus also contributing to the militarization of the land issue.

70.4 Amazon: Result of Systemic and Supra-systemic Interactions

The systemic perspective, based on the assumption that 'the whole is more than the sum of its parts', implies that current events in the Brazilian Amazon cannot be understood by looking solely at the subsystems (federal Amazonian states) but by observing the web of relationships linking subsystems, the system, and the suprasystem. Since its discovery the Amazon has been characterized by an externally oriented model, for which the Pombal period, the rubber boom, and the developmentalism strategy are good examples.

During the military period since 1964 strong links were established with foreign capital. The Brazilian market was open to public and private enterprises and the government obtained foreign credits, especially from the World Bank and the *Interamerican Development Bank* (IDB) for mega-projects, such as the Trans-Amazon highway, the *Polonoroeste Programme*, the *Greater Carajás Programme* and hydroelectric projects.⁸ These programmes led to heavy immigration, an invasion of the Indian land and a high rate of deforestation.

7 It can be argued that the economic history of the Brazilian Amazon has been shaped by extractivism. Thus, forest products (cacao, rubber, spices) were important since the colonial period. Extractivism was not limited to forest products. The extraction of minerals (gold, diamonds etc.) has been of great importance. Fishing has always been important, and the major source of protein for the local population.

8 The World Bank co-funded the Trans-Amazon highway. For the *Polonoroeste* the World Bank provided a US\$350 million credit for the highway through Rondônia and Mato Grosso. In 1986 the World Bank approved a US\$500 million power sector loan to *Eletrobás* (Brazilian state electricity company). For the *Greater Carajás Programme* the World Bank approved US\$300 million.

The discussion of environmental security and social conflicts in the Brazilian Amazon and the particular contribution of environmental change will be placed in a systems perspective because:

- a.) The Brazilian Amazon as an ecogeographical entity constitutes an open system.
- b.) The Brazilian Amazon is not a homogeneous, but a highly complex open system.
- c.) Therefore, no single component can exist entirely separate. Rather, each component somehow affects and is affected by all other components.⁹
- d.) The behaviour of the social groups in the study area are strongly influenced by the components of the Brazilian Amazon. Thus, to a certain extent one can understand the dynamics of *garimpeiros*, *fazendeiros*, Indians, *caboclos*, *posseiros*, *sem terra*, etc. by looking at the relationship between the system and the subsystems, as well as the type of structure resulting from their interrelation.
- e.) The governments have been subject to intense influences from the suprasystem. The international sphere has influenced the environmental variable positively and negatively.

Traditionally many external factors have influenced the Amazon. Lately, most influences are related to the protection of the Amazonian forest, indigenous communities and the idea of establishing Amazonia as a global common (even though it is a shared natural resource), based on the argument that the Amazon is crucial for the global environment. There are also influences from the system to the suprasystem due to the transboundary externalities of environmental change. Therefore, the issue of Amazonian management is an international political one. At the international level its management has implications for climate change and biodiversity. On these global issues the international community bases its claims on the management and preservation of the Brazilian rainforest.

Brazil responded to these international influences by stressing its sovereignty over the Amazon, but accepting some global environmental standards and the importance of international co-operation. The government stressed its rights and responsibilities, the principle of national sovereignty and national security for the management of the Amazon basin thus linking environmental management with security.

9 This can be explained for the *Polonoroeste* project where huge colonization schemes were among the basic causes for the disastrous failure of this project in Rondônia.

70.5 Sovereignty in the Brazilian Amazon

In 1989, José Sarney declared “the Amazon is ours”, because “it is situated in our territory”¹⁰ as a clear expression of sovereignty. Several actors, especially NGOs, have challenged Brazilian sovereignty over the Amazon rainforest on ecological grounds as its importance extends beyond Brazil because the Amazon rainforest flows across the borderlines of the sovereign Brazilian space and that it shared by nine nation-states. The territorial political space does often not coincide with that of ecosystems that ignore geopolitical boundaries. Thus, sovereignty conceived in its traditional meaning as rule over a fixed territory becomes problematic.

The Brazilian Amazon shows that in the environmental arena sovereignty no longer serves as the source of a state’s freedom to manage natural resources as they please without caring for international standards. Sovereignty no longer enables states to exert effective supremacy over what occurs in their territories. Sovereignty involves the state in one aspect of a transnational process, e.g. on multinational investment, the global ecology, drug dealers etc. Thus, sovereignty is less a territorially defined barrier than a bargaining resource for politics characterized by complex transnational networks (Keohane 1995: 176–77).¹¹

For two reasons the the military is preoccupied with the Amazon. The first refers to the physical space, and the second to the international valuation of that physical space. Both are different but interrelated. The borders of the Brazilian Amazon stretch to 16.500 km. The Amazonian region extends to 10.948 km, four times the distance from Madrid to St. Peter-

sburg and the equivalent of approximately 70 per cent of Brazil’s international borders (Dreifuss 1998: 15). This is accompanied by a low population density, poor communications, and mineral resources. These factors make the Brazilian Amazon very vulnerable.

The second reason is reflected in the constant reaffirmation of Brazilian territorial integrity, unity and sovereignty. These concepts have a special meaning for the Amazonian region. Over the past 180 years international agencies, countries and individuals have intervened in the management of the Brazilian Amazon. In 1989 Al Gore was quoted as saying, “contrary to what Brazilians think, the Amazon is not theirs, but belongs to all of us”. Francois Mitterand stated that Brazil needs to accept a “relative sovereignty” over the Amazon. In 1992 Mikhail Gorbachev argued that Brazil should delegate parts of its rights over Amazonia to a competent international organism (Chagas 1997, quoted by Dreifuss 1998: 18).¹² In the military perspective, the preservation of territorial integrity and unity is constantly reasserted as crucial. For the armed forces, “sovereignty is preserved as long as possession and jurisdiction over the territory is guaranteed, along with its indivisibility and the possibility of political actions that aim to preserve our vital interests.” They have argued that the flexibilization of the concept of sovereignty cannot cross this limit.¹³

70.6 Internationalization of the Brazilian Amazon

Repeatedly Brazil has been asked to assume its responsibility vis-à-vis the international community. This so-called internationalization of the Amazon has been perceived as a real threat in Brazilian circles. Thus, in 1991 the congressional commission of inquiry on the internationalization of the Amazon was established and asked to investigate the existence of clandestine airports and the activities of religious missions in parts of Roraima supposedly provoked the internationalization of the Amazon. In its final report the CPI stressed the development model and the mineral riches. Many denunciations were couched as an Anglo-American neo-imperialist conspiracy where the environment served as a pretext for the new interna-

10 See: “Brazil angrily unveils plans for the Amazon”, in: *Washington Post*, 7 April 1989.

11 Conca (1994a) summarizes the sovereignty discussion pointing to two perspectives. The first argues that there is erosion and weakening of sovereignty and that sovereignty and ecology are at odds because ecosystem and environmental processes do not respect state borders, thus, sovereignty itself becomes a key institution of a global-scale environmental destruction. The second claims that international processes, and in particular, the emergence of multilateral institutions for environmental protection, do not erode state sovereignty and may even strengthen it. By placing states at the centre of institutional responses and strengthening their capacity to act collectively, the menu of choices available to states is being expanded not restricted (Conca 1994a: 702).

12 Carlos Chagas: “Querén Internacionalizar a Nossa Amazônia”, in: *Manchete* (Rio de Janeiro), 5 July 1997.

13 See: *O Brasil e suas Forças Armadas* (Brasília: Estado-Maior das Forças Armadas. Presidência da República, 1996): 19.

tional order and where NGOs played a leading role (Kolk 1996: 121). Feeling threatened by environmental issues and their consequences for the state in crucial economic areas, sovereignty and nationalist claims increased. The environment replaced the east-west conflict in the view of the military for domestic purposes.

The Brazilian preoccupation with the internationalization of the Amazon can be seen in three responses: a) the programme of debt-for-nature swaps, b) the *Calha Norte* project, and c) in the *Nossa Natureza* programme. The United States, France and the Netherlands put forward a proposal for debt-for-nature swaps, where a portion of Brazil's foreign debt would be exchanged for conservation projects. With his new policy (*Nossa Natureza*) Sarney rejected the programme as an infringement of national sovereignty and he stated that "there is no international capital which can buy even one metre of Amazon soil". The worries were that debt-for nature swaps could lead to the creation of a large Amazon reserve to protect the environment, but also to a future internationalization and exploitation of minerals by international forces under the pretext of the environment.

The *Calha Norte* project aimed to intensify the military presence in the northern Amazon. During the transition from the military to civilian government, it was justified by several reasons. One was the possibility of a binational Yanomani Indian park, and that such a park along the Venezuelan-Brazilian border could evolve into an independent indigenous state, manipulated from abroad. The *Nossa Natureza* programme was to diffuse international pressure with regard to the rate of deforestation, the murder of Chico Mendes and the Indian manifestation in Altamira. The centrepiece of the proposal was a five-year US \$ 100 million programme for an agro-ecological zoning of the Amazon. This programme "our nature" had a nationalistic connotation reassuring Brazilian sovereignty over the Amazon.

70.7 Militarizing the Amazon or Greening the Military?

The involvement of the military in environmental matters was not only evident during the military regime, but also in the subsequent civilian period. The traditional preoccupation with national integration was increasingly overlain by concerns that Brazilian sovereignty over the Amazon was challenged, and this became the dominant theme in Sarney's response to international criticism. After the military regime the

Secretariat for National Defence (SADEM) was created which co-ordinated *Nossa Natureza*. President Collor integrated SADEM into the *Secretariat for Strategic Affairs* (SAE 1997) as the Department for Special Programmes. Another department for macro-strategies co-ordinated the *Ecological-Economic Zoning* (ZEE). SAE was given an important role in the preparation of environmental policy (Kolk 1996: 110). The former *Environment Secretariat* (SEMA) and the *Forestry Institute* (IBDF) were combined as the unified environmental agency (IBAMA). This was nominally under the Ministry of the Interior, but operating with financial autonomy under the leadership of Sarney's former press spokesman Fernando Mesquita.

A recent example of military participation in designing and co-ordinating environmental policies is the establishment of the *Protection System for Amazonia* (SIPAM), and the *Surveillance System for the Amazon* (SIVAM). The SIPAM has three regional bases (Portho Velho, Manaus, Belém), and general headquarters in Brasilia. Under SIPAM the SIVAM is operated as a civilian-military project within SAE. The principal aim of SIVAM is to effectively implement the SIPAM, thus providing the Brazilian government with necessary information for sustainable development, especially on control of land occupation and use, surveillance and control of borders, identification of illegal activities, and economic and ecological zoning. The infrastructure consists of a remote sensing network, which includes eight meteorological and environmental satellites, five sensor-equipped Embraer ERJ 145 aircraft for *aerial early warning* (AEW) that can obtain images through the dense forest cover and provide information on the quality of the soil. It includes three Embraer 145 RS planes for remote sensing, and twenty radar stations co-ordinated by Cindacta, which already controlled air traffic (Dreifuss 1998: 28–29).¹⁴ SIVAM was placed into the sovereignty discourse. Raytheon and the Brazilian authorities stated that among the principal benefits Brazil will gain from SIVAM is the capacity control the area and to promote the integration of communities among themselves and with the ecosystem, guaranteeing Brazilian sovereignty in the Amazon forever.

Thus, the environmental discussion on the Brazilian Amazon has been large framed in the security context. The defender of national integrity and independ-

14 Information given by Coronel Antonio Faria, Secretaria de Assuntos Estratégicos, conference at 4th *National Encounter of Strategies Studies*, Unicamp, Campinas, 10–15 May 1998.

ence has reacted with scepticism to notions of transboundary effects of environmental change in the Amazon.

Despite its scepticism, the military avoided a position of open confrontation on the environmental management of the Amazon. They are actively participating in this process through their influence in SIVAM and in the elaboration of the *Macro-Zoneamento Ecológico-Econômico da Amazonia*. A document from 1995 stated that through SAE environmental worries and needs, and a wealth of natural resources (biodiversity, water, minerals) are emphasized without diminishing the importance of the national frontier.

The combination of these factors could result in a change of paradigm from frontier development to sustainable development. This was partly stressed in a statement by the Chief of Staff of the Army, General Gleuber Vieira: "the new mission is co-operating with socio-economic development."¹⁵ But it remains to be seen if the framing Amazonian policies in a security framework will mean a 'militarization of environmental policies' in the Amazon or whether it will produce a 'greening of the army apparatus' (López 1999).

70.8 Environment and Security: Politicization, Militarization and Securitization of the Brazilian Amazon

Up to now in the Brazilian Amazon environmental issues has been politicized and to a certain extent militarized. In the Brazilian Amazon security has become a comprehensive concept, but it cannot be argued that the environmental sector has been fully securitized.

70.8.1 Politicization of the Environment

Environmental issues in the Brazilian Amazon have been politicized due to a strong relationship between public spending, infrastructure development and environmental policies. An issue is politicized when it becomes part of public policy, requiring government decision and resource allocation (Buzan/Wæver/de Wilde 1998). In this region such processes can be easily perceived. Brazilian governments since Getulio Var-

gas have undertaken great efforts to oversee its development. Several state agencies have been created, substantial resources have been allocated, and large-scale projects have been undertaken. Examples are the creation of the *Bank of Amazonia* (BASA), the *Northern Brazil Electricity Board* (ELECTRONORTE), the *National Indian Foundation* (FUNAI) and the *Ministry of the Environment, Water Resources and Legal Amazon* (MMA). In addition, large amounts of resources have been allocated through the *Superintendency for the Development of the Amazon* (SUDAM), and the *Investment Fund for Amazônia* (FINAM).

70.8.2 Militarization of Environmental Issues

In the Brazilian Amazon environmental issues have to certain extent been militarized. An issue is militarized if that issue is part of the ordinary tasks and/or duties carried out by the military apparatus, irrespective whether emergency actions have been taken to face a given threat. The Amazon has been a concern for the armed forces. The most important agency for Amazonian development (SUDAM) is a direct product of the military regime. In most agencies dealing with the management of the Amazon there is some military involvement. Several presidents of the *National Indian Foundation* have come from the army, and the military has always been involved in environmental and indigenous policies in the Amazon.

In 1985, the *National Security Council* (CSN) took over the task of demarcation of Indian lands. In 1988 the CSN managed the *Project for the Protection of the Environment and the Indigenous Communities* (PMACI). The *Indian Missionary Council* (CIMI) criticized the military intervention on Indian lands, and during the 1990's the *Indian Council of Roraima* (CIR) denounced several times that the Army assumed exclusive powers over the Raposa/Serra do Sol Indian Area along the Brazil-Venezuela border whose demarcation process was stopped due to political and military pressure. The main concern by the army seems to be that the demarcation could put the sovereignty of Brazil at risk, because the Macuxi, Ingariko, Wapixana, and Taurepang Indians could claim their independence.

In all most important projects in the Amazon (e.g. in the *Calha Norte*) the military was involved. The *Secretariat for Strategic Affairs* (SAE) was involved in designing and implementing environmental policies, it co-ordinated the Ecological-Economic Zoning and implemented the Surveillance System of the Amazon re-

15 General Gleuber Viera, chief of staff of the army, in his conference at the 4th National Encounter of Strategic Studies, Unicamp, Campinas. 10-15, May 1998.

gion (SIVAM). All these examples illustrated the extensive military involvement in the management of the Brazilian Amazon.

70.8.3 Toward a Comprehensive Security Concept in the Amazon

This case shows that we also witness a process of declining military threats in developing countries. Brazil has borders with all other South American countries (except Ecuador and Chile), but its concerns are less related to potential problems with other countries in border regions or to a potential invasion from a neighbouring country. This does not mean that the borders are irrelevant for security matters. In the Amazon borders are still a reference point in military terms mainly because they are perceived by the army as vulnerable areas, due to low population. For instance, Tabatinga with only 28,000 inhabitants is the most important town on the Colombian border.

But there have been recently many declarations by army officials that in the Brazilian Amazon security have become a comprehensive concept. According to the *Secretariat for Strategic Affairs* (SAE 1997) the targets to be reached by 2020 are the full and sustainable utilization of national territory and maritime space. In the SAE's view contemporary geopolitical thinking focuses on necessary political and scientific definitions of realistic parameters for sustainable development of both the Amazonian border and region. The issues that have been included in this comprehensive concept reflect such new threats as environmental protection, controlling drug trafficking, halting smuggling of timber, rare minerals and biodiversity, controlling and supervising the use of land, fighting forest fires and illegal mining, surveillance and border control, etc (Dreifuss 2000). Significant resources that have been allocated by the government to the Amazon are presently used to mitigate the impact of or threats by drug traffic, land conflicts, and environmental disruption.

In the Brazilian Amazon military threats are no longer seen as the only and most important ones. Military and political experiences in the region have highlighted that the Amazon is one of the most sensitive areas of Brazil, and that its defence cannot be reduced to military dimensions. General Gleuber Vieira, a former chief of the Brazilian army, has argued that the armed forces have an additional target, or mission, of "co-operating with socio-economic development" (cited by Dreifuss 2000: 213). For SIVAM an important shift in the perception of threats can be ob-

served. SIVAM concentrates on these 'new' types of threats such as environmental change (deforestation, fires), identification of illegal activities (drug trafficking, gold smuggling) and land conflicts (land occupation and use).

70.9 Resource Scarcity vs. Abundance in the Brazilian Amazon

Under certain circumstances there is a connection between environmental factors and violent conflicts. For the Brazilian Amazon environmental change in most cases is no direct source of social conflicts, but an important aggravating factor of conflicts acting through its side-effects. In the Brazilian Amazon in most situations environmental scarcity is no key factor producing social conflicts. Thus, the hypothesis that the more natural resources are available in a system, the less likely conflicts are among its components, must be revised.

Social conflicts are defined as social action carried out by actors sharing a social framework which constitutes its system. Thus, social action is a goal-oriented behaviour, but it also defines a sort of social group identity. This is because the ideas, interests, etc. that define individuals become the basis for collective actions that engage participants in a dispute. One can see opposing interests and, therefore, potential for conflicts. Thus, whenever the term social conflict is used it will be within this framework, meaning the condition under which one social group (e.g. miners) is engaged in conscious opposition to one or more social groups (e.g. Indians), because they are pursuing incompatible goals (land integrity vs. mineral exploitation), and when this opposition is accompanied by violent behaviour (Dougherty/Pfaltzgraff 1990: 187).

The Amazon shows that a conflict occurs when one party's claim to or use of one given good negatively affects the interests of some other party, and when no alternative seems to exist that will satisfy the aspirations of those parties involved with divergent interests or values. This situation may occur due to the lack of a good to meet the basic needs of the parties involved (*basic scarcity*), or, as in Roraima when ample supply of valuable goods (gold) induces competition over access to or use of that good. This latter case explains the conflicts between indigenous population and *garimpeiros* in Roraima, where most conflicts are not generated by scarcity, but rather by the richness of the subsoil.

When such conflicts exist, they are especially severe if one or all parties have rigid aspirations they regard as legitimate and when the disputed object has a high market or user value for the parties involved. This is the case of conflict over mineral resources in Indian lands. In summary, the emergence of conflicts in the Amazon as a whole may depend more on access to resources, and its intensity could be more related to the market and user value of that resource than on environmental scarcity. As the case of Roraima has shown, the abundance-scarcity debate and its influence on conflict formation are linked to the possibility of access of interested parties. This has materialized through the invasion of Indian lands by small gold prospectors and the subsequent conflict of interest over the exploitation of gold and other minerals, as for example in Roraima the Yanomani reserve and the Raposa Serra-do Sol area. Thus, conflicts do emerge because the claim made by one party such as *garimpeiros* to use or exploit a given good, such as gold, must negatively affect the interests of another party, in Roraima the Yanomani and Makuxi. The above does not necessarily mean that in Roraima the goods or services provided by the environment are not enough for those who want or need it. Rather it refers to a situation where the richness of the subsoil and the environmental change produced by the exploitation of such resources negatively affects one party. This is being aggravated by rigid aspiration of both parties and the market value of the good in question.

Finally, the role of scarcity must be distinguished at different levels. While in the Amazon as a whole there is no environmental scarcity, at a local level the situation is often very different. There are several scenarios where scarcity is evident, notably in the southern Amazon, as in the southern part of Pará, the eastern border of Pará with Maranhão, the northern part of Tocantins, and a large part of Rondônia present several scarcity scenarios. However, other parts of the Brazilian Amazon such as the northern part of the Amazon (Roraima and Amapá) face a very low level of environmental disruption and almost no scarcity in terms of forest, water, and other natural resources. Thus, in analyzing scarcity one must be aware of the problem of scale.

70.9.1 Role of Environmental Change in the Brazilian Amazon?

Environmental change should be understood as a large-scale natural or human-induced destabilizing in-

terference in the environment. The focus is on environmental change rather than on environmental scarcity. Besides the definition of environmental conflicts a second aspect must be revised. It is insufficient to argue that the environment plays a role as has been argued in other studies, notably Homer-Dixon's (1999, 2000/2001) work. For analytical purposes environmental change must be placed as an interactive source generating social conflicts, and how and with what other sources environmental change interacts to generate social conflicts. Two roles must be distinguished: trigger and aggravator.

A trigger of a conflict is a proximate cause where a factor triggers the system beyond a critical threshold. If environmental change acts as a trigger, the process of environmental change must be acute. For instance, a strong drought, an enormous flood, or a high degree of deforestation would have to take place. A claim that environmental change is an aggravator suggests that the factor interacts with other factors to produce conflicts. Most cases in the Brazilian Amazon can be placed within this framework. There is empirical evidence that environmental change can act as an aggravator. For instance in terms of soil, the low ecological carrying capacity of the Amazon basin, especially in the tropical *terra firme* soil, brings about specific limitations to colonization and agro-pastoral activities. Thus, the rapid decline in agricultural production on colonized soil inhibits capital accumulation, settlement stability and consequently the construction of stable social relations. This situation causes permanent migration, accompanied by further deforestation resulting in most cases in open conflicts on access to land-resources.

Another example is open conflicts as a result of forest depletion in the Brazilian Amazon. Ranching activities and the process of deforestation has had a direct effect on the lives of the forest-dwellers. The most evident conflict has been the expropriation of the customary lands of forest peoples. This situation has to do with the surviving strategies of several groups such as Indians, rubber trappers, nut collectors, and *Quilombos*, whose way of living is strongly related to nature, and their social organization is based on the communal use of natural resources. This way of living is in opposition to the private exploitation of these resources by miners, large landowners, mining companies, and logging enterprises, etc. The most well-known case related to open conflicts due to forest depletion has been the assassination of Chico Mendes, the former president of the Rubber Trappers Union.

70.9.2 Contribution of Environmental Change to Social Conflicts

The contribution of environmental change to social conflicts in the Brazilian Amazon may be understood as indirect and/or interactive. This means that social conflicts are understood partially as the outcome of the social and environmental side effects of environmental change. Here the process of environmental change in relation to other variables can produce either social conflicts or widen the scope of existing conflicts. In the Brazilian Amazon this would mean that deforestation, pollution from mining activities, and flooding in connection with other sources will produce social conflicts and/or contribute to social conflicts by introducing more entropy to a system that is already in turbulence. However, what is going to be more important in the final analysis is to see what specific role environmental change as an independent variable is going to play, for instance as a trigger or aggravator. As a trigger environmental change basically releases accumulated non-environmental social pressures, and as an aggravating factor environmental change adds to other factors producing conflicts.

71 Politics of Environment in the Caucasus Conflict Zone: From Nationalizing Politics to Conflict Resolution

Vicken Cheterian

71.1 Introduction

This chapter argues that for the past two decades environmental politics was part of a nationalizing project in the Caucasus. It reviews the conditions for the emergence of environmentalist movements in the Soviet Union, and why they lost the leadership of independent politics to nationalist forces. It also addresses the security dilemma that led to a series of violent ethno-territorial conflicts in the Caucasus, which have undermined regional security and stability. It argues that environmental politics continue to remain expressions of national projects, and as such unsuitable neither for addressing regional environmental concerns, nor for solving complex security problems. It concludes by looking at newly emerging environmental movements that carry the potential of separating environmental politics from nationalizing projects, and create the necessary conditions for environmental cooperation on the regional level. To conclude, the example of the rise and fall of environmentalist movements in the Caucasus and other post-Soviet republics should make international organization highly cautious about rapid transplantation of value-charged projects, which could take another life of its own under new socio-political conditions and in societies having a plurality of historic trajectories.

Political reforms under Mikhail Gorbachev's *glasnost* had created new conditions under which various ideological currents could compete to mobilize a population that was denied independent political activism for decades. Environmental movements were the first to mobilize street demonstrations with thousand of participants in the various regions of the Soviet Union, including in the South Caucasus.¹ Soon after-

wards, national movements in the republics, and democratic forces in the centre, overshadowed the green movements and took over the leadership of rapidly developing mass movements, pushing environmental politics into a long eclipse. In recent years, environmental politics has made a comeback to the South Caucasus. The work of international organizations, a newly emerging environmental consciousness in the capitals, and the utilization of environmental concerns on a regional level by ruling administrations, has reintroduced environmental politics into public discourse after an absence of a decade and a half. In this context, it is important to see the conditions in which environmental politics rose and collapsed, its association with other political currents and ideas, to appreciate the political underpinnings of the new environmentalists, and their place in the newly emerging political landscape.

The question remains to be seen whether the new interest towards the environment will help emerge a larger and independent green political movement, after the failure of environmentalists of the perestroika generation. Another unknown is to see how the emergence of a new movement will change the political construct of the South Caucasus, and have an impact on the security problems that the region inherited at the moment of the collapse of the Soviet Union. Yet, those various groups invoking the environment have different motivations and seek separate objectives. While for international initiatives like the *Environment and Security Initiative* (EnvSec, box 71.1), the declared objectives are to understand the overlap between environmental problems and regional security, in order to bring concrete solutions to environmental problems, and thus building trust on a regional, and political level, national governments, local environmental groups, and established green parties, each seek different objectives while evoking the environment (figure 71.1).

1 During the Soviet period, the region was known as 'Transcaucasus', and since independence the three independent republics of Armenia, Azerbaijan, and Georgia are referred to as the 'South Caucasus'.

Box 71.1: EnvSec activities with a specific focus on the Southern Caucasus. **Source:** EnvSec; at: <<http://www.envsec.org/about.php>> and <<http://www.envsec.org/southcauc/index.php#maps>>. Published with permission of EnvSec.

The *Environment and Security Initiative* (EnvSec) seeks to facilitate a process whereby key public decision-makers in *South Eastern and Eastern Europe, Central Asia* and the *Caucasus* are able to motivate action to advance and protect peace and the environment at the same time. ... It works to assess and address environmental problems, which threaten or are perceived to threaten security, societal stability and peace, human health and/or sustainable livelihoods, within and across national borders in conflict prone regions. The Initiative collaborates closely with governments, particularly foreign, defence and environment ministries, national experts and NGOs. ... EnvSec has carried out assessments and published reports ..., for understanding the linkages between environment and security in the political and socio-economic reality of these three regions. The Initiative develops and implements work programmes aimed at reducing tensions and solving the problems identified. Through extensive regional consultations and multi-stakeholder participation the initiative seeks to:

- Identify environment and conflict hotspots by carrying out desk and field assessments
- Present the results of the assessments in graphically rich maps, reports and web site and draw the attention of politicians and people to situations and hot spots where risks are high
- Help societies to deal with priority issues by raising awareness, building capacities and strengthening institutions
- Support concrete action and catalyse specific solutions for the identified security-relevant environmental problems on the ground

These challenges are being tackled with a combination of political, socio-economic and environmental insights as well as the capacity and skills of the six partners. EnvSec also collaborates with think tanks and research institutes to increase the understanding of the interdependency of natural resources, socio-economic development and political stability.

EnvSec was established in 2003 by the *United Nations Environment Programme* (UNEP), the *United Nations Development Programme* (UNDP), and the *Organization for Security and Co-operation in Europe* (OSCE). The *North Atlantic Treaty Organization* (NATO) became an associate member of the Initiative in 2004, through its Public Diplomacy Division. From 2006 onwards the Initiative is strengthened with two new members: the *United Nations Economic Commission for Europe* (UNECE); and the *Regional Environment Center for Central and Eastern Europe* (REC).

EnvSec is governed by a Management Board, which consists of representatives of the partner agencies. The EnvSec activities are co-ordinated by the EnvSec Secretariat consisting of two bodies: (i) a coordination unit comprised of a Coordination Officer and Regional Desk Officers from the partner organizations, and (ii) an administrative unit hosted by UNDP Regional Centre for Europe and the CIS. An Advisory Board

comprised of donors, national government focal points from recipient countries and other stakeholders provides scientific and policy advice for the Initiative through annual meetings.

EnvSec in the Southern Caucasus

The Southern Caucasus ... has seen multiple inter-state and ethnic conflicts in its recent past, some of them escalating to full-scale warfare. In this context, the lack of regional cooperation threatens to exacerbate environmental issues, themselves a source of potential conflict in the region. Among the environmental concerns identified by EnvSec in the Southern Caucasus are the management of shared natural resources (not least in the Kura-Araks river basin which covers a large part of the region), pollution from ageing industries and irrigation networks, and uncontrolled growth of capital cities. Disagreements about real or perceived environmental threats, such as those related to the environmental conditions of the 'frozen conflict' zones, Metzamor nuclear power plant or the Baku-Tbilisi-Ceyhan trans-regional pipeline further complicate the picture. On the positive side there are quite a few opportunities to foster cooperation between the countries in the environmental field.

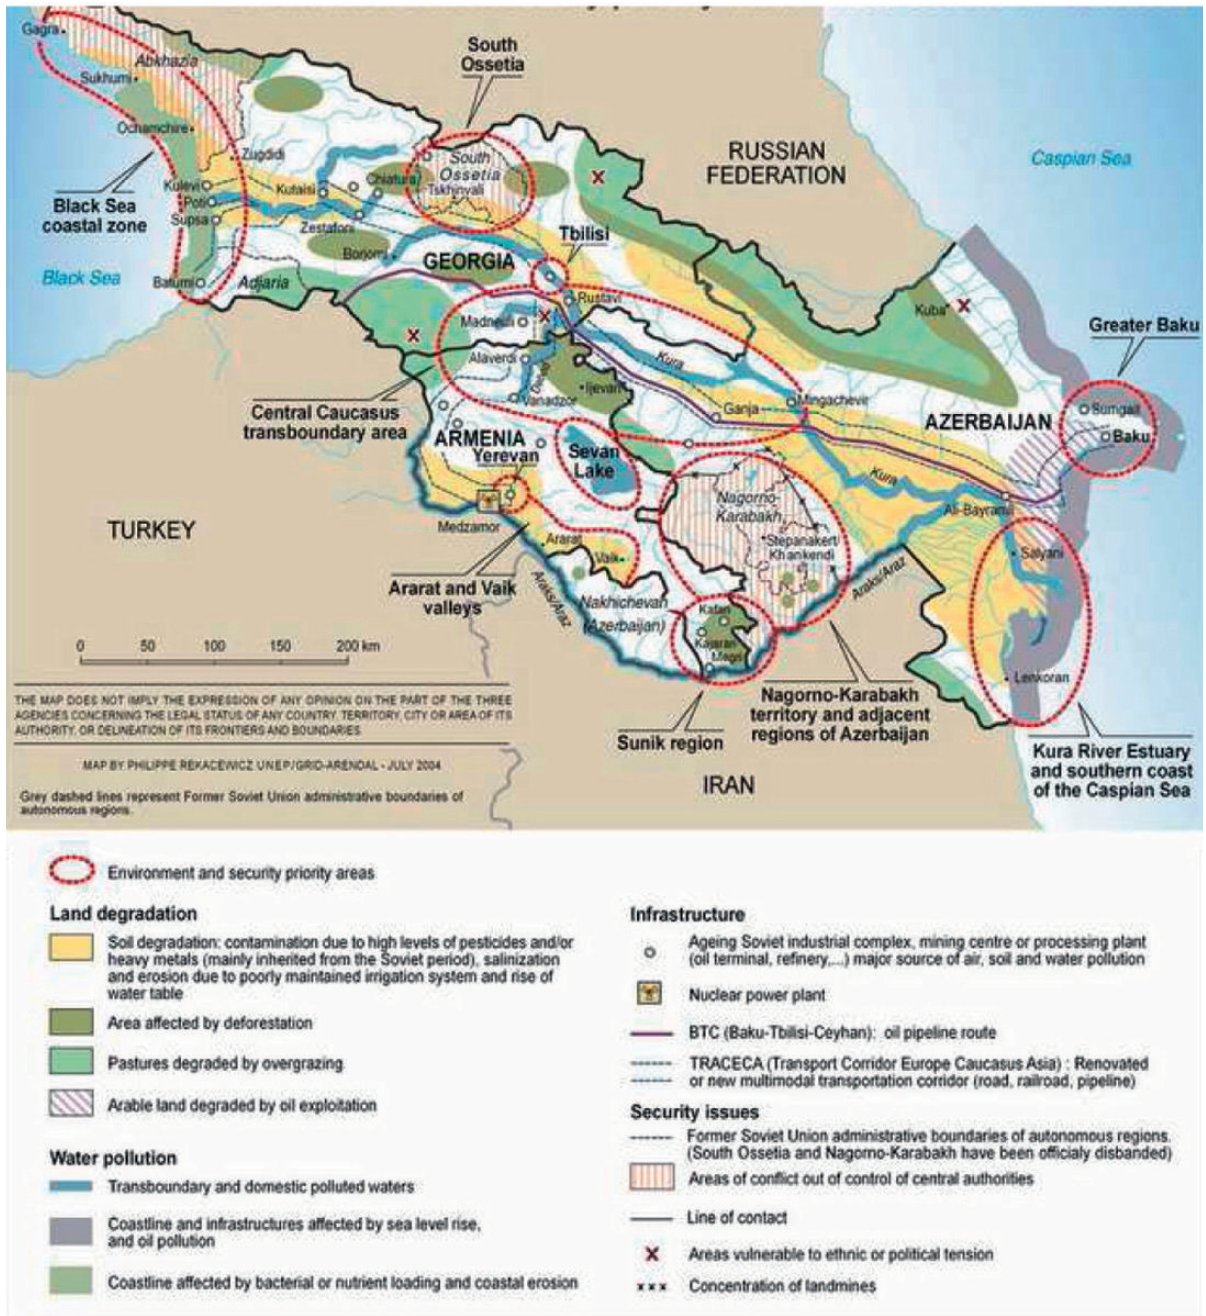

The EnvSec assessment of environment and security linkages in the Southern Caucasus was presented at the Ministerial meeting of EECCA [Eastern Europe, Caucasus and Central Asia]^{a)} countries in Tbilisi on 22 October 2004. EnvSec has identified the frozen conflict zones in South Ossetia, Nagorno-Karabakh, and Abkhazia as areas where more detailed assessment can help facilitate a broader understanding of current environmental challenges. EnvSec has supported monitoring and management of the Kura-Araks river basin, strategic environmental assessments, the establishment of public environmental information centres ('Aarhus centres'), and media training. In the view of reducing tensions in mountainous areas and promoting cooperation for protection and sustainable management, EnvSec also supports transboundary cooperation on the protection of the Caucasus mountains. The process of negotiating a legal framework will proceed, and it is closely linked to a similar mountain protection project in South Eastern Europe.

71.2 Environmentalists and Nationalists in the Caucasus

Three political currents can be distinguished among Soviet dissidents in the South Caucasus: a) environmentalists who were relatively tolerated by the authorities, b) human rights groups who received a strong

impetus after the signing of the Helsinki Final Act (1975),² and c) groups struggling for national rights. The national groups embraced a large panorama including intellectuals fighting against linguistic assimilation and groups calling for national independence, such as the United National Party in Armenia (Mouradian 1990: 256). While distinguishing these currents,

there was a very important overlap among them, as the same group or individual used one discourse for one audience and a different one when the audience changed. For example, Zviad Gamsakhurdia,³ a leading Georgian dissident and co-founder of Georgian Helsinki Group, tended to use a human rights discourse when addressing external audiences (Russian, Western), and a nationalist one while addressing the Georgian public. Similarly, the line separating nationalist dissidents and environmentalist activists was not always clear-cut.

But among the several competing ideological currents it was the nationalist movements that eventually succeeded in monopolizing the new political space. For Mark Beissinger, who has studied nationalist mobilization during perestroika and afterwards, the reason why nationalism – emerging from a tide of larger movements – became the dominant force should be explained by an “interaction between pre-existing structural conditions, institutional constraints, and even specific processes” (Beissinger 2002: 49, 79).

To put it another way, to understand why nationalism became the main ideological framework to challenge Soviet order a look at the institutions and structures created by the Soviets is useful, which had both structures for mobilization (e.g. the Karabakh movement started with debates within the regional Soviet of Mountainous Karabakh Autonomous Region), and the legitimacy it enjoyed within the societies.

Another interpretation about the failure of the environmentalists (or human rights movements) to lead the emerging mass movements in the late 1980’s is that those two currents addressed specific issues, and not radical social transformation. When the Soviet Union was about to collapse, there was a need, a public demand to substitute the heavily centralized state system with something different, and here the nationalist movements were better equipped, since they pro-

posed an alternative model of statehood and state ideology, legitimized both by past historic references, but mainly legitimized by the Soviet administrative ethno-territorial divisions. Therefore the small nationalist groups found themselves on the top of a potent popular movement which soon became the leading political current mobilizing the masses, and leading them simultaneously towards national independence (decolonization) and systemic transformation (privatization of the economy and socio-economic ‘transition’).

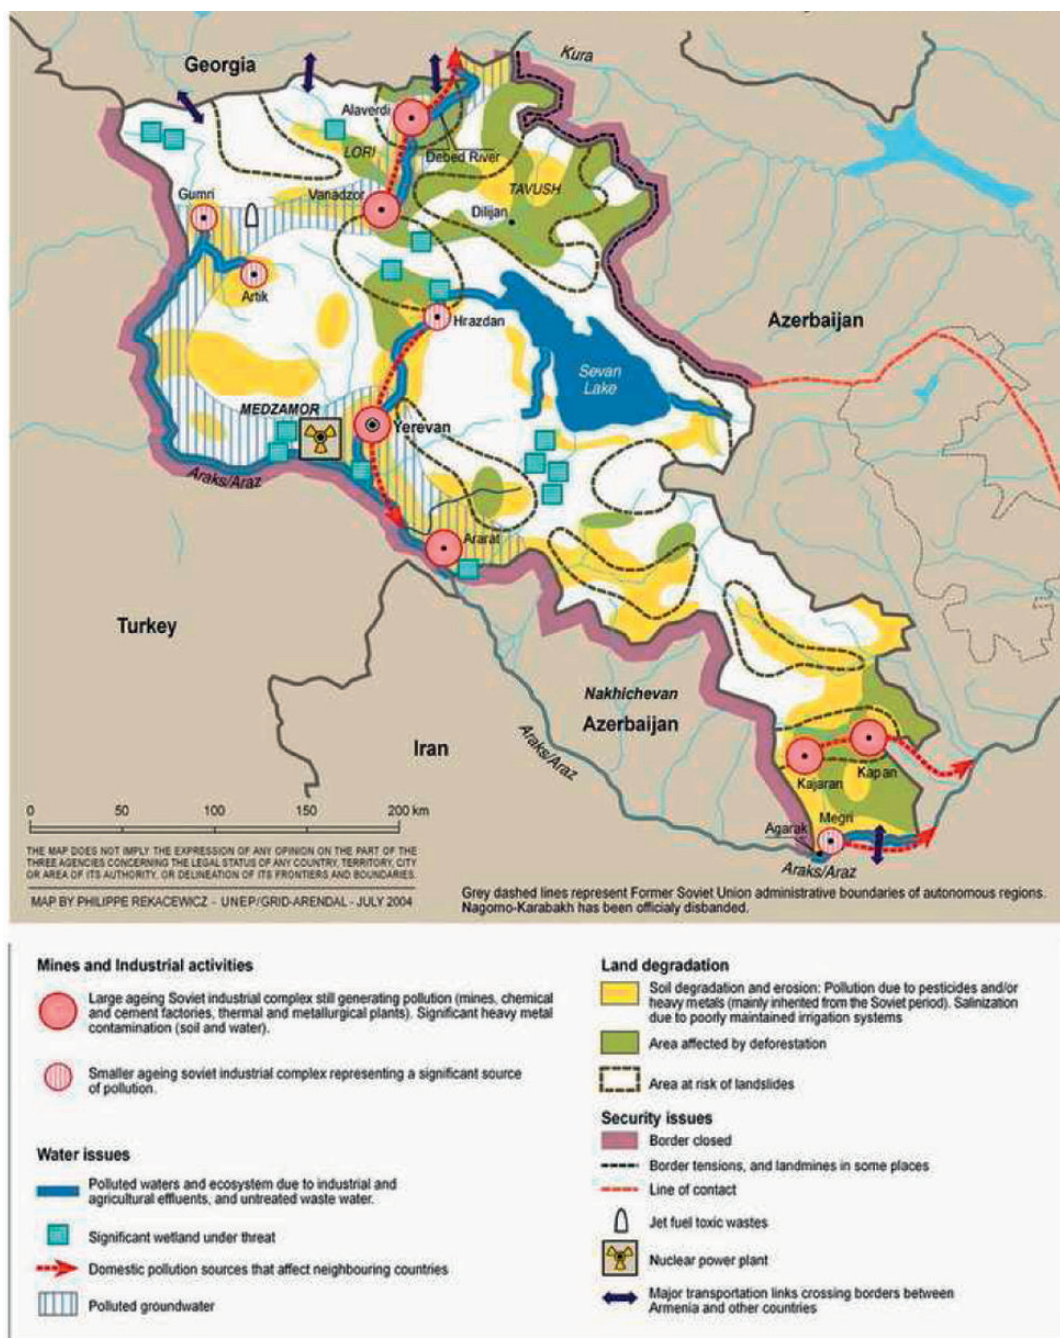

The short prominence of the environmentalists in the mid 1980’s was the result of the activism of environmentalists for several decades, who walked on a tightrope between what was tolerated by the ruling party, and between organizing independent political initiatives that went against the logic of party monopoly in politics. The rapid modernization in the Soviet Union clashed with the alarming degradation of the natural environment. Small dissident groups composed of urban educated circles such as scientists, teachers and artists, opposed industrial projects as early as in Khrushchev era. The mobilization of Russian environmentalists against industrial projects on the shores of Lake Baikal starting from 1966 found echo among the Soviet intelligentsia. In the same period, in the Armenian capital Yerevan scientists and various representatives of the intelligentsia mobilized to save Lake Sevan from drying up. From 1949 to 1962, in the years when the water of Sevan was heavily utilized, the lake dropped by one meter per year, or, in other words, the lake volume dropped from 58 billion cubic meters to 33 billion cm. In those years the level of Sevan had dropped by 18.5 metres as a result of the utilization of its waters to generate hydroelectric power (Sovedagan Hayasdan 1987: 84). This mobilization recorded a victory: Soviet authorities eventually agreed to reduce the utilization of the water from this lake and in 1981 the Soviet authorities built a 49 km tunnel to divert Arpa River to flow into the lake to stabilize Sevan and later to increase its level by 6 meters. Since 2002, and due to heavy snowfall and better utilization of its resources, the level of Sevan has increased by another 2.4 meters (figure 71.2).

Without doubting the sincere concerns for the fate of the Sevan and the fears about the dramatic consequences its shrinking or even disappearance could have caused, nevertheless there was an overlap between environmental concerns and national sentiments. The Armenian intelligentsia had limited possibilities to express its opposition to the confiscation of its national sovereignty by the Soviet central authorities. In this context, the mobilization for the defence

2 “The Final Act of the Conference on Security and Cooperation in Europe”, known also as Helsinki Final Act, or Helsinki Accords, was signed on 1 August 1975 in Helsinki by the USSR, USA, Canada, and 32 European states. Its inclusion of “Respect for human rights and fundamental freedoms” led to the creation of human rights groups in various Soviet cities. See: <http://www.osce.org/documents/mcs/1975/08/4044_en.pdf>.

3 Zviad Gamsakhurdia later became the first freely elected president of Georgia (1991-1992), but an armed opposition overthrew his rule in early 1992, opening the way for the return of Eduard Shevardnadze to lead Georgia. Gamsakhurdia died in mysterious circumstances in Western Georgia in late 1993.

Figure 71.2: National environment and security issues in Armenia. **Source:** EnvSec; at: <<http://www.envsec.org/southcauc/maps/armenia.jpg>>. Published with permission of EnvSec.

of Lake Sevan can be understood not just as a movement opposing industrial projects that had catastrophic consequences on the ecosystem of the lake, but also as an expression of dissent from a national group against the arbitrary rule of the authorities of a vast empire. The success of this and similar movements legitimized the expression of environmental

concerns, and created a space where the public discussion was tolerated by officials.

In the early years of Gorbachev's perestroika, the environmental issue was added to the agenda after the Chernobyl nuclear accident in April 1986 (chap. 61 by Sergunin). Besides debates on the risk of nuclear power, articles criticizing the management of the envi-

ronment appeared in various papers, both central and in the republics. The authors – often governmental health officials – revealed the content of official studies, described the interrelationship between the intensive use of pesticides, emissions, radiation, and the increase of childhood mortality.⁴ Once such articles were tolerated, at least their authors were not arrested by the secret police, the militants took a step further and started organizing public action.

The first independent street demonstrations in Armenia, Azerbaijan and Georgia were on environmental issues. In 1987 several thousand people demonstrated demanding the closing down of the Metamor nuclear plant, located at only 25 kilometres from the Armenian capital, which got a sense of urgency after the Chernobyl catastrophe. Others gathered in Yerevan demanding the closing down of the Nairit synthetic rubber plant in the southern industrial quarter of the city.

In 1988, in neighbouring Georgia the intelligentsia mobilized against the Caucasian Mountain Railway project, that aimed to link the north Caucasus with the south⁵, by piercing eleven tunnels, constructing eighty-five bridges, and extending 300 kilometres through the Caucasus range (Gayan 2004: 424). Here, the national concerns were even more apparent: the Georgian protesters opposed not only the distortion of the mountain landscape, but also feared that such a project would bring large numbers of foreign (mainly Russian) workers to isolated mountain communities, further destabilizing the tense inter-ethnic relations in the republic (figure 71.3).

In the same year, in Soviet Azerbaijan the first mass demonstration, which took place in November 1988, was to protest alleged plans of the authorities in Nagorno Karabakh, an Autonomous Region with ethnic Armenian majority but situated within Soviet Azerbaijan, to cut down the forest of Topkhana near the town of Shushi/Shusha, for the construction of an aluminium plant (figure 71.4).

Was the topkhana demonstration about the environment? Here are the recollections of one Azerbaijani journalist:

... I asked my parents what had happened. ‘Topkhana,’ they said. ‘Armenians were cutting down Topkhana.’ No further explanation was needed. Any Azerbaijani could understand everything with that one word. Topkhana is a forest. A large old forest in a State Preserve. It has grand oak trees which have been standing, they say, for more than 300 years old. But it’s more than that. The forest is associated with the entire region around Topkhana, especially the vicinity of Shusha, which symbolizes the best, the noblest and the highest level of our culture. We’re so proud of the level of civilization that has emerged from that region – the depth of thoughts and dimensions of beauty. It’s the birthplace of so many cultural giants – artists, writers, poets, playwrights, musicians, composers, and intellectuals. And so the land has become sacred to us. Historically, we are psychically and emotionally attached. So those demonstrations about Topkhana were not really about trees or ecology at all. The issues penetrated so much deeper; outsiders had challenged our authority over our own resources – both physical and cultural.⁶

The overlap between national concerns and environmental claims is striking. A tree is not a tree, and the land is a symbol of the nation, and not part of a natural habitat to preserve. The enemy is not polluting modernization, but the other, the ‘foreigner’ laying claim on the territory of ‘our nation’. And as the authorities had shown tolerance towards environmental dissidence, green movements succeeded in mobilizing all those forces who were opposing the Soviet officialdom, and who found refuge among the ranks of the environmental movements. But soon, the successes recorded by environmental demands – the railway project in Georgia was shelved few weeks after the start of street demonstrations – only helped to radicalize the emerging mass movement. This radicalization shifted not only the focus of the emerging mass movement but also transformed its nature further away from environmental concerns, or at least discourse. In this sense, environmentalist movements can be seen as the precursors of the national movements that mobilized hundreds of thousands in the streets of the three capitals. Or, to put it in another way, the environmentalist movements can be seen as part of the “nationalizing stances”, in the words of Roger Brubaker (1996: 63–64), which on the ground of the weakening Soviet state advanced the national project. The environmental movement in the South Caucasus

did not defend the *environment* per se, but the land, the air, the mountain, the lake, the forest of the *nation*. They did not oppose the modernizing, industrializing policies of the Soviet Union because they de-

manded a cleaner air and water and sustainable usage of resources, but wanted to replace the Soviet by the national.

71.3 Popular Nationalism and the Security Dilemma in the South Caucasus

The reforms initiated from above weakened the Communist Party structures in the Soviet Union, and espe-

cially in the national republics. As the Soviet state was collapsing, its legitimate heir in the eyes of the international community was the union republics based on national principles. Yet, not all emerging national movements coincided with the territorial divisions of the union republics, creating clashes within as well as

across those borders. In the Caucasus, five conflicts tore the region apart, three of them in the southern part. The main reason of those conflicts was essentially in the national revolutions that overthrew the Soviet administration in the republics, thus bringing a new generation of radical politicians to power. The second major reason was the clash between the various national movements that mobilized to take over the space left behind by the exit of the Soviet Union from history.

The irreconcilable fraction of the dissidents against the Soviet system was composed of nationalist intelligentsia. Their main subjects of struggle in Soviet times were the defence of the national language and culture, which sometimes took mass expressions as in Georgia in 1978 (Carrère d'Encausse 1978: 218) when a project for the reform of the constitution aimed at making Russian the official language in the republic. The more radical forces among the national movements called for secession from the Soviet Union. Here too the nationalist discourse directed towards the interior often overlapped with the human right discourse directed to the outside audience. Yet, a harsh repression that followed paralysed their network and exiled their leaders, opening the space for the emergence of environmental opposition movements.

In the late 1980's activists coming from the nationalist dissident groups succeeded in overtaking the environmentalists and taking control of the newly mobilizing mass movement. As the national movements filled the main squares of Yerevan and Tbilisi, the budding environmental movements were left under a complete eclipse, overtaken by accelerated history where new concerns and the rapidly radicalizing political agenda of national independence overtook the quest for closing down sources of pollution. The strength of the national movements was visible to all: they succeeded in mobilizing hundreds of thousands in strikes and demonstrations which paralysed the Soviet state. The timid attempts of the Red Army to repress the mass demonstrations, such as in Tbilisi in April 1989, or in Baku in January 1990, helped only to further de-legitimize the Soviet institutions, and further strengthen nationalist demands to self-determination and sovereignty of the nation. There was a new sense of strength about the power of the nation mixed with anxiety and uncertainty about the coming backlash, leading to the conclusion that only an independent nationhood could guarantee the security of its people.

The success of the nationalist movements should be found in the nature of the Soviet state itself. The Soviet ideology claimed that its administrative subunits were "national in form and socialist in content", yet the Soviet policies of ethnically defined territorial administrations in which one ethnic group was privileged further strengthened national consciousness, and sharpened inter-ethnic rivalry. The Soviet experiment paradoxically developed ethnic-territorial entities with national intelligentsia (Suny 1993: 84-126), while repressing not only nationalist expression, but also sovereignty of the entities it developed.

In the late perestroika period (1988-1991) the nationalist movements in the Caucasus were fighting on two fronts. First, they were struggling against the double-headed Communist Party (the central authorities in Moscow and the authorities in the republics) to replace them by taking over political power. After an initial attempt at repression, the local Communist Parties in Armenia, Azerbaijan and Georgia were replaced by the representatives of the national movements. This transfer of power occurred without violence in Armenia and Georgia, where the election of Levon Ter-Petrossian was recognized by the old nomenklatura who gave up power peacefully. In Georgia the election of Zviad Gamsakhurdia led to an initial transfer of power, but later a vast coalition of nationalists, armed groups and former Communists toppled the new president and brought back to power the former Soviet foreign minister Eduard Shevardnadze. Although the civil war to topple Gamsakhurdia did not last more than two months, its wounds are still visible within the Georgian society. In Azerbaijan, the struggle between the Communist nomenklatura and the emerging nationalist opposition led to clashes in Baku in 1992, and the overthrow of the former Communist boss Ayaz Mutalibov, and the election of a former dissident Abulfaz Elchibey to head the state. A year of economic collapse and military defeats in Karabakh weakened Elchibey, and an armed rebellion led to the return to power of Heidar Aliiev, the long-time leader of Soviet Azerbaijan.

Next to fighting the Soviet order to take power, rival nationalist movements were often in competition, leading to clashes to control land and people. This triangular struggle turned the Caucasus into the major battlefield of the collapsing Soviet Empire.

The first nationalist mobilization was around the Karabakh issue, an autonomous region with an Armenian majority, but placed within Azerbaijan by the Soviets (Donabédian/Mutafian 1991). The refusal of Moscow to change the status quo, anti-Armenian po-

groms in Azerbaijani cities, population transfers between Armenia and Azerbaijan, and the growing clashes between armed village committees in the Karabakh area increasingly degenerated the situation into a civil war. The end of the USSR transformed the nature of those conflicts. Initially considered 'internal affairs' of the Soviet Union, starting from 1992 the Karabakh conflict has pitted the two newly independent states of Armenia and Azerbaijan against each other in an undeclared war. At the time of signing a cease-fire in May 1994, Azerbaijan had lost control over the autonomous region, and several regions surrounding it, to Armenian forces.

In Georgia, the rise of Georgian nationalism led to new fears among the third of the population, composed of ethnic and linguistic minorities. The Georgian national movement and their struggle against Moscow, for example, raised fears among the autonomous entities in Georgia inhabited by non-Georgian ethnic groups, such as the Abkhaz and the Ossets (figure 71.3). For Georgian nationalists like Zviad Gamsakhurdia, any political expression coming from those entities was the result of a plot from the Soviets to destroy the will of the Georgians to national independence, cutting all possibilities of negotiations. Three regions in Soviet Georgia enjoyed autonomous status of different degrees, including South Ossetia, Abkhazia, and Ajaria. Minority groups feared that Georgian nationalism, and breaking-away from the USSR, would diminish or even whip-out the autonomous status they enjoyed. As a result, nationalist movements emerged in those regions, leading to armed clashes first in South Ossetia in 1989, and when a cease-fire arrangement was reached there in summer 1992, Georgian Armed forces entered Abkhazia provoking a thirteen month long war, before being defeated.

The outcome of those wars was the emergence of three 'black holes' in the South Caucasus: Karabakh, South Ossetia, and Abkhazia are de facto state yet remain unrecognized entities (Cheterian 2001: 30-42). The specificity of those conflicts is that the smaller entities emerged as victorious in the military conflicts pitting them against larger national groups. This could be explained by a number of factors: the power struggle in Tbilisi and Baku providing the chance for military victories for the minority groups, and the weakness of the newly developing independent states and their incapacity to mobilize forces for those wars.

71.4 New States, Unrecognized States, and Security

Initially, the new national leadership in power was sensitive towards the environmental problems left behind by the Soviet system, and tried to address them. In Armenia, for example, the Metzamor nuclear power plant was shut down, following the double shocks of Chernobyl in 1986, and the earthquake that hit northern Armenia in 1988. Yet, within few years the concerns of both the ruling elites and the public changed rapidly. The conflicts and their victims, the refugees and the internally displaced peoples (1.4 million in the South Caucasus out of a total population of 16 million), the collapse of the planned economy, the economic blockades, the energy crisis in Armenia and Georgia, the dramatic fall in the living standards, all those problems engendered by the collapse of the Soviet system pushed environmental concerns into oblivion. In 1994 five years after being shut down, the Metzamor nuclear plant was reactivated, and no one went to demonstrate against it.

The post-Soviet Caucasus emerged as a major region of instability. The appearance of unrecognized, but de facto independent states of Karabakh, Abkhazia, and South Ossetia, with disciplined armed forces, political leadership, and territories under their control, continues the high tension. Although cease-fire agreements were reached in these three conflicts, several hundred victims are recorded yearly as a result of land mines and sniper fire on the warfronts. Villages, towns, agricultural land and various infrastructure systems remain abandoned in the frontline areas, while large military forces preserve a delicate balance of power. The relative calm has seen major exceptions as well, when clashes in Abkhazia in May 1998 and October 2001, and in South Ossetia in summer 2004 increased fears of another cycle of violence.

A second source of regional instability is the result of social polarization in each of the three republics. As a result of massive privatization of the Soviet inheritance, there has been a social stratification unseen in generations. A small minority which dominated the state structure has succeeded in increasing its wealth, while the vast majority of the population saw its former living standards fall dramatically. The political manipulations of the elite such as during the key elections has further alienated the population, and at times ignited revolts, such as in Georgia in November 2003. The monetarization of social relations has transformed the former social traditions and values, and

has created a fertile ground for the emergence of radical, religious-inspired movements.

A third source of regional instability has been great power competition to dominate this geopolitically relevant region, and access to natural resources. The South Caucasus is the only geographic link between the Caspian Sea and the steppes of Central Asia beyond it, and Western markets, without passing neither through Russia nor Iran. With growing uncertainty in the Middle East and the rise in global consumption of oil, the relevance of Caspian hydrocarbon resources to international politics has increased (Cheterian 1997; Dekmejian/Simonian 2003). While Washington is trying to connect the newly independent republics of the Caucasus and Central Asia to Western economic interests, by promoting such projects as the Baku-Ceyhan pipeline linking the offshore Caspian resources with the Turkish Mediterranean terminal, Moscow is trying to regain its lost influence in the region by developing an integrated energetic system, under the domination of Russian companies. Although this power competition did not yet spill-over into resource wars, it nevertheless increased the tensions over the existing cracks of the regional security architecture (Aydin/Kaptanoglu 2008; chap. 30 by Winrow).

While the Caucasus region remains a highly volatile zone, its source of instability between the late 1980's, and since the mid-1990's should be distinguished: while in the time of the Soviet collapse it was popular nationalism that challenged the existing order that led to mass violence, since the mid-1990's the source of instability comes from the dominant state structures which bears in itself the nationalizing project as state ideology, and tries to impose itself from above. There are numerous examples to support the state-sponsored nationalizing project: in Georgia with the coming of Mikheil Saakashvili to power as a result of the Rose Revolution of 2003, official calls for the 'reunification' of Georgia by force if necessary became part of regular official discourse. In the Azerbaijani exclave of Nakhichevan, several hundred soldiers destroyed an ancient Armenian cemetery at Jugha in a matter of few days in December 2005, destroying several hundred *khachkars* or cross-stones traditionally used by Armenians as tombstones.⁷ The nationalizing state could not bear the existence of its arch-rival over its own territory, even in the form of a century-old cemetery. When national independence was achieved, and ceasefire arrangements were reached on the fronts of Karabakh and Abkhazia, popular nationalism lost its mobilizing edge. Current nationalism is

state-sponsored nationalism, unlike the nationalism of the 1980's which was a revolutionary nationalism.

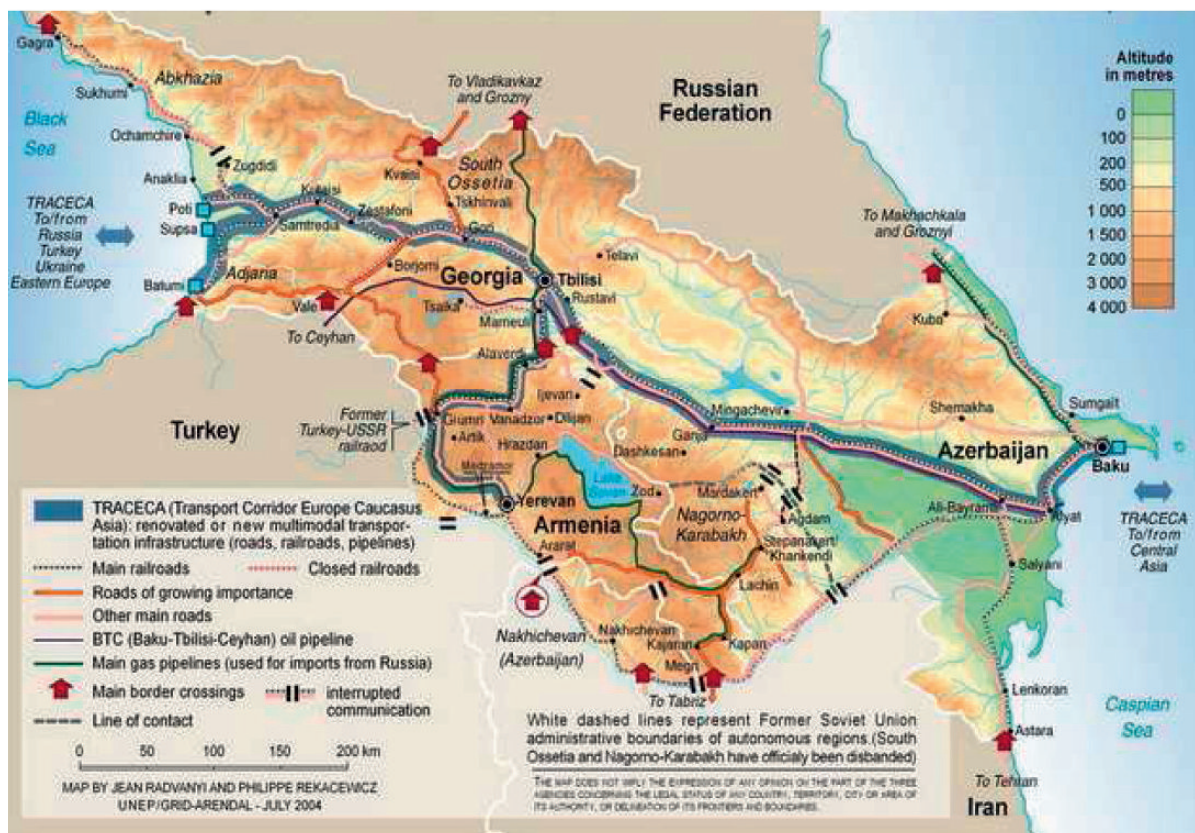

71.5 Environment and Conflict Transformation

The development of the Caspian offshore hydrocarbon production dominated the agenda of the Caucasus starting from the second half of the 1990's, and enhanced the international economic interest for this region. The signing of the 'Deal of the Century' on September 1994 between the Azerbaijani government and a consortium of Western oil companies led by the British Petroleum, with a total capital of nearly 8 billion US\$, transformed the nature of the political struggle in the Caucasus, and created direct American and European interests in the region. The struggle over the control of the territories took a new form: In the second half of the 1990's Baku substituted its military efforts to regain control over Karabakh with an 'oil diplomacy' in which it distributed contracts to exploit Caspian offshore oil in exchange for diplomatic support to pressure Armenia on the Karabakh issue. While the multi-billion Western investments brought the Caucasus and the adjacent Caspian region into international attention - and great power rivalry dubbed as the 'new great game' by the mass media - neither oil interests nor diplomatic initiatives brought any substantial change on the warfronts or the security problems of the South Caucasus.

Yet, Caspian hydrocarbon development had major effects on the political developments in the South Caucasus. First, it froze the existing conflicts. Any new military initiative would endanger investment and construction projects. Second, the starting of massive oil exports will pump millions of petrodollars to Azerbaijan, and indirectly to its neighbouring regions, thus alleviating the pressing socio-economic problems, that were so acute that they eclipsed other issues. Lastly, the involvement of Western capital in the projects of exploitation and transportation of Caspian oil ignited an important campaign mainly in the UK about the threats of pipeline construction on the environment⁸, and thus brought a new interest both lo-

7 Stephen Castle, "Azerbaijan 'flattened' sacred Armenian site", in: *The Independent*, London, 30 May 2006; at: <<http://www.independent.co.uk/news/europe/azerbaijan-flattened-sacred-armenian-site-480272.html>>; see also Sarah Pickman, "Tragedy on the Araxes", in: *Archaeology*, 30 June, 2006; at: <<http://www.archaeology.org/online/features/djulfa/index.html>>.

cally and internationally on the state of the environment in the South Caucasus (figure 71.5).

The new interest in the South Caucasus for environmental issues should be divided into two groups. The first is the continuation of the nationalizing project described above. In the Soviet times, the overlap between nationalism and environmentalism was carried out by the Soviet era semi-dissident intelligentsia, but today this project is carried out by state officials, or political groupings that are the direct heirs of the Soviet environmentalists-turned-nationalists.

The examples are numerous. Recently, Georgian authorities have complained about forests cut in South Ossetia and Abkhazia. Such claims have a different emotional undertone compared to complaints about cutting down of forests in other regions of Georgia, currently under the control of the Georgian central government. Azerbaijani authorities have similarly complained to international organizations about reports saying that radioactive material is being kept

in occupied Azerbaijani regions of Fizuli, Aghdam, Lachin, and Ghubati.⁹ In a similar direction, the Azerbaijani authorities accused the Karabakh Armenian de facto government of deliberately destroying 60 square kilometres of forests in territories occupied by Karabakh Armenians. Azerbaijani authorities have also complained that Armenia is deliberately polluting the Arax River. For example in 2006, the Azerbaijani Ministry of Ecology and Natural Resources complained that due to military exercises the Armenian armed forces used chemical materials which is “extremely dangerous for the environment” and that “the environmental situation in the Araz [Arax] River is worse and added that five of the 21 species of fish have gone extinct in the river as a result of contamination by Armenia in the past 10–15 years.”¹⁰

8 See for example: “Baku Ceyhan Campaign”, at: <<http://www.bakuceyhan.org.uk/about.htm>>.

9 Yashar Aliyev: “Letter dated 12 November 2003 from the Permanent Representative of Azerbaijan to the United Nations addressed to the Secretary General”, United Nations, General Assembly, Security Council, document number A/58/594-S/2003/1090; at: <http://www.mfa.gov.az/eng/armenian_aggression/conseq.pdf> (23 May 2006).

Another example of instrumentalization of environmental concerns for the sake of national foreign policy objectives could be brought from the Caspian Sea. In May 2007 Mr. Oleg Mitvol, deputy director of the Federal Service for the Oversight of Natural Resources of Russia, raised concern over the environmental damage caused by the international oil consortium active in the Caspian Sea. During an OSCE Economic and Environmental Forum held in Prague, and said that more than ten thousand seals died in 2007 alone. He added that Russian “scientists believe that these [seal] deaths are caused by oil production”.¹¹ The northern part of the Caspian Sea in western Kazakhstan, the home of the Caspian seals (*Phoca caspica*), was a natural resort during the Soviet times, but since the emergence of the newly independent states it became a major zone of oil production.

How much Russian concerns are limited to the environment of the Caspian basin? The overlap with other foreign policy concerns can be made here: Russia opposed the construction of a Caspian underwater pipeline as part of the Nabucco project to transport Central Asian natural gas to European markets, without passing through Russian territory. This project is in direct competition with a Russian-sponsored ‘Southern Stream’ pipeline, which aims to transport Central Asian as well as Russian gas to Europe though another underwater pipeline, this time crossing the Black Sea. Turkey has equally referred to ‘environmental concerns’ to oppose the exportation of Caspian oil through Russia and then via the Bosphorus by super tankers, and instead insisted on the construction of the 1,760 km long *Baku-Tbilisi-Ceyhan* (BTC) pipeline. Once again, the ‘environment’ as part of the concern was little more than an alibi, if one looks that serious concerns about the construction of the BTC pipeline were simply disregarded by the same authorities in Ankara.

It would be naïve to regard such ‘concerns’ as a newly emerging environmental sensitivity among the officialdom in the South Caucasus or in its neighbouring capitals.¹² It would be closer to reality and to the record of this region’s politicians to describe these new concerns on the state of the environment outside the control of their respective governments as part of

the on-going struggle for domination of the territory, its resources and population, a new form of continuation of the conflicts that erupted with the rise of the nationalist movements, or the geopolitical competition over the Caspian energy resources that followed.

More interesting is the mobilization, albeit very diffuse, against new industrial projects. As mentioned above, the Baku-Ceyhan pipeline construction attracted much attention. Opposition against the pipeline was strong in Georgia, where the Green Alternative NGO launched a campaign against its construction. Its activism, including a court case against Baku-Ceyhan, found large public sympathy. The pipeline crossed the Borjomi region, and environmentalist fear any spill as a result of corrosion would cause much harm to the protected forests of the area, and to the Borjomi mineral water sources, a major Georgia export. Movements of protest also erupted in the Armenian capital Yerevan, against the illegal cutting of trees in various parks of the capital, to use the space for construction. Several demonstrations were organized in the city jointly by NGO activists and students. Cutting trees is a highly symbolic issue in Armenia, because the forest cover areas has already shrunk from 13 per cent of the general surface in late Soviet times, to 9 per cent currently. Public indignation has grown in recent years as local officials have continued the destruction of the remaining forests for exportation and private profit.

Demonstrations against cutting of trees and forests in Armenia, and against the pipeline project in Georgia are new in their nature. They do not oppose the project of the ‘other’ on the land of the ‘nation’ but oppose deals and policy options made by the leadership of the newly independent states. Will such isolated outbursts lead to the birth of a new movement? The emergence of an environmental consciousness independent from the national project remains a precondition for addressing the side effects of new in-

10 “Azeri Ministry Says Armenia polluting Environment in Occupied Lands”, in: *Ayna*, Baku, 13 May 2006. English translation in: *BBC Monitoring*, 13 May 2006.

11 Jeffery Donovan, “Caspian: Russia Urges OSCE to Probe Energy Firms”, in: *Radio Free Europe/Radio Liberty*, Prague, 22 May 2007.

12 The politicization of environmental concerns was highly evident in the case of the ‘fires’ in Karabakh and territories surrounding it under the occupation of Armenian forces. Azerbaijani officials considered these fires as deliberate Armenian acts, but when the special envoy of OSCE to Karabakh, Andrzej Kasprzyk, following a detailed study, failed to accuse the Armenians of being responsible of those ‘fires’ he came under heavy pressure from the Azerbaijani authorities. See: Shahin Abbasov and Khadija Ismailova: “Azerbaijan Targets OSCE Special Representative for Criticism”, in: *Eurasia Insight*, 28 August 2006; at: <<http://www.eurasia-net.org/departments/insight/articles/eavo82806.shtml>>.

dustrial projects, and for looking at the environment in a broader context, surpassing the border of the nation.

The precondition of the development of an autonomous environmentalist movement is its dissociation from the nationalizing project in case they intend to become an independent political force, and not just an appendix of nationalist forces in power. Environmentalists need to distinguish themselves from the ruling powers which are nourished by nationalist ideology in order to be able to address both past and more recent environmental ills. Such a movement could simultaneously create bridges within the fractured Caucasus, but also beyond by associating with global values and social movements, and succeed bringing a new view to the security problems plaguing the Caucasus from the moment of the Soviet collapse. While outside interventions such as the EnvSec initiative could stimulate some groups or transport certain ideas, an autonomous environmentalist movement in the Caucasus can only emerge if it spreads its roots in the local, poor soil, and it will only emerge if it finds a role to play in the local historic narrative.

72 Environmental Security in the Asia-Pacific Region: Contrasting Problems, Places, and Prospects

Jon Barnett

72.1 Introduction

Other chapters in this volume have explored the diverse terrain of alternative dimensions of security beyond conventional security issues. In this larger landscape, diverse social groups – ranging from the global community (*common security*) to individuals (*human security*) – can all be construed as *insecure* either chronically, or at certain points in time, from various risks. Things that people value – such as sufficient food, economic opportunities, political freedoms, personal safety, environmental services, and good health – can be at risk, and can be seen as sectoral components of (in)security (UNDP 1994). Various processes put at risk the things that people value, including violent conflict, economic fluctuations, persecution, and environmental change.

As this book has ably demonstrated, the alternative security agenda is therefore vast and broad. Within this pantheon of issues, places, and processes, this chapter outlines environmental security issues in the Asia-Pacific region. It therefore ‘limits’ itself to one major sectoral component of security – the environment – and one region – Asia-Pacific. It begins by defining what it means by security and environmental security (72.2), which is then followed by a brief background to the Asia-Pacific region (72.3). Next, the chapter reviews some of the major environmental security issues in the region (72.4). It then discusses two key case studies of environmental insecurity in the region which relate to both the smallest atoll countries of Kiribati, the Marshall Islands, Tokelau and Tuvalu (72.5), and China as the largest country in the region (72.6). These two cases provide a useful contrast and reveal much about the diverse nature of environmental insecurity in the region (72.7). The chapter concludes that environmental insecurity in the region is caused by economic rather than demographic changes (72.8).

72.2 Security and the Environment

‘Security’ is the condition of being protected from or not exposed to danger. It is “the assurance people have that they will continue to enjoy those things that are most important to their survival and well-being” (Soroos 1997: 236). Security can be likened to vulnerability in that assessments of security (should) entail: the identification of risks, the identification of entities exposed to risks, the assessment of options to respond to risks (either by mitigating the risk, or by adapting to or recovering from the risk event), and assessments of net outcomes once response options have been deployed (Alwang/Siegel/Jorgensen 2001). There is some utility in applying this vulnerability approach to national security issues, even if such orthodox security assessments are rarely so formulaic.

There is widespread agreement that individuals and groups are vulnerable to various forms of environmental change, giving rise to the concept of ‘environmental security’. The publication of *Our Common Future* (Brundtland Commission) in 1987 marked the beginning of the official use of the term ‘environmental security’, although there is no agreed definition of it (Dalby 2002). To do so first requires defining environmental *insecurity*, which is taken here to mean “the vulnerability of individuals and groups to critical adverse effects caused directly or indirectly by environmental change” (after Barnett 2001: 17). Environmental security is therefore taken here to mean “the ability of individuals and groups to avoid or adapt to environmental change without critical adverse effects” (after Barnett 2001: 129). “Critical adverse effects” here means changes to which individuals and groups cannot adapt so that their livelihoods are substantially negatively affected. Examples of environmental insecurity include: desertification as a cause of migration from pastoral homelands in the Sahel (Franke/Chasin 1980); water scarcity and pollution causing morbidity and economic collapse in the

Figure 72.1: The Asia-Pacific Region.

Aral Sea (Weinthal 2002); and violence (in part) in response to the environmental impacts of the Panguna mine on Bougainville (Böge 1999).

72.3 The Asia-Pacific Region

There is no clear agreement on which countries comprise 'the Asia-Pacific' region. For the purposes of this chapter the region is taken to include the countries of Eastern Asia (excluding Myanmar and North Korea) and the Pacific Islands, as shown in table 72.1 (although this is based on membership of the Asian Development Bank, which excludes a number of the Pacific Island countries and territories such as American Samoa, the Northern Marianas, French Polynesia, Guam, New Caledonia, Niue, Pitcairn Island, Tokelau, and Wallis and Futuna).

The combined population of the countries shown in table 72.1 is 1.86 billion, or approximately 30% of the world's population. Countries and territories range in size from one of the world's smallest sovereign states in Tuvalu with 11,000 people living on approximately 26 km² of land, to the world's most populous country of China which has a population of 1.3 billion living on approximately 9.3 million km² of land.

Population growth has long been considered to be a significant cause of environmental insecurity (Myers 1987; Ehrlich/Ehrlich 1991), although this has been powerfully contested for just as long (Conca 1994b; Deudney 1991; Hartmann 1998). Growth rates vary markedly throughout the region, with negative growth rates in the Cook Islands and East Timor (a temporary effect of violence in 1999), and relatively slow growth rates in China, the Federated States of Micronesia, Samoa, Taiwan, and Tonga. However,

Viet Nam	80,900	1.5	430	7.1	13.1

demographic momentum is important: for example, while China's population growth rate is low (0.9% per annum), it is nevertheless likely to add a further 200 million people by the year 2050; whereas in the Solomon Islands, which has a high population growth rate (3.7% per annum), a doubling of the population will add an extra 500,000 people. Of course, in both these cases, and throughout the region, the effects of population growth on environmental insecurity are wholly contingent on the ability of social-ecological systems to sustain larger numbers of people. This makes it impossible to make generalizations about the environmental security risks of

population growth in specific countries, and for the region as a whole.

In terms of both the way human activities affect environmental change, and the way environmental change affects people, more significant factors than population growth are levels of economic development and poverty. Table 72.1 shows some basic indicators of poverty and economic growth. The Asia-Pacific region contains some very wealthy countries such as South Korea, Singapore, and Taiwan, whose growth has been achieved by rapid growth in industrial production and services. There are many countries pursuing this path to growth, most notably

Table 72.2: Population Change for Selected Asia-Pacific Countries. **Source:** UN (2004a).

Country /Territory	1950	2000	2050	2100

China, but also Indonesia, Thailand, and Vietnam. However, the majority of countries, including Cambodia, East Timor, Laos, Papua New Guinea, the Solomon Islands, and Vanuatu, are not yet developing in this way, and poverty in these countries remains high.

72.4 An Overview of Environmental Insecurity in the Asia-Pacific Region

The nature of economic development throughout the region causes environmental problems. For example, in the formerly centrally-planned East Asian economies of Cambodia, the Lao People's Democratic Republic (Lao PDR), and Vietnam, transitions towards more market-oriented systems of economic organization have been underway since 1979 (St. John 1997; Bilskie/Arnold 2002). In Cambodia and Lao PDR the aftermath of conflict and economic transition has resulted in increased foreign investment in resource extraction. In Cambodia, the most identifiable environmental impact of this has been large-scale exploi-

tation of forests due to commercial logging (Le Billion 2000). However, increased harvesting for fuel wood and agricultural encroachment, possibly in response to changed land tenure policies, have also taken their toll on forests (Kingdom of Cambodia 2002). The degradation of forests is not just Cambodia's most pressing environmental problem, it is also arguably its most pressing development problem (Le Billion 2000). Forestry has also intensified in Lao PDR, although the major source of private foreign investment has been in hydropower developments along the Mekong River (Bakker 1999). Indeed, across the region rates of deforestation are high (Dauvergne 2002; Elliott 2003; Haque 2001), and this is associated with human insecurity and political unrest in Melanesia (ACF 2002; Dauvergne 1998; Kabutaulaka 2001; Liloqula/Pollard 2000; Matthew/Gaulin 2001; Scheyvens/Lagisa 1998).

Vietnam's transition has not led to intensive development of a single resource as it has in Lao PDR (water) and Cambodia (forests), instead it has increased industrial production and so increased energy use and associated pollution (Tuan 1997). Adger (2000) reports that in Vietnam the state has prioritized in-

creased agricultural production and economic growth ahead of environmental sustainability. A range of agricultural reform policies, including increasing security of land tenure and the decollectivization of farming, has seen a privatization of agricultural production which has increased productivity but affected a decline in collective actions to maintain common property resources (Adger 1999; Gomiero/Pettenella/Trieu/Paoletti 2000). Increasing income inequality as a result of transition has created a class of low income people dependent on natural resources for their livelihoods, leading them to increase resource use to accumulate wealth (Adger 1999; Gomiero/Pettenella/Trieu/Paoletti 2000).

Transformations in agricultural production are also occurring elsewhere in Southeast Asia, and in many places have been a cause of deforestation and population displacement (de Koninck/Dery 1997). Migration has led to conflict - which can at times be violent - over land and resources in immigrant communities (Koczburski/Curry 2004; Peluso/Harwell 2001). Agricultural intensification has resulted in more intense use of fertilizers and pesticides, leading to soil and water contamination (Elliott 2003). Approximately 20% of Asia's land area suffers from some form of land degradation (WRI 1992). Increasing use of coastal and marine resources is leading to should it be intensification of marine pollution and deterioration of fish stocks clearing of mangroves, and degradation of coastal environments (Elliott 2003; Haque 2001). In Thailand, for example, aquaculture has destroyed 87% of mangrove stands (Seager 1995) and has marginalized many coastal residents (Stonich/Vandergeest 2001); and 65% of South Korea's coastal wetlands are at risk due to planned coastal reclamation developments (Haque 2001).

Associated with industrial expansion in many countries has come increasing demands for energy and water, with consequences for environmental insecurity. Throughout the early 1990's regional energy demand grew at 4.7% per annum, and while this slowed after the 1997 Asian financial crisis, forecasts show that energy demand is likely to outstrip economic growth rates in the future (Saha 2003). The need to fuel growing demand led to proposals to develop nuclear power in Indonesia, the environmental risks of which have been characterized as security issues (Barnett 1997) which arguably outweigh the environmental problems associated with development of conventional sources of energy (Saha 2003). The environmental and social consequences of this rapid increase in energy supply and demand are numerous,

including urban air pollution, acid rain, and growing emissions of greenhouse gases (Haque 2001). Growing demand for water has led to more intense use of water resources, leading to political stress in the case of transboundary basins such as the Mekong (discussed below), and constraints on production, impacts on human health, and the risk of large-scale migration in the case of China (discussed below).

Throughout the region most of the poorest people are those who are most dependent on natural resources to sustain their livelihoods because they have little income with which they can purchase their basic needs. Thus people in rural and remote areas are vulnerable to changes in resource abundance due to violent conflicts and hazardous events such as cyclones and droughts. They are also considered to be the most vulnerable to climate change (Bohle/Downing/Watts 1994; Kates 2000; Lal/Harasawa/Murdiyaso 2001). Their low levels of income also mean that their livelihoods are highly sensitive to economic changes that can result in unemployment, rising commodity prices, and the introduction of fees for previously free public goods such as education and health care. Under such circumstances people tend to increase the use of natural resources to augment declining purchasing power (Kessler/Van Dorp 1998; Opschoor/Jongma 1996; Reed 1996). However, responsibility for large-scale environmental changes and resulting insecurities rests more with the agents of development within and beyond a country rather than with the poor (Barnett 2001).

Associated with agricultural and industrial transformation has come increasing urbanization in the Asia-Pacific region. There are seven cities in East Asia with more than 10 million people (Elliott 2004). Urban air pollution exceeds World Health Organization standards in many of these cities (Elliott 2004). In the Pacific Islands urbanization is increasingly a cause of environmental insecurity (Cocklin/Keen 2002). In many parts of the urban Pacific water supply and water contamination impact on human security, waste disposal systems are poor, and so morbidity levels are relatively higher than in rural areas (Cocklin/Keen 2000; UNEP 1999).

There have been and remain significant violent conflicts in the Asia-Pacific region since 1945 and these have exacerbated environmental insecurity in many countries. Notable in terms of recognized environmental impacts are the Indochina wars that killed and maimed millions of people, caused massive damage to infrastructure, involved large-scale use of defoliants and landmines, and have left large amounts of

Table 72.3: Some Selected Environmental Problems For Selected Countries In The Asia-Pacific Region. **Source:** Compiled by the author.

Country /Territory	Problem(s)	Ostensible Cause
Cambodia	Deforestation	Logging, fuel wood collection, agricultural expansion
China PR	Water scarcity and pollution	Industrialization, agricultural intensification
	Air pollution	Industrialization
Cook Islands	Cyclones	Climate variability
Fiji Islands	Cyclones	Climate variability
	Soil loss	Agriculture
French Polynesia	Land loss	Nuclear testing
Indonesia	Deforestation	Logging, agricultural expansion, fires
	Air pollution	Fires, industrialization

	Water pollution	Waste disposal, sea-level rise
Korea Republic	Coastal degradation	Coastal reclamation
Lao PDR	River flow	Hydropower
Malaysia	Air pollution	Fires, industrialization
Marshall Islands	Coastal erosion	Sea-level rise
	Water pollution	Waste disposal, sea-level rise
	Land loss	Nuclear and missile testing
Nauru	Soil loss	Phosphate mining
Niue	Cyclones	Climate variability
Papua New Guinea	Deforestation	Logging
	Water pollution	Mining
	Cyclones / drought	Climate variability
Samoa	Cyclones	Climate variability
Singapore	Air pollution	Fires, industrialization
Solomon Islands	Deforestation	Logging
Thailand	Coastal degradation	Aquaculture
Timor-Leste	Soil erosion	Fuel wood harvesting
	Drought	Climate variability
Tonga	Coastal erosion	Sea-level rise
Tuvalu	Coastal erosion	Sea-level rise
	Water pollution	Waste disposal, sea-level rise
Vanuatu	Cyclones	Climate variability
Viet Nam	Air pollution	Industrialization
	Land degradation	Agricultural intensification

unexploded ordnance throughout Cambodia, Lao PDR, and Vietnam (Westing 1976, 1980a). However, there have been violent conflicts in many countries since 1945, including in China, East Timor, Fiji, Indo-

nesia, the Korean Peninsula, Malaysia, Papua New Guinea, the Philippines, the Solomon Islands, and Thailand. Violent conflict continues in Indonesia, Lao PDR, the Philippines, and Thailand (HIIK

2004). In many ways the ability of these countries to avoid critical environmental problems is hampered by the effects of warfare. In East Timor, for example, violent conflict has led to significant demographic changes, large-scale damage to public infrastructure, minimal bureaucratic capacity, no environmental policies, an unskilled workforce, a small private sector, a lack of experience with democracy and self-rule, and very high levels of absolute poverty – all of which create substantial environmental problems and in many ways reduce capacity to manage them (Barnett 2006; Nevins 2003; Saldanha 2001; Sandlund/Bryceson/de Carvalho/Rio/da Silva/Silva 2001).

So, there are a diverse range of environmental and resource issues occurring at a range of scales in the Asia-Pacific region that can and have been understood as security problems. Some of these have distinct transboundary characteristics. There are at least five transboundary environment and resources problems that have at various times been framed as security issues. First, the regional security implications of dam construction, increased demands for water, and works to improve navigation on the Mekong River have been considered to be a point of contestation between the six countries within the Mekong River Basin (Cambodia, China, Lao PDR, Myanmar, Thailand, and Vietnam) (Dupont 2001; Jacobs 2002; Toset/Gleditsch/Hegre 2000). Changes in water use upstream have also created conflict among local communities downstream (Hirsch/Wyatt 2004). The Mekong River Commission is the pre-eminent organization entrusted with the coordination of water in the basin; however its membership does not include China, which controls the upper reaches of the catchments (Jacobs 2002; see Affeltranger in this volume).

Second, there is ongoing concern about territorial claims to the Spratley Islands in the South China Sea, the value of which is not just their strategic significance, but also because ownership of them confers access to reserves to maritime and sea-bed resources (Denoon/Brams 2001; Klare 2001; Magno 1997). Potential conflicts over maritime boundaries exist in the Pacific Islands region as well (Anthony 1991), and also between Australia, East Timor, and Indonesia (McBeth 2004; Mercer 2004). However, the motive for contending maritime claims has rather more to do with access to resources than it has with environmental issues *per se*.

The third transboundary environmental security issue is the problem of air pollution which Haque (2001) argues is a source of tension among North East Asian countries. This issue has received in-

creased attention since the 1997 forest fires in the Sumatra and Kalimantan regions of Indonesia, which caused a large smoke haze that had widespread health, environmental, and economic impacts. The cost to Singapore's economy, for example, has been estimated to be between US\$ 163–286 million (cited in Quah 2002: 429). The fires were the result of seasonal burning to clear land for cultivation, however, in the context of logging, and the severe El Niño drought in 1997, the usual haze was significantly intensified as many fires burned out of control. Regional cooperation is seen as being critical to solve the problem, and while some modest steps have been taken in this direction, on balance little seems to have been achieved (Bin Jaafar 1999; Elliott 2003; Quah 2002). The fourth transboundary problem – climate change – also concerns atmospheric pollution, the security risks of this to Pacific atoll countries is discussed later in this chapter.

The fifth major transboundary environmental security problem is the long-standing issue of nuclear testing in the Pacific Ocean (Firth/von Strokirch 1997). The issue has been less contentious since the cessation of French nuclear tests in 1995, but the very significant longer-term health and environmental risks posed by these most recent tests and by earlier US and British tests still remain (Anderson 1995). In the Marshall Islands, United States nuclear tests have rendered whole islands uninhabitable, and have affected large-scale forced migration within the country (Kuletz 2001; Seager 1993).

In terms of these regional environmental problems, regional organizations have been called upon to develop solutions as part of both a common and comprehensive security approach. In South East Asia the pre-eminent regional organization in this regard is the *Association of South East Asian Nations* (ASEAN), and it has been increasingly addressing environmental concerns, albeit with limited success (Elliott 2003; Haque 2001). Dokken (2001) has argued that framing regional environmental problems as security issues is a desirable strategy to raise awareness of the dangers of latent environmental conflicts. In the South Pacific the Pacific Islands Forum is the most important regional security institution (McDougall 2002). The Forum has long been concerned about environmental risks to national and human security and its annual communiqués have frequently referred to climate change as a security problem. *The South Pacific Regional Environmental Programme* (SPREP) is the region's pre-eminent environmental organization, although it faces difficulties working

across the wide diversity of social and environmental systems in the region (Turnbull 2003).

As a way to provide some insight into the specific causes and risks of environmental insecurity in the region two case studies will now be discussed: the issue of climate change in Pacific Island atoll countries, and the problem of water scarcity and pollution in China.

72.5 Climate Change and Environmental Insecurity in Pacific Island Atoll Countries

Atolls are rings of coral reef which enclose a lagoon. Around the rim of the reef there are often low islets called *motu* which are made of materials washed up from the reef (Nunn 1994). Motu have an average height above sea level of approximately two metres. Three Pacific Island Countries - Kiribati, the Marshall Islands, and Tuvalu, and one dependent territory - Tokelau - are comprised entirely of atolls.

The Pacific atoll countries have high population densities, ranging up to 32,000 people/km² at Ebeye in the Marshall Islands (Purdie 1999: 74). Population growth is generally high. The gross domestic product of all four countries is low, and land-based agriculture is limited to a few crops. Kiribati and Tuvalu are official 'Least Developed Countries' (LDC) in the United Nations system, and Tokelau would certainly qualify for this category were it independent.

In addition to their high population densities, minimal agricultural production, low elevation, and small economies, the Pacific atoll countries have some common environmental problems that increase their vulnerability to global warming. Principal among these problems is the quantity and quality of fresh water. Water resources are restricted to a narrow lens of subterranean freshwater and rain storage tanks. Groundwater resources are susceptible to contamination from solid and human wastes including oil and insecticides, and from salt water (UNEP 1999a). Freshwater lenses are rapidly depleted in times of low rainfall. Coastal erosion is also a problem. Safe disposal of solid and biological waste disposal is difficult as there are no 'safe' places to dispose of wastes on highly populated atolls with porous soils and sensitive reefs. Wastes contaminate fresh water, pollute coastal waters, and cause deterioration of reefs.

The Intergovernmental Panel on Climate Change has stated that "emissions of greenhouse gases and aerosols due to human activities continue to alter the

atmosphere in ways that are expected to affect climate," and that "global average temperature and sea level are projected to rise" (IPCC 2001d: 3-8). Climate scenarios suggests mean sea levels are likely to rise by between 9 and 88 cm by the year 2100, a rate at least twice as fast as that experienced over the past 100 years (IPCC 2001). A 32 cm rise in sea level is considered to have serious implications for the continued viability of ecological and social systems on low-lying coral atolls (Pearce 2000). The costs of adapting to sea level rise are in many cases prohibitive, with one study estimating the cost of protecting the main commercial and government area of the Marshall Islands (the Jaroj-Wulka-Telap area on Majuro) to be up to 4 times Gross Domestic Product (Holthus 1992). It is not surprising then, that in his rating of susceptibility to damage from climate change Pernetta (1990: 23) lists only the atoll countries as 'Category A', saying that they may be "devastated" by climate change.

An increase in global mean surface air temperature of between 1.4 and 5.8 °C by 2100 is also described by the scenarios (IPCC 2001). It is expected that there will be only small changes in mean annual rainfall across the region, but the intensity of rainfall events is expected to increase by some 20-30% over tropical oceans (Jones/Henne-sy/Page/Walsh/Whetton 1999). This suggests that flooding events may increase in frequency and intensity in the future, particularly when combined with rising sea levels and more intense storms and storm surges. If they occur, these changes in precipitation will place considerably greater stress on water resources in the region, including more frequent droughts, and may enhance the spread of vector borne diseases such as malaria and dengue fever (Nurse/Sem 2001). While not proven to be a function of climate change, it is noteworthy that there have been more frequent and intense El-Niño events since the 1970's (IPCC 2001). A severe El Niño in 1997/8 led to a severe drought in the Marshall Islands.

These changes in climate may have negative impacts on agriculture in atoll countries. Agricultural production is vulnerable to heat stress, changes in precipitation and soil moisture, incursion of saline water from rising sea levels, and increased damage from extreme events. Food security in the region may therefore become less predictable, particularly if coastal zones are degraded, artisanal fisheries are affected, and climate-induced changes in atmosphere-ocean regimes affect seasonal abundance and distribution of deep-water fisheries (McLean/Tysban

2001). In conjunction with the likely increased spread of vector borne diseases and more frequent and severe extreme events, this greater food insecurity is likely to degrade human health in the region.

Climate change is likely to cause increases in sea-surface temperature. This poses risks to atoll formation because coral reefs are highly sensitive to sudden changes in sea surface temperature, which tends to result in large-scale bleaching episodes (Hoegh-Guldberg/Hoegh-Guldberg/Stout/Cesar/Timmerman 2000). So, if reefs fail to grow and sea levels rise, coastal erosion on atolls will increase, flooding events will increase, freshwater reserves will become increasingly contaminated, and food from agriculture will substantially decrease. Ultimately these factors may mean that some atolls are unable to sustain present numbers of people.

Climate change is also expected to have substantial impacts on the economies of atoll countries. The World Bank (2000) estimates that by 2050 Tarawa atoll in Kiribati could face an annual damages bill of US\$ 8–16 million (some 13–27% of current Kiribati GDP), with up to US\$ 430 million of fixed capital at risk from inundation. In the Marshall Islands just one area – the Jaroj-Wulka-Telap area at Majuro – is both the commercial and government centre of the country, housing some 15,000 people, the government, water and power plants, two ports, a hospital and a community college; and so severe erosion or storm damage there would have massive repercussions for the country as a whole (Holthus 1992). So, the socio-economic impacts of global warming may be “so profound that they dwarf any strategic issue currently confronting a major peacetime economy” (Hoegh-Guldberg/Hoegh-Guldberg/Stout/Cesar/Timmerman 2000: 4).

Climate change may mean that atoll environments are unable to sustain human habitation (Barnett/Adger 2003). It is therefore a security issue for atoll countries. As a global problem with serious implications for atoll-people, the environmental security dynamic of climate change includes global, regional, national, and local levels of action. Actions to reduce the level of greenhouse gas emissions and to adapt to changes are security responses as much as they are sustainable development measures. Atoll countries have sought to mitigate against the problem through lobbying for reductions in greenhouse emissions at meetings of the United Nations Framework Convention on Climate Change (UNFCCC). They are also preparing to adapt to the impacts of climate change. In both respects, the efficacy of these actions may be limited: the atoll countries have some moral power in

UNFCCC negotiations, but not enough to overcome the economic concerns of high greenhouse gas emitting countries; and the range of adaptation options available to them is constrained by both the physical properties of their islands and the lack of financial capital available to implement strategies.

72.6 Water and Environmental Insecurity in China

Water is arguably China’s most critical natural resource. In addition to problems with flooding, in some places water is scarce, and in many places water is polluted. The problem of water scarcity has attracted considerable attention from the international community. Its effects on domestic food security and subsequently world food markets have been popularized by Brown (1995, 2004a), and there is concern in the United States that China’s water problems may be a cause of mass migration (Economy 2004; Haque 2001), violence (Economy 1999; Wang 2003), and political instability (Economy 2004).

China’s water problems are the result of interlocking changes that have occurred as a consequence of economic reforms begun in 1978. This economic transition has involved the marketization of production and distribution systems. This began with decentralized state control in rural areas which allowed farmers to expand their incomes through the intensification of agricultural production (Blaikie 1985; Muldavin 2002). This included increased consumption of irrigation water, particularly in the north of China, leading to increased withdrawals of both surface and ground water. For example, the area of irrigated land in the Yellow River basin increased more than nine times between 1950 and 2000, accounting for much of the 39% increase in water use in China’s north between 1980 and 1993 (Heilig 1999; Cai/Rosengrant 2004).

Fertilizer use also increased by as much as 260% between 1980 and 2002 (FAOSTAT 2004), and this has been a significant cause of increased water pollution. Intensification of production also led to a threefold increase in the area of land under permanent crops between 1978 and 2002 (FAOSTAT 2004). Because farming is not the most profitable activity in China, the low rate of returns relative to other investment options has constrained investments in sustainable water use.

Between 1980 and 2003 total production of cereals increased by 39%, and there was a fourfold in-

crease in the production of meat and vegetables (FAOSTAT 2004). This increased agricultural production seems to have been achieved with little increase in water; between 1980 and 1997 agricultural water use increased by between 1.2% to 4% (UNDP 2002; Mei 1999). Between 1980 and 1997 agriculture's share of all Chinese water use decreased from 88% to 72% (Mei 1999). These data therefore suggest that the water scarcity problem may be largely a product of the growth of industrial and urban uses which are consuming an increasing share of available water resources, and demanding yet more (Nyberg/Rozelle 1999; Yang/Zehnder 2001; Bellier/Zhou 2003).

In 1978, at the start of transition, China's urban population was officially 80 million (Wang/Webber/Zhu 2002a). According to the UNDP (2004) this had increased more than sixfold to 490 million by 2002 - a rate of increase far in excess of national population growth. This growth has contributed to water scarcity problems in China because, as more and more people live within cities and become more affluent, they consume and demand more water. Urban use has been the fastest growing sector of water use in China, with municipal uses of water increasing by 10.1% per annum throughout the 1990's (Economy 2004). Income growth has been rapid in both rural and urban areas, but relatively more rapid in cities (Wang/Webber/Zhu 2002a), including a sixteenfold increase in per capita GDP in Shanghai between 1978 and 2002 (Economy 2004). As incomes continue to rise there has been a decline in the proportion of cereals being consumed, and an increase in consumption and production of more expensive, higher quality food products, especially animal products (Heilig 1999; Tian/Chudleigh 1999). Increasing production of meat has entailed increased production of feed grains, so that between 1991 and 1996, the production of coarse feed grain increased more than any other cereal (Tian/Chudleigh 1999). These urban-driven changes in demand and supply are important for water use since fruits, vegetables, nuts, dairy products, and meat are *less* water efficient (they use more water per calorie delivered) than either wheat or corn.

Transition led to large-scale industrialization throughout China. By 1997 over 85% of Chinese exports were manufactured goods, up from 50% in 1980 (Wang/Webber/Zhu 2002b). China is now the world's 5th largest exporting country and 6th largest importing country (WTO 2003). Industrialisation developed most intensely in the coastal and southern provinces where both the area under cultivation and

agricultural output declined, and industrial water use increased by as much 200% (Heilig 1999). Nationwide, industrial uses of water doubled between 1980 and 1997 (UNDP 2002), and throughout the 1990's industry's water demand grew at 5.4% per annum (Economy 2004). These industrial uses have contributed to the increased demand for water, and also to water pollution. In particular, the more than 500,000 rural Township and Village Enterprises seem to be exempt in both policy and practice from environmental regulation, and their emissions are not monitored, even though they are thought to be responsible for approximately half of all pollution in China (Economy 2004; Vermeer 1998).

In the regions where industrialization has been most rapid there have been the largest declines in allocation of labour, land, and finance for agricultural purposes. This shift of capital away from agriculture occurred rapidly in the southern and coastal regions that have the most abundant water resources and are the most suitable for agricultural production. This has in turn caused some shift in the location of agricultural production to the drier north of China. These areas are not able to meet the gap in supply created by reduced production in the south without extensive use of irrigation and fertilizers, leading to overdrawing of ground water and excessive water pollution. As a result, water use for irrigation in the northeast of the country increased by 39% between 1980 and 1993 (Heilig 1999). Agriculture in the North China Plain is now nearly totally dependent on irrigation, and the volume of water used for irrigation on the Plain exceeds rainfall by some 200-300% (Zhen/Routray 2002). There is much evidence to suggest that irrigation on the North China Plain is unsustainable (Nyberg /Rozelle, 1999; Zhen/Routray, 2002). For example, the water table is reported to be falling by as much as 1 m/year (World Bank 2002a), and may have dropped 20 m in some areas and up to 70 m in others (Foster/Garduno/Evans/Olson/Tian/Zhang/Weizhen/Han 2004; Varis/Vakkilainen 2001).

The majority of rural people in the north of China are dependant on agriculture for their livelihoods. Household incomes are low with generally few alternative opportunities for income generation (Barnett/Webber/Wang/Finlayson/Dickinson 2005). The implications of changes in farmers' entitlements to useable water (a function of quantity, cost, and water quality) may be profound as they may trigger large-scale rural-urban migration (Economy 2004). There are also risks, however, in the widely advocated solution of water pricing which, given that hun-

dreds of millions of rural people in northern China depend on water for their livelihoods, may drive many from the land and into the cities (Webber/Barnett/Wang/Finlayson/Dickinson 2005).

As a consequence of these changes China faces serious water problems. Over half of China's 300 cities experienced water shortages in the 1990's and of these 108 cities are considered to have serious water shortages (Qi/Guodong/Masao 1999). Most of these are located in the North of the country. These shortages extend to urban electricity plants and factories, many of which have experienced temporary closures due to water shortages (Qi/Guodong/Masao 1999). The estimated cost of lost production in cities due to water shortages is reported to be US\$ 11 billion per annum (WRI 1999). At the ends of many rivers, including most famously the Yellow River, water no longer flows for significant periods throughout the year (Lohmar/Wang/Rozelle/Huang/Dawe 2003; Jun 2004). Many lakes are also contracting due to excessive water withdrawals (Smil 1997).

The UNDP (2002) has described water pollution in China as 'lethal'. Over 80% of China's rivers have some degree of contamination, and most cities' water supplies have serious water contamination problems (Qi/Guodong/Masao 1999). China's 2002 *State of the Environment Report* reports that in 2002, 70% of the 741 river sections monitored in China's seven major river basins were unfit for human contact (pollution levels at or above Grade IV standard) (SEPA 2002). Less than one quarter of China's largest 27 cities have water quality that meet national standards, and more than 90% of sampled sections of urban rivers contain water that is unsuitable for human contact (UNDP 2002, WRI 1999). As a consequence more than 700 million people in China drink water that is harmful to their health, and there is increasing evidence that the incidence of cancers is associated with pollution of drinking water (Banister 1998, UNDP 2002, WRI 1999). The costs of the health impacts of water pollution have been valued at US\$ 3.9 billion (World Bank 1997).

The security risks that water pollution and scarcity pose to people, and perhaps the Chinese state itself, stem entirely from economic development which arose out of a set of incremental policy experiments that proved to be wildly successful in economic terms, but which seem to be far less successful in environmental terms. The development of policy to manage these problems has been far slower than the rate of change in water use and pollution (World Bank 2002a).

72.7 Discussion

The cases of climate risks to Pacific Island atoll countries, and water scarcity and pollution in China, reveal much about the diverse nature of environmental insecurity. For small countries like the Pacific atoll countries, the risks posed by climate change are largely due to global emissions of greenhouse gases to which these countries contribute almost nothing. So, apart from local environmental problems that slightly reduce the capacity of ecosystems to adapt to climate change (and these endogenous problems are not worse than, and indeed may be far less than occurs in most other countries), the risks posed to these countries are overwhelmingly external in origin.

In the case of China, the risks to people, the economy, and possibly even political stability created by water scarcity and pollution are almost entirely internal in origin. To the extent that China is seeking to grow its economy and alleviate poverty through exports of manufactured goods (a not unusual development strategy that has proved highly successful for all the OECD countries), there is some external dimension to this problem. Nevertheless, for the most part the causes of China's water problems are its internal policies to promote growth and the responses of entrepreneurs to these policies. Of course the physical geography of both these very small low-lying atoll countries, and China where water is abundant in the south and east but increasingly scarce to the north and the west, are also important determinants of risk.

In terms of response options too there are marked differences between the atoll countries and China. Given the largely exogenous nature of the risks to the atoll countries, the most effective response will be the reduction of greenhouse gases to reduce the rate of climate change. Therefore the atoll countries have been very active in negotiations at meetings of the United Nations Framework Convention on Climate Change. The second response option for atoll countries is preparing to adapt to the effects of climate change through promoting sustainable development. To this end some degree of external assistance is required, and so these countries have been active in regional and global negotiations on assistance for adaptation. In China, because the cause of water problems is largely endogenous, solutions must come from within the country. The principal option is enhanced governance of water resources, including improving legislation and management institutions. However, systems for environmental policy-making

and implementation in China are not well developed, and despite gradual improvements much more needs to be done (Economy 2004; UNDP 2002; Vermeer 1998; World Bank 2002a).

Table 72.4: Contrasting Climate Change and Atoll Countries with Water Problems in China.
Source: Compiled by the author.

	Atoll Countries	China
Problem	Climate Change and Sea-Level Rise	Water Scarcity and Pollution
Major Cause	<u>External in origin</u> Greenhouse Gas Emissions	<u>Internal in origin</u> Industrialization
Minor Cause	<u>Internal in origin</u> Pollution and use of ecosystems	<u>External in origin</u> Global economic integration
Primary Solution	<u>External in origin</u> Reductions in Greenhouse Gas Emissions	<u>Internal in origin</u> Improved governance of water resources
Secondary Solution	<u>Internal in origin</u> Progress towards sustainable use of ecosystems	<u>External in origin</u> Integration of environmental considerations into trade rules

The nature of the risks and effectiveness of response options determines the extent to which people and institutions in both the atoll countries and China are insecure (vulnerable to) from environmental change. The prognosis for the atoll countries is less promising than for China. In the atoll countries the slow rate of progress on reducing emissions of greenhouse gases, and the generally limited range of adaptation options suggest that environmental insecurity from climate change remains high. In China, the risk and the re-

sponse options are within the purview of the State, and seem tractable (Heilig 1999; Smil 1997; Yang/Zhender 2001). Yet failure to respond effectively may mean deteriorating living standards for many millions of people, large-scale migration, and increased risks to regime security.

72.8 Conclusions

This chapter has outlined a wide range of environmental security issues in the Asia-Pacific, and discussed two cases in some depth. Given that the Asia-Pacific region contains some 30 % of the world's population living in very different socio-ecological contexts, it is not surprising that environmental security issues differ widely throughout the region. Environmental insecurity in the region is caused by economic rather than demographic changes; for while population continues to grow in many countries, the larger drivers of change are economic developments that lead to, among other things, greenhouse gas emissions, overuse and pollution of water, deforestation, and air pollution.

Solutions therefore lie in constraining the externalities of economic development, through, among other processes: improved land use planning at national and local levels, reducing the rate of greenhouse gas emissions through the use of sustainable energy technologies, adoption of cleaner production technologies, adoption of sustainable harvest targets, and reducing consumption in developed countries. Failure to address environmental problems through these and other methods may, and in some cases is already causing widespread and significant impacts on people's livelihoods.

73 Security at the Poles: The Arctic and Antarctic

Gunhild Hoogensen

Caution should be exercised about labeling every form of pollution or human-induced scarcity as a threat to security. But if the most serious warnings about global warming turn out to be correct, mankind faces a security problem on par with great-power war.

Nils Petter Gleditsch (2003: 477)

73.1 Introduction

Environmental security is a concept that has been, and continues to be, subject to controversy. Should environmental issues be ‘securitized’? If so, in which cases? Security pertains, even amongst many critical security studies scholars, to immediate threats that requires urgent action, and such immediacy is often not clear and present when it comes to the environment: “The environmental sector displays more clearly than any other the propensity for dramatic securitizing moves but with comparatively little successful securitization effects” (Buzan/Wæver/deWilde 1998: 74). Since environmental threats seem to be largely gradual, and therefore do not require immediate action, ‘urgency’ is often added to the environmental security recipe through the possibility of conflict. Homer-Dixon’s (1991; 1994; Homer-Dixon/Schwartz/Deligiannis 2000; chap. 20 by Homer-Dixon/Deligiannis) argument that under certain conditions of environmental scarcity, the likelihood of conflict increases, is now well known, as are the critiques (Gleditsch 1998). But these arguments do not address the relevance of environmental security that does not raise the immediate possibility of conflict. Additionally, environmental security has been problematic in that 1. the traditional machinery of security (the military) has largely been exempt from environmental considerations and been a source of environmental degradation; 2. ‘securing’ today’s North American lifestyles is largely contrary to the goals of ‘securing’ the environment; 3. development (i.e. ‘modernity’) appears to work against environmental protection; and 4. current modernization practices are not sustainable, and therefore a possible threat to environmental security (Krause/Wil-

liams 2003). One of the central problems with the environmental security debate is the tension between economic development and the environment. Both are relevant to the widened security agenda, but are pitted against one another, with little available in the way of a solution.

Against this background of controversy and scepticism, this chapter will discuss the nature of environmental security, and its relevance in two regions that are relatively peaceful and pristine – the Arctic and Antarctic. The overarching question is whether or not the concept of environmental security is relevant and useful here, and if so, in what way? In this chapter the author will argue that the concept is relevant but context dependent.

The security of the Arctic and Antarctic are deeply connected to the environment, both with regard to the impacts of humans on the environment, but also the subsequent impacts of the environment upon humans. Despite these regions being on the ‘outskirts’ of our usual social focus, these regions matter to the rest of the world: the environmental linkages between the polar climates and the rest of the planet are extremely complex and non-linear (SCAR 2005b), and the Arctic and Antarctic influence climate over a large part of the globe (IPCC 2001e; ACIA 2004). In both the Arctic and Antarctic (but more so in the Arctic) it becomes very clear that the ‘categories’ we use to identify security, from military to human security, are very fluid, and very closely linked to each other. Economic security cannot be completely isolated, for example, from environmental security or political security. This chapter will focus on the impacts of climate change and how this phenomenon has and con-

tinues to impact the many security dynamics of the Arctic and Antarctic.

The chapter will first present a brief discussion of environmental security (73.2), followed by a description of the regions (73.3). Both regions may be cold, but have little in common socially and politically. A discussion will follow on the impacts of climate change on these regions (73.4 and 73.5), as well as their ways in which environmental security is relevant to each, (73.6).

73.2 Environmental Security

In/security is about the expression of vulnerabilities and sources of fear (negative security), and of capabilities and enabling (positive security) – people, societies, groups have been able to ensure their security by a variety of means, to ensure that life continues, and make sure a good life can be found (Bajpai 2004; Hoogensen 2005c; 2008). The debate centres explicitly on the identification of threats, but also implicitly on assumptions about who (or what) provides security and who or what causes the threat (though not always adequately). Most conceptions of security assume that the state is the main, if not sole, provider of security, regardless of the security referent (global society, state, society or individual). The cause of the threat is an ‘other’, an ‘enemy’. The identification of threats and provision of security is based on the need to protect human values; if what we value is threatened, we wish to take steps to eradicate the threat (McSweeney 1999). Recognizing the role values play in the security debate is especially important when discussing environmental security, which is often down-played, or less-valued (particularly in comparison to other threats, such as large scale conflict). How we value the environment plays a large role in the efficacy of an environmental security concept.

Environmental security is illustrative of the complexity of the security debate, as it is relevant to not one, but a multiple of referents and ‘security providers’ (global society, the state, the individual) but often with varying agendas and meanings. In the polar regions all three referents are crucial and relevant; from individuals and societies, to states, and international regimes and organizations – all are significant to both the identification of threats as well as securing the environment for generations to come (both within and outside the regions). It is also this same multiplicity of actors who are often the cause of environmental threats (IPCC 2007f).

The development of the concept environmental security demonstrates the importance of the various referents. Discussions about global environmental threats largely began with the United Nations Conference on the Human Environment in 1972 (Buzan/Wæver/deWilde 1998). The term environmental security was popularized in the Brundtland Commission (1987) report *Our Common Future*. At that time the term largely reflected traditional security definitions, in that linkages were made between the environment and large scale warfare, particularly nuclear war. It also highlighted the extent of environmental degradation and devastation that would be and is caused due to other weapons of mass destruction, and the arms culture (WCED 1987: 19). Additional attempts at widening security to include, among other things, the environment have followed (Ullman 1983; Mathews 1989). There has been movement beyond such a tight link with traditional security interests, but there is no agreed upon definition of ‘environmental security’ (Moss 2003; Brauch 2003). Many of the operational definitions of environmental security have not moved far beyond the state focus¹, where environmental security is largely a tool of the state – a concept employed by the military, and potentially used as a justification for the continued exploitation of resources to ‘secure’ the North’s consumerist lifestyle (Dalby 1997, 2008).

However, an ‘exploitative’ focus is not a given at the state or inter-state level. The 2004 Hague Conference on Environment, Security and Sustainable Development claimed that it was very important to link the environment to security, particularly as global actors continue to fail to meet the challenges of increasing ecological problems, particularly climate change (Spencer 2004). The creation of global environmental regimes and organizations such as the *United Nations Environment Programme* (UNEP), the *Intergovernmental Panel on Climate Change* (IPCC), the *United*

1 U.S. Department of State, 2001: “What is environmental security?”, in: U.S. Department of State (Ed.): *Environmental Security Threat Report* (Washington, D.C.: U.S. Department of State); at: <<http://www.state.gov/p/eur/rls/rpt/2001/5882.htm>> (23 May 2006). Although the 2007 Presidential State of the Union Address in the United States was noted for its ‘recognition’ of climate change and environmental issues, it nevertheless framed this recognition in terms of securing resources for the United States, and reducing energy dependence upon foreign sources. See: <<http://www.whitehouse.gov/news/releases/2007/01/20070123-2.html>> (24 January 2007): 1.

Nations Framework Convention on Climate Change (UNFCCC), among others, demonstrate the increasing value of the environment and commitment of global actors to the issue. The move is also towards an ‘ecological’ security that identifies ecosystems and ecological processes as the security referent (Barnett 2001; Barnett/Matthew/O’Brien 2008).

Examining environmental security in relation to human security (Brauch 2005, 2005a; Rechkemmer 2006), and giving it a stronger ecological security orientation, moves the concept away from its state-based roots, and reflects mounting concerns about environmental degradation, and the importance of human relationships to the environment, including not only state and international actors, but individuals/communities (Reay 2006). This approach speaks to the security of multiple referents, the actors which cause the insecurity, and reflects the importance of values in our determination of security. As such, environmental security is connected to our ‘security of expectations’ recognized by Jeremy Bentham as a central condition of human well-being, reflecting the human need to rely upon the continued existence of that which we value (Hoogensen 2005b). When security of expectations decreases, as it does due to the unpredictability of climate change, the threat must be met. Arctic societies are attempting to do just that, but need the awareness of states and the international community to contribute to their own attempts to adjust, mitigate, and prevent changes that might cause irreparable harm.

73.3 The Arctic and Antarctic Regions

The Arctic and Antarctic are unique as regions, climatically, socially, and politically. While the Arctic region is a shared territory between eight sovereign nations (Russia, Canada, USA, Norway, Sweden, Denmark (Greenland), Finland and Iceland), Antarctica is an international territory that recognizes no territorial claims by any state, agreed upon through the Antarctic Treaty that came into force in 1961. However conflicts continue between claiming nations such as Chile and the UK, and Chile and Argentina (Buzan/Wæver 2003; Sicker 2002). Antarctica is additionally a continent surrounded by water (Southern Ocean), enclosed by the southern sixtieth parallel (Sicker 2002). The Arctic however, is unique as it is not composed of eight complete states; almost all of the eight states that govern the Arctic are partially located outside of the Arctic region and have their political centres far to

the south of the region (Young/Einarsson 2004). The Arctic is composed of a part of each of the eight (with the exception of Iceland). It is also predominantly an ocean, surrounded by land (Verhaag 2003). This is not a typical definition of a region, which is traditionally determined by state boundaries (Hoogensen 2005a; Buzan/Wæver 2003). In fact, because the Arctic is not defined by state boundaries, there is little agreement on what the boundaries of the Arctic actually are (Verhaag 2003; ACIA 2004; Young/Einarsson 2004). The “lines” often used to define the Arctic include the Arctic Circle (defined by the latitudinal point where the sun does not come above the horizon at winter solstice and does not fall below the horizon during summer solstice), the latitude of 60°N, treelines, the extent of permafrost and sea ice, climatic boundaries, and internal political jurisdictions (for example, Nunavut, Northwest Territories, Nenets autonomous region, etc). For the purposes of this chapter the boundaries of the Arctic as proposed by the *Arctic Human Development Report* (AHDR) and the *Arctic Monitoring and Assessment Programme* (AMAP) will apply.² The region of the Antarctic is here defined as the Antarctic continent, the Southern Ocean south of the Antarctic convergence (approx. 58°S), and the sub-Antarctic islands.³

Both regions are, relatively speaking, very cold, although Antarctica is considerably colder than the Arctic, and far less habitable for humans (Verhaag 2003). These colder temperatures have given way to some dominating stereotypes of the regions as cold, barren, generally lifeless (besides a smattering of Inuit and polar bears), and just generally “a desolate hinterland of little international relevance” (Young 1989, in: Verhaag 2003). This view has and continues to negate not only the diversity of life in these regions and particularly the far North, but also the cultural heritages, resilience, and experiences of various and different Arctic

2 The AHDR uses the AMAP definition of Arctic boundaries with a few differences pertaining to jurisdictional and administrative boundaries. Thus the Arctic in this case includes Alaska, Canada north of 60°N and including northern Quebec and Labrador, Greenland, Faroe Islands, Iceland, the northern parts of Sweden, Norway and Finland, and northern Russia (Murmansk Oblast, Nenets, Yamalo-Nenets, Taimyr, and Chukotka autonomous regions, Vorkuta city, Norilsk, Igrska and the areas of Sakha Republic closest to the boundaries of the Arctic Circle). AHDR, 17–18.

3 This definition of the Antarctic region is taken from the definition provided in *Climate Change 2001* (IPCC 2001).

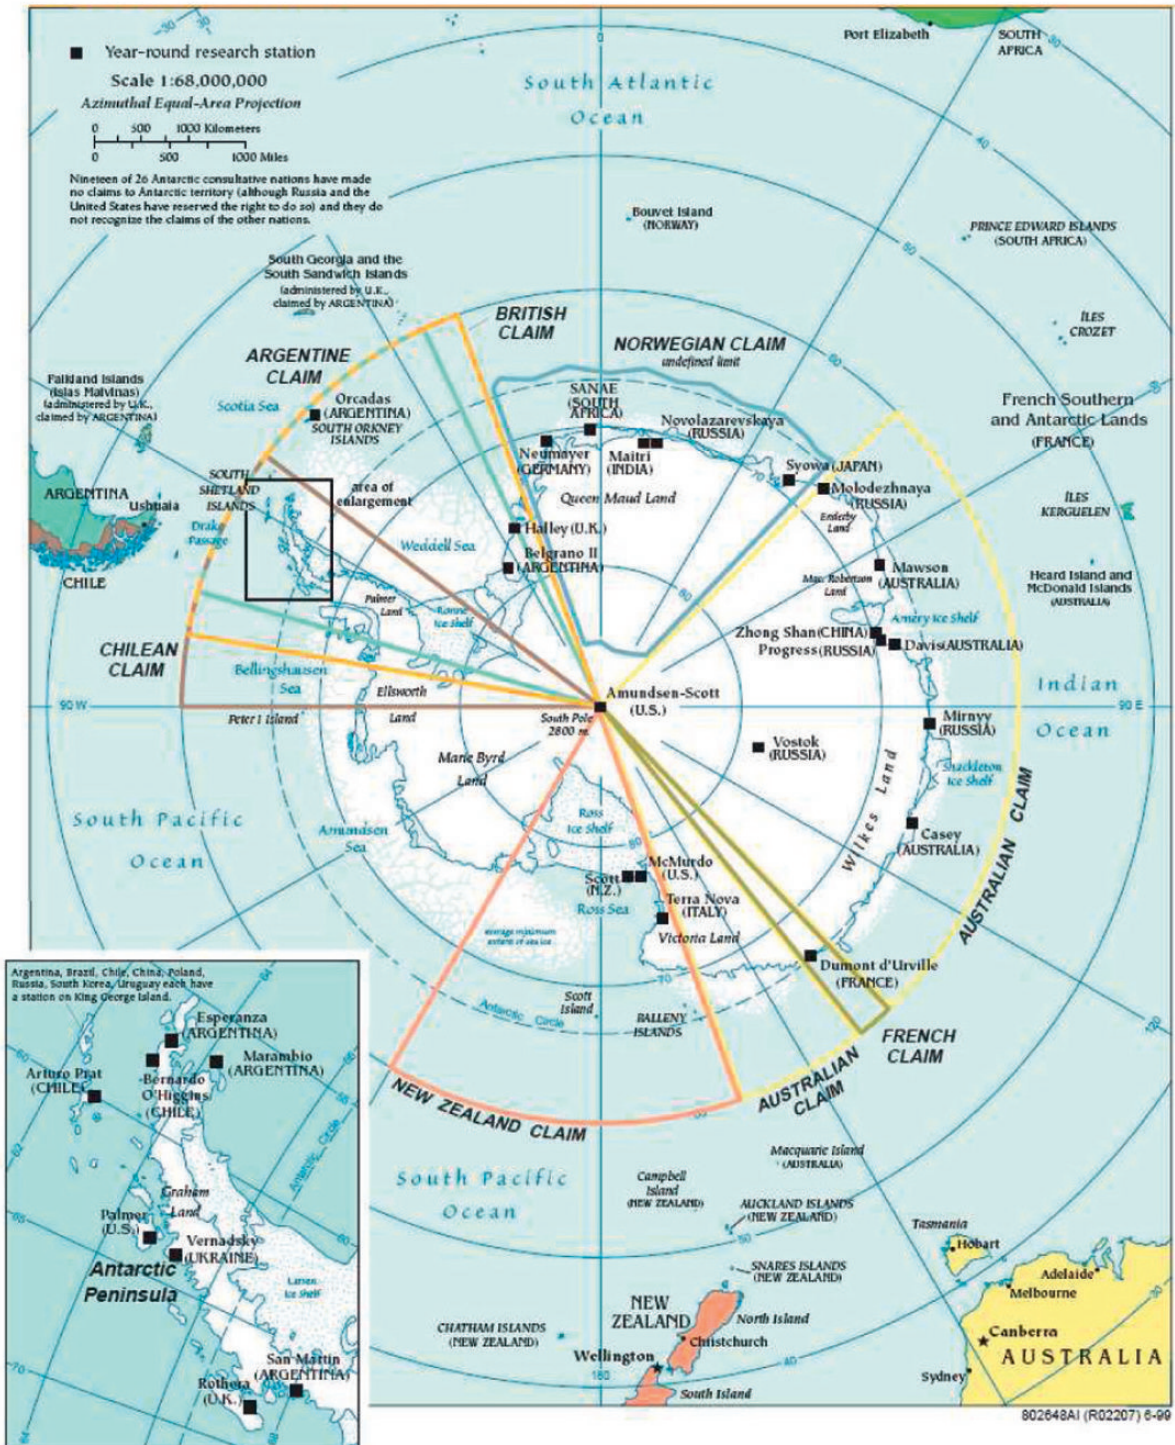

Figure 73.1: Map of the Arctic Region. **Source:** University of Texas at Austin, Perry-Castañeda Library Map Collection; at: <http://www.lib.utexas.edu/maps/islands_oceans_poles/arctic_ref802647_1999.jpg>. This map is in the public domain and is used here to roughly illustrate the region. However, see also the AMAP and AHDR maps which depict more recent manifestations of the 'boundaries' of the Arctic.

peoples. The temperatures in the Arctic in fact vary a great deal; the Norwegian Arctic is considerably warmer, at least on the coast due to the Gulf Stream,

than the Canadian or Russian Arctic. This in turn has affected the levels and types of habitation in the Arctic.

Figure 73.2: Map of the Antarctic Region. **Source:** University of Texas at Austin, Perry-Castañeda Library Map Collection; at: < http://www.lib.utexas.edu/maps/islands_oceans_poles/antarctic_ref802648_1999.pdf>. This map is in the public domain.

The stereotypical view of the poles as cold and largely uninhabited has also distorted perceptions about how many people live in these regions, and

have often led to a conflation of the two - the poles are identical. They are not however. In total, and ranging in density across the eight Arctic nations, over 4

million people live in the region (Bogoyavlenskii/Siggner 2004). The distribution of indigenous and non-indigenous peoples varies widely across the Arctic; in the Canadian Arctic for example, Nunavut is composed of 85 per cent Inuit, whereas the Yukon Territory is 75 per cent non-indigenous (AHDR 2004). Across the whole of the Arctic, non-indigenous peoples number in the majority (ibid). There are no indigenous inhabitants in the Antarctic, however it is “populated” by permanent and summer staff at research stations, ranging from approximately 4000 in the summer, to 1000 in the winter.

Both the Arctic and Antarctic are rich in natural resources; Antarctica in marine and wildlife, minerals, oil and gas, as well as fresh water (over 70 per cent of the Earth’s fresh water is in Antarctica), and the Arctic in marine and wildlife, on and off-shore oil reserves, and coal (Joyner 1987; Verhaag 2003).

73.4 Climate Change and Security in the Arctic

Of all the environmental issues that have emerged in the past few decades, global climate change is the most serious, and the most difficult to manage. Climate does not just affect people directly: it also affects all other environmental and ecological processes, including many that we might not recognize as related to climate (Dessler/Parson 2006: 1–2). Climate change is similarly of such a scope that it warrants urgent attention and securitization (Barnett 2001: 118).

The Polar Regions, particularly the Arctic, make for a clear case study of the effects of climate change. The impacts of climate change are most profoundly felt in the Polar Regions, particularly the Arctic (Gabrielsen/Winter 2005; ACIA 2004; IPCC 2001e). The warming temperatures are already impacting wildlife as well as Arctic human communities, and will have increasing effects on energy, marine life and activities, transport, fisheries, and culture. Arctic peoples have been used to change in the past, whereby adaptation, flexibility and building capabilities and capacities has always been a part of Arctic life (ACIA 2004); communities by and large ensured their own (positive) security according to their needs. The problem now is that various factors, particularly environmental, are changing so fast that it is very difficult for communities to adapt quickly enough. We therefore need increased awareness about environmental insecurity of the Arctic to be able to provide what is now

needed for adaptation, mitigation, prevention, and rectification, if possible. The Antarctic additionally provides an interesting comparison for dealing with diverse pressures.⁴

Security considerations in the Arctic have been traditionally dominated by national security agendas focused on territorial integrity of the state through political and military means. Insofar as the traditional security approach has affected the Arctic, it has been, for example, an early warning zone for incoming missiles (between the USA and the Soviet Union), or as in the case of Iceland and Greenland, ‘stepping stones’ of security between Europe and North America (Solheim 1994). In fact, if the Arctic had any meaning to security at all during the Cold War, it was as a military ‘theatre’ for the USA and Soviet Union and their nuclear arsenals, as well as nuclear targets (Heininen 2004). It additionally served well as a region for testing weapons as well as conduct military training, including in Norway, which was the only NATO nation sharing a land border with the Soviet Union (Heininen 2004). The relevance of traditional security to the Arctic can be seen in the renewed interest in oil extraction and export from the Barents region, whereby Russia and Norway are still in dispute over the demarcation of territorial waters which has a significant impact on access to the estimated vast oil reserves; it is to this region that the USA is increasingly looking as a source of oil to reduce its dependency upon the Middle East, seeing the dispute between Norway and Russian as a ‘security issue’.⁵

Although the military and political aspects of security are still considered relevant in the Arctic context, a broader sense of security issues is beginning to dominate, particularly with regard to the environment: climate change, the extraction of natural resources (primarily oil), the increase in persistent organic pollutants, and the preservation of the Arctic ecosystem (Verhaag 2003). These are not divorced however from the military legacy as a large degree of the environmental problems now experienced in the Arctic

4 The ways in which Arctic communities are trying to adapt to rapid change in the region is the subject of a number of new international research projects, in particular connected to the upcoming *International Polar Year (IPY) 2007–2008*. These projects are meant to fill a knowledge gap on how communities are and will be able to provide security for themselves in increasingly unpredictable environments.

5 “Gas fuels new cold war in the Arctic”, in: *Scotland on Sunday* (4 June 2006); at: <<http://news.scotsman.com/international.cfm?id=824612006>>, 31 March 2007: 1.

stem from previous military activities, particularly regarding nuclear waste (Heininen 2004; MFA 2005; chap. 61 by Sergunin).

Traditional, state-based approaches have not addressed environmental security with a more human, societal, or ecological focus. A more multidimensional environmental security focus is required, reflected already to some degree through the international treaty system established for the Antarctic. (Joyner 1987; Verhaag 2003; SCAR 2005a, 2005b). The ACIA notes that global temperatures are increasing at unprecedented rates in the Arctic (ACIA 2004), which has now been even further emphasized by the Fourth IPCC Assessment Report (2007). The key findings of the ACIA indicate that the Arctic is warming much more quickly than originally thought, with greater impacts than originally predicted. What this means is that the Arctic is now predicted to warm between 4–7°C in the next century, thereby increasing the current rate of sea ice and glacier melt, increasing Arctic precipitation and reducing seasonal variation (shorter, warmer winters), and increasing insect outbreaks, forest fires, and invasion of non-indigenous species, all of which will impact on humans and wildlife alike, including the erosion of cultural and social identity of many Arctic people.

The Arctic ice is, in many respects, the “canary in the mine” that serves as a warning of what we can expect with climate change (Gabrielsen/Winther 2005: 45). Models that have been instrumental in the creation of the ACIA demonstrate that changes in the ice will not become significantly noticeable before the year 2020, but then show very rapid ice melt thereafter, indicating that most of the Barents Sea will be ice free by 2050, and by 2075 the “entire area between northern Novaja Zemlja, Frans Josef Land and Svalbard will be, practically speaking, ice free year-round” (Gabrielsen/Winther). The sea ice is critical to both wild and human life, and the effects of climate change on the sea ice will impact on Arctic eco and social systems with threats and challenges never before faced in the region (Gabrielsen/Winther).

One of the important indicators we can look at to see the effects of climate change is the rate of toxin transfer in the region. Decades of research has already taken place with regard to the impacts of *persistent organic pollutants* (POPs), mercury and lead on Arctic wildlife, and more recently Arctic scientists have put human communities in focus (Gabrielsen 2003; AMAP 2002a; AMAP 2002b). In little less than twenty years, an increasing amount of contaminants have reached the Arctic from non-Arctic sources,

through atmospheric as well as water (oceans and rivers) transport systems. These toxins are transferred to the Arctic at increasing rates as the sea ice melts.

The absence of ice increases the ocean drift, bringing environmental toxins such as *persistent organic pollutants* (POPs) and *Polychlorinated biphenyls* (PCBs) to the Arctic even more quickly than before. These toxins enter the marine ecosystem through biomagnification (increasing toxicity as one moves up the food chain) and bioaccumulation (increasing toxicity as the animals get older) (AMAP 2002a). The toxins are not soluble in water but are very soluble in fat, and are thus retained in the fat stores of animals and humans. As the sea ice continues to melt, the animals dependent upon the ice for survival and hunting begin to starve and live off of their own fat stores. The toxins are then released into the animal systems, usually during critical times of pregnancy and nursing. Thus far the only immediate solution is to reduce marine food source intake, upon which many Arctic communities rely.

POPs have been linked to increases in breast cancer, impacts on reproductive health, and transfer to children through breast milk (AMAP 2002a). For example, children and pregnant women in Norway are additionally warned against eating particular products containing cod livers that would not have undergone processing for cleaning of pollutants. Sockeye salmon are returning to their spawning grounds in Canada and Alaska and transporting higher and higher levels of contaminants such as methyl-mercury, and higher levels of mercury have been reported in the Russian Arctic. Higher levels of mercury have been identified in maternal blood and hair samples as well as cord blood in northern Quebec mothers (Gabrielsen 2003). In general, there are noticeable trends of increased toxicity in human systems in the Arctic regions.

Research efforts are currently underway to investigate the possibility of pollutants causing mixed gender in men living in North Norway, as has already been noted in polar bears. A number of polluting chemicals emanating from agriculture and industry mimic sex hormones such as estrogens and are known as *endocrine disrupting chemicals* (EDC).⁶ Research has already documented that pollutants exported from southern regions have resulted in low sperm counts and poor sperm quality amongst men living in northern regions. Further investigations are being made

6 “Skal lete etter miljøgifter i finnmarkinger” (Looking for toxins in Finnmarkers) *Nordlys* (09 July 2004): 6–7.

into the possibility that these chemicals are causing testicular cancer as well. The health of the ecosystem, impacted as greatly as it is by climate change, is integrally linked to the culture of many indigenous and non-indigenous peoples in the Arctic. Environmental exploitation without any sense of sustainability threatens Arctic lifestyles and well-being by wreaking havoc on cultural, ethnic and national identities and security.

73.5 Climate Change and Security in Antarctica

The Antarctic is a region under dispute; however, the territorial claims waged upon it have been frozen through the introduction of the Antarctic Treaty.⁷ Various traditional security interests have been mitigated through this treaty, disallowing military activity and making the region a nuclear-free zone, and it holds in abeyance any territorial claims (Verhaag 2003). Despite its mineral wealth and the creation of the 1988 Antarctic Minerals Convention spurred on by the 1973 OPEC oil crisis (which would have allowed for mining and oil extraction), the UN declared the Antarctic a natural reserve (1998 Madrid Protocol), and prohibited mining activities for the next 50 years (Firth 2005). For the time being then, the Antarctic is solely used for peaceful and scientific purposes.

The Antarctic has not yet experienced significant warming across the region (IPCC 2007). There continues to be, as stated in the previous IPCC (2001e) report, no significant change in Antarctic sea ice, although the 2001 report did indicate a significant warming trend at that time. Despite these slower changes however, climate change has had an already significant impact on the biodiversity of Antarctic life. According to the *Scientific Committee on Antarctic Research* (SCAR), the increased human traffic to Antarctica has caused “considerable damage by way of local species extinctions and wholesale alteration of ecosystems” (SCAR 2005a: 3). The incidence of invasive species has drastically increased to Antarctica and the sub-Antarctic islands. This has largely been due to human traffic – coming in through clothing, baggage, attached to fresh vegetables, hulls of ships, anchor chains and in ballast water (SCAR 2005a: 3). Due to “increases in temperatures over the past 50 years, the usual climatic barriers have been less effectual against

colonization of invasive species introduced by human activity (SCAR 2005a: 3). Though protected as a natural reserve through the Antarctic treaty, peace and nature have led to a different type of economic activity. Access to Antarctica has increased so much so that tourist numbers have increased four fold since 1992 (reaching over 24,000 tourists by the 2001–2002 season), add to that the numbers of researchers (over 4,000 in 2001–2002), and the numbers of ships arriving from all over the world (60 ships from approximately 30 cities from around the world) (SCAR 2005a). Human contact is threatening the very region of the world that humans have decided to protect.

Ice core samples taken on Antarctica have demonstrated that climate has always changed, however, they also demonstrate that human activity has increased levels of greenhouse gases at unprecedented rates.⁸ The implications of ice melt on Antarctica are significant, as the ice sheets contain vast reserves of water and would contribute to global sea rise, and measurements of sea ice is considered to be a ‘very sensitive indicator’ for climate change.⁹ Current research anticipates modest rises in temperatures over the next 50 years on Antarctica, but due to the lack of long-term data (little is known beyond the past 50 years) it is very difficult to know if and how climate is changing on the continent (IPCC 2001b).¹⁰ Where reported warming has had an impact is on the Antarctic Peninsula which has experienced the highest rise in temperature in the whole of the Southern Hemisphere, and which has been attributed to the melting of the Wordie Ice Shelf and part of the Larsen Ice Shelf.

One of the greatest potential impacts of climate change and the Antarctic upon the rest of the world will thus be through its sea ice, which plays a critical role in the development of ocean circulation, salinity and temperature change, as well as sea levels. Human reliance (expectation) on the oceans plays an enormous role in economies, food access, health, lifestyles, cultures and identities, making events in seem-

7 The original signatories were the UK, South Africa, Belgium, Japan, USA, Norway, France, New Zealand, the USSR, Argentina, Australia and Chile.

10 BAS [British Antarctic Survey], 2005: *Antarctic climate change ñ a position statement* at: <http://www.antarctica.ac.uk/Key_Topics/Climate_Change/Climate_Change_Position.html> (7 October 2005).

ingly far reaches of the earth (like the Antarctic with its negligible human population) become relevant to more populated communities. The Southern Ocean surrounding Antarctica has had, and will continue to have, effects on the development of global fisheries for example. With changes in temperature some fisheries will disappear while others will likely develop (although not necessarily within the same regions), impacting on the distribution and value of particular stocks, as well as “increase or decrease local economies by hundreds of millions of dollars annually” (IPCC 2001b). The krill fishery in the Southern ocean for example is documented to be affected by the sea ice position, such that the further south the position of sea ice (due to melting), the lower the production of krill (IPCC 2001b: 817–818).

Although climate changes in the Antarctic are predicted to be considerably slower than in the Arctic, these changes could initiate “millennial scale processes with the potential to cause irreversible impacts on ice sheets, global ocean circulation, and sea level rise” (IPCC 2001b: 831). The Antarctic therefore needs attention and protection. What is interesting is that those nations which are interested in the Arctic have been well aware of these needs of this special region for a significantly long time, and have acted to protect the region.

The Antarctic Treaty System, in force since 23 June 1961, was enacted to ensure “in the interests of all mankind that Antarctica shall continue forever to be used exclusively for peaceful purposes and shall not become the scene or object of international discord”¹¹ The treaty system also includes later agreements such as the Protocol on Environmental Protection to the Antarctic Treaty, the Convention for the Conservation of Antarctic Seals and the *Convention on the Conservation of Antarctic Marine Living Resources* (CCAMLR), as well as the Convention on the Regulation of Antarctic Mineral Resource Activities (which has not been ratified). The parties to these agreements have agreed to give up “some sovereignty” on Antarctica in exchange for protecting the natural and scientific wealth of the region (Verhaag 2003: 577). Being protected as a natural reserve, the Antarctic constitutes the operationalization of a global, environmental security framework.

73.6 Concluding Remarks

This chapter has provided just a small snapshot of some of the environmental security issues in the specific contexts of the Arctic and Antarctic as they pertain to climate change. Of course, these two regions differ considerably from one another; the Antarctic is not experiencing the equivalent and alarming climate change of the Arctic, nor does it have the same effect on vulnerable populations. However, climate change is having an impact on the region, and these changes are predicted to become more significant over time, which will have not only regional but global effects. Environmental change at the poles is not relevant just to those in close proximity to these regions – in this respect these regions, and particular the Arctic, is indeed a ‘canary in the mine’. The effects of climate change here are and will continue to impact other parts of the world. “One of the most identifiable visual impacts of climate change in Europe can be observed in the cryosphere through the retreat of glaciers, snow cover and Arctic sea ice. ... In Europe a large number of all catastrophic events since 1980 are attributable to weather and climate extremes: floods, storms and droughts/heatwaves” (EEA 2004: 4–5).

But is this still a security issue? A traditional definition of security would suggest no, due to the relative gradual nature of the change. Some have argued the case of ‘abrupt climate change’ scenarios, arguing for why climate change would constitute a security issue, framing the issue again more traditionally in terms of an immediate threat (Schwartz/Randall 2003). Access to and conflict over resources are highlighted, with models suggesting mass migration from the European Arctic (Scandinavia) southward, leading to various conflict scenarios (Schwartz/Randall 2003). Such ‘abrupt’ scenarios are not impossible, but not substantiated by current scientific evidence. However, though climate change will most likely continue to be relatively gradual, its affects are significantly noticed, and the threat of change, instead of being abrupt, will be long-term and sustaining. Our ‘security of expectations’ is affected by the forthcoming changes, as what we value both locally and globally could very well disappear and significantly alter human and ecological systems, demonstrated by the experiences in the Arctic now, not just with increased food toxicity as discussed here, but the impacts of the changing environment on the changing access to resources (oil and gas, fisheries, animal husbandry), and on societies (increasing rates of disease, suicides, migration).

11 See at: <http://www.scar.org/treaty/at_text.html>, 13 November 2006: 1.

The increasing global attention being given to climate change additionally demonstrates the value placed on the environment, by individuals, states and the international community. These are also, however, the primary actors driving this change and causing the threat (IPCC 2007f). Placed at odds with each other are different values - the environment versus economic security. Political conditions amongst claimant states in the Antarctic made it possible for the value of the environment to stand above others, rejecting (for now) the potential for considerable mineral development and creating environmental security in the region. The situation has been different in the Arctic, however, as the context is so different with diverse populations, sovereign states, and weather conditions. The toxins entering the Arctic come largely from industrial efforts to the south (which have little hint of ceasing), and resource opportunities that are opening up in the Arctic due to climate change only increase the pressures for economic exploitation (with not all of the eight Arctic states applying environmental regulations in similar ways, if at all). The nature of environmental security assumes additional roles for all security actors to contribute to the creation of environmental security: not just agreements between states are needed, but actions on the parts of societies, firms, and individuals. For example, NGOs were instrumental in the overturning of the Minerals Convention for the Antarctic, and public opinion in a variety of regions is increasing momentum and pressure on local groups and authorities to reduce carbon emissions and waste. Environmental security at the poles is dependent upon adaptation, mitigation and future prevention, all of which is connected to human activity and the desire to effect positive, less harmful change, both for the present and future generations.

74 Human Security Concepts in Policy and Science

Hans Günter Brauch

Security ... means safety from the constant threat of hunger, disease, crime and repression. It also means protection from sudden and hurtful disruption in the pattern of our daily lives – whether in our homes, in our jobs, in our communities or in our environment.

Human Development Report 1994: New Dimensions of Human Security (UNDP 1994: 3).

Human security complements state security, enhances human rights and strengthens human development. It seeks to protect people against a broad range of threats to individuals and communities and, further, to empower them to act on their own behalf. And it seeks to forge a global alliance to strengthen the institutional policies that link individuals and the state – and the state with a global world. Human security thus brings together the human elements of security, of rights, of development.

The Commission on Human Security's definition of human security: to protect the vital core of all human lives in ways that enhance human freedoms and human fulfilment. Human security means protecting fundamental freedoms – freedoms that are the essence of life. It means protecting people from critical (severe) and pervasive (widespread) threats and situations. It means using processes that build on people's strengths and aspirations. It means creating political, social, environmental, economic, military and cultural systems that together give people the building blocks of survival, livelihood and dignity.

Human Security Commission: *Human Security Now* (CHS 2003: 2,4).

143. We stress the right of people to live in freedom and dignity, free from poverty and despair. We recognize that all individuals, in particular vulnerable people, are entitled to freedom from fear and freedom from want, with an equal opportunity to enjoy all their rights and fully develop their human potential. To this end, we commit ourselves to discussing and defining the notion of human security in the General Assembly.

UN General Assembly, *World Summit Outcome* (UN/A/60/1), 24 October 2005: 3I of 38.

74.1 Introduction¹

After the end of the Cold War 'human security' has evolved as a new security concept² on the international policy agenda due to two major reports (UNDP 1994, CHS 003). By shifting the focus from the 'state-centred' perspectives of national, international, and global security to a 'people-' or 'human-centred' perspective, the security concept was *deepened* vertically and the exclusive focus on the state was questioned by

adding the individual human being, communities, society, or humankind as new referent objects.

Since the late 1990's two different concepts were promoted in the political realm. The governments of Canada, Norway, and the European members of the *Human Security Network* (HSN) preferred a narrow concept focusing on 'freedom from fear' that dealt with humanitarian initiatives and human rights (chap. 75 by Fuentes/Brauch; chap. 83 by Black/Swatuk). The government of Japan and the *Friends of Human Security* (FHS) opted for a wider concept that includes with 'freedom from want' the human development agenda (chap. 84 by Shinoda).

In the scientific discourse, the Copenhagen School (Buzan/Waever/de Wilde 1998) proposed a

1 The author would like to thank three reviewers for critical comments and very helpful suggestions for revising the text.

horizontal widening of the primarily ‘state-centred’ national and international security concept. Buzan critiqued the human security concept (Buzan 2002, 2004). Several proponents of a narrow human security concept (Mack 2004, 2004a; Krause 2004, 2008; Mac Farlane/Khong 2006) opposed its horizontal widening to include other policy agendas of development and environment policy. No agreement exists in science and politics on definitions, referent objects, scope and boundaries, as well as on policy goals and human security agendas.³

As the security concept, human security has also been a ‘contested concept’ (Gallie 1955–1956) both in the political realm, where it first emerged, and in scientific discourses, where it has been proposed as an alternative normative paradigm. In the social sciences, the concept has been widely discussed in *development* (Picciotto/Olonisakin/Clarke 2007; Ulbert/Werthes 2008) and *peace studies* (Tadjbakhsh/Chenoy 2006; Thakur 2006/2007), and to a lesser extent in *environmental* (Page/Redclift 2002; Dodds/Pippard 2005) and *security studies* (Dannreuther 2007; Booth 2007) where many realists ignored this discourse (Kolodziej 2005).

The human security concept responds differently to key questions (Møller 2003: 278–279; Hintermeier

2008: 660) of: 1) *Security for whom or what?* This refers to the referent objects of security (states, communities, individuals); 2) *Security for which values?* This points to the values at risk (for states: sovereignty, territorial integrity; societies: collective identities; individuals: well-being, quality of life, safety, physical survival); 3) *Security from whom or what?* This refers to threats, challenges, vulnerabilities, and risks that pose security dangers and concerns (for ‘national security’: other states, non-state actors; for ‘human security’: the state, globalization, nature, humankind and its economic and consumptive behaviour); and 4) *Security by what means and strategies?* This refers to military, political, economic means, and to reactive and proactive strategies (MA 2005). For achieving human security both reactive and proactive strategies for achieving sustainable development are essential. The answers to these four questions differ for national, international, and global security, and for ‘people-’ or ‘human-centred’ concepts of societal, communal, and personal security (Brauch 2008g: 28–29).

The paradigmatic shift from ‘national security’ to ‘human security’ implies a change in the reference objects, in the values to be protected, of the security dangers and concerns which individuals and humankind face and have to cope with, as well as in the policy agendas and strategies for achieving human security. Human security does not replace national, regional or international security of the world of states, but it shifts the focus from nation states to ‘We the peoples of the United Nations’ referred to in the Preamble of the UN Charter, from sovereignty to human well-being and survival, from the fixation with the ‘other’ (state, ethnic or religious group) to ‘us’ as the cause (e.g. of global environmental change and global warming) and the victims of ‘our own consumptive behaviour’ (through an increase in the number and intensity of hydro-meteorological hazards).

Human security requires a fundamental shift in the thinking on security (of worldviews and mindsets, Brauch 2003g), it addresses different policy requirements and needs, and it requires horizontally integrated political coping strategies where the role of development and environment policies is vital and the role and missions of the military changes from fighting wars to *protecting* the people against genocide, natural hazards where the society and social movements have to play a vital role in *empowering* the people to build resilience and to enhance their coping capacities. Thus, the human security concept implies fundamental changes in the priorities of nation states in fulfilling the basic human needs of its people, to

2 According to Jolly and Basu Ray (2006: 4) the human security concept “emerged as part of the holistic paradigm of human development cultivated at UNDP by former Pakistani Finance Minister Mahub ul Haq, with strong support from economist Amartya Sen.” In January 1990, a North-South Roundtable on the “Economics of Peace” in Costa Rica, called for “a new concept of global security” where the “orientation of defence and foreign policy objectives changed from an almost exclusive concern with military security ... to a broader concern for overall security of individuals from social violence, economic distress and environmental degradation.” This would require “attention to causes of individual insecurity and obstacles to realization of the full potential of individuals.” The participants included President Oscar Arias (Costa Rica), President Obasanjo (Nigeria), Robert McNamara (USA), Jim Grant (UNICEF), Maurice Strong (Canada), Inga Thorsson (Sweden), Brian Urquhart (UN). Among the experts were Richard Jolly, Mary Kaldor, Julian Robinson, Anthony Sampson, Kennedy Graham (all UK), and Herbert Wulf (Germany).

protect its human beings from manifold security dangers and to empower them to cope with these manifold security dangers.

While the theory of *securitization* was developed by the Copenhagen School for a widened security agenda for a world of states, the human security concepts and policy agendas enhance the role of the societal groups and of knowledge-based scientific epistemic communities (such as the IPCC) as new *securitizing actors* that have put issues of global environmental change and climate change on the top policy agendas of nation states and of the global and re-

gional UN system, the Bretton Woods institutions, of the G-8, G-5, G-77, as well as of the European Union (chap. 4 by Brauch; chap. 11 by Oswald/Brauch).

Thus, the policy debate and the scientific discourse on human security has become an essential part of the broader reconceptualization of security dangers and concerns focusing on different soft security threats, challenges, vulnerabilities, and risks caused by and affecting the well-being and survival of humankind and human beings alike. Human security has the human being and humankind as a referent object, whose values at risk are human well-being, quality

of life and survival, and whose sources of threat are the state, globalization, and nature (Møller 2003: 279).

While the narrow Canadian conceptualization of human security is limited to the political and military dimension, the wider Japanese notion includes the economic dimension, while the all-encompassing UNDP concept (1994) covers the societal and environmental⁴ dimension as well. Human security has been discussed in relationship to *national* (Đurđević-Lukić 2004), *international* (Dannreuther 2007) or *global security* (Stoett 1999) but also with several sectoral security concepts, especially with *water* (chap. 41–58), *food* (chap. 33–35), *health security* (chap. 38 by Leaning; Leaning/Aries 2000, 2001; Szreter 2003; Chen/Leaning/Narasimhan 2003), *livelihood security* (chap. 36 by Bohle; Bohle/O'Brien 2007). Oswald (chap. 90) proposed a composite concept that links human with gender and environmental security.

This chapter maps the policy debates and offers a brief overview of scientific discourses on human security, and discusses its political utility by addressing these research questions:

- How can 'human security' be contextualized in the framework of the reconceptualization of security?
- How has the human security concept evolved, been defined, and conceptualized in the political and scientific realm, and which states have supported the concept for which reasons, and which policy agenda have they promoted herewith?
- Have the promoters of the human security concept succeeded to put new policy items on the national and international policy agenda, and have they been implemented?

The chapter reviews the evolution of the human security concept as a policy (74.2) and a scientific concept (74.3), examines the four conceptual pillars and the related national and international agendas and the role of UN agencies (74.4), and it concludes with a brief assessment of its past impact and an outlook of the potential for security (Dalby 2009) and a sustainable peace policy in the Anthropocene (74.5).

4 This has been covered elsewhere in detail by Brauch (2005, 2005a, 2006e, 2006h, 2007, 2007a, 2007b, 2007c, 2008g); Barnett 2001.

74.2 Evolution of Human Security as a Policy Concept

Human security is a highly disputed political concept whose political and intellectual origins have been widely analysed in the literature.⁵

74.2.1 Human Security and the United Nations

Since the publication of the 1994 HDR (UNDP 1994), the human security concept has been discussed within the UN system, by the UN Security Council during Canada's membership (1999–2000) when it succeeded to adopt the 'Protection of Civilians in Armed Conflict' as a new agenda item (Dedring 2008). The Canadian approach (chap. 83 by Black/Swatuk) focused on 'freedom from fear' (landmines, small arms, cluster bombs, protection of civilians, and responsibility to protect).

Japan (chap. 84 by Shinoda) launched and funded the *Commission on Human Security*, co-chaired by Sadako Ogata and Amartya Sen (2001–2003) that resulted in the report: *Human Security Now* (CHS 2003). In May 2004 the *Human Security Unit* (HSU) was established in the United Nations' *Office for the Coordination of Humanitarian Affairs* (OCHA⁶),

5 MacFarlane and Khong (2006) provide a comprehensive critical history of the evolution of the human security concept and its relationship to the UN. Jolly and Basu Ray (2006) offered a brief history of the evolution of the concept and assessed its application in 13 UNDP national human development reports on Afghanistan, Latvia, Macedonia, Philippines, Moldova, Kyrgyzstan, Lesotho, Mozambique, Sierra Leone, Timor-Leste, Bulgaria, Estonia, Solomon Islands. UNESCO (2008) summarized its own activities and publications from 1996 to early 2008. See also: Tadjbakhsh/Chenoy (2006); Kaldor (2007); Ulberth/Werthes (2008). For bibliographies see: Harvard Program on Humanitarian Policy and Conflict Research (August 2001); at: <<http://www.gdrc.org/sustdev/husec/Bibliography.pdf>>; Sara Edson, Centre For History And Economics, King's College, University of Cambridge (June 2001); at: <<http://www.humansecurity-chs.org/activities/meetings/first/bibliography.pdf>>; Human Security Gateway, bibliography; at: <<http://www.humansecuritygateway.info/feeds/feedsById3.xml>>. 6 See for details; at: <<http://ochaonline.un.org/Home/tabid/2097/Default.aspx>>.

whose objective is to “integrate human security in all UN activities,” to manage the *United Nations Trust Fund for Human Security* (UNTFHS) that was set up in 1999 and funded by Japan, and to promote activities on human security. Japan also co-chairs - together with Mexico - the *Friends of Human Security* (FHS) and it also chaired the Peacebuilding Commission.

Former UN Secretary-General Kofi Annan (2001, 2005) had repeatedly endorsed the concept. References to human security were included in the report of the *High Level Panel on Threats, Challenges and Change* (December 2004) and in his report *In Larger Freedom* (March 2005) where he distinguished among ‘freedom from want’ (human and sustainable development agenda), ‘freedom from fear’ (collective security, terrorism, WMD, reducing risk of war and use of force), and ‘freedom to live in dignity’ (rule of law, human rights, democracy).

These efforts cumulated in paragraph 143 of the ‘Outcome Document’ in which the UN GA committed itself to define and discuss ‘the notion of human security’. The World Summit in September 2005 had also reached a consensus on three issues relevant for human security: a) the establishment of a Peacebuilding Commission; b) the creation of a new Council on Human Rights and on the adoption of the principle of the ‘responsibility to protect’ (ICSS 2001), and the right to intervene in case of genocide and major human rights violations (Einsiedel/Nitzschke/Chhabra 2008).

74.2.2 Debate on Human Security in the UN General Assembly

On 15 February 2008, the *Friends of Human Security* (FHS) submitted a compendium of human security-related initiatives and activities by its members and United Nations agencies, funds and programmes to the President of the General Assembly (A/62/695).⁷ On 22 May 2008 the UN GA held its first thematic debate on human security.

This debate was opened by the President of the UNGA, Srgjan Kerim (FYR of Macedonia)⁸ and with a keynote speech by HRH Prince El Hassan bin Talal (Jordan)⁹ to which three state groups (Slovenia for the EU, Iraq for the Arab group, and Tonga for the SIDS) and 22 member states, among them the co-chairs of the FHS (Japan, Mexico), six members of the HSN (Greece, Austria, Chile, Switzerland, Thailand, Canada) and 14 other countries from Asia (Mongolia, Turkey, Qatar, Philippines, Kazakhstan, Republic of Korea, Israel), Africa (Egypt, Sudan), Europe (Monaco, Portugal) and Latin America (Colombia, Cuba, Brazil) contributed.¹⁰

While none of the five permanent member countries in the Security Council contributed to the debate, two candidates for a permanent seat (Japan and Brazil) participated, although with different perspectives. Among the 25 state representatives, only Cuba openly rejected the concept, Brazil raised many questions, and Egypt and Colombia pointed to the principles of national sovereignty and nonintervention (Art. 2,7, UN Charter). A large majority of states pointed to individuals, (poor) communities, (vulnerable) people (women, children, elderly, migrants) or peoples but not to humankind as a referent object. Egypt, Colombia, Cuba, and Brazil stressed that the nation state remained the key referent of security and opposed the

⁷ This document (A/62/695) lists the “Human security-related initiatives and activities of the following members of the Friends of Human Security: Chile, Japan, Mexico, Slovenia, Switzerland and Thailand, and of 17 UN organizations: DESA, OSAA, FAO, IAEA, ILO, UNDP, UNESCO, UNFPA, UN-Habitat, UNHCR, UNICEF, UNIDO, UNIFEM, UNMAS, UNODC, WFP and WHO.

⁸ The President of the UNGA, Srgjan Kerim (Macedonia) pointed to a wide range of security dangers ranging “from hunger, poverty, to armed forces, human trafficking, environmental degradation, international terrorism and breaches of human rights of all kind.” He called for a “new culture of international relations - with the precept of human security at its core” that is “embedded in the UN’s ideals.” Source: <<http://www.un.org/ga/president/62/statements/humansecurity220508.shtml>>.

⁹ HRH Prince El Hassan bin Talal (Jordan) argued that human security should “contain the imperative of *human survivability* and *resilience*.” He reviewed current global conditions, distinguishing among nine security concepts of population, food, resource, environmental, energy, monetary, cultural, preventive, and state and market security. He suggested that “responsibility and authority must shift from governments downwards to individuals. Communities and civil society, and upwards to international organizations, regional systems and networks”, as states and markets are not equipped to address the many new security dangers of the present and future. Table 74.2: Systematic overview on referent objects, key values, nature of threats, and agents of insecurity and policy agendas referred to in the debate in the United Nations General Assembly on 22 May 2008. **Source:** speeches analysed by the author.^a

Country	Referent Object	Key goals and values	Nature of threats	Source	Policy agenda
Slovenia (EU, HSN, OECD, OSCE, NATO)	Individual	Promote people's rights and freedoms, protect them from both violent and non-violent threats	Hunger, poverty, infectious disease, environmental degradation, climate change, armed conflicts, crime, repression, terrorism, forced migration, human trafficking	Individuals Environment, states	Humanitarian Law (protection)
Iraq (Arab group)	Peoples, states have exclusive responsibility to ensure HS	Discussion of HS must respect principles of sovereignty, non intervention, right to self determination. Opposed to 'responsibility to protect'. achieve the MDGs	Disease, illiteracy, vulnerable groups (women, children), natural and man-made disasters, climate change, WMD, mines, arms trafficking, food and water security, international conflicts	Foreign intervention, terrorist groups	State sovereignty, respect of UN Charter, respect for traditional rules of diplomacy
Tonga (SIDS)	People, Poor communities	Right to development, protect livelihood and dignity of people, basic need of food, water, shelter, livelihood	Climate change, intensive flooding, coastal settlements, decline in food production, water stress, health implications, infectious diseases, malaria, dengue, increase migratory pressures, droughts, natural disasters	Human-kind, nature	Development Environment Climate change
Japan (FHS, OECD)	Individual, vulnerable people and communities	Freedom from fear, freedom from want, enjoy their rights, fully develop their potential culture of empowerment and protection	Wide range of threats, conflict, violence, poverty, underdevelopment, infectious disease, human rights violations, natural disasters		Human development
Mexico (FHS, OECD)	Human person	Political, legal, economic, social, cultural, civil, military means of protection of a person	Climate change, natural disasters food crises, food security scheme, early warning and proactive action small and light arms, control traffic of these weapons	Human-kind, nature	Disarmament development environment
Greece (HSN, OECD, OSCE, EU, NATO)	Human being, vulnerable population groups, women, children, elderly, migrants	People can live in security and dignity human rights education protecting women and children from violence freedom from fear, want, and freedom to live in dignity	Antipersonnel landmines, small and light weapons, threats from human conflict, natural disasters, poverty, discrimination, disease, scarcity of natural resources climate change, vulnerable regions, pre-existing conflicts, poverty, unequal access to resources, weak institutions, food insecurity, disease	Peoples, states, nature	Disarmament, human rights environment (climate change, disasters)
Mongolia	individual	Food and physical security, preventive measures to reduce vulnerability and minimize risk, human rights covenants, right to development, protection of people in violent conflict, of migrants, human life and dignity	Food crisis regionalism, ethnicity, mass migration, communal violence, ecological vulnerability	nature	Human rights development environment

Table 74.2: Systematic overview on referent objects, key values, nature of threats, and agents of insecurity and policy agendas referred to in the debate in the United Nations General Assembly on 22 May 2008. **Source:** speeches analysed by the author.^a

Country	Referent Object	Key goals and values	Nature of threats	Source	Policy agenda
Turkey (OECD, OSCE, NATO)	Peoples, states	Right of people to live in freedom and dignity, free from poverty and despair, strengthen human rights and development	Hunger, disease, natural disasters, environmental problems	Environment	Human rights development Environment
Monaco	Human being	Development agenda, civil society, protection of the child	Desertification and biodiversity loss, impacts of natural disasters on conflicts		Protection, development
Qatar (Arab League)		Fundamental right of all to education on human rights and democracy			Human rights education
Egypt (Arab League, AU)	Individual, peoples, state to provide security	Debate in UNGA to be based on nonintervention, development and human rights, human development, health education, protection of women and children, human development, dignity	Natural and environmental disasters, climate change, nuclear disasters, acquisition and stockpiling of nuclear weapons and other weapons of mass destruction, landmines, illicit trade with small and light weapons, integrated approach to food security		Human rights, development environment (climate change, disasters)
Austria (HSN, OECD, OSCE, EU)	People, individual, most vulnerable women	Freedom from fear and want, equal opportunity to enjoy their rights and develop their potential, live in dignity free of poverty and despair human rights education psycho-social rehabilitation of children	Cluster bombs, landmines children and armed conflict small and light weapons human trafficking women, peace and security climate change		Humanitarian law, human rights disarmament
Portugal (OECD, OSCE, EU, NATO)	People	Human dignity through human rights	Climate change and DRR strategies		Human rights, climate change
Chile (HSN, OAS)	Individual community	Human rights and dignity, security and development disarmament and humanitarian law human health, pandemics, children in conflicts	Natural disasters		Human rights, disarmament disasters
Colombia (OAS)	State has primary responsibility	Development, peace and security and human rights	Too broad, difficulty to find agreement on relevant threats		Development, peace and security human rights
Philippines (ASEAN)	Human person	Human security is at the heart of UN Charter quality of life	Food security, health security, environmental security, energy security, political security		

Table 74.2: Systematic overview on referent objects, key values, nature of threats, and agents of insecurity and policy agendas referred to in the debate in the United Nations General Assembly on 22 May 2008. **Source:** speeches analysed by the author.^a

Country	Referent Object	Key goals and values	Nature of threats	Source	Policy agenda
Cuba (OAS)	Human security an empty rhetorical phrase opposed	protect sovereignty of the state	unjust, unequal, unsustainable international order, unequal trade, impenetrable markets of industrialized countries, speculation, restrictions on technology transfer unsustainable production and consumption, climate change, nuclear weapons		
Switzerland (HSN, OECD, OSCE)	People	Humanitarian law, reduction of armed violence, conflict prevention	Armed violence impedes development, organized crime, gangs, gender-based violence small arms and light weapons	Armed conflict	Humanitarian law and disarmament
Thailand (HSN, FHS, ASEAN)	Vulnerable people	Freedom from want and fear, human trafficking MDGs, global partnership for development	human trafficking underdevelopment		Human development, protection
Brazil (OAS)	Sceptical of scope and purpose	Right to development, economic and social development, human rights education	Hunger and poverty, underdevelopment, climate change, MDGs, food prices, HIV/AIDS, gender-motivated violence		Development, human rights
Kazakhstan (OSCE)			Natural disasters, climate change, proliferation of weapons of mass destruction, water scarcity food crisis		Disarmament, climate change
Canada (HSN, OECD, OSCE, NATO)	World's people individual	Freedom, democracy, human rights, rule of law, protection of civilians, of children in armed conflicts, landmines, ICC, tribunals for human life, dignity, safety			Disarmament, human rights
Sudan (AU, Arab League)	Definition of HS must respect state sovereignty and its responsibility for HS	Social peace and stability, access to food, education, health, respect of fundamental rights and freedoms, right of refugees to return to their homes	Conflicts, civil wars, lack of respect of basic principles of international law and practices (e.g. right to self determination, non intervention)	Interventionist states	Define HS within the exclusive framework of UN Charter and by the GA
South Korea (FHS)	Individual community	need of people on the ground (economic security of people)	Food crisis violence against women, sexual violence		Development protection
Israel	People, individual		Climate change, environment, sustainable development, nonproliferation, human rights, armed conflict, culture of hate, crime prevention, terrorism and others		protection development environment

a. The author is grateful to Béchir Chourou for translating the statements of Iraq and Sudan from Arabic into English and for preparing them for inclusion in this table.

debate on humanitarian interventions (responsibility to protect). Among the key goals and values, the states referred to their respective priorities, national actions or international initiatives. All references to security dangers and concerns indicate a widening of the understanding of security. Of 25 countries (table 74.2), 12 states referred to climate change, ten mentioned natural disasters and food crises (food security), and six included diseases (health security) as human security issues.

This first thematic debate on human security in the General Assembly documents the diversity of responses, conceptual and policy approaches where most sceptics and opponents preferred to remain silent. In these statements a *widening, deepening and sectorialization* of the security concept could be mapped. The adherents to a narrow (violence, weapons, protection of vulnerable people, promotion of human rights) and of a wider conceptualization of human security (development and environmental agenda, climate change, natural disasters) stressed their different preferences and conceptualizations. Several members of the HSN also referred to their achievements to adopt the landmine convention (1999) and to negotiate an agreement to ban cluster bombs (2008). Canada, Austria, Switzerland, Slovenia, Greece, and Chile were quite successful in creating awareness for the protection of civilians in armed conflicts and addressing the role of women as victims and as actors on international peace and security.

74.2.3 UNDP: From Concept to Action

While the human security concept was conceptually developed by Mahbub ul Haq (Pakistan) and Amartya Sen (Bangladesh/India), many countries in the South and of the G-77 remained sceptical of all securitization efforts pertaining to development and environmental issues. The *Human Development Report* (HDR) of 1994 (UNDP 1994) “was written as a basis for UNDP input to the 1995 Copenhagen World Summit on Social Development” but UNDP failed to have its conceptual suggestions included on the agenda for the Copenhagen Summit and in its final documents. Its challenge of sovereignty “was deeply problematic for many southern states and for Russia and China” but also within UN bodies (e.g. in DPKO and in UNHCR) the “development side of security met with little enthusiasm” (MacFarlane/Khong 2006: 149).

Within UNDP the concept was applied in *National Human Development Reports* (NHDRs).¹¹ Jolly and Basu Ray (2006: 1–2) reviewed 13 NHDRs

focusing on “definitions, key components, originality of analysis, measures, statistics, methodology and policy conclusions.” They analysed in detail the case study on Afghanistan (chap. 94 by Tadjbakhsh). They concluded that these NHDRs “reinforce the value of human security as an operational approach to people-centred security that is able to identify priorities and produce important conclusions for national and international policy.” They argued with regard to the UN’s Peacebuilding Commission that such analyses “could help provide a frame of reference to ensure a broad approach to peacebuilding related to the wider issues of human security.”

In its contribution to the survey of activities of UN organizations on human security-related issues (CGA/62/695 of 15 February 2008), UNDP listed 25 regional, national, and sub-national reports. Its *Bureau for Crisis Prevention and Recovery* (BCPR) conducted security-related projects, on *Small Arms and Light Weapons, including Disarmament, Demobilization and Reintegration* (SALW); *Mine Action* (MA); *Conflict Prevention* (CP); and *Justice and Security Sector Reform* (JSSR). The survey offers a country-specific project list of the BCPR’s activities and of UNDP’s projects supported by the UN Trust Fund for Human Security. These projects have dealt with post-conflict recovery issues and hardly focused on the wide scope the initial all-embracing UNDP concept had suggested and the statements of the state representatives during the debate on 22 May 2008 have indicated.

74.2.4 UNESCO: Promoting Human Security (1996-2008)

Krause (2008: 46–47) argued that most activities in promoting human security in developing countries have been conducted by UNESCO through conferences in all parts of the world. The survey (GA/62/695: 37–43) that was done in preparation for the first debate on the human security concept in the General Assembly provides a comprehensive overview of all official statements, publications, and proceedings of international conferences. It offers a list of completed and ongoing projects as well as a list of eight UNESCO projects supported by the United Nations *Trust Fund for Human Security*. According to the

11 The 13 NHDRs covered Afghanistan, Latvia, Macedonia, Philippines, Moldova, Kyrgyzstan, Lesotho, Mozambique, Sierra Leone, Timor Leste, Bulgaria, Estonia, and Solomon Islands.

strategic objectives of UNESCO's medium term strategy, its member states emphasized the need to comprehend the multidimensional nature of the concept of human security. Accordingly, UNESCO addresses

the need to prevent conflicts at their source [...] through its global network of peace research and training institutions, thereby reinforcing human security." One of the Organization's expected outcomes is 'the elaboration of integrated approaches to human security at the regional, subregional and national levels, targeting the most vulnerable populations, including the prevention and resolution of conflicts."¹²

As part of its task in the areas of education, science and culture, since 1996 UNESCO has promoted the human security concept along two major fronts:

On the one hand, it is engaged in enriching the concept of human security through relating it to the actions of peoples, nations and international organizations. On the other, UNESCO is exploring different approaches to various complex and interconnected human security issues, taking into account the impact of globalization, the promotion of human rights, and concerns about security in the larger sense of the term (Foreword by Pierre Sané, UNESCO 2008: xiii).

As a platform for the international dialogue on human security, UNESCO avoided a strict definition and addressed instead "the specific needs ... of individuals and communities confronted by extreme poverty, conflict and post-conflict situations, or environmental degradation" but it also referred to fundamental freedoms: "human dignity", "the intellectual and moral solidarity of mankind" and it invoked "the spiritual and religious traditions" as part of the cultural diversity. Since 2000, UNESCO has promoted human security within the ethical, normative, and educational framework at the regional level by commissioning studies and organizing regional and sub-regional conferences thus to foster an inclusion of human security issues into the curricula at the national and local level. In preparation of its Medium-Term Strategy (2008-2013), UNESCO published two reports on its achievements between 1996 and 2008 and to assess emerging societal challenges (Sané 2008: xv, 2008a): a) *Human Security: Approaches and Challenges* (UNESCO 2008); and b) *Rethinking Human Security*.

Moufida Goucha reviewed UNESCO's action on peace and security during its first five decades (1945-1995) and in the last two medium-term strategies for 1996-2001 and 2002-2007, first framing security

(UNESCO 1998) within its 'Culture of Peace' agenda and from 2000 to 2007 as integrated approaches to human security (UNESCO 2008: xvii-xxiii).

An international meeting of directors of peace research and training institutions in 2000 helped to frame an "Agenda for Human Security in the Twenty-first Century" (UNESCO ¹2001, ²2005). In December 2005 a high-level meeting of experts and representatives of the *Human Security Network* (HSN) discussed an outline of its assessment report (UNESCO 2008) and addressed new challenges (UNESCO 2008a). In March 2006, an Intersectoral Group on Human Security was created to ensure that all activities on human security should be based on an interdisciplinary approach in which all UNESCO areas were represented.

The second publication on *Rethinking Human Security* (UNESCO 2008a) focused on: a) human security and human rights interaction (Benedek 2006, 2008); b) the ethical challenges of human security in the age of globalization (Burgess 2008); c) on conceptualizing the environmental dimension of human security in the UN (Brauch 2005, 2005a, 2006e, 2006h, 2008g); d) addressing the gender dimension of human security (Moussa 2008; chap. 90 by Oswald); e) building the agenda of human security: policy and practice within the *Human Security Network* (Krause 2008, 2008a); f) on basic elements of a policy framework for human security (Oquist 2008), and g) on the uncertain future of human security in the UN (Owen 2008).

UNESCO's (2008) assessment report reviewed UNESCO's action in the field of human security (pp. 1-78), before it discussed (pp. 79-112) UNESCO's regional and sub-regional recommendations for the promotion of human security issues as they evolved from the regional meetings and publications examining the ethical, normative, and educational frameworks in Africa (Goucha/Cilliers 2001; van Wyk 2007), in Arab States (Chourou 2005; UNESCO 2007), in East Asia (Lee 2004, UNESCO 2004), Central Asia (Tabyshaliev 2006) and South-East Asia (Acharya 2007), in Latin America and the Caribbean (Goucha/Rojas 2003; Fuentes/Rojas 2005), as well as in Eastern Europe (Tadjbakhsh/Tomescu-Hatto 2007) and in Western Europe (Burgess et al. 2007).

In early 2008, UNESCO listed these five ongoing projects that focused on: 1) *Promoting Human Security in the Arab States Region*¹³; 2) *Promotion of Human Security Concept in Rural Areas in China* (GA/62:695: 41); 3) *Human Security in China: A North-East Asian Perspective* (GA/62:695: 41-42); 4) *Con-*

12 31 C/4 Approved, Medium-Term Strategy 2002-2007, Paris, France, November, 2001.

tributing to the eradication of poverty by strengthening human security in Benin, Burkina Faso, Mali, Niger and Senegal (GA/62:695: 41–42).

In close cooperation with other UN organizations and supported by the United Nations Trust Fund for Human Security, UNESCO has conducted projects on poverty reduction in Bosnia Herzegovina (with UNDP), on the improvement of human security in São Paulo (Brazil) in cooperation with UNFPA, WHO and UNICEF; a programme on the sustainable rehabilitation of war victims in Burundi (with UNICEF, UNIFEM and UNDP); on basic education and vocational training for children and youth at risk in Cambodia; on capacity building for integrated psychological, pedagogical, and medico-social rehabilitation of school children and educational personnel in Chechnya (with WHO); on the rehabilitation of boarding schools and provisions of refresher training courses for headmasters and teachers in the Dzud affected Gobi Desert provinces in Mongolia; on a community learning centre in Nepal; and on promoting the human security concept in the Arab Region (A/62/695: 43).

These regional discussions launched by UNESCO brought regional experts together and enhanced their awareness for a different conceptualization of security, what has been reflected in the curricula of some universities (e.g. in Thailand) and may trigger future research. While these initiatives have focused on the educational and research sector, their impact on present or future policy agendas, programmes, and their implementation will be difficult to assess.

74.2.5 United Nations University

Within the United Nations system, the United Nations University in Tokyo¹⁴ has addressed scientific issues that were related to issues on the human security research agenda. In its Strategic Plan 2000, UNU (2000: 7–9) referred to “human security” as one of four powerful ideas for the new millennium, besides “development as freedom”, “risk societies”, and “comprehensive development”. The *UNU Strategic*

Plan 2002 stressed the “need for a stronger global governance system” focusing on “the maintenance of world peace, human security and development as well as the sustainable management of the world’s resources” to provide “global public goods, such as financial stability and environmental security, and fight ‘global public bads’ such as organized crime, terrorism, and illegal trade” (Brauch 2005, 2005a).

Quoting van Ginkel (2000), the former Rector of UNU, “in policy terms, human security is an integrated, sustainable, comprehensive security from fear, conflict, ignorance, poverty, social and cultural deprivation, and hunger, resting upon positive and negative freedoms.” UNU’s former Vice-rector Thakur (2004: 347; 2006) rejected both a national security concept and an all-inclusive security agenda.

UNU never had a human security programme. In October 1996 UNU organized a global seminar on *Our Planet and Human Security* (Inoguchi/Serita 1996).¹⁵ Only one volume of UNU-Press on *Asia’s Emerging Regional Order* addressed the need to reconcile traditional and human security (Tow/Thakur/Hyun 2000). Besides Ramesh Thakur (2004, 2006, 2008), Edward Newman (Newman/Richmond 2001) and Albrecht Schnabel (2004, 2008) addressed human security-related issues in their own publications: There was some cooperation between UNU and the *Human Security Commission*. UNU has also contributed financially to launching the *Human Security Report* (Human Security Centre 2005).

The United Nations University Institute on Environment and Human Security (UNU-EHS) in Bonn was established in late 2003 to develop the environmental dimension of human security further, not only the scientific conceptual debate, but also its operational consequences for capacity building primarily to enhance governance capabilities within the UN system and in the member states. From its perspective, the concept of human security is closely related to vulnerability, “the latent threat that some dimensions of human insecurity could manifest themselves in crises and disasters”. In a speech to the World Conference on Disaster Reduction (WCDR) in January 2005, UN Undersecretary-General van Ginkel emphasized to re-

13 This project has been jointly implemented by the League of Arab States (LAS), the Human Security Unit (HSU/OCHA) and UNESCO. For details see at: GA/62/695

14 See for details at: <<http://www.unu.edu/>>. Its “Peace and Governance Programme” has worked in the past on human security issues, although it presently does not refer to human security as a research item.

15 This report addressed the relationship of human security with sustainable development (Ayala-Lasso 1996), women and human rights (Mongella 1996), the linkage with world security (Iokibe 2006), on human development and the mismanagement of tropical forests (Kazadi 2006) on globalization and human development (Kaul 1996) and on the UN in the post-Cold War international order (Roberts 1996).

duce “vulnerabilities and improving coping capacities, through education and capacity development, strengthening response preparedness and vigilance.” He pointed to the activities of UNU-EHS “to create indicators to measure the vulnerability of communities to disasters. ... Such assessments will help policy-makers set priorities for disaster prevention” (cited in Birkmann 2006).

Through UNU-EHS, the university is working to anticipate the cumulative effects of such long-term, creeping environmental disasters for humankind as desertification, steadily falling levels of groundwater, land degradation, and other consequences of environmental neglect. Janos Bogardi, Vice-rector a.i. for Europe, co-authored the concept of ‘freedom from hazard impact’ (Bogardi/Brauch 2005).¹⁶

74.2.6 Pacesetters of the Human Security Concept

Krause (2002, 2008) has critically analysed to which extent the concept of human security had an innovative impact on foreign and security policy innovations of states in international organizations that have resulted in a rather narrow policy agenda that has focused on issues of disarmament (antipersonnel landmines, small and light weapons, cluster bombs), organized violence, and on the protection of civilians (women and children) in armed conflicts related to ‘freedom from fear’ but also on democratic governance, rule of law, and human rights education. Krause (2008: 45–46) correctly noted that a significant contribution to the conceptualization of human security was made by states as part of specific policy initiatives and by international organizations rather than by civil society and individual scholars. To a significant degree the human security agenda has also been donor driven.

For the agenda setting for human security issues within the UN system, three countries had been the pacesetters: Canada (chap. 83 by Black/Swatuk) and Norway as promoters of a more narrow approach to human security that focused on containing violence and furthering human rights, and Japan as a proponent of a wider conceptualization that was closer to UNDP’s initial very wide concept that linked ‘free-

dom from fear’ with the development agenda of ‘freedom from want’.

For the Japanese Foreign Ministry (1999, 2000; chap. 84 by Shinoda) human security “comprehensively covers all the menaces that threaten human survival, daily life, and dignity ... and strengthens efforts to confront these threats,” while for the Canadian Department for Foreign Affairs human security recognizes “that lasting security cannot be achieved until people are protected from violent threats to their rights, safety or lives” (Alkire 2003: 30–31; McRae/Hubert 2001; Mack 2004; Krause 2004).

For the *International Commission on Intervention and State Sovereignty* (ICISS 2001) in its report: *The Responsibility to Protect*, human security meant: “their physical safety, their economic and social well-being, respect for their dignity and worth as human beings, and the protection of their human rights and fundamental freedoms.” During the first decade of the *Human Security Network* (HSN) the policy agendas gradually widened to comprise all four pillars (table 74.1) and associated policy agendas of the human security concept (chap. 75 by Fuentes/Brauch).¹⁷

Since June 2006, Japan has promoted the *Friends of Human Security* (FHS): “as an unofficial, open-ended forum based in New York ... to provide an informal forum for United Nations Member States as well as relevant international organizations to discuss the concept of human security ... to seek a common understanding of human security and explore collaborative efforts for mainstreaming it in United Nations activities.”¹⁸

The *Human Security Doctrine for Europe* (Glasius/Kaldor 2005) was the result of the *Study Group on Europe’s Security Capabilities* that was convened by Mary Kaldor at the request of EU Secretary-General Javier Solana in 2003.¹⁹ The report called for a fundamental rethinking of Europe’s approach to security. Among its key claims and suggestions are:

17 The activities of the HSN are well documented at: <<http://www.humansecuritynetwork.org/>>.

18 See for an announcement in May 2006 in Bangkok of Japan’s intention to launch the FHS; at: <http://www.mofa.go.jp/policy/human_secu/state0606.html>.

For the summaries of the chair of the first three meetings at: <http://www.mofa.go.jp/policy/human_secu/friends/index.html>. Japan chaired the first FHS meeting in October 2006, the second and third meetings in 2007 were co-chaired with Mexico. The fourth meeting in April 2008 was attended by representatives of 86 countries and 18 international organizations.

16 See: Janos Bogardi, “Evolution of the Human Security Paradigm”, presentation at the International Seminar of the Greek Presidency of the Human Security Network, Athens, 29–30 May 2008; at: <[http://www2.mfa.gr/softlib/bogardi.rpps#339,4,Evolution of the security paradigm](http://www2.mfa.gr/softlib/bogardi.rpps#339,4,Evolution%20of%20the%20security%20paradigm)>.

Human rather than nation-state security should be at the heart of European policy. Instead of defeating enemies or pacifying warring parties, EU missions should focus on protecting civilians, through law enforcement with the occasional use of force. To carry out such missions, the European Union needs an integrated civil-military force of 15,000 personnel, at least one third of whom would be civilians with various professional skills and experiences. ... The Study Group has developed seven principles for Europe's security policy that apply to prevention, conflict and post-conflict contexts alike and which are intended to guide the actions of high-level EU officials, politicians in the member states, diplomats, and soldiers and civilians in the field alike. In order to carry out operations based on human security, the EU will need new greater human resources and skills. At present, Europe has 1.8 million people under arms but only a fraction can be deployed in crisis zones. Police and other civilian professionals will also be needed.²⁰

While members of the European Commission have repeatedly referred to the human security concept, so far no major initiatives have been taken to implement the policy suggestions made by this study group. At the 17th Japan-EU Summit, on 23 April 2008, both partners included a reference to human security in their joint press statement: "Japan and the EU reaffirmed their intention to cooperate in the area of human security by promoting this concept in the General Assembly of the United Nations and other international fora, and to pursue dialogue on human security."²¹ Slovenia during its EU presidency opened the discussion on human security in the General Assembly on 22 May 2008, noting that human security has "been acknowledged and mainstreamed" into the "2005 EU Consensus on Development," and into its 2007 communication on humanitarian assistance, and that several EU mechanisms contribute both to 'freedom from fear' (Common Foreign and Security Policy, European Security and Defence Policy, EU Civil

Protection Mechanism, Stability Instrument, Crisis Management tools) and 'freedom from want' (ECHO, EU Development Cooperation).²²

In substance, several initiatives by the HSN and FHS both within the UN System (UN Security Council, General Assembly, Peacebuilding Commission) but also outside (e.g. the antipersonnel landmine convention (1999) and the convention against cluster bombs (2008) have succeeded despite the opposition of several permanent members of the UN Security Council (Bosold 2008).

The human security concept has offered smaller and medium countries an opportunity to promote their humanitarian agenda in cooperation with the European Union, Japan, and with member countries of the G-5 and G-8 while many members of the G-77 have resisted efforts to widen and to deepen the security concept, fearing that this may be used by powerful countries in the North to legitimate interventions into the internal affairs of countries in the South. Specific human security activities of UN member states have focused on the linkages with development (Bumtawi-Sam 2008), on human rights (Benedek/Kettemann 2008), on intervention and the responsibility to protect (Thakur 2008). Human security concepts and agendas have also been discussed in Africa (Hendricks 2008), Asia (Caballero-Anthony 2008), in Latin America (Stanley 2008), and for the Near and Middle East (Chourou 2005; Bastý 2008).

74.3 Human Security as a Scientific Concept

The policy debate within the UN system and the initiatives by members of the HSN and participants of the FHS were instrumental for an emerging scientific discourse on human security. In their "archaeology of human security" MacFarlane and Khong (2006: 19–138) traced the conceptual tension between the state and the people with regard to security from the pre-modern era through the absolutism and constitutionalism in the Westphalian system, the age of nationalism to the period between the world wars, and during the Cold War and the evolving critique of national security.

In the scientific discourse, since the 1980's, already prior to the global turn, a few scholars called for an expanded concept of international security (Westing

1986: 183–203) and for a comprehensive or human security approach (Westing 1993).²³ But the scientific human security discourse was triggered by the UNDP (1994) HDR in political science, international relations (Ulbert/Werthes 2008; Fabra Mata 2007)²⁴, and especially in the peace studies (debates in *Security Dialogue*) and in the development community (McGrew/Poku 2007), but also in geography (Lonergan 1999; Bohle/O'Brien 2007), international law (von Tigerstrom 2007), in education (Nelles 2003), philosophy (Fabra Mata 2007), in theology (Eisen 2008), and even in the health sciences (chap. 38 by Leaning). As this debate has been well documented elsewhere only a few controversies will be highlighted.²⁵

Alkire (2003: 15–39; 2004) pointed to the many different definitions of human security as: “a) safety from chronic threats such as hunger, disease and repression; b) protection from sudden and hurtful disruption in the patterns of daily life”; of the *Commission on Human Security* (2003) that focused on threats from both poverty and violence aiming: “to protect the vital core of all human lives in ways to enhance human freedoms and human fulfilment,” a goal that should be realized “by joint strategies of protection and empowerment.”

The encompassing human security concept suggested by UNDP (1994) was critiqued as being too wide for analytical research (Mack 2004). The narrow concept of ‘freedom from fear’, represented by the *Human Security Network* (HSN) requires from the states “to provide security – in order that individuals can pursue their lives in peace” (Krause 2004). For the security studies community, the state remains the major referent object that is to be secured while both human security visions deal with the protection of the individual. Mack (2004) argued that the state-centred security paradigm cannot deal with threats to the individual emanating from the state, and that it can hardly explain state collapse. The first *Human Security Report* (2005) adopted “a narrowly focused definition of

human security in which the threat is the relatively conventional one of political and criminal violence” (Mack 2004).

Within international relations, the human security concept has remained controversial. While many neo- or structural realists and the strategic studies community (Paris 2001, 2004), as well as ‘state-centred’ peace researchers (Buzan 2000, 2002; Müller 2002; Brock 2008) have rejected the human security concept, authors with liberal and constructivist perspectives and from peace research have rallied behind this concept. However, some proponents are critical of a wide concept as ‘freedom from want’ (Krause 2004; Mack 2004) and have argued instead for “pragmatism, conceptual clarity, and analytic rigor” (Owen 2004: 375). But most authors of a forum in *Security Dialogue* (2004) supported a wide agenda that includes ‘freedom from fear’ (violence) and ‘freedom from want’ (development).

Human security as an analytical and theoretical tool differs from human security as a political mandate. Uvin (2004) uses the concept as a “conceptual bridge between the ... fields of humanitarian relief, development assistance, human rights advocacy, and conflict resolution” (Owen 2004). For Hampson (2004) human security gives voice to the politically marginalized, while Acharya (2004) interpreted it as a response to the globalizing of international policy, and for others human security is a response to genocide and limits of sovereignty justifying humanitarian interventions.

Newman (2001) distinguished four interpretations of human security referring to basic human needs, an assertive or interventionist focus, social welfare or a development focus, and new or non-traditional security issues like drugs, terrorism, small arms, and inhumane weapons. The victims of *human security challenges* have been: “1) victims of war and internal conflict; 2) persons who barely subsist and are thus courting ‘socio-economic disaster’; and 3) victims of natural disasters” (Suhrke 1999) that create severe humanitarian emergencies.

Thomas and Tow (2002, 2002a) distinguished general human security ‘threats’ such as hunger and disease, and specific ones, such as “single actions that have an immediate effect on the safety or welfare of victims and demand immediate remedy”, to which ‘peacekeeping’ emerges as a major response along with peace-enforcement measures. For humanitarian interventions human security and traditional responses to crises overlap. They conclude that human security could be considered “a valid paradigm for

24 Fabra Mata, Javier: “Playing the Right Game? Human Security Research and its Implications in Policy-making” Paper presented at the annual meeting of the International Studies Association 48th Annual Convention, Chicago, Chicago, IL, USA, Feb 28, 2007; at: <http://www.allacademic.com/me-ta/pr180091_index.html>.

25 In the academic human security debate no common definition on human security has emerged after twelve years. Alkire (2004: 359) noted more than 30 definitions.

identifying, prioritizing and resolving emerging transnational security problems”, and that the model offers ways to respond to these challenges by “safeguarding and improving the quality of life” for individuals and groups.

Bellamy and McDonald (2002) argued that this effort to make human security policy relevant “risks losing its emancipatory potential.” They preferred the approach suggested by Thomas (1999) that human security should stress “the security of the individual and that security is achieved only when basic material needs are met.” They suggest that the focus of human security should be humans (basic human needs) and their ability to “participate in collective endeavours,” and the state “as the primary agent of human insecurity.” Thomas and Tow (2002) argued that “state security and human security are interlinked” and that “state security is a means of providing human security,” but that “outwardly aggressive and inwardly repressive regimes can be a major source of human insecurity.” Mack (2002) observed that “it is impossible to explore causal relationships between violence, on the one hand, and indicators of underdevelopment, on the other, if all are subsumed under the rubric of human insecurity.”

To overcome the dispute between the proponents of a narrow and a wide human security concept, Owen (2004) suggested combining the wide definition of UNDP (1994) with a threshold-based approach “that limits threats by their severity rather than their cause.” He suggested that each category of threats should be “treated separately for the purpose of analysis.” For Owen (2004) “human security is the protection of the vital core of all human lives from critical and pervasive environmental, economic, food, health, personal and political threats” regardless of whether people are affected by floods, communicable disease, or war, but all those threats would be included “that surpass a threshold of severity [and] would be labelled threats to human security” (2004).

Fukuda-Parr (2003: 1–13) referred to several new threats to human security in the era of globalization: a) global crime; b) human trafficking; c) instability and contagion in financial markets; d) labour market insecurities and threats to job security; e) spread of diseases; and f) conflicts within national borders. From this perspective, human security requires a strategy for better social protection.

Khagram, Clark, and Raad (2003: 107–135) discussed both environmental threats (and their impacts on human survival, well-being, and productivity) and environmental opportunities for human security. Envi-

ronmental change can have direct and immediate effects on well-being and livelihoods; it can also impact on health, economic productivity, and political instability. Environmental threats can affect “individuals, families, communities, social organizations, identity groups (women, children), diasporas, governments and biological species.” Also, a single environmental threat “can have potentially adverse effects at multiple scales from the household to the planetary.” The effects (e.g. of climate change) can be both local and global, and they may impact today or in the future. On the other hand, environmental protection, cooperation, and peace-making can improve human security.

Mary Kaldor (2007: 182–187) who headed the *Study Group on Europe's Security Capabilities* (Glasius/Kaldor 2005) placed human security “at the sharp end of human development.” In her view: “It is about crisis management. It includes both civilian and military elements; it offers a way to act, a set of principles for crisis management.” In order to put the concept into practice she suggested five principles (as both ends and means) for the implementation of human security “in a continuum of varying degrees of violence that always involved elements of both protection and reconstruction:” 1) the primacy of human rights; 2) legitimate political authority; 3) multilateralism; 4) the bottom-up approach; and 5) a regional focus.

Kaldor (2007: 190–191) claimed that even after the new wars have been stabilized, “individuals still experience high levels of physical insecurity as a consequence of high crime rates, high human rights violations and high levels of violence against women.” Furthermore, she argued that “physical insecurity is linked with material insecurity. New wars involve high levels of population displacement, rapid urbanization, loss of rural livelihoods, destruction of infrastructure and productive assets, and greater vulnerability to natural disasters.” She suggested that a human security approach to these new security dangers “would aim both to stabilize conflicts and address the sources of insecurity.” This requires public security, Kaldor argued, based on the rule of law and effective law enforcement, what implies for international organizations: a) an expanded international presence; b) new human security forces; and c) a legal framework.

The economic and social priorities for conflict prevention include, in Kaldor’s (2007: 193–195) view: a) combining humanitarian and development assistance; b) creation of legitimate employment and self-sustaining livelihoods; c) institution-building, includ-

ing the rule of law; d) attention to the importance of infrastructure and public works; e) education and social services; f) generating tax revenues. She concluded that a human security approach could benefit development by: a) “providing the conditions (physical safety, rule of law and sustainable institutions) that are integral to development;” b) focusing on human development and strengthening weak institutions; and c) stressing the needs of individuals and communities and thus protecting the humanitarian space.

There has also been an intensive scientific discourse on human security concepts and issues in and with scholars from developing countries, many in the framework of regional conferences organized by UNESCO. For Neff (2003: 40), a Latin American scholar teaching in Canada, human security “is founded on the notion of mutual vulnerability” and for him the “central theme of human security is the reduction of collective and shared risk through analysis, decisions, prevention and action at reducing the causes and circumstances of insecurity.” Human security “focuses on the causes of violence and stresses the need to control the latter by attacking its roots and the factors of its recurrence, not only its expression.”

For Hugo Palma (2003: 111), a Peruvian diplomat, human security deals with internal security and has two aspects that refer to “hunger, sickness and repression, but also to absolute disruption of daily living,” like “natural catastrophes or series of crises that can lead to human tragedies.” For Palma, “human security can be threatened by economic, food, health, personal security, environmental, community or cultural and political problems.”

Miriam Kornblith (2003: 321), a researcher from Venezuela, suggested to develop an objective and subjective human security index and pointed to several challenges for human security in Latin America and in the Caribbean.

Adrian Bonilla, an academic subdirector of FLACSO from Ecuador (2003: 337–351), applied the concept to the fight against drugs in the Andean region, while Ernesto López (2003: 353–363), a scholar from Argentina, outlined a human security agenda for the MERCOSUR dealing with both ‘freedom from want’ and ‘freedom from danger’.

Chari and Gupta (2003: 1–21) from India noted the potential dichotomy of ‘national’ and ‘human security’ if the state and the individual are at variance. In the UNDP (1994: 8) definition “individuals and collectives ... were made the referents of security, and threat perceptions were reformulated in this perspective.”

For the former Pakistani finance minister, World Bank and UNDP official, Mahbub-ul Haq, human development was the bedrock of security and he called for “securing people from economic deprivation, disease, hunger, social conflict and environmental degradation.”

Chari and Gupta (2003: 8–9) listed among the major threats to human security: “challenges of globalization, questions of energy security, mass migration and gender discrimination.” They pointed to “the right to live” as the basic value of human security, and “violence – physical, socio-economic, or psychological – directed against citizens exacerbates human insecurity.” For them, human security “is inextricably linked to human rights, human development and human governance” and “the state should be vitally concerned with human security to ensure its own security.” For South Asia, a further erosion of human security arises from the environmental degradation of water, forests, farmland, and fisheries. They define human security as freedom from fear (anxiety) and want (certitude, protection). To avoid a trivialization of human security by overextending it, Chari and Gupta (2003: 16–17) have proposed:

1. to distinguish “between threats to human security that are amenable to state intervention and others that must be left to public and social action;”
2. non-military threats to human security may become legitimate as threats to state or societal interests if they “meet rigorous criteria for securitizing those threats and disaggregating them into their component sectors;” and
3. threats to human security may be linked with other threats, e.g. environmental degradation can trigger internal displacement of people leading to growth in slums where many people live in fear and suffer from want, thus the effects of environmental degradation lead to human insecurity.

Abdus Sabur (2003: 35–51; chap. 76 below) from Bangladesh saw a major outcome of the rethinking of security since 1990 in “the idea that the security of an individual in terms of his physical safety, human dignity and development is as important as the security of the state” (Sabur 2003: 37). While national security requires investment in the military, “human security needs investment in human development and humane governance.” But with regard to South Asia, Sabur (2003: 47) has noted a lack of attention on human security so far while traditional security issues have dominated. While the primary responsibility for ensuring human security remains with the state, within

the state, non-state actors, civil society, and NGOs play a major role in ensuring human security also regarding actions caused by the state.

Adil Najam (2003: 1–24), a Pakistani scholar who is teaching in the USA, analysed many roots of human insecurity in South Asia that is the world's poorest region (with a GNP/capita below that of Sub-Saharan Africa), the world's most illiterate region; and the region with the highest human deprivation. Based on a project with colleagues from India, Pakistan, Bangladesh, Sri Lanka and Nepal on non-traditional security issues, Najam (2003: 21–22) drew five lessons:

- For South Asia ... environment and security are at best conceptualized within the context of sustainable development;
- The challenge of environment and security in South Asia is principally a challenge at the domestic, even local, level; but it is a challenge common to the region;
- The challenge of environment and security in South Asia is ... not just a problem of resource endowments or geography but, quite distinctly, a problem of institutions and governance; it is only because the issue is the latter rather than the former that we have the ability to change the situation;
- The possibility of an eruption of interstate violence in South Asia over environmental issues is slim; however, given the region's history of distrust and dispute between nations, environmental differences can add to existing tensions and apprehensions, thereby perpetuating the general sense of insecurity that pervades interstate relations in the region;
- There is the potential – albeit small – for a generation for security relations in South Asia, based on the principles of mutual trust, harmony and cooperation rather than on legacies of distrust and dispute, to emerge there around the nexus of environment and security.

Besides Latin America and South Asia, the concept has also been widely debated in Africa. The UN *Office of the Special Adviser on Africa* (OSAA 2005) in a report: *Human Security in Africa* discussed in the framework of the Commission of Human Security's report (CHS 2003) the challenges to human security posed by conflicts and for people on the move. It specifically addressed problems of protection and empowerment of women as well as policy issues of recovering from violent conflict, of governance and participation, of food and health security and of edu-

cation. It also offered many specific recommendations for action. But the study hardly reflected the contributions by African scholars to this debate.

On the political level the debate on human security in Africa was triggered by a *conference on security, stability, development and cooperation* (CSS-DCA) in Kampala in 1991 where 500 African politicians and leaders adopted the Kampala Document that formed the basis for the comprehensive security agenda of the African Union. The human security concept influenced both the *New Partnership for Africa's Development* and the adoption of a *Common African Defence and Security Policy* (2004). While there was agreement on the goals of human security there was disagreement on the policy priorities for achieving them (Hendricks 2008: 137–142).

In June 2001, the *International Institute for Security Studies* (ISS) in Pretoria hosted UNESCO's regional conference on *Peace, Human Security and Conflict Prevention in Africa* (Goucha/Cilliers 2001: vi–vii) that addressed four complementary objectives that were considered as crucial for furthering human security in Africa:

- promoting human capacity-building in the member states of the region;
- helping African countries to establish a strategy for the prevention of HIV/AIDS and other contagious diseases;
- mobilizing and acting as a catalyst for international cooperation in support of initiatives by African Member States; and
- promoting the active participation of communities and representatives of civil society in the planning and implementation of development programmes.

The Pretoria meeting proposed to reinforce many dimensions of human security, including “the relation between human security and the culture of peace, the need for further research on human security indicators, the function of early-warning systems, the policy-building on African parliamentarians, common legislative agendas as HIV/AIDS, poverty, environment, and human rights” (Goucha/Cilliers 2001: vii). After a theoretical conceptualization of human security based on scholars from Europe and Southern Africa by Sagaren Naidoo (2001) all other contributions addressed policy issues of potential relevance for human security.

A study by Hussein, Gnisci and Wanjiru (2004)²⁶ for the Sahel and West Africa Club offered an overview of human security concepts and initiatives and raised the implications for West Africa. It addressed two main issues of a) security system reform (SSR)

and b) regional peace initiatives, and identified these strategic challenges of:

- translating the concept of human security into practice,
- enhancing security sector reform,
- laying the foundation for a coherent security regime in Africa,
- operationalizing the role of ECOWAS in stabilization and peacekeeping efforts,
- achieving greater self-sufficiency in peacekeeping operations,
- coordinating military assistance regionally,
- halting the proliferation of small arms, light weapons and antipersonnel mines.

With the support of the Danish Embassy in South Africa Keith Muloongo, Roger Kibasomba, and Jemina Njeri Kariri (2005) published case studies of seven countries in Southern Africa that analysed the linkage between poverty and human security (Mutesa/Nchito 2005), on multipolarity politics and human security (Mpagala/Lwehabura 2005; Mataure 2005), on security of the young (Kaungulu Ngoy 2005; Correira de Barros 2005; Mlambo 2005) and on rural insecurities (Dzimba/Matooane 2005).

This selective review of definitions of human security and of threats for human security as well as issue areas of relevance for human security documents both the diversity and the lack of a clear consensus that did not facilitate the communication with policy-makers and their efforts to move from declaratory statements to concrete policy initiatives and actions. Thus, after 14 years of debate on human security in the social and human sciences the conceptual discourse remains inconclusive and the used human security definition depends on the approach, preferences of the respective author or donor.

Both in the policy debate and in the scientific discourses on human security the environmental security dangers and concerns were in most cases ignored. But new challenges are being posed by the environmental dimension of human security (Barnett 2001; Brauch 2005, 2005a, 2006, 2006e, 2006h, 2008g) that have led to a proposal for a fourth pillar of human security that is gradually being taken up by governments in the HSN (e.g. by Thailand in 2006 and Greece in 2008).

26 This *Issues Paper* offers a good overview of the contributions of African and international scholars and a comprehensive list of organizations working on these issues in Africa and in the rest of the world.

74.4 Policy Debates, Pillars, and International Agendas

Kofi Annan argued (2005) that human security should be based on three pillars of ‘freedom from want’ (human and sustainable development agenda), ‘freedom from fear’ (the traditional peace and security agenda), and ‘freedom to live in dignity’ (democracy, rule of law and human rights agenda). Stimulated by the *Study Group for Europe’s Security Capabilities* (2004) Ulbert and Werthes (2008: 19) also referred to three dimensions of human security as a) humanitarian security (freedom from fear), b) equality and social justice (freedom from want), and c) liberty and human rights (rule of law or ‘Rechtssicherheit’).

In analogy to Franklin D. Roosevelt’s four basic freedoms in the Atlantic Charter (1941) of the freedom of speech and expression, of the freedom from fear and want, Bogardi and Brauch (2005; chap. 1 by Brauch) suggested to add a fourth conceptual pillar of ‘freedom from hazard impact’ by reducing vulnerability and enhancing coping capabilities of societies confronted with natural and human-induced hazards by empowering people and enhancing their resilience (UNU-EHS 2004, 2008; Oswald 2008, 2008a).

74.4.1 Human Security Agendas

These four pillars of a wide human security concept refer to four different human security agendas that have been listed by the UN member states participating in the first thematic discussion on human security on 22 May 2008. Table 74.3 offers an overview of these four pillars and the associated policy agendas. While in the first three pillars human beings are conceived as victims of multiple security dangers caused by their own state (repression), during internal violent conflict and wars, and of economic, social and legal deprivation, in the fourth pillar human beings (as individuals) and humankind (as a species) are considered both as a cause of new environmental security dangers (due to anthropogenic climate change) and as a victim of human-induced natural hazards (storms, floods, droughts, heat waves, cold spills). While a huge scientific and policy-related literature exists on the first three pillars, the fourth conceptual pillar of ‘freedom from hazard impact’ is increasingly being discussed by the natural hazard community (UNU-EHS, UN-OCHA, UN/ISDR, HSN). Thus, the following section will primarily focus on this fourth evolving human security pillar.

Table 74.3: Four Pillars of Human Security. **Source:** The table was stimulated by Ulbert and Werthes (2008:21) who developed it based on Hampson/Daudelin/Hay/Martin/Reid (2002: 33).

74.4.1.1 The Humanitarian Agenda

The urgency in addressing the humanitarian agenda has been stressed in many reports of the former Secretary-General Kofi Annan (1999, 2005). He suggested that “the United Nations must be transformed into the effective instrument for preventing conflict” by addressing these priorities: a) to prevent terrorism; b) to achieve progress on both disarmament and non-proliferation; c) to reduce the prevalence and risk of war; d) to agree on principles with regard to the use of

force; e) to achieve more effective cooperation to combat organized crime; f) to prevent illicit trade in small arms and light weapons, and g) to remove the scourge of landmines.

The latter was achieved outside the Conference on Disarmament (CD) and against the opposition of three permanent members of the Security Council under the joint leadership of Norway and Canada that both took the initiative in 1999 to establish the HSN. The major activities of the HSN have focused on the humanitarian agenda on those issues of disarmament

where no progress was possible within the Conference on Disarmament: on antipersonnel landmines (Matthew/Mc Donald/Rutherford 2004), on small and light weapons (Gasparin Alves/Cipollone 1998; Pirseyedi 2000; Kytomäki/Yankey-Wayne 2005), and on cluster bombs.

The second area of activities has focused on the *protection* of civilians in armed conflict (Dedring 2008), especially of women, children, and the elderly (Oswald 2008). Many of these activities were supported by the *International Federation of the Red Cross - Red Crescent Society* (IFRC-RCS) and by humanitarian organizations that support a prohibition of indiscriminate conventional weapons (cluster bombs, laser weapons) by creating new legal instruments of humanitarian law (Brauch 2003: 27). A third area dealt with the *empowerment* of women in areas of peace and security (UN SC Res. 1325) and with issues of gender security, and a fourth focus was on the responsibility to protect (ICISS 2001; Thakur 2006, 2008: 110-122).

74.4.1.2 The Human and Sustainable Development Agenda

In the post-Cold War period, the development and security linkage has been addressed by scientists and practitioners in both communities (Uvin 2008, Klingebiel/Roehder 2008; Katseli 2008). Mahbub ul Haq's concern with human development was instrumental for the adoption of the human security concept by UNDP (MacFarlane/Khong 2006; Jolly/Das Ray 2006) and this approach was developed further in the report of the *Human Security Commission* (CHS 2003). It has served UNDP as a conceptual basis for the assessment of the development policies and practices of several countries, and many specific projects have been conducted by UNDP and many national and multilateral development agencies.

Kofi Annan (2005) referred to the shared vision of development that was adopted with the *Millennium Development Goals* (MDGs) that were reaffirmed in 2005, with the "global partnership for development" that "is grounded in mutual responsibility and accountability - developing countries must strengthen governance, combat corruption, promote private sector-led growth and maximize domestic resources to fund national development strategies, while developed countries must support these efforts through increased development assistance, a new development-oriented trade round and wider and deeper debt relief."²⁷ Annan referred to the following policy priorities: a) to ensure *environmental sustainability*; b) to

develop tools for mitigating *climate change*; c) to take concrete steps on *desertification* and *biodiversity*; d) to adopt stronger mechanisms for *infectious disease* surveillance and monitoring and a world-wide early warning system on *natural disasters*; e) to support *science and technology* for development, *regional infrastructure* and institutions, reform of *international financial institutions*, and more effective cooperation; and f) to manage *migration* for the benefit of all.

In a recent assessment Butsumtwi-Sam (2002, 2005, 2008: 92) concluded that the realization of human security goals in the human development context has been rather dim. A significant change would have required a reform of existing power structures and institutions with a specific focus on macroeconomic structures and distribution mechanisms.

74.4.1.3 The Rule of Law and Human Rights Agenda

Under 'freedom to live in dignity' Kofi Annan (2005) argued that action was needed on the following three priorities:

- a.) *Rule of law*: The international community should embrace the 'responsibility to protect', as a basis for collective action against genocide, ethnic cleansing, and crimes against humanity. All treaties relating to the protection of civilians should be ratified and implemented. Steps should be taken to strengthen cooperation with the International Criminal Court and other international or mixed war crimes tribunals, and to strengthen the International Court of Justice.
- b.) *Human rights*: The Office of the High Commissioner for Human Rights should be strengthened with more resources and staff, and should play a more active role in the deliberations of the Security Council and of the proposed Peacebuilding Commission. The human rights treaty bodies of the UN system should also be rendered more effective and responsive.
- c.) *Democracy*: A Democracy Fund should be created at the UN to provide assistance to countries seeking to establish or strengthen their democracy.

During its first decade (1998-2008), the members of the *Human Security Network* have succeeded to put many of these issues on the agenda of the UN Security Council, of the General Assembly, and of many

27 See Annan (2005): Executive Summary; at: <<http://www.un.org/largerfreedom/summary.html>>.

other international bodies.²⁸ Canada was instrumental in launching the debate on the *Responsibility to Protect* (ICISS 2001), while Austria and Switzerland launched the UN Security Council Resolution 1325 (October 2000) on the role of women in international peace and security (Ulbert 2008), Austria has stressed human rights education while Slovenia focused on the protection of children in armed conflict.

There are a few cases where scientists had an impact on the national and international human security agenda, and were instrumental for furthering their implementation, as for example Wolfgang Benedek of the University of Graz (Austria), Keith Krause of the University of Geneva (Switzerland)²⁹ or Andrew Mack of Fraser University in Vancouver (Canada).³⁰

Benedek (2006, 2008) and together with Kettmann (2008) reviewed the conceptual relationship between human security and human rights pointing to commonalities and differences, discussing the relevance of human security for implementing human rights as well as the relevance of human rights for achieving human security. They concluded that this relationship has contributed to a dual added value.

Benedek significantly contributed to the activities of the HSN in the area of human rights education after the adoption of the “Graz Declaration on Principles of Human Rights Education and Human Security” at the 5th Ministerial in Graz in May 2003. His institute launched the *HUMSEC Project* with the support of the 6th EU Framework Programme, “whose purpose is to contribute to a better understanding of the link between transnational terrorist groups and

criminal organizations in the Western Balkans and their role in the peacebuilding process in the region.”³¹ Benedek (2006, 2008) has also been involved in the human rights education initiatives within UNESCO. This is a positive example where policy-oriented conceptual work in international law had a direct impact through the endorsement by the HSN on other international organizations.

74.4.1.4 The Climate Change and Natural Hazard Agenda

Bogardi and Brauch (2005) proposed ‘freedom from hazard impacts’ as a fourth pillar of human security that should focus on reducing vulnerability of societies confronted with natural and human-induced hazards, and by enhancing resilience, disaster preparedness, and response (UNU-EHS 2005; Brauch 2005). While such natural hazards cannot be prevented, the impact of these tragic events can be reduced by early warning and better disaster preparedness. ‘Freedom from hazard impact’ would imply that people can mobilize their resources to address sustainable development goals.

To achieve this goal requires four hazard-specific policies and a combination of technical, organizational, and political measures in case of:

- *Slow-onset hazards*: sea-level rise and temperature increase due to climate change require a) long-term strategies for *reducing greenhouse gas emissions*, b) measures of *adaptation* (dams in affected areas), and c) *mitigation* (restriction of housing in coastal areas);
- *Rapid-onset hydro-meteorological hazards*: Climate change has contributed to an increase of extreme weather events. This requires *disaster preparedness* (education, training, infrastructure) and *disaster response* on the national and international level. Different early warning systems are needed for storms (early warning centres, infrastructure), floods (vulnerability mapping), forest fires (monitoring from space and plains), and droughts (precipitation monitoring from satellites);
- *Rapid-onset geophysical hazards*: earthquakes, tsunamis, volcanic eruptions and their possible extreme consequences require improved early warning systems (closer cooperation among seismic and volcanic research centres, tsunami early warning systems), better disaster preparedness (vulner-

28 See the guiding principles adopted on 20 May 1999 at the first ministerial of the HSN in *Lysøen (Norway)*. See text at: <<http://www.humansecuritynetwork.org/principles-e.php>>.

29 Krause is founder and programme director of the *Small Arms Survey* project, and has jointly edited its annual yearbook since 2001. See at: <<http://www.smallarmssurvey.org/files/sas/about/mission.html>>. It offers the principal international source of public information on all aspects of small arms and as a resource for governments, policy-makers, researchers, and activists. Its international staff works closely with a worldwide network of researchers and partners. So far seven volumes of the *Small Arms Survey* (2001, 2002, 2003, 2004, 2005, 2006, 2007) were published; at: <<http://www.smallarmssurvey.org/files/sas/publications/yearb2007.html>>.

30 Mack founded the Peace Research Centre in Canberra, then moved to the UN Secretariat to become an adviser of Kofi Annan and later launched the Human Security Centre in Vancouver that publishes the *Human Security Report* and two *Human Security Briefs*.

31 See the documentation at: <<http://www.humsec.eu/cms/index.php?id=333>>.

ability mapping), improved national and international disaster response, and clear guidelines for post-hazard reconstruction activities;

- *Human induced disasters*: technical (malfunctioning of technical systems, collapse of buildings, dams), industrial (e.g. chemical industry, nuclear reactors) and traffic accidents (road, railway, ships, airplanes, etc.) as well as *intentional malicious acts* by states in war (attacking objects containing dangerous forces, dams, energy, and chemical plants) and by non-state societal (terrorists) and economic (organized crime) actors or a combination of these.

'Human security as freedom from hazard impact' is achieved when people who are vulnerable to and at risk of these manifold environmental hazards and disasters (floods, landslides, and drought) that are often intensified by other associated societal threats (poverty), challenges (food insecurity), vulnerabilities and risks (improper housing in highly vulnerable flood-prone and coastal areas) are better warned of impending hazards, prepared and protected against these impacts and are empowered to prepare themselves effectively to cope with the 'survival dilemma' (Brauch 2000, 2004, 2005). Such extreme events often pose for the most vulnerable three 'no-win' alternatives: a) to die, b) to be forced to migrate, or c) to struggle for their own survival and that of their community. The concept of human security is closely related to 'vulnerability', the latent threat that some dimensions of human insecurity could manifest themselves in crises and disasters.

While hazards and vulnerabilities lead to a direct deterioration of human security, especially for those segments of a society with low coping capacities, strategies to reduce environmental, economic and societal vulnerability by environmental, economic and social policies and measures, and to improve coping capacities (by disaster preparedness, management and response) will contribute to reducing the risks for different strata of the society and thus improve their human security.

During the last 30 years evidence has pointed to a marked growth in the frequency and magnitude of natural hazards and their economic consequences (MunichRe 2000–2007; IPCC 2001, 2007a; UN/ISDR 2004; UNDP 2004). The statistical and political evidence underlines the necessity to study and document the environmental, economic and social vulnerabilities and thus also the environmental dimension of human security that can only be achieved through a dynamic equilibrium between humankind and its surroundings. From a human security perspective many environmental threats, challenges, vulnerabilities, and risks exist for the major referent: the individual human being or humankind (table 74.4).

Addressing the environmental dangers to human security (Brauch 2005a: 64, table 4) requires a complex combination of strategic instruments and policies to reduce the vulnerability to natural hazards and the related risks for human beings and affected societal groups. Thus a dual strategy is needed for dealing with:

Table 74.5: ‘Human Security’ Policies and Measures for Coping with Environmental Threats, Challenges, Vulnerabilities, and Risks for ‘Ecosystems’ and ‘Sustainability’. **Source:** Compiled by the author.

Strategies and means for coping with	Threats of	Challenges of	Vulnerabilities of	Risks of
	Environmental Security for			
Sustainable development policy goals	• Air (climate), soil, water	• agriculture and food security	• vulnerable people (old, children, women, indigenous groups)	
Environment policy (implementation of environmental treaties, regimes)	• Climate change, soil erosion, water scarcity and degradation	• economy • agriculture • tourism • health	• rural livelihood • urban habitat • transport and economic infrastructure	• reducing exposure of people with low resilience
Early recognition (research, education, training, agenda setting)	• Extreme weather events (storm, flood, drought)	• agriculture (shift in crops)	• city planning • building standards	• enhancing knowledge of these people
Early warning of hazards and disasters	• Hydro-meteorological (storms, floods, drought) and geophysical (earthquake, volcano, tsunami) hazards	• agriculture (specific crops) • public health	• vulnerability mapping of hazard prone areas and housing	• enhancing training of these people
Effective disaster preparedness and rapid disaster response		• (inter)national organizations and resources	• vulnerability mapping of hazard prone areas and housing	• enhancing protection of these people
Humanitarian aid	• Hazards and conflicts	• access to affected areas	• spread of infectious disease	• reducing low recognition
Refugee assistance	• Distress migration	• environment • food supply	• refugees (in times of conflict)	• old, weak and poor

- *short-term situational* impacts of extreme weather events and natural hazards; and
- *longer-term structural impacts* of global environmental change.

A conceptual and a policy-oriented mainstreaming is needed to address both impacts. Usually there has been a preference for short-term reactive policies of disaster response, and a hesitation towards long-term proactive climate change policies by reducing greenhouse gas emissions in the domestic energy and transport sector. Effective climate policies with legally binding obligations may be the most cost-effective solutions to counter the projected increase in extreme weather events. To respond to these complex and manifold environmental security ‘threats, challenges, vulnerabilities, risks’ as well as to those posed by manifold hazards, it is primarily *proactive* non-military policies and measures (table 74.5) which are needed.

With regard to the work of international organizations, a dual mainstreaming may be needed:

- to incorporate a ‘human security’ perspective into ‘environmental security initiatives’, such as ENVSEC and the “green diplomacy” of the Euro-

pean Union (chap. I by Brauch); chap. 71 by Cheterian.

- to include an ‘environmental security dimension’ into the work of the Human Security Network (HSN) and elaborating it further in the context of the report of the Commission on Human Security (CHS 2003) and of the Friends of Human Security.

During its ministerial meetings in Bangkok (May 2006) the HSN referred to ‘freedom from hazard impact’, and in Athens (2008) by addressing the socially vulnerable people due to climate change the HSN moved towards the environmental dimension of human security.

74.5 Human Security in the Anthropocene

The focus of both the HSN and of the FHS has been on the first three pillars of human security. The discussion on the ‘environmental dimension of human security’ (Brauch 2008g) and on ‘freedom from hazard impact’ points to a new challenge that humankind, or ‘us’ are posing a threat to the quality of life

and survival of our species. Crutzen (2002) coined the term of the 'Anthropocene' for a new era in earth history (chap. I, 4, II, 98, 99).

The recognition that the enemy is 'us' or more specifically our way of life, our consumptive behaviour, our burning of fossil fuels since the Industrial Revolution, our waste of energy that has caused an increase in the number and intensity of hydro-meteorological hazards, as well as in the number of people killed and affected and in the number of economic damages (IPCC 2001a; MunichRe 2006) has significant implications for the thinking on security in general and on human security in particular.

This 'enemy' cannot be contained by military logic or force. Rather the armed forces as a significant consumer of fossil fuels in peace and even more in war times directly contributes to this threat. The realist tradition as well as critical schools of security studies have difficulties in addressing this new 'enemy' to our own well-being and survival. Addressing climate change as an issue of 'national security' within the traditional worldview of the analyst or mindset of the policy-maker does not offer a solution. But also the prevailing tendency in the scientific discourse and in the policy debates on human security that focus on the individual as the 'victim' of threats posed by states (repressive governments within or by outside powers) cannot address or cope with this new security danger. This enemy being 'us' cannot be bombed, brought to justice, prosecuted and detained in prisons.

Georg Boomgarden, the State Secretary in the German Foreign Office, stated on 26 June 2006 at a conference on "desertification as a security threat":³²

If we ask ourselves who the enemy is in climate change, using the concepts of classic security policy, we must conclude that we are turning nature itself into an enemy, ... and with this enemy, neither deception nor deterrence is going to be of any use. The later we adapt, the greater the cost will be.

This new threat requires a new paradigmatic shift in our thinking and a new basic contract between the state(s), the society, and the economic sector. Only together these three actors can address this threat.

32 See the Conference Report: *Desertification: a security threat? - Analysis of risks and challenges. A conference on the occasion of the World Day to Combat Desertification 2007* Federal Foreign Office, Berlin, June 26, 2007 (Berlin: GTZ, August 2008): at: <<http://www.auswaertiges-amt.de/diplo/de/Aussenpolitik/InternatOrgane/VereinteNationen/VN-Engagements/DesertificationAndSecurity-Download.pdf>>.

But the precondition is a recognition of this threat that does not require intelligence agencies and classified information. This knowledge is public and has been assessed so far in four assessment reports by the IPCC that has become an indirect securitizing actor by putting this message on the top agenda of international politics, of international organizations, and of national governments.

Its third working group on mitigation of climate change (IPCC 2007b) has reviewed both bottom-up and top-down studies and has compiled key mitigation technologies and practices currently available and projected to be commercialized before 2030 in the sectors of energy supply, transport, buildings, industry, agriculture, forestry, and waste management (IPCC 2007b: 10). However, neither pure technological fixes nor technocratic strategies will be able to implement the changes needed to cope with the environmental dangers posed by climate change impacts for human security. In the summary for policy-makers the mitigation report of the IPCC (2007b: 21) concluded:

Making development more sustainable by changing development paths can make a major contribution to climate change mitigation, but implementation may require resources to overcome multiple barriers. There is a growing understanding of the possibilities to choose and implement mitigation options in several sectors to realize synergies and avoid conflicts with other dimensions of sustainable development.

This revolutionary change towards a new sustainable paradigm called for by Clark, Crutzen, and Schellnhuber (2004) requires multi-, inter-, and transdisciplinary research, translation of the key results through the media to the public and to education, and an integration in curricula. It requires a gradual and drastic change in our consumptive behaviour and our use of fossil energy. Sustainability as intergenerational justice requires proactive policy initiatives instead of incremental policy responses with a focus on national 'security first' scenarios or policy strategies. This transition challenges policy mindsets, powerful bureaucracies within government, and lobbies from outside that have succeeded in the past and present to delay proactive sustainable policy initiatives.

In coping with the security dangers and concerns posed by global climate change, international relations and national politics in the Anthropocene era of earth history require a rethinking of the content of 'international peace and security' as referred to in the UN Charter and most particularly in Art. I.1 on the purposes of the United Nations: "to maintain interna-

tional peace and security”, ... “to develop friendly relations among nations”, ... “to achieve international cooperation”, and “to be a centre for harmonizing the actions of nations in the attainment of these common ends.”

The scientific discourses and policy debates on the reconceptualization of security, specifically on ‘human security’, as well as the debate on ‘sustainable peace’ may be interpreted as a policy-relevant effort to adapt these contested policy ‘concepts’ to the new conditions for policy-making in the Anthropocene era in an effort to realize both sustainable and human development paths.

But the victims are not only ‘they’, the poor people in developing countries – e.g. in Bangladesh – that have been affected most by climate change and hazard impacts. The people in the North are also increasingly the victims of winter storms (e.g. Lothar), hurricanes (e.g. Katrina in 2005) and flooding, drought, heat waves and forest fires in OECD countries in North America, Europe, and in the Far East and Pacific regions. These challenges have so far not been conceptualized and dealt with as international, national or human security issues. However, this triple securitization of issues of global environmental change (climate change, water, and desertification) is just emerging.

The shift in the thinking from the individual or community as the victim, to humankind as the new collective security danger, implies a search for new soft security policies, strategies, and measures beyond the armed forces and their operational logic and toolkit. The security dangers for humankind in the Anthropocene age confront us with a puzzle, scientists, citizens and policy-makers will be forced to gradually understand and to find new concepts as policy guidelines. By securitizing – but not militarizing – these challenges they have been put on the top of national and international policy agendas and public concerns. Problem recognition is a precondition for anticipatory learning and proactive policies. Policy concepts, such as human security, have already played a crucial role in the process of problem recognition, contextualization, and policy framing.

ject of security to the individual, the community, the people or humankind.

While no agreement could be reached both in the political and scientific realm on the definition of human security, the concept helped to legitimate four distinct policy agendas for humanitarian initiatives and sustainable development, for sustaining the rule of law and human rights and addressing global climate change and human-induced hydro-meteorological natural hazards. The author called for developing the environmental dimension of human security both conceptually and politically by interpreting the coping strategies (of both adaptation and mitigation) in the context of a widened and deepened understanding of security, where the human security concept has played an important role.

The transition towards the Anthropocene era necessitates a fundamental shift in the understanding of the threat posed by global environmental change to both national and especially human security that also requires a change in the thinking on security and in the policy response to this challenge. This argument will be developed further in chapter 99 below.

74.6 Conclusions

This chapter reviewed both the policy debates and the scientific discourses on human security since the publication of the *Human Development Report 1994* by UNDP. The subsequent debate and discourse has shifted the focus from the state as the key referent ob-

75 The Human Security Network: A Global North-South Coalition

Claudia F. Fuentes Julio and Hans Günter Brauch

75.1 Introduction^{1, 2}

The concept of human security represents an effort to move away from traditional conceptions of security and towards a definition that more thoroughly captures the new security challenges facing countries and individuals. This shift reflects a notable conceptual transition away from the perspective that dominated the Cold War, which emphasized state-centric actions and the role of military power, and thus advocates a new perspective based on the security of individuals. This new era is characterized by threats that are more diffuse and diverse than simply military attacks against territory, and recognizes that many non-state actors have the potential to threaten security (Brauch 2005, 2005a, 2008, 2008a, 2008b, 2008c, chap. 74).

The first effort to define the concept of human security was made by the UN Development Programme in 1994. UNDP's vision was broad, and was grounded in seven dimensions of security: economic, food, health, environmental, personal, community, and political security (UNDP 1994). UNDP aimed to redirect the international discourse on security, shifting from a territorial conception towards one that emphasizes sustainable human development (Krause 2005).

In the subsequent years, human security was increasingly adopted in the international community.

One example was the extent to which the campaign that led to the Mine Ban Treaty, known as the Ottawa Convention, explicitly adopted the language of human security into its efforts. The cause was further advanced through reports by UN agencies that helped stimulate a public debate about the security of individuals in the context of civil wars and humanitarian interventions. It is notable that the concept of human security thus emerged not from the academic world but rather as part of the international policymaking process (Annan 2001, 2005).

Although the theoretical framework for human security continues to be debated, the concept increasingly has been invoked by governments, international institutions (UNDP, UNESCO, UNU) and NGOs in diverse areas of international policy. Countries such as Canada and Japan have defined human security as a pillar of their foreign policies as well as a foundation for efforts toward international cooperation. Other countries such as Chile and Mali have incorporated human security into their foreign policies, but to a lesser degree.

Thus the concept of human security has become a rallying point for international cooperation, a so-called 'political *leitmotif*' for a diverse set of actors. In other words, it has become "a more or less coherent idea which shapes the attitude and performance of actors" at the international level and helps "to formulate political agendas or to guide decisions." Moreover, that coherency remains even though some criticize the concept for its flexibility and ambiguity (Werthes/Debiel 2006: 12).

This chapter examines the work of the *Human Security Network* (HSN) as an example of a policy framework for coordination and action on the part of countries united by a commitment to applying a human security perspective to international problems. It thus addresses the following questions: Why has this group of such diverse countries united to promote human security at the international level? How have they coordinated decisions on which issues to address?

1 Claudia Fuentes received support for this chapter as part of FONDECYT research project #1050231. She also relies on the previous publications by Fuentes/Rojas (2005, 2005a).

2 The additions for the last three presidencies of Thailand, Slovenia and Greece (2005-2008) by Brauch (2006h) partly rely on a contract study for UNESCO. They are also based on the websites of the Human Security Network <<http://www.humansecuritynetwork.org/menu-e.php>> as well as on the websites of the Foreign Ministries of Slovenia <http://www.mzz.gov.si/en/foreign_policy/human_security_network_hsn/> and Greece <http://www.mfa.gr/www.mfa.gr/Articles/en-US/ts18052007_KL2115.htm>.

How have they managed to build consensus around concrete actions?

The chapter first analyses the objectives of the HSN (75.2) and explores the reasons for which the member countries have chosen to join forces to advocate for these objectives at the international level. It examines the specific agenda items on which the HSN member states have focused their efforts, as well as the mechanisms for coordination that have allowed concerted collective action (75.3). It concludes with reflections on the role of the HSN in the international community (75.4).

75.2 Background and Objectives of the Human Security Network

The Human Security Network (HSN) emerged as part of a bilateral agreement between Canada and Norway, signed on the island of Lysoen, Norway in 1998, the objective of which was to generate consensus on a theoretical framework and action agenda for human security (Fuentes 2002, 2003). The agreement had been preceded by their successful coordination as part of the international campaign that culminated in the Ottawa Convention.

In addition, the 1998 agreement called upon other countries to join their effort to push forward the human security agenda. In 1999, the Human Security Network held its first official meeting, thus becoming a group of like-minded countries that, through informal and flexible mechanisms, would seek to generate consensus and promote practical actions as part of this agenda. In February 2008, the HSN has included thirteen countries: Austria, Canada, Chile, Costa Rica, Greece, Ireland, Jordan, Mali, Norway, Slovenia, South Africa (observer), Switzerland and Thailand. During the 8th Ministerial meeting in Bangkok on 1 June 2006, Japan initiated a policy: “Toward forming friends of the Human Security.”³

The Chairman’s Summary of the First Ministerial Meeting of the HSN stated that “human security has become both a new measure of global security and a new agenda for global action.”⁴ Furthermore, the HSN argues that “the network plays a catalytic role by bringing international attention to new and emerging issues. By applying a human security perspective to international problems, the network aims to energize political processes aimed at preventing or solving conflicts and promoting peace and development.”⁵ In a recent document that developed a medium-term work plan, the HSN further specified its objectives by draw-

ing international attention to emerging threats to people’s safety, security and well-being,

- Identifying concrete areas for collective action on human security,
- Promoting greater understanding of, and support for, human security issues, and
- Advancing human security issues at the regional level, within regional groups, and through international negotiations and conferences.⁶

This declaration reflects two key related elements that converged and led to the creation of the Network. First, the HSN is a group of like-minded countries united by common values. They are spread across the globe, but they share economic interests, political orientation and similar conceptions of their role in the international community. The HSN is thus a coalition of countries from the South and North whose fundamental connection is an agenda based on the promotion of democratic principles and human rights. The coalition includes countries from every continent that range the spectrum in terms of indicators such as economic growth and human development (see table 75.1). Nonetheless, they are united by values demonstrated in their declaration, “A commitment to human rights and humanitarian law is the foundation for building human security.”⁷

Traditionally, international coalitions have arisen among geographically proximal countries who seek to strengthen ties with an eye toward regional cross-border cooperation. Currently, however, such alliances have diversified, and now more often tend to entail coalitions based on shared values, rather than shared borders. One such transnational project has been the campaign against hunger and poverty involving Brazil, Chile, Spain and France, in which they have lobbied for the United Nations to take action. In fact, Chile provides a particularly interesting example, since it has placed international cooperation at the centre of its foreign policy, with particular emphasis on such non-traditional coalitions based on common interests and values rather than territorial aims (see: Michelle Bachelet Platform, in: Fuentes/Fuentes 2006).

Second, the HSN is an example of a 'new diplomacy' based on 'soft power'. The member countries of the *Human Security Network* see in the coalition the potential to bolster their collective influence in the international community. Given the countries involved, that power clearly is not a result of military strength or the capacity to coerce (i.e. hard power) but rather the result of the capacity to 'seduce' other countries using ideas, values and principles. Joseph Nye describes soft power as:

the ability to get what you want through attraction rather than coercion and payments. It arises from the attractiveness of a country's culture, political ideals and

policies... When you can get others to admire your ideals and to want what you want, you do not have to spend so much on sticks and carrots to move them in your direction. Seduction is always more effective than coercion (Nye 2004: Preface IX)

Indeed, the countries of the Network, including its founders, Canada and Norway, and epitomized by the member state Switzerland, have relatively little military power. But at the same time they are seen as powerful international actors due, in large part, to their capacity as negotiators. In addition, other member countries of the HSN, such as Chile, actively seek the respect of the international community for their commitment to promoting democratic principles after years of military dictatorship. These countries thus seek to strengthen their international influence by helping unite countries around shared values.

Lloyd Axworthy, former Foreign Minister of Canada, described the agreement between Canada and Norway that formed the HSN in the following terms:

As we saw in the development of the Landmine Treaty, 'soft power techniques' such as ideas, negotiation and bridge building, have become effective new tools of international diplomacy... Canada's partnership throughout the process that led to the Treaty demonstrates that our shared values and approaches to foreign policy can make a difference in the international agenda.⁸
