Foreword

The year 2007 could perhaps accurately be described as the year when climate change finally received the attention that this challenge deserves globally. Much of the information and knowledge that was created in this field during the year was the result of the findings of the Fourth Assessment Report (AR4) of the Intergovernmental Panel on Climate Change (IPCC), which were disseminated on a large scale and reported extensively by the media. This was the result not only of a heightened interest on the part of the public on various aspects of climate change, but also because the IPCC itself proactively attempted to spread the findings of its AR4 to the public at large.

The interest generated on the scientific realities of climate change was further enhanced by the award of the Nobel Peace Prize to the IPCC and former Vice President of the US, Al Gore. By taking this decision in favour of a leader who has done a great deal to create awareness on climate change, and a body that assesses all scientific aspects of climate change and disseminates the result of its findings, the Norwegian Nobel Committee has clearly drawn the link between climate change and peace in the world.

There are several reasons why unmitigated climate change can be considered as a potential source of conflict and disruption of peace. The impacts of climate change are varied and can become serious unless effective steps are taken to stabilize the earth's atmosphere and the consequent changes in climate that would occur in the absence of such actions. Firstly, there is now adequate evidence to show that several extreme events are becoming more frequent and more intense. These include extreme precipitation events, heat waves, floods as well as droughts. Impacts of climate change include sea level rise which threatens several low lying islands as well as coastal areas. Melting of ice bodies such as glaciers across the globe and impacts on human health as well as on biodiversity are also projected to become much more serious over time. Climate change can also cause irreversible changes such as a threat to extinction of several species. Of all those species that were assessed by the IPCC, 20 to 30 percent were seen to face the threat of extinction with temperature increases of over 1.5 to 2.5 °C. Impacts on agriculture could also be serious, and there is already some evidence of a decline in productivity and yield of some species as a result of climate change. Recent research in India shows such a trend in the case of wheat productivity.

All of this means that human society could suffer serious consequences as a result of climate change which could not only result in conflict over resources such as water, exhibiting increasing scarcity in several parts of the world, but also lead to displacement of populations linked with these factors. Particularly vulnerable are the megadeltas in Asia, which include cities like Shanghai, Dhaka and Calcutta. These are centers not only of large populations, but also substantial assets of property and infrastructure. The threat of coastal flooding can, therefore, have high magnitude impacts on these megadeltas.

The growing impacts of climate change make it essential for communities and countries to adapt to the impacts of climate change. However, these impacts and the costs of adaptation will increase disproportionately as the impacts become more severe. Hence, an essential policy that would be required for minimizing the negative impacts which would otherwise take place in the future would be to carry out effective mitigation of greenhouse gas (GHG) emissions. The IPCC has clearly brought out several measures and options by which mitigation can take place with existing technologies and methods, but these would have to be supported by appropriate policies to be put in place by governments, including agreements at the global level. Fortunately, the costs of mitigation have been assessed as being very low and the co-benefits in the form of lower levels of local pollution, higher levels of energy security, improved health etc. would make these mitigation options far more attractive than has been believed by certain sections of society which have been resistant to action.

This book serves an extremely useful purpose, because it covers several critical elements of climate change and the challenges that are thrown up by consideration of the impacts of climate change and security issues related to it. Such a volume is not only highly readable for a very wide audience, but also contains valuable information and research based analysis that would provide a valuable reservoir of knowledge to researchers and students working in this field.

New Delhi, September 2008

R. K. Pachauri
Director General, The Energy and
Resources Institute (TERI)
Chairman, Intergovernmental Panel
on Climate Change (IPCC)
Peace Nobel Laureate, 2007

Foreword

International discourse on the link between declining natural resources and instability, tensions and even conflicts has reached a new and urgent level in the early 21st century.

This is in part as a result of growing understanding that on many of the sustainability indicators humanity is pushing the limits - if not pushing past the limits - on many key fronts.

UNEP's latest Global Environment Outlook-4 puts these sobering realities into sharp focus.

- In 1987, around 15 per cent of global fish stocks were classed as collapsed. GEO-4 says this has roughly doubled to 30 per cent.
- 20 years ago around a fifth of fish stocks were deemed over-exploited this has now risen to about 40 per cent.
- Land use intensity, with links to land degradation, soil erosion, water scarcity, nutrient depletion and pollution has increased. In 1987, a hectare of cropland yielded 1.8 tonnes. Now the intensity is 2.5 tonnes.
- In Latin America and the Caribbean, desertification - caused by deforestation, over grazing and inadequate irrigation - affects a quarter of the region.
- Available freshwater resources are declining; by 2025, close to two billion people are likely to live with 'absolute' water scarcity.
- Populations of freshwater vertebrates have declined on average by nearly 50 per cent since 1987 as compared with an around 30 per cent decline for terrestrial and marine species.
- About 40 per cent of big estuaries in the United States including those that link to the Gulf of Mexico and Chesapeake Bay suffer severe eutrophication - which can lead to deoxygenated 'dead zones' - because of nitrogen enrichment.
- In the Caribbean, over 60 per cent of economically important coral reefs are threatened by sediments, pollution and over-fishing.
- War and conflict has raised the number of refugees and internally displaced people in West Asia to about four million.

On top of these come the ever more worrying impacts of climate change, outlined in the 4th assessment of the Intergovernmental Panel on Climate Change (IPCC).

It is not by chance that the IPCC - jointly established by UNEP and the World Meteorological Organisation - jointly won the Nobel Peace Prize.

How indeed will the world cope with the millions of people on small islands and in low lying areas such as Bangladesh who are set to lose their land, livelihoods and their homes?

What will tens of million - if not hundreds of millions - of people in Asia, Africa and Latin America do when the glaciers melt away turning many of the world's mighty rivers into seasonal, rather all year round runs.

It is for these very reasons that climate change and security was placed in 2007 and for the first time, on the agenda on the UN Security Council.

Also why it has begun animating leading members of the military in countries such as Australia, the United States and the United Kingdom.

There is clearly an urgent need to bring more intelligence and creative solutions to the way we manage the world's ecosystems and the nature-based assets that fundamentally underpin human well-being while also investing in a new and more sustainable energy mix.

The returns, both economic and social, are potentially enormous from overcoming poverty and providing the food and livelihoods for over six billion people - shortly rising to nine billion - and at the same time delivering equity and stability to communities and countries across the globe: in short a peace policy for the new millennium.

So I welcome this *Security Handbook for the Anthropocene - Facing Global Environmental Change: Environmental, Human, Energy, Food, Health and Water Security Concepts* and its 100 peer-reviewed chapters as an eye-opener to both the challenges but also the opportunities of our age.

I hope that private foundations and donors can ensure that its important ideas, debates and essential reading find their way equally onto the library book shelves of the South as well as the nations of the North.

Nairobi, September 2008

Achim Steiner
UN Under-Secretary General and
Executive Director
UN Environment Programme (UNEP)

Foreword

This volume – *Facing Global Environmental Change: Environmental, Human, Energy, Food, Health and Water Security Concepts* – is of utmost importance for Africa. I am pleased that one of the coeditors is a Kenyan and 15 authors come from, live or worked on problems related to the challenges facing the African continent during this century.

This scientific peer-reviewed volume with 100 chapters contributes to global dialogue and learning based on topical new evidence from several disciplines and mutual respect for cultural diversity. Africa has already been severely affected by the effects of global environmental change during the 20th century due to progressing desertification, drought, famine as well as floods and heat waves that have killed and affected or forced millions of Africans to leave their homes.

This book deals in detail with these natural hazards and their often severe impacts Africa has been facing. Chapters in this book discuss the severe food insecurity and the impact of HIV/AIDS and of other pandemics on national and human health security and the need for a sustainable energy system. Problems of water security in the Nile Basin and in other parts of Africa have triggered cooperative solutions, as with the Nile Basin Initiative. In the past environmental security problems have repeatedly contributed to conflicts in Sub-Saharan Africa and they stress an urgent need for Pan-African as well as national human and environmental, water, food and health security approaches across Africa and elsewhere

The fourth IPCC Assessment Report of 2007 has stressed that climate change will have many negative impacts for the African people regarding their access to clean water, sufficient food, stable health conditions, ecosystem resources, and security of settlements. In the view of the IPCC there is also high confidence that many semi-arid areas, e.g. in North and Southern Africa will become severely water-stressed, and by 2020, between 75 and 250 million people are projected to experience increased water stress.

Climate change will not only affect food security, but also exacerbate malnutrition. By 2020, in some African countries, yields from rain-fed agriculture could be reduced by up to 50 per cent. Agricultural production and access to food will be severely compromised. Africa is also likely to be strongly affected by climate change, because of its limited adaptive capacity to projected climate change impacts. Furthermore, several African mega-deltas, due to large populations and high exposure to sea level rise, storm surges, and river flooding will also suffer from the impacts of global environmental and climate change to which Africans have historically contributed little.

This huge volume of excellent scholarship from all parts of the world helps to sensitize policy makers but also a young generation of professors and students globally but specifically in the most affected countries in the South for the need for proactive and cooperative action and for a global science partnership to reduce the worst impacts of the projected trends in business as usual strategies.

This book deserves many readers in all parts of the world, but especially in those countries where university and research libraries are unable to afford such references books. It is my sincere hope that this high-quality and multidisciplinary study and reference book and its key messages will be made available with the support of private foundations and public donors to the young generation in the global South that will face these challenges to their security in the 21st century. I wish the book-aid project success for the benefit of university libraries and research institutes and their readers in Africa, Asia and Latin America.

Foreword

The title of this volume - *Facing Global Environmental Change: Environmental, Human, Energy, Food, Health and Water Security Concepts* - sums up many of the dilemmas and challenges facing policy-makers today. First, environmental change is global; no part of the world is spared. Second, we have to face change now; ignoring the challenge is not an option if our children are to thrive. Third, in an increasingly connected world, security is more than just the absence of war; it depends on diverse, but linked - indeed, often competing - factors such as political, social, economic, and environmental interests. Central to these, as the title of this book suggests, is the environment.

As a large and economically powerful union, the EU enjoys economies of scale. These can be exploited to address environmental threats - at local, national, and Union levels. It is sobering to recall, however, that even the enlarged EU is not autonomous and that the health of the European environment also depends on policies and practices in other parts of the world. Nowhere is this more evident than with climate change. Changes and challenges are now global, and thus our policy responses must be global too. Our security is indivisible, but our responses remain all too clearly fractured and divided.

Second, the concept of 'sustainable development' shows that time is a crucial factor in environmental security. The future can only be secured insofar as we act responsibly now; prevarication will have costs which future generations will pay. This implies urgent choices now. Fortunately, the developing science of costing environmental goods and services suggests that taking action on the environment not only has costs, but also has significant short- to medium-term financial and other benefits. Nonetheless, questions remain as to when best to take action and how such action can accommodate political and economic timetables.

Third, the environment is indeed a key component of modern security. Environmental degradation may destabilize societies by reducing economic opportunity. Degraded environments can be breeding grounds for other social ills, such as impaired human health or declining social cohesion. Developing countries with populations directly dependent on environmental resources are also particularly vulnerable to conflict over access to limited or declining resources. Environment is thus central to modern security, but also needs to be integrated with other factors such as energy, mobility, and food requirements. The question for policy-makers is how, in practical terms, to align these diverse interests.

Since the end of the Cold War, the security debate has changed fundamentally. A study which addresses the new challenges and suggests responses will therefore be a welcome addition to the policy-maker's toolkit. For this reason, I warmly welcome this volume.

Acknowledgements

This volume emerged from a series of ten panels on “Reconceptualizing Security in an Era of Globalization” at the 5th Pan-European Conference on International Relations in The Hague, The Netherlands, 9–11 September 2004, and from two previous workshops at the 45th annual ISA Convention in Montreal, Canada, 17–20 March 2004 and two panels at the 20th IPRA conference in Sopron, Hungary, 5–9 July 2004 were early versions of selected chapters were presented.¹ Most chapters were subsequently commissioned from invited experts from different disciplines and all parts of the world and all submissions were anonymously peer reviewed and subsequently revised by the authors.

Financial contributions for these workshops and for the preparation and production of this book were made by the following donors: the Berghof Foundation for Conflict Research in Berlin, the European Commission and NATO in Brussels, the Netherlands Organisation for Scientific Research (NOW) in The Hague and by Springer-Verlag in Heidelberg.

Hans Günter Brauch is grateful to the Berghof Foundation for Conflict Research in Germany, a private scientific foundation, and to the chairman of its Funding Committee, Prof. Dr. Horst Fischer (GTZ Brussels). A foundation grant covered a part of the editorial and production costs of this book. He is especially grateful to the founder of the Berghof Foundation, Prof. Dr. rer. nat. Georg Zundel, a former Professor at the University of Munich, who died on 11 March 2007.² For more than three decades, the Berghof Foundation has funded often unconventional, trans- and multidisciplinary and goal-oriented international research and scientific cooperation.

- AFES-PRESS received a financial support under grant SNE-3-CT-1003-503699 from the DG Aerospace and Industry, European Commission to cover the costs of an AFES-PRESS research team consisting of three AFES-PRESS board members from Germany, The Netherlands and Poland, of two associated colleagues from Tunisia and Egypt and four Ph.D. candidates from Germany, France and Italy to participate at three workshops during 2004:
 - at the 45th ISA Convention in Montreal Canada, 17–20 March 2004;
 - at the 20th IPRA Conference in Sopron, Hungary, 5–9 July 2004;
 - at the 5th Pan-European Conference on International Relations, 8–11 September 2004.and to start with the review, editorial and production process of the two volumes emerging from these workshops as well as to prepare two workshops in 2005 in Istanbul and Bonn.
- AFES-PRESS appreciates a subsidy from NATO contributing to a realization of the workshop in The Hague enabling the participation of seven colleagues from NATO Mediterranean dialogue countries (Algeria, Egypt, Israel, Jordan, Tunisia, Turkey) and from Palestine.
- Prof. Dr. John Grin would like to thank the Netherlands Organisation for Scientific Research (NOW) in The Hague that covered the travel costs of two participants and co-editors from Mexico and India for the third workshop in The Hague.

1 The contributions have been documented for the workshop in Montreal at: <http://www.afespress.de/html/download_isa.html>; for the workshop in Sopron at: <http://www.afespress.de/html/download_sopron.html> and for the workshop in The Hague at: <http://www.afespress.de/html/the_hague_programme.html>.

2 The previous volume in the Hexagon Book Series was dedicated to the memory of Prof. Dr. Georg Zundel.

The editors of this book would like to thank their institutions for permitting to use a part of their time and their infrastructure for the realization of this project:

- *PD Dr. Hans Günter Brauch* would like to thank Úrsula Oswald Spring for her good cooperation, scientific advice, friendship, encouragement and support, Czeslaw Mesjasz and John Grin for their good advice, friendship and support and all co-editors for their devotion and hard work as reviewers and contributors. Without this global team this volume would not have been possible.
- *Prof. Dr. Úrsula Oswald Spring* is grateful to the Centre for Regional Multidisciplinary Studies (CRIM) and the National University of Mexico (UNAM), for permitting her to allocate a part of her research time to this project. As the first MunichRE chair on Social Vulnerability at UNU-EHS she appreciates the support of UNU-EHS in Bonn and of the MunichRe Foundation. Finally, she wants to thank AFES-PRESS for permitting her to use its research library and office facilities during her stay in Europe in the summers of 2005, 2006 and 2007 and for the intellectually stimulating professional discussions with Hans Günter Brauch.
- *Prof. Dr. Czeslaw Mesjasz* would like to thank Lidya for her patience and support and Hans Guenter Brauch for his compassion, hard work, inspiration and friendship.
- *Prof. Dr. John Grin* wishes to thank his fellow editors, especially Hans Günter Brauch, who pairs incredible energy to patience and understanding. He owes his assistant Amy-Jane Gielen for relieving him of many other duties, thus being able to spend time on this volume, and his family for adding the sort of duties which keep one in healthy balance.
- *Prof. Dr. Patricia Kameri-Mbote* would like to thank her husband John Mbote for his unwavering support, patience and friendship and Hans Guenter for spurring team spirit and getting work done.
- *Prof. Navmita Chadha Behera* would like to thank Hans Guenter for his encouragement and hard work, and all co-editors for good cooperation and to Ajay and her daughter Ananya for their unfailing support and patience.
- *Dr. Heinz Kruppenacher* would like to extend his appreciation and gratitude to his partner Pia for her patient support.

Hans Günter Brauch would like to thank Dr. Christian Witschel, Editorial Director Geosciences, Springer-Verlag, for his support of this project and his patience with an international team and Ms. Christine Adolph and Ms. Almas Schimmel, the producers of this book within Springer-Verlag, for their efficient coordination and implementation of this project, as well as the many other unnamed persons within Springer-Verlag for their devotion to this publication.

All editorial decisions were made by the editors in their personal capacity only. The funders had no influence on the themes of this book and on the views expressed by its authors. None of the authors and editors receives any personal remuneration from this collaborative research project. Any income will be used by AFES-PRESS, a non-profit scientific society under German law, for future projects to further global scientific cooperation including the book-aid project for Third World Libraries.³

3 See the book aid project for vol. 1 at: <http://www.afes-press-books.de/html/book_aid_project.htm> and for vol.3 at: <http://www.afes-press-books.de/html/book_aid_project_hex3.htm>; and for this vol. 4 at: <http://www.afes-press-books.de/html/book_aid_project_hex4.htm>.

All editors are grateful to Thomas Bast, who in his quiet and efficient way, acted as the webmaster and produced several versions of the proofs, the whole layout as well as the index.

The editors and the producer would like to thank Ms. Patrizia Kummer, director of D.T.u.L. GmbH in Fellbach near Stuttgart, for permitting the producer to use the infrastructure of her company for this book selflessly. This support has greatly facilitated the work of the producer.

The editors are grateful to Ronald Lappin, the International Programme Director of *Gute Bücher für Alle* e.V., in Mosbach (Germany), for his extremely careful language editing. He speaks many languages and thus he could often anticipate what the non-native speakers intended to express, and adapt the language of most non-native speakers to proper British English.

Last but not least, the editors are grateful to the 130 authors and editors, coming from 47 countries and many scientific disciplines for their contributions to this book and for their readiness to reflect the critiques and suggestions of the anonymous reviewers trying to look beyond the boundaries of their respective discipline and expertise.

The editors are grateful to *Prof. Dr. Rajendra K. Pachauri* (India), Director-General of TERI and Chairman of the Intergovernmental Panel on Climate Change (IPCC), to *Mr. Achim Steiner* (Germany), UN Under-Secretary General and Executive Director, UN Environment Programme (UNEP), to Her Excellency *Amb. Prof. Dr. Joy Ogwu*, Permanent Representative of the Federal Republic of Nigeria to the United Nations, and to *Mr. Stavros Dimas* (Greece), Commissioner for the Environment in the European Commission for their forewords, and to *Luc Gnacadja* (Benin), Executive Secretary of the United Nations Convention to Combat Desertification (UNCCD), *Dr. Sálvano Briceño* (Venezuela), Director of the Secretariat of the International Strategy for Disaster Reduction (UN/ISDR), *Michael Zammit Cutajar* (Malta), former Executive Secretary of the UN Framework Convention on Climate Change (1996–2002), and to *Dr. Vandana Shiva* (India), a recipient of the alternative Nobel Prize, for their perceptive preface essays.

Permissions and Credits

The editors and authors are grateful to the following publishers and authors who granted permission to use copy-righted materials:

- The copyright for the photos of La Paz for the book cover was granted by Mr. Fabien Nathan, IHEID, Geneva, Switzerland. Fabien.Nathan@iued.unige.ch. The cover is based on two photos of Villa Nuevo Potosi, La Paz, Bolivia and of a group of people in San Juan Tembladerani Parte Baja, La Paz, Bolivia that were taken in 2006 by Fabien Nathan.

The authors of the forewords and preface essays supplied the photos and obtained the permission from the photographers and copyright holders to use them.

- The photo of *Prof. R. K. Pachauri* was provided by the author.
- The photo of *Mr. Achim Steiner* was provided by the UNEP Secretariat, Nairobi.
- The photo of *Amb. Prof. Dr. Joy Ogwu* was provided by the Permanent Mission of Nigeria to the United Nations and was made available by Gloria Starr Kins, Editor in Chief, Society and Diplomatic Review, New York, NY, USA.
- The photo of *Commissioner Stavros Dimas* is from the website of the European Commission.
- The photo of *Luc Gnacadja*, Executive Secretary, UNCCD Secretariat was provided by his staff.
- The copyright holder of the photo of *Sálvano Briceño* is National Geographic, Natalie Biraben and Tom Wagner SM from whom the permission has been obtained by the author.
- The photo of *Michael Zammit Cutajar* was provided by the author.
- The photo of *Vandana Shiva* was taken from her website. The copyright holder for the photo is Nic Paget-Clarke <<http://www.inmotionmagazine.com/shiva.html>>.

In chapter 1, *Hans Günter Brauch* acknowledges that

- *Figure 1.1*: Green Diplomacy Milestones June 2003–June 2005 was taken from the website of the European Commission (<http://ec.europa.eu/external_relations/env/milestones.pdf>) that is in the public domain.

In chapter 3, *Rik Leemans* appreciates the permission of the Millennium Ecosystem Assessment (2005) and the World Resources Institute (WRI) to use these two figures:

- *Figure 3.1*: The linkages between ecosystem serviced and human well-being.
- *Figure 3.2*: The conceptual framework of the Millennium Ecosystem Assessment.

In chapter 4, *Hans Günter Brauch* would like to thank the copyright holders for permission to reproduce the following figures:

- *Figure 4.1*: The new security danger in the Anthropocene posed by changes in atmospheric CO₂ measured at the Mauna Loa Observatory in Hawaii (1958–2007). Source: Pieter Tans, NOAA/ESRL, 12 May 2008; at: <http://www.esrl.noaa.gov/gmd/ccgg/trends/co2_data_mlo.html>. Reprinted with permission of NOAA.
- *Figure 4.2*: Increase in the average global temperature (1900–2000). Source: IPCC (2007: 11); at: <http://www.ipcc.ch/graphics/graphics/ar4-wgt/ppt/spm.ppt#262,5,Figure_SPM.4>. Reprinted according to the terms of the IPCC.
- *Figure 4.3*: DPSIR model of EEA. Source: Jochen Jesinghaus. Reprinted with permission.

- *Figure 4.5*: Vulnerability framework. Components of vulnerability identified and linked to factors beyond the system of study and operating at various scales. Source: Turner/Kasperson/Matson/McCarthy/Corell/Christensen/Eckley/Kasperson/Luerse/Martello/ Polsky/Pulsiphera/Schiller 2003: 8076). © 2003, National Academy of Sciences, U.S.A. Reprinted with permission of PNAS.

For the remaining figures the permission was granted for the copyright holders by the colleagues and institutions listed below:

- *Figure 4.6*: Map of potential policy-relevant tipping elements in the climate system overlaid on global population density. Source: Lenton, Held, Kriegler, Hall, Lucht, Ramsdorf and Schellnhuber (2008: 1187). Reprinted with permission of Prof. Schellnhuber, director of PIK (Potsdam, Germany) and with consent of PNAS that hold the copyright for an earlier version.
- *Figure 4.7*: Regional hotspots and security risks associated with climate change. Source: WBGU (2008: 4). Reprinted with permission of WBGU.
- *Figure 4.8*: Poll by GlobeScan Incorporated: “Climate change: A serious problem or not?” 25 April 2006. Source: <<http://www.worldpublicopinion.org/pipa/articles/btenvironmentra/187.php?nid=&cid=&pnt=187>>. Reprinted with permission.
- *Figure 4.9*: Pew poll of 27 June 2007: “Is Global Warming a problem?” Source: <<http://pewglobal.org/reports/display.php?ReportID=256>>. Reprinted with permission of PEW.

In chapter 5, *Wolf Dieter Blümel* acknowledges the permission of the copyright holders to reproduce and to adapt the following figures:

- *Figure 5.1*: Reconstruction of the Holocene climatic fluctuations. Source: Adapted from Schönwiese (1995).
- *Figure 5.2*: Refuges of the Amazonian rainforest during the last glaciation, compared with the present situation. Source: Adapted from Haffer (1969) and Veit (2007).
- *Figure 5.3*: Development of the land use expansion in Germany since the European peoples’ migration. Source: Adapted from Bork/Bork/Dalchow/Faust/Piorr/Schatz (1998).
- *Figure 5.7*: The last phase of the ‘Little Ice Age’. Source: Adapted from Ruess (2005).
- *Figure 5.8*: Reconstruction of weather and seasons in the 16th century. Source: Hummler (1994).
- *Figure 5.9*: Phases of the Maya collapse during early medieval times. Source: Adapted from Arz/Haug/Tiedemann (2007).

For the following figures the author used his own photos and graphs and for the table he relies on his previous publication in German for which he holds the copyright:

- *Figure 5.4*: The hyper-arid Skeleton Coast Desert (Namibia): Numerous stone settings of wooden-made wind-shelters, charcoal, bone-remnants of antelopes or lions and ostrich-pearls refer to a former savannah-ecosystem in the present desert. Source: photo by Blümel (2006).
- *Figure 5.5*: 14C-radiocarbon dated by B. Kromer proves the medieval age of these archaeological findings. Source: photo by Blümel (2006).
- *Table 5.1*: Stratigraphic Table of the Late Glacial and Holocene. Source: Blümel (2006: 18) adapted from the National Atlas of the Federal Republic of Germany 2003.

Permission to use these photos that were taken in January 2007 was granted by Hans Günther Brauch:

- *Figure 5.10*: The Mayan Archaeological Site of Palenque, Chiapas (Mexico) experienced its climax between the 7th and 10th centuries AD and was deserted by 950 AD.
- *Figure 5.11*: The Mayan Archaeological Site of Uxmal, Yucatán (Mexico) that was suddenly deserted without any signs of destruction from wars.
- *Figure 5.12*: The Mayan Archaeological Site of Chichén Itzá, Yucatán (Mexico).

The following figure is in the public domain:

- Figure 5.6: Albrecht Dürer's (1525): *Apocalyptic Riders* symbolizes the horrors of the 'Little Ice Age'. Source: Internet.

In chapter 6, *Arie S. Issar* and *Mattanyah Zohar* are grateful to Dr. Witschel of Springer-Verlag for permission to use the following six figures and five tables from their previous book that was published by Springer in 2004 and 2007:

- Figure 6.1: Overall Map of the Near East and Maps of Sub regions.
- Figure 6.2: Map of Mesopotamia.
- Figure 6.3: Map of Egypt.
- Figure 6.4: Map of the Levant.
- Figure 6.5: Map of Anatolia.
- Figure 6.6: Main Climate Changes During the Past 7,000 Years.
- Table 6.1: General historical archaeological timetable for the past ten millennia in the Near East
- Table 6.2: Historical archaeological timetable of the Near East, from 10,000 to 3,000 BCE.
- Table 6.3: Historical archaeological timetable of the Near East, from 3,000 to 1,500 BCE.
- Table 6.4: Historical archaeological timetable of the Near East, from 1,500 to 100 BCE
- Table 6.5: Historical archaeological timetable of the Near East, from 0 to 1,500 CE

In chapter 7, *Yannis Kinna*s appreciates the permission of Karen O'Brien and Hans Günter Brauch to use the following two tables:

- Table 7.1: Seven dimensions of human security of UNDP and vulnerability concepts. Source: Vogel and O'Brien (2004: 6).
- Table 7.4: Land Area and Population for Small Island States. Source: Brauch (2005: 68) based on IPCC 1998: 338; UN (2001). Reprinted with permission of the author.
- The other two tables rely on UN sources and are in the public domain:
- Table 7.2: List of Small Island Developing States (UN Members). Source: UN Office of the High Representative for the least Developed Countries: *Landlocked Developing Countries and Small Island Developing States* (2005).
- Table 7.3: List of Small Island Developing States (Non-UN Members/Associate Members of the Regional Commissions). Source: UN Office of the High Representative for the least Developed Countries: *Landlocked Developing Countries and Small Island Developing States* (2005).

In chapter 9, *Andreas Rechkemmer* is grateful to WWF to use the first figure while the second figure is in the public domain.

- Figure 9.1: Living Planet Index. Source: *Living Planet Report 2004* – Published in October 2004 by WWF © Text and graphics: 2004 WWF. All rights reserved.
- Figure 9.2: Schematic Description of Development Pathways in Drylands. Source: Millennium Ecosystem Assessment (2005). This is in the public domain.

He furthermore appreciated the permission of the copyright holder to use the text in these two boxes:

- Box 9.1: Number of Refugees and Migrants Globally. Source: Dow/Carr (2005).
- Box 9.2: Eighth Proposal by the German Advisory Council on Global Change for Managing migration through cooperation and further developing international law. Source: WBGU summary; at: <http://www.wbgu.de/wbgu_jg2007_kurz_engl.html>.

In chapter 10, Ali Ghazi is grateful to Hans Günter Brauch who added the following seven figures to illustrate his chapter that are all in the public domain (FAO, UNEP).

- *Figure 10.1*: NOAA Satellite Image of Algeria. Source: FAO Country Profiles and Mapping Information System, Algeria; at: <<http://www.fao.org/countryprofiles/Maps/DZA/19/im/index.html>>. This FAO document is in the public domain.
- *Figure 10.2*: Map of Land Cover in Algeria. Source: FAO, at: <<http://www.fao.org/country-profiles/maps.asp?iso3=DZA&lang=en>>.
- *Figure 10.3*: Precipitation in Algeria. Source: FAO Country Profiles and Mapping Information System, Algeria; at: <<http://www.fao.org/countryprofiles/Maps/DZA/06/pp/index.html>>.
- *Figure 10.4*: Districts in Algeria. Source: FAO Country Profiles and Mapping Information System, Algeria; at: <<http://www.fao.org/countryprofiles/Maps/DZA/16/ad/index.html>>.
- *Figure 10.5*: Farming Systems in Algeria. Source: FAO Country Profiles and Mapping Information System, Algeria; at: <<http://www.fao.org/countryprofiles/Maps/DZA/01/fs/index.html>>.
- *Figure 10.6*: Water and Wind Erosion in Algeria. Source: UNEP/ISRIC, CRU/UEA; at: <<http://lada.vrtualcentre.org>>.
- *Figure 10.7*: Salinization and chemical deterioration severity in Algeria. Source: UNEP/ISRIC, CRU/UEA; at: <<http://lada.vrtualcentre.org>>.

Two tables are in the public domain relying on data by the Algerian government:

- *Table 10.1*: Overview of the areas affected by Silting.
- *Table 10.2*: Sensitivity of Administrative Districts in Steppe Land to Desertification.

In chapter 11, *Úrsula Oswald Spring* and *Hans Günter Brauch* rely on boxes, figures and tables that are in the public domain:

- *Box 11.1*: Ministerial Declaration of The Hague on Water Security in the 21st Century, 22 March 2000. Source: <http://www.worldwatercouncil.org/fileadmin/wwc/Library/Official_Declarations/The_Hague_Declaration.pdf>.
- *Box 11.2*: Principles for Effective Water Governance. Source: GWP IWRM Toolbox; at: <http://www.gwpforum.org/gwp/Media/Toolbox/main_features.pdf>.
- *Table 11.3*: ‘Virtual Water’: Average requirement of water in productive activities. Source: FAO (2000). This table is in the public domain.

or for which permission was granted by one of the authors or the copyright holder:

- *Table 11.1*: Fundamental policy directions and water security perspectives. Source: Falkenmark and Rockström (2005: 22). Permission was granted by the author.
- *Table 11.2*: Distribution of Freshwater Resources in the World. Source: Shiklomanov (2005: 11). Permission was granted by the author.
- *Figure 11.1*: Environmental Water Scarcity Index by River Basin. Source: World Resource Institute (2003); at: <<http://www.iucn.org/themes/wani/eatlas/html/gm16.html>>. The WRI was informed three times and did not object the reproduction under the fair use clause.

Úrsula Oswald Spring obtained the permission from her Mexican colleagues to reproduce their figures she used and modified in her previous Spanish book published in 2005.

- *Figure 11.4*: Logic of the Values of Water. Source: Ramos (2004), modified by Oswald Spring (2005: 147).
- *Figure 11.5*: Sustainable Economy of Water. Source: Sandoval 2000, modified by Oswald Spring (2005: 153).

The International Food Policy Research Institute, Washington, D.C. granted permission for Rosegrant, Cai, and Cline (2002c) to use the following tables and figures from their publication:

- *Table 11.4*: Scenarios for rain-fed and business as usual production. Source: Rosegrant/Cai/Cline (2002c: 21, table 2).

- *Table 11.5*: Irrigation water supply reliability index by regions. Source: Rosegrant/Cai/Cline (2002c: 7, table 1).
- *Figure 11.2*: Per capita domestic water consumption in 1995 and 2025. Source: Rosegrant/Cai/Cline (2002c: 5, figure 4).
- *Figure 11.3*: Water consumption by sector in 1995 with projections to 2025. Source: Rosegrant/Cai/Cline (2002c: 6, figure 5).
- *Figure 11.8*: Total water consumption for irrigation with projections to 2025. Source: Rosegrant/Cai/Cline (2002c: 2, figure 2).
- *Figure 11.9*: Potential irrigation consumption with projections to 2025. Source: Rosegrant/Cai/Cline (2002c: 6, figure 6).
- *Figure 11.10*: Irrigation and rain-fed production in cereals Source: Rosegrant/Cai/Cline (2002c: 8, figure 8).
- *Figure 11.11*: Sustainable consumption of water in rural and urban areas. Source: Rosegrant/Cai/Cline (2002c: 15, figure 15).

The WBGU granted permission to use the following figures from its Flagship Report of 2007/2008:

- *Figure 11.6*: Conflict constellation 'climate-induced degradation of freshwater resources: key factors and interactions'. Source: WBGU (2008: 83)
- *Figure 11.7*: Conflict constellation 'climate-induced increase in storm and flood disasters: key factors and interactions'. Source: WBGU (2008: 109).

In chapter 12, *Wolfgang Lutz* based his figures and tables on UN sources that are in the public domain and used his own calculations or previously co-authored publications:

- *Figure 12.1*: Average annual population growth rates of selected world regions, 1950-2050. Source: United Nations 2003 (medium variant).
- *Figure 12.2*: Proportion of population above age 80 in Western Europe. Author's calculation.
- *Figure 12.3*: Population (in millions) aged 20-65 by level of education, according to the 'ICPD' scenario in four megaregions, 2000-2030. Source: Goujon/Lutz 2004: 138.
- *Table 12.1*: Life expectancy at birth and total fertility rates by selected regions (1950-2050). Source: United Nations 2003 (medium variant).
- *Table 12.2*: Population (in millions) aged 20-65 by education and gender in 2000 and in 2030 according to the 'constant' and the 'ICPD' scenarios. Source: Author's calculations (together with Anne Goujon).

In chapter 13, *Ben Wisner and Juha Uitto* used in their tables UN sources that are in the public domain and a variety of other cited sources.

- *Table 13.1*: Population of megacities with 10 million inhabitants (1950-2015). Source: UN Populations Division (2006).
- *Table 13.2*: Comparison of Four Megacities. Sources: *Manila and Tokyo*: Fuchs/Brennan/Chamie/Lo/Uitto 1994; Yeung/Lo 1996; Tayag 1999, Velasquez/Uitto/Wisner/Takahashi 1999; *Tokyo*: Takahashi 1998, 1999; Tokyo Metropolitan Government 1995; *Manila*: Tayag 1999; Asian Development Bank (ADB) 2000, 2002; Bankoff 2003b; *Mexico City*: Cruz 1993; Gilbert 1994, 1996; Roland/Gordon 1996; Puente 1999a, 1999b; *Los Angeles*: Wisner 1999a, 1999b, 2003a; Bolin/Stanford 1998; General: U.N. 1999.

Most tables are based on both authors' field work:

- *Table 13.3*: Groups Perceived by Disaster Management Professionals to be Highly Vulnerable to Disasters (per cent of officials).
- *Table 13.4*: Knowledge of Vulnerable Groups and Planning of Programmes to Reduce Vulnerability In Mexico City and Los Angeles (per cent of officials).
- *Table 13.5*: Groups Perceived by Disaster Management Professionals to be Highly Vulnerable to Disasters (per cent of officials).

- *Table 13.6*: Knowledge of Vulnerable Groups and Planning of Programmes to Reduce Vulnerability (per cent of officials).
- *Table 13.7*: Social Capital and Trust Matrix.

In chapter 16, *Nana K. Poku and Bjorg Sandkjaer*, drafted these diagrams and table based on their own data or on data by UN organizations that are in the public domain:

- *Figure 16.1*: Percentage of Africans living on less than a dollar a day. Source: UN (2005).
- *Figure 16.2*: Number of People Living with HIV/AIDS in Sub-Saharan Africa. Source: World Bank (2005).
- *Figure 16.3*: Impact of HIV/AIDS on population growth for selected southern African states. Source: UN/DESA Population Division (2005).
- *Figure 16.4*: Impact of HIV/AIDS on life expectancy at birth, 1970-2015. Source: UN/DESA Population Division (2005).
- *Figure 16.7*: Conceptual framework for impacts of HIV/AIDS on democratic processes. Source: Authors.
- *Table 16.1*: Human Development in selected African countries. Source: UNDP 2006.

The following two diagrams by the authors rely on other data that are cited.

- *Figure 16.5*: Women in Parliament 2004. Source: Population Reference Bureau (2005).
- *Figure 16.6*: Number of Adults Receiving Antiretroviral Treatment in sub-Saharan Africa. Source: Simulation based on Salomon/Hogan/Stover/Stanecki/Walker/Ghys/Schwarländer (2005).

In chapter 17, *Sophia Benz* added two tables and a figure that are based on her own research Benz (2005):

- *Figure 17.1*: The Final Theoretical Model.
- *Table 17.1*: Results of Final OLS Regression Analyses (with HIV-Prevalence as the dependent variable)
- *Table 17.2*: Measurement and Data Sources (all variables)

In chapter 18, *Janos J. Bogardi, Jörn Birkmann, Niklas Gebert and Neysa J. Setiadi* included six figures that rely on their own research and on previous publications for which they obtained the permission from the respective copyright holders:

- *Box 18.2*: 14 Indicators for assessing emergency planning for the city government.
- *Figure 18.1*: The BBC conceptual framework. Source: Birkmann 2006: 34, based on Bogardi/Birkmann (2004) and Cardona (1999, 2001).
- *Figure 18.2*: The Risk Hierarchy. Source: Adapted from Cannon (2006: 11).
- *Figure 18.3*: Map of recent and plausible future sources of Sumatran tsunami. Source: Borrero/Sieh/Chlich/Synolakis (2006: 19674).
- *Figure 18.4*: Indices of the household preparedness level in three different hazard zones. Source: Own figures based on data from Hidayati/Permana/Pribadi/Ismail/Meyers/Widayatun/Handayani/Bustami/Daliyo/Fitranita/Nagib/Ngadi/Kumoro/Rafliana/Argo (2006).
- *Figure 18.5*: The knowledge and attitude index based on different levels of education. Source: Own figures based on data from Hidayati/Permana/Pribadi/Ismail/Meyers/Widayatun/Handayani/Bustami/Daliyo/Fitranita/Nagib/Ngadi/Kumoro/Rafliana/Argo (2006).
- *Figure 18.6*: Sources of information about tsunami and earthquakes from specific sources. Source: Own figures based on data from Hidayati/Permana/Pribadi/Ismail/Meyers/Widayatun/Handayani/Bustami/Daliyo/Fitranita/Nagib/Ngadi/Kumoro/Rafliana/Argo (2006).

Permission was granted by the authors to use the text in this box:

- *Box 18.1*: Questionnaire contents for households. Source: Authors based on Hidayati/Permana/Pribadi/Ismail/Meyers/Widayatun/Handayani/Bustami/Daliyo/Fitranita/Nagib/Ngadi/Kumoro/Rafliana/Argo 2006. Summary of the authors based on components of the study's questionnaire.

In chapter 19, *Imtiaz Ahmed* is grateful to the respective copyright holders for permission to reproduce several photos, maps and tables.

- *Figure 19.1*: Maps of Bangladesh, A: Climate-related Natural Events, and B: Internal Migration. Sources: A: Ericksen/Ahmad/Chowdhury (1996: 264); B: Ericksen/Ahmad/Chowdhury (1996: 245). Permission was granted by Springer-Verlag, the successor of Kluwer Academic Publishers.
- *Figure 19.2*: Map of Bangladesh. Source: Official map of the government of Bangladesh that is in the public domain.
- *Figure 19.3*: A snake charmer among the 213 people stranded at Satgachi, West Bengal, pleads for food, 4 February 2003. Source: *Frontline*, 20,4 (February 2003): 15-28. Reprinted with permission.
- *Figure 19.4*: Indian government's construction of a fence on the Indo-Bangladesh border. Source: BBC News/South Asia, Tripura, Tuesday, 28 June, 2005; at: <www.bbc.com>; Photos by Bapi Roy Choudhury that are reprinted with permission of the photographer.
- *Figure 19.5*: The fence on the Indo-Bangladesh border. Source: Photos by Bapi Roy Choudhury and Shubhashish Roy that are reprinted with permission of the photographers.
- *Table 19.1*: Reasons for leaving Bangladesh (multiple responses).
- *Table 19.2*: Original home of environmental refugees. Source: Author's calculation from a survey conducted by Ranabir Samaddar of Maulana Azad Institute of Asian Studies, Calcutta (1996).
- *Table 19.3*: Incidence of Distress Selling (percentage of villages). Source: Sen/Hashemi/Ahmed (1998); also Ahmed (1999b: 38). Reprinted with permission of the publisher.

In chapter 20, *Thomas Homer-Dixon and Tom Deligiannis* three figures were drafted by the authors for this volume and the fourth is taken from a previous publication by one author:

- *Figure 20.1*: Supply-induced scarcity.
- *Figure 20.2*: Demand-induced scarcity.
- *Figure 20.3*: Structural scarcity.
- *Figure 20.4*: The Toronto Group's Core Model of the Causal Links between Environmental Scarcity and violence. Source: Homer-Dixon (1999). Reprinted with permission of the author.

In chapter 21, *Simon J.A. Mason, Tobias Hagmann, Christine Bichsel, Eva Ludi and Jacob Arsano* reproduced a map with the permission of the copyright holder and compiled a table based on data by UN organizations that are in the public domain:

- *Figure 21.1*: Countries of the Nile Basin. Source: From Amer et al. (2005) © EAWAG, Duebendorf, 2005; reproduced with permission of Eawag.
- *Table 21.1*: Food security in the Nile Countries, Source: Mason 2004, based on data from: a) FAO (2000b); b) FAO (2000a); c) FAO (2000c); d) UNDP (2000); and e) UNFPA (2002) that are in the public domain.

In chapter 22, *Saleem H. Ali* produced a new table based on his own analysis.

- *Table 22.1*: Divergent Arguments on Sustainability of Mineral Extraction Activities.

In chapter 23, *Klaus-Dietmar Jacoby* relies in his tables and figures on official IEA data for which permission was granted by IEA to reproduce them in this volume:

- *Figure 23.1*: IEA Gulf War Contingency Response Plan.
- *Figure 23.2*: Stock release and increased production, 2005 IEA Collective Action.
- *Figure 23.3*: Oil import dependence in IEA.
- *Figure 23.4*: Natural gas import dependence in IEA.
- *Table 23.1*: Total IEA Response, 2005 IEA Collective Action.
- *Table 23.2*: World Primary Energy Demand in the Reference Scenario (Mtoe).
- *Table 23.3*: World Oil Production in the Reference Scenario (million barrels per day).

The Copyright for the IEA figures and tables remains with IEA.

In chapter 24, *Leo Schrattenholzer* used three tables from previous publications to which he was a co-author and a table and figure of colleagues at IIASA for which permission was obtained.

- *Figure 24.1*: Annual Production and Known Reserves of Crude Oil and Natural Gas (1945-1995). Source: Nakicenovic/McDonald/Grübler (1998).
- *Table 24.1*: Typology of Long-Term Energy-Economy-Environment Scenarios according to IPCC-SRES. Source: Nakicenovic/Swart (2000); Metz/Davidson/Swart/Pan (2001). Permission was granted by the IPCC. This table was taken from the IPCC Special Report on Emissions Scenarios (2001) that was published by Cambridge University Press.
- *Table 24.2*: Selected results and indicators of sustainable development scenarios. Indicators of long-term energy security are emphasized. Source: Schrattenholzer/Miketa/Riahi/Roehrl/Strubegger/Totschnig/Zhu (2004).
- *Table 24.3*: Selected results and indicators of CO₂ mitigation scenarios. Indicators of long-term energy security are emphasized. Source: Schrattenholzer/Miketa/Riahi/Roehrl/Strubegger/Totschnig/Zhu (2004).
- *Table 24.4*: Selected results and indicators of high-impact scenarios. Indicators of long-term energy security are emphasized. Source: Schrattenholzer/Miketa/Riahi/Roehrl/Strubegger/Totschnig/Zhu (2004).

In chapter 25, *Werner Zittel and Joerg Schindler* in six figures and one table provided their own analysis that are partly based on other cited statistical sources:

- *Figure 25.1*: Oil production of countries/regions outside OPEC and FSU. Estimates for 2005 based on government statistics, analysis and projection by LBST. Source: IHS 2003; BP St. Rev. 2005
- *Figure 25.2*: Annual gas production 1920-2004 and extrapolation. Source: History: IHS Energy (2005); projection: LBST (Schindler/Zittel 2006).
- *Figure 25.3*: Gas production forecast for Russia. Source: Laherrere (2003), LBST estimate (2004).
- *Figure 25.4*: Worldwide Gas production according to LBST Scenario Calculations. Source: IHS Energy (2005); BP Statistical Review of Energy (2005); Projection: LBST (2005).
- *Figure 25.5*: 'High fossil' scenarios of future production of fossil and nuclear fuels. Source: for oil and gas: Campbell/ASPO (2005); coal and nuclear scenario: LBST (Schindler/Zittel 2006).
- *Figure 25.6*: 'Low fossil' scenario of future production of fossil and nuclear fuels. Source: for oil, gas, coal, and nuclear scenario: LBST (Schindler/Zittel 2006).
- *Figure 25.7*: Possible market penetration of renewable energy sources. Sources: LBST (Schindler/Zittel 2006).
- *Table 25.1*: Remaining proven oil reserves for 'ME Five'. Sources: [1] O&GJ, 19 December 2005 (for 1 January 2006); [2] BP, June 2005 (until end of 2004); [3] ASPO Newsletter, 62, February 2006; [4] Bakhtiari, February 2006.

In chapter 26, *André P.C. Faaij* drafted two figures and compiled two tables that are based on cited scientific sources that are used under the fair use clause:

- *Figure 26.1*: Projections for global final energy demand for the four IPCC scenarios and energy models as used in Fig. 2.2. (A1, A2, B1, B2). Source: Based on IPCC (2000).
- *Figure 26.2*: Geographical potential of woody biomass energy crops as assessed for the four SRES scenarios over time, as well as the simulated total primary energy consumption. Source: Based on Hoogwijk/Faaij/Eickhout/de Vries/Turkenburg (2005).
- *Table 26.1*: Overview of the global potential bio-energy supply in the long term for a number of categories, and the main pre-conditions and assumptions that determine these potentials. Sources: Compiled by the author based on: Hoogwijk/Faaij/van den Broek/Berndes/Gielen/ Turkenburg (2003); Berndes/Hoogwijk/van den Broek (2003); Smeets/Faaij/Lewandowski/Turkenburg (2007); Hoogwijk/Faaij/Eickhout/de Vries/Turkenburg (2005).
- *Table 26.2*: Generic overview of performance projections for different options and biomass markets on shorter (~5) and longer (>~20) years. Source: Based on data in Faaij (2006).

In chapter 27, *David Faiman* drafted eight figures and compiled one table based on statistical data published by IEA (2003) that are in the public domain:

- *Figure 27.1*: World electricity production during the years 1994-2003. Growth rate = 395 TWh per year.
- *Figure 27.5*: Electricity production in Mexico during the years 1994-2003. Growth rate = 8.2 TWh per year.
- *Figure 27.6*: Electricity production in Chile during the years 1994-2003. Growth rate = 2.5 TWh per year.
- *Figure 27.7*: Electricity production in Spain during the years 1994-2003. Growth rate = 10.6 TWh per year.
- *Figure 27.8*: Electricity production in South Africa during the years 1994-2003. Growth rate = 4.0 TWh per year.
- *Figure 27.9*: Electricity production in Saudi Arabia during the years 1994-2003. Growth rate = 5.7 TWh per year.
- *Figure 27.10*: Electricity production in India during the years 1994-2003. Growth rate = 23.4 TWh per year.
- *Figure 27.11*: Electricity production in Australia during the years 1994-2003. Growth rate = 6.6 TWh per year.
- *Table 27.1*: World electricity generation statistics on a regional basis and linear projections to the year 2012.

Two figures are based on photos taken by the author for which he holds the copyright:

- *Figure 27.3*: CPV cell module exposed at 1000X at the 400 m² *PETAL* solar dish test facility in Sede Boqer, Israel.
- *Figure 27.4*: A large pre-commercial CPV system under test in Phoenix, AZ, USA.

One figure and one table are based on internet sources that are in the public domain:

- *Figure 27.2*: Distribution of the world's deserts. Source: U.S. Geological Survey; at: <<http://geology.com/records/sahara-desert-map.gif>>.
- *Table 27.2*: Estimated area of desert land required for enabling each geographical region to freeze its fossil fuel requirements at the anticipated 2012 level. Source: <www.geosource.ac.uk/worldguide/guide_deserts.html> after Chambers Book of Facts (2003).

In chapter 28, *Franz Trieb, Wolfram Krewitt and Nadine May* used several figures that are based on studies (MED-CSP 2005; TRANS-CSP 2006) to which they contributed:

- *Figure 28.1*: Countries of the EU-MENA region analysed within the MED-CSP Study.
- *Figure 28.2*: Gross electricity consumption of countries analysed.

- *Figure 28.3*: Water demand projection in the MENA countries in the MED-CSP scenario.
- *Figure 28.4*: Maps of renewable energy yields of different sources in the EU-MENA.
- *Figure 28.5*: Annual Direct Solar Irradiance in the Southern EU-MENA Region.
- *Figure 28.6*: Share of different technologies for electricity generation in the year 2000.
- *Figure 28.7*: Total electricity consumption and share of different technologies for electricity generation in the analysed countries in the year 2050 according to the MED-CSP scenario.
- *Figure 28.8*: Annual electricity demand and generation within the countries analysed in the MED-CSP scenario.
- *Figure 28.9*: Installed power capacity and peak load within the analysed countries in the MED-CSP scenario.
- *Figure 28.10*: Example of electricity costs and learning in the MED-CSP scenario. Source: MED-CSP 2005.
- *Figure 28.11*: CO₂ emissions of electricity generation in million tons per year for all countries for the MED-CSP scenario and emissions that would occur in a business as usual case (BAU).
- *Figure 28.13*: Three samples of high voltage direct current (HVDC) interconnections between Europe, the Middle East, and North Africa (EUMENA) analysed for potential environmental impacts and costs. Source: TRANS-CSP (2006).
- *Figure 28.14*: Vision of a future Trans-Mediterranean HVDC electricity grid interconnecting sites of high renewable electricity potentials in Europe and beyond. Source: Trieb/Mueller-Steinhagen (2007).
- *Figure 28.15*: A scenario of the power sector in 30 European countries aiming at economic and ecological sustainability using a balanced mix of national and imported renewable electricity sources. Source: TRANS-CSP (2006).
- *Table 28.1*: Some characteristics of contemporary power technologies. Source: The authors.

For one additional figure the permission was granted by the authors.

- *Figure 28.12*: A new circuit of development: CO₂ reduction in Europe fosters development for North Africa and the Middle East. Source: Kabariti/Moeller/Knies (2003). Permission was granted and a more recent version was supplied by Gerhard Knies.

In chapter 30, *Gareth M. Winrow* compiled two tables based on published sources under the fair use clause:

- *Table 30.1*: Electricity Demand Scenarios by MENR (kWh). Source: Isik (2004: 4).
- *Table 30.2*: Natural Gas Supply and Demand Scenarios (bcm). Source: BOTAS website; at: <http://www.botas.gov.tr/eng/naturalgas/ng_sup_dem.asp> (21 September 2005).

In chapter 31, *Nogoye Thiam* produced three diagrams and one table based on published sources by the IEA, the national energy ministries of Mali and Senegal, the U.S. Department of Energy and reproduced two maps from US universities that are all in the public domain:

- *Figure 31.1*: 1973 and 2003 Regional Shares of Total Final Energy Consumption. Source: IEA; at: <<http://www.iea.org/statist/index.htm>>.
- *Figure 31.2*: Africa's Share of Total Primary Energy Supply in 2003. Source: IEA (2006); at: <<http://www.iea.org/statist/index.htm>>.
- *Figure 31.3*: Energy consumption profiles for Mali and Senegal in 2004. Source: Produced by this author based on annual reports by the National Ministries of Energy in Mali and Senegal.
- *Figure 31.4*: Map of oil and gas fields and pipelines in West Africa: Source: U.S. Department of Energy; at: <<http://www.eia.doe.gov/emeu/cabs/archives/africa/wafrica.pdf>>.

- *Figure 31.5*: West African Gas Pipeline (WAGP). Source: U.S. Department of Energy, Energy Information Administration; at: <<http://www.eia.doe.gov/emeu/cabs/wagp.html>>.
- *Figure 31.6*: Map of Mali. Source: The University of Texas at Austin, Perry-Castañeda Library Map Collection; at: <http://www.lib.utexas.edu/maps/africa/mali_rel94.jpg>. The map is in the public domain.
- *Figure 31.7*: Map of ECOWAS countries. Source: University of Purdue, West Africa Power Pool Development Group, ECOWAS; at: <<http://www.purdue.edu/dp/energy/images/ECOWAS.gif>>. The map is in the public domain.
- *Table 31.1*: Stoves Efficiency. Source: Ministry of Energy and Mines and PERACOD (2005).

The text in the following boxes is based on the author's research:

- *Box 31.1*: West African Gas Pipeline (WAGP).
- *Box 31.2*: Biofuel: Mali's experience with pourghere.
- *Box 31.3*: The West African Power Pool (WAPP).

In chapter 32, *Rolf Linkohr* reproduced one map for which permission was obtained.

- *Figure 32.1*: Solar cell land requirements where six boxes (100 km on a side), in areas of high solar radiation, can each provide 3.3 TW of electrical power. Source: Smalley (2005).

In chapter 33, *Úrsula Oswald Spring* designed and reproduced figures, compiled tables and wrote text in boxes that rely on the author's previous publications and on new research:

- *Figure 33.1*: Conditions of the Structural Adjustment Policy (SAP) of the IMF for Debt Repayment in Developing Countries. Source: Strahm/Oswald (1990: 130).
- *Figure 33.6*: International migrants and refugees (1960-2005). Source: UN (2006); at: <<http://esa.un.org/migration/>>.
- *Figure 33.11*: Food sovereignty: equal access to food and symmetrical access to food consumption. Source: Chávez/Ávila/Shamah (2007); modified by Oswald (2007a).
- *Table 33.1*: Models of World Global Food Consumption by Social Classes. Source: Lang/Heaseman (2004 or 2005: 195), modified by Oswald.
- *Table 33.4*: Advantages and disadvantages in the food production sectors. Source: Compiled by the author.
- *Box 33.4*: Major survival strategies. Source: Oswald (1991, 2007, 2008a).

The following figures were reproduced from websites of international organizations and national agencies that are in the public domain:

- *Figure 33.2*: Vicious circle of hunger, undernourishment, poverty, and ignorance. Source: Chávez/Ávila/Shamah (2007: 208).
- *Figure 33.3*: Food Production, Prices, and Undernourishment. Source: FAOSTATS Millennium Ecosystem Assessment.
- *Figure 33.4*: The Global Hunger Index Progress towards the MDGs. Source: IFPRI (2007); at: <<http://www.ifpri.org/media/20071012GHI/GHIMap07hr.jpg>>.
- *Figure 33.5*: Proportion of Undernourished in Developing Regions. Source: FAO/IFAD/WFP (2002: 9).
- *Figure 33.7*: Undernourished Population in Latin America and in the Caribbean. Source: The estimates by CEPAL (2004) are based on FAO data.
- *Figure 33.8*: Comparison of national surveys on food, nutritional stage of children below 5 years of age. Source: National Nutritional Survey (INNSZ 1974, 1979, 1989, 1996).
- *Figure 33.9*: Map of municipalities in Mexico with high and very high needs for nutritional attention. Source: Chávez/Ávila/Samah (2007), based on the National Survey of Nutrition (2005).
- *Figure 33.10*: Programme 'Fome zero' (without hunger) in Brazil. Source: Instituto Cidadania (2001), São Paulo, Brazil.

- *Table 33.2:* Social Vulnerability and Internal Gaps in Wealth and Income in Mexico. Source: INEGI (2005) and Bank of Mexico (2004).
- *Table 33.3:* Nutritional Priority in 2,443 Municipalities in Mexico. Source: Chávez/Ávila/Shamana (2006); based on the National Survey of Nutrition (INNSZ 2005).
- *Box 33.1:* The evolution of the concept of food security within the FAO.
- *Box 33.2:* Concept of food sovereignty as developed by social movements.
- *Box 33.3:* Food Sovereignty Document, September 2005. Source: <http://www.aefjn.be/index.php?option=com_content&task=view&cid=31&Itemid=37>.

In chapter 35, *Selim Kapur, Burcak Kapur, Erhan Akca, Hari Eswaran and Mustafa Ayдын* have designed the following figures and compiled the table based on their own research and on governmental sources:

- *Figure 35.1:* The irrigation basins of the GAP. Source: <www.gap.gov.tr>.
- *Figure 35.2:* Agricultural added value in the GAP per capita
- *Figure 35.3:* Actual and potential salinity of the Harran Plain in 1985. Sources: Dinç/Kapur (1991); Şenol/Yeğingil/Dinç/Öztürk (1991); Özkutlu/Ince (1999).
- *Figure 35.5:* Harran project activity chart. Source: modified from Kapur/Eswaran/Akça/Dinçil (2002).
- *Table 35.1:* Comparison of the whole product in Turkey with increase of some crops after the GAP irrigation.

The permission was obtained by the authors to reproduce these figures:

- *Figure 35.4:* The land suitability map of the Harran Plain. Source: Şenol/Yeğingil/Dinç/Öztürk (1991).

In chapter 36, *Hans-Georg Bohle* reproduced this figure that is in the public domain.

- *Figure 36.1:* The Sustainable Livelihood Framework. Source: DFID (1999).

In chapter 37, *Guénaél Rodier and Mary Kay Kindhauser* based table 37.1 on WHO data:

- *Table 37.1:* Cases and deaths from recent outbreaks. Source: WHO Statistics; at: <<http://www.who.int/research/en/>>.

In chapter 38, *Jennifer Leaning* created two figures based on data by UN and UNDP publications and designed a figure based on UNWTO data that are all in the public domain:

- *Figure 38.1:* Population of the World 1950-2050 according to different projection variants. Source: Created by the author based on data from: United Nations Population Division, World Population Prospects: The 2006 Revision Population Database; at: <<http://esa.un.org/unpp/>>.
- *Figure 38.2:* Urban and rural population of the world, 1950-2030. Source: Created by the author based on data from: United Nations Population Division, World Urbanization Prospects: The 2007 Revision Population Database; at: <<http://esa.un.org/unup/index.asp>>.
- *Figure 38.3:* Growing Disparities between the Rich and the Poor. Source: Based on data from: UNDP (2006: 288-290). In 1980 data were available on fewer countries than in 2004.
- *Figure 38.4:* Change in water run-off compared with average 1961-1990 (%) for 2050 based on IPCC Scenario A1. Source: UNDP (2006: 162); at: <<http://www.hdr.undp.org>>.
- *Figure 38.5:* International Tourist Arrivals (1950-2005). Source: Created by author based on data from: UNWTO (2006: Annex 3); at: <<http://www.worldtourism.org/facts/menu.html>>.

In chapter 39, *Fred Eboko and Tereza Nemeckova* reproduced a figure that is in the public domain:

- *Figure 39.1*: Political Map of Southern Africa (2005). Source: University of Texas at Austin, Perry-Castañeda Library Map Collection; at: <http://www.lib.utexas.edu/maps/ciao7/bots-wana_sm_2007.gif>.

They produced four tables based on data by international organizations and national agencies that are in the public domain:

- *Table 39.1*: HIV and AIDS statistics in Sub-Saharan Africa, 2001 and 2007 Source: UN-AIDS (2007: 7).
- *Table 39.2*: Botswana key figures (2007). Source: OECD (2007: 135).
- *Table 39.3*: HIV prevalence by residence and age (2003), in percentages. Source: AIDS surveillance 2003; at: <www.naca.gov.bw/documents/flyer_english_A4.pdf>: 3.
- *Table 39.4*: HIV prevalence among men and women aged 15-49 years (2003), in percentages. Source: AIDS surveillance 2003; at: <www.naca.gov.bw/documents/flyer_english_A4.pdf>: 3.

In chapter 40, *Isabel Fischer and Mohammad Musfequs Salehin* reproduced a figure from a previous publication of one author and compiled a table based on UNDP data that are public:

- *Figure 40.2*: Health, poverty and human security interactions. Source: Salehin (2005: 10).
- *Table 40.1*: Country Facts Vietnam, Bangladesh and Japan. Source: UNDP's HDR (2007/2008), selected Indicators for Vietnam, Bangladesh and Japan; at: <<http://hdrstats.undp.org/indicators/>>.
- *Box 41.1*: Millennium Development Goals on Health Issues. Source: United Nations Millennium Declaration; at: <<http://www.un.org/millennium/>>; UNDP (2000): Millennium Development Goals, at: <<http://www.undp.org/mdg/basics.shtml>> and at: <<http://www.undp.org/mdg/goallist.shtml>>.

For the reproduction of this figure they obtained permission from the copyright holder:

- *Figure 40.1*: Human Security and its Relationship to Health. Source: Chen/Narasimhan (2003: 6).

In chapter 41, *Tony Allan* offered his own scientific estimates in the following five tables to data supplied in the literature:

- *Table 41.1*: Estimates of global use of water and 'trade' in virtual water. Source: Hoekstra/Chapagain (2004) and author's estimates.
- *Table 41.2*: Population estimates for more and less developed economies – UN medium variant in millions. Source: UN 2004, Medium Variant, US Census Bureau, historic estimates and author's interpolations.
- *Table 41.3*: Water use estimates per head in litres per day assuming level use by less developed economies and a reduction by users in more developed economies. Source: Hoekstra/Chapagain (2004) and author's estimates.
- *Table 41.4*: Water use in more and less developed regions on the basis of population estimates [medium variant] and projected use in Laces same as in 2000. Source: Author's estimates.
- *Table 41.5*: Estimates of water use per head – more and less developed economies. Source: Chapagain/Hoekstra (2004b) and author's estimates.

He obtained the permission of the authors to reproduce this table and figure:

- *Table 41.6*: Global Virtual Water Crop and Livestock Related 'Exports' and 'Imports' by region. Source: Chapagain/Hoekstra (2004): 46.

- *Figure 41.1*: The national water footprint per capita and the contribution of different consumption categories for some selected countries. Source: Hoekstra/Chapagain (2007: 44).

In chapter 42, *Vandana Shiva* compiled table 42.1 comparing the Himalayan and the Peninsular Components.

In chapter 43, *Bastien Affeltranger* compiled two tables based on published sources:

- *Table 43.1*: Mekong River Basin - Hydrological contributions from riparian countries Source: Wolf (1999).
- *Table 43.2*: Estimation of damages of the 2005 flood in the Lower Mekong countries. Source: MRC Website; at: <<http://www.mrcmekong.org/programmes/flood.htm>>.

In chapter 44, *Mustafa Aydin and Fulya Ereker* appreciate the permission of the copyright holders to reproduce the following figures and tables.

- *Figure 44.1*: General Layout of the Euphrates-Tigris Basin. Source: Altýnbilek (2004: 17).
- *Figure 44.2*: Average Annual Flow Values for Euphrates-Tigris Rivers. Source: Altýnbilek (2004: 19).
- *Figure 44.3*: Dams in the Euphrates-Tigris Basin. Source: Allan (2002, Annexes).
- *Table 44.1*: Potential Water Demands on the Euphrates (mcm). Source: Beaumont (1998: 179).
- *Table 44.2*: Potential Water Demands on the Tigris (mcm). Source: Beaumont (1998: 182).
- *Table 44.3*: GAP Land and Water Resources Development Projects. Source: GAP Regional Development Administration (2006: 2).

In chapter 45, *Bassam Ossama Hayek* reproduced this map that is in the public domain:

- *Figure 45.2*: Map of Jordan. Source: University of Texas at Austin, Perry-Castañeda Library Map Collection; at: <http://www.lib.utexas.edu/maps/middle_east_and_asia/jordan_rel_2004.jpg>. This map is in the public domain.

The following figure and table was reproduced from a publication of the Jordanian Ministry of Water and Irrigation that is in the public domain:

- *Figure 45.3*: Water use distribution among sectors (million cubic meters supplied), in 2000. Source: Ministry of Water and Irrigation (2002: 9).
- *Table 45.1*: Projected water demand per sector (million cubic metres, MCM). Source: Ministry of Water and Irrigation (2002: 9).

Permission was granted by Otto Simonett of UNEP/GRID with the consent of the designer to reproduce this figure:

- *Figure 45.1*: Availability of Freshwater in 2000. Average River Flows and Groundwater Recharge. Source: Designed by Philippe Rekacewicz, UNEP/GRID-Arendal (2000); in: World Resources Institute: *World Resources 2000-2001, 'People and Ecosystems: the Fraying Web of Life'* (Washington, D.C.: WRI); at: <<http://maps.grida.no/go/graphic/freshwater-availability-groundwater-and-river-flow>>.

In chapter 48, *Emad Adly and Tarek Ahmed* reproduced the following three maps and satellite images as well as four tables that are based on sources that are in the public domain:

- *Figure 48.1*: The Nile River Basin. Source: NBI (2005); at: (<<http://www.nilebasin.org>>).
- *Figure 48.2*: Satellite Image of the Nile River. Source: NASA, Visible World; Credit Jeff Schmaltz, MODIS Rapid Response Team, NASA/GSFC, Sensor Terra/MODIS, 27 August 2003; <<http://veimages.gsfc.nasa.gov/5724/Egypt.A2003235.0845.250m.jpg>>.

- *Figure 48.3*: Rainfall Patterns in the Nile Basin. Source: SPIDER International Ltd. (1994, 1997): *Water Resources Atlas of the River Nile Basin* (Ottawa: Canadian International Development Agency).
- *Table 48.1*: Population Growth in the Nile Basin Countries. Sources: Data for 1950 and 2000 and projections for 2025 and 2050: UN (2007); at: <<http://esa.un.org/unpp>>. Compiled by H.G. Brauch, 23 January 2008.
- *Table 48.2*: Per Capita Share of Water Consumption (m³/year) in Riparian Countries in 1995, and Anticipated Share in 2025 and 2050. Source: FAO, Natural Resources Management and Environment Department, 1997: *Irrigation Potential in Africa: A Basin Approach* (Rome: FAO); at: <www.fao.org/docrep/w4347E/w4347eok.htm>.
- *Table 48.3*: Estimated Water Balance of Egypt in 1997 and 2017 (in km³/year). Source: Egypt, Ministry of Water Resources and Irrigation (2002).
- *Table 48.4*: Indicators Used to Report on the State of Food Security in Egypt. Source: Egypt, Ministry of Water Resources and Irrigation (2003).

In chapter 49, *Patricia Kameri-Mbote and Kithure Kindiki* reproduced three maps that are in the public domain (FAO, USDA) and obtained permission from the copyright holders to reproduce the first map:

- *Figure 49.1*: Landcover Classes in the Nile Basin. Source: IUCN: *Water Resources E Atlas. Watersheds of the World*; at: <<http://www.iucn.org/themes/wani/eatlas/html/af15.html>>; © World Resources Institute (2003). WRI was informed three times and did not object the reproduction under the fair use clause.
- *Figure 49.2*: The Upper Nile Basin and Lake Victoria. Source: USDA, Production Estimates and Crop Assessment Division Foreign Agricultural Service; at: <http://www.fas.usda.gov/pecad/highlights/2005/09/uganda_26sep2005/images/nile_basin.htm>.
- *Figure 49.3*: Population Distribution on the Nile Basin in 2005 and 2030. Source: FAO <<http://www.fao.org/images/PopulationDistribution29Nov.png>>.
- *Figure 49.4*: Figure 50.4: Dominant Crops in the Nile Basin Farming System. Source: FAONile; at: <<http://www.fao.org/images/dorminantcrops.png>>.

In chapter 50, *Peter Ashton and Anthony Turton* designed three figures based on data that are either in the public domain or on their own data.

- *Figure 50.1*: Map of Africa showing the locations and names of the continent's 63 international (shared) river basins. Source: Map modified and redrawn from UNEP (2002: 27), plus own data.
- *Figure 50.2*: Map of Southern Africa, showing the international (shared) aquifer systems used by the SADC states. Source: Map is drawn from data in UNESCO-ISARM (2004: 7), plus own data.
- *Figure 50.3*: Map of Southern Africa showing the locations of large water supply dams in relation to the shared river basins in Southern Africa. Source: Map drawn from data in WCD (2000: 370), plus own data.
- *Box 50.1*: “Protocol on Shared Watercourses in the Southern African Development Community (SADC)” signed in 2000.

Two additional figures were drafted and two tables were compiled by the authors:

- *Figure 50.4*: Map of the Southern African Hydropolitical Complex.
- *Figure 50.5*: Schematic diagram illustrating the relationships between shared river basins within the SADC region and countries comprising the Southern African Hydropolitical Complex. Source: amended and redrawn from Turton (2003a: 294); Ashton/Turton (2004: 7).
- *Table 50.1*: Countries sharing the international river basins found in the SADC region.
- *Table 50.2*: Projected Population Growth in SADC Countries, compared with other African regions.

In chapter 51, *Martin Kipping* appreciates the permission by the copyright holder to reprint the following map:

- Table 51.1: The Senegal River Basin. Source: Brantly/Ramsey (1998: 108).

In chapter 52, *Maëlis Borghese* used these three figures based on her diploma thesis:

- Figure 52.1: Scheme: Realist-Oriented Regime Formation Process in Transboundary Basins. Source: Based on Borghese (2005).
- Figure 52.2: Scheme: Integrated Model of Regime Formation. Source: Based on Borghese (2005)
- Figure 52.6: Volta Basin Regime Genesis. Source: Based on Borghese (2005).

For the remaining figures and tables the author obtained the permission from the copyright holders:

- Figure 52.3: Map: Representation of the Volta River Basin Showing Political Boundaries. Source: UNEP (2002: 2).
- Figure 52.4: Freshwater Stress and Scarcity in Africa by 2025. Source: UNECA (2000); UNEP (1999).
- Figure 52.5: Map: Environmental Critical Areas in the Volta Basin. Source: UNEP (2001), RCN 2/4.
- Table 52.1: Distribution of the Basin in the Six Riparian Countries. Sources: Data for the Volta River Basin are from respective UNEP National Reports (UNEP 2001a, 2001b, 2001c, 2001d, 2001e, 2001f).
- Table 52.2: Annual Rainfall and Evaporation in the Riparian Countries of the Volta Basin. Source: Barry/Obuobie/Andrein/Andah/Pluquet (2004: 13).
- Table 52.3: Population projection in the Volta River basin. Source: UN, cited from: Barry/Obuobie/Andrein/Andah/Pluquet (2004: 22).

In chapter 53, *Stefan Lindemann* used one figure based on his diploma thesis:

- Figure 53.1: Political determinants of water regime formation and water regime effectiveness.

In chapter 54, *Martin Kipping* is grateful to the copyright holders to reproduce the following:

- Figure 54.1: The Aral Sea Basin's Main Watercourses. Source: McKinney (2003: 189).
- Table 54.2: Origin of River Flow and Water Allocation in the Aral Sea Basin. Source: Adapted from McKinney (2003: 193).

He compiled the following table based on data that are in the public domain or on research by the author:

- Table 54.1: Socio-economic Indicators of the Aral Sea Basin's Riparian Countries (2005). Source: CIA Factbook (2005).
- Box 54.1: The Malthusian Discourse.

In chapter 55, *Eva Rakel* obtained permission from the copyright holders to reproduce:

- Figure 55.1: Map of Central Asian Countries. Source: Everett-Heath (2003).
- Figure 55.2: Images of a Shrinking Aral Sea (1960-2010). Source: Spoor/Krutov (2004/2005): 285.
- Figure 55.3: Water Issues in the Ferghana Valley. Source: Victor Novikov; Philippe Rekacewicz, UNEP/GRID-ARENDAL, April 2005, see at: <<http://www.relief-web.int/rw/RWB.NSF/db900LargeMaps/AHAA-6CYLV7?OpenDocument>>. This figure is in the public domain.
- Figure 55.4: Three Dimensional View of the Ferghana Valley Region. Source: UNEP and: <<http://www.reliefweb.int/rw/RWB.NSF/db900LargeMaps/AHAA-6CCRDG?OpenDocument>>. This figure is in the public domain.

In chapter 56, *Julia Wunderer* compiled four tables based on public data:

- *Table 56.1*: Framework of Conflict Dimensions. Source: The author.
- *Table 56.2*: Conflict Dimensions of Water-Related Conflicts in Central Asia. Source: The author.
- *Table 56.3*: The Central Asian Water Agreements. Source: Compiled by the author.
- *Table 56.4*: Central Asian Participation in International Water Law. Source: The author.

In chapter 57, *Christopher Martius, Jochen Froebrich and Ernst-August Nuppenau* developed their own figures and table based on public data:

- *Figure 57.1*: Irrigated Lowlands of the Amu Darya (Amu Darya Lowlands or ADL). Source: The authors.
- *Figure 57.2*: Essential Utility Aspects of Water and Cross-cutting Themes for Achieving IWRM in the Amu Darya Lowlands. Source: The authors.
- *Figure 57.3*: Generalized pattern for implementing key activities as partial elements within an IWRM framework. Source: The authors.
- *Table 57.1*: Examples of key technologies to be implemented in the framework of an IWRM concept for the ADL. Source: The authors.

In chapter 58, *Mara Tignino* compiled a table based on public data and used a map that is in the public domain:

- *Figure 58.1*: Map of current International Committee of the Red Cross Water and Sanitation Programmes around the world. Source: ICRC; at: <www.icrc.org>.
- *Table 58.1*: Excerpts of relevant instruments on water security during armed conflicts.

In chapter 61, *Alexander Sergunin* included five maps that are all in the public domain:

- *Figure 61.1*: Map of the Russian Federation. Source: Map 3840, Rev. 2, January 2004. United Nations, Department of Peacekeeping Operations, Cartographic Section. Reprinted with permission.
- *Figure 61.2*: Political Map of Belarus (1997). Source: Map 3776, Rev. 3, January 2004. United Nations, Department of Peacekeeping Operations, Cartographic Section. Reprinted with permission.
- *Figure 61.3*: Political Map of Ukraine (1993). Source: Map 3773, Rev. 4, January 2005. UN, Department of Peacekeeping Operations, Cartographic Section. Reprinted with permission.
- *Figure 61.4*: Key Environmental Problem Areas in Russia. Source: University of Texas at Austin, Perry-Castañeda Library Map Collection; at: <http://www.lib.utexas.edu/maps/commonwealth/russia_environmental98.pdf> from the *Handbook of International Economic Statistics* (1996).
- *Figure 61.5*: Map of Radiation Hotspots Resulting from the Chernobyl Nuclear Power Plant Accident in 1986. Source: University of Texas at Austin, Perry-Castañeda Library Map Collection; at: <http://www.lib.utexas.edu/maps/commonwealth/chornobyl_radiation96.jpg> from *Handbook of International Economic Statistics* 1996.

In chapter 62, *P.S. Ramakrishnan* used two figures and a table from his previous publications:

- *Figure 62.1*: Demojong, the land of hidden treasures: Pictorial depiction of holy sites in West Sikkim, Eastern Himalayas. Source: Ramakrishnan (1996).
- *Figure 62.4*: Interdisciplinary interactions called for in tropical forest management and conservation. Source: Ramakrishnan (2001).
- *Table 62.1*: TEK centred on the socially selected keystone species, *Quercus* spp., acting as a trigger for rehabilitation of the mountain landscape in the Central Himalaya. Source: Ramakrishnan (2001).

The Map of India is in the public domain:

- Figure 62.2: Map of India. Source: University of Texas at Austin, Perry-Castañeda Library Map Collection; at: <http://www.lib.utexas.edu/maps/middle_east_and_asia/india_polo1.jpg>.

He appreciates the permission of the author and publisher to reproduce this figure:

- Figure 62.3: Broad agro-ecosystem typologies linked to species richness (x-axis) and agro-eco-system complexity. Source: Swift/Anderson (1993).

In chapter 63, *Miranda A. Schreurs* reproduced one map that is in the public domain:

- Figure 63.1: Map of East Asia (political), 2004. Source: University of Texas, Austin, PLC map collection.

To reproduce the text in the box permission was granted by the IEA:

- Box 63.1: “China’s Share of World Energy Demand will Continue to Expand”. Executive Summary. Source: IEA (2007: 6-7).

In chapter 64, *Mohammad El-Sayed Selim* used one map that is in the public domain:

- Figure 64.1: Map of the member states of the Arab League. Source: <<http://www.usira-qprocon.org/images/Maps/Arableague.html>>.

In chapter 66, *Robin Twite* reproduced three photos on the security fence separating Israel and the West Bank for which he obtained permission from the photographer Dr. Gershon Baskin.

In chapter 67, *Mohammed S. Dajani Daoudi* compiled a table based on public sources:

- Table 67.1: Total agricultural areas in dunums, annual production in tons, and value in US\$ in the eastern part of Israel’s segregation zone. Source: ARIJ, Agriculture & Biodiversity Research Unit (2003).

In chapter 69, *Sam Moyo* reproduced nine figures from which permission was granted by UNEP-GRIP and the designer Philippe Rekacewicz, UNEP-Arendal. These figures are all in the public domain:

- Figure 69.1: Major River Basins of Africa. Source: UNEP-GRIP, Vital Graphics; at: <<http://www.unep.org/vitalwater/03.htm#04>>.
- Figure 69.2: Fresh Water Stress in 2000 and Projection for 2025. Source: UNEP-GRIP, Vital Graphics; at: <<http://www.unep.org/vitalwater/25-waterstress-world.htm>>.
- Figure 69.3: Water Availability and Water Stress in Africa in 2000 and 2005. Source: UNEP-GRIP, Vital Graphics; at: <<http://www.grida.no/climate/vitalafrica/english/15.htm>>.
- Figure 69.4: Aridity Zones in Africa. Source: UNEP-GRIP, Vital Graphics; at: <<http://www.grida.no/climate/vitalafrica/english/25.htm>>.
- Figure 69.5: Deforestation in Africa. Source: UNEP-GRIP, Vital Graphics; at: <<http://www.grida.no/climate/vitalafrica/english/07.htm>>.
- Figure 69.6: Food Production in Africa and the World. Food Production Index, Net per Capita (PIN base 1989-1991). Source: UNEP-GRIP, Vital Graphics; at: <<http://www.grida.no/climate/vitalafrica/english/26.htm>>.
- Figure 69.7: Food Shortages, chronic malnutrition, famines and conflicts in Africa during the 1990’s. Source: UNEPGRIP, Vital Graphics; at: <<http://www.grida.no/climate/vitalafrica/english/27.htm>>. Permission was obtained from Philippe Rekacewicz, UNEP-Arendal.
- Figure 69.8: Freshwater Stress and Scarcity in Africa by 2025. Source: UNEP-GRIP, Vital Graphics; at: <<http://www.unep.org/vitalwater/25-waterstress-africa.htm>>.

- *Figure 69.9*: People Affected by Natural Disasters in Africa. Source: UNEP-GRIP, Vital Graphics; at: <<http://www.grida.no/climate/vitalafrica/english/o8.htm>>.

In chapter 71, *Vicken Cheterian* is grateful to ENVSEC and to UNEP/GRID for permitting him to reproduce the following box and five maps from its publications on the Caucasus:

- *Box 71.1*: EnvSec activities with a specific focus on the Southern Caucasus. Source: EnvSec; at: <<http://www.envsec.org/about.php>> and <<http://www.envsec.org/southcauc/index.php#maps>>.
- *Figure 71.1*: Environment and Security Priority Areas in the Southern Caucasus. Source: EnvSec; at: <<http://www.envsec.org/southcauc/maps/priorities.jpg>>.
- *Figure 71.2*: National environment and security issues in Armenia. Source: EnvSec; at: <<http://www.envsec.org/southcauc/maps/armenia.jpg>>.
- *Figure 71.3*: National environment and security issues in Georgia. Source: EnvSec; at: <<http://www.envsec.org/southcauc/maps/georgia.jpg>>.
- *Figure 71.4*: National environment and security issues in Azerbaijan. Source: EnvSec; at: <<http://www.envsec.org/southcauc/maps/azerbaijan.jpg>>.
- *Figure 71.5*: Transportation and communication links in Southern Cascaia Source: EnvSec; at: <<http://www.envsec.org/southcauc/maps/transport.jpg>>.

In chapter 72, *Jon Barnett* is grateful for permission to reproduce this map:

- *Figure 72.1*: The Asia-Pacific Region. Source: The author.
- The following two tables rely on data by the ADB and the UN that are in the public domain.
- *Table 72.1*: Selected Indicators on the Asia-Pacific Region. Source: ADB (2004).
- *Table 72.2*: Population Change for Selected Asia-Pacific Countries. Source: UN (2004).

The author compiled the following two tables based on his own research:

- *Table 72.3*: Some Selected Environmental Problems for Selected Countries In The Asia-Pacific Region. Source: Compiled by the author.
- *Table 72.4*: Contrasting Climate Change and Atoll Countries with Water Problems in China. Source: Compiled by the author.

In chapter 73, *Gunhild Hoogensen* included two maps that are in the public domain:

- *Figure 73.1*: Map of the Arctic Region. Source: University of Texas at Austin, Perry-Castañeda Library Map Collection; at: <http://www.lib.utexas.edu/maps/islands_oceans_poles/arctic_ref802647_1999.jpg>.
- *Figure 73.2*: Map of the Antarctic Region. Source: University of Texas at Austin, Perry-Castañeda Library Map Collection; at: <http://www.lib.utexas.edu/maps/islands_oceans_poles/antarctic_ref802648_1999.pdf>.

In chapter 74, *Hans Günter Brauch* compiled five tables based on sources that are in the public domain or were adapted and developed further based on the cited literature:

- *Table 74.1*: Contextualizing human security concepts, pillars, and policy agendas. Source: compiled by the author.
- *Table 74.2*: Systematic overview on referent objects, key values, nature of threats, and agents of insecurity and policy agendas referred to in the debate in the United Nations General Assembly on 22 May 2008. Source: speeches analysed by the author.
- *Table 74.3*: Four Pillars of Human Security. Source: The table was stimulated by Ulbert and Werthes (2008: 21) who developed it based on Hampson/Daudelin/Hay/Martin/Reid (2002: 33).
- *Table 74.4*: Compilation of Human Security Threats, Challenges, Vulnerabilities, Risks: Source: Brauch (2005a: 80).

- *Table 74.5:* ‘Human Security’ Policies and Measures for Coping with Environmental Threats, Challenges, Vulnerabilities, and Risks for ‘Ecosystems’ and ‘Sustainability’. Source: compiled by the author.

In chapter 75, *Claudia F. Fuentes Julio and Hans Günter Brauch* compiled the following four tables based on data that are in the public domain and on their previous publications.

- *Box 75.1:* Excerpts from the paper for the Greek Presidency on: “Human security and the climate change impact on vulnerable groups” of 8 May 2007. Source: HSN, documents of the 9th Ministerial in Slovenia, 17–18 May 2007; at: <<http://www.humansecuritynetwork.org/docs/2007-ministerial-meeting-04-greek%20paper.doc>>.
- *Table 75.1:* Countries of the Human Security Network. Source: Population: PRB 2005: 2005 *World Population Data Set*; Human Development Index. GDP per capita: UNDP 2005; Membership in multilateral international organizations. Source: Compiled and updated by Hans Guenter Brauch.
- *Table 75.2:* Agendas of nine Ministerial Meetings of the HSN (1999–2007). Source: Compilation by the authors based on “Chair’s Summary” of the Ministerial Meetings of the HSN.
- *Table 75.3:* List of Lead and Partner Countries for HSN Activities. Source: at: <<http://www.humansecuritynetwork.org/docs/Table%20of%20Lead%20and%20Partner%20Countries-e.php>>.
- *Table 75.4:* The Human Security Network and the four pillars of the Human Security Concept. Source: Hans Günter Brauch for UNESCO (2006, 2008).

In chapter 76, the three tables are based on compilations by the author *Abdus Sabur*:

- *Table 76.1:* Dimensions of National and Human Security.
- *Table 76.2:* Human Security Issues and Possible Responses.
- *Table 76.3:* Human Security Issues in South Asia and Possible Responses.

In chapter 77, *Sascha Werthes and Tobias Debiel* reproduced a figure from a previous publication in German:

- *Figure 77.1:* The Horizontal and Vertical Security Agenda Extension. Source: Debiel/Werthes (2005: 10).

In chapter 78, *Béchir Chourou* acknowledges the permission of the copyright holder to use the following material:

- *Figure 78.2:* Western Sahara. Source: Map 3175, Rev. 2, January 2004. United Nations, Department of Peacekeeping Operations, Cartographic Section. Reprinted with permission; at: <<http://www.un.org/Depts/Cartographic/map/profile/wsa-hara.pdf>>.
- *Table 78.1:* Direct and Indirect Threats to Human Security. Source: Bajpai (2000: 40).

The following map and the material reproduced in the table are in the public domain;

- *Figure 78.1:* Map of the wider Maghreb consisting of Algeria, Libya, Mauritania, Morocco and Tunisia. Source: This map is in the public domain and not protected by copyright; at: <http://www.maghrebarab.com/maghreb_arab_map.html>.
- *Table 78.3:* Selected social and economic indicators for the ‘Core’ Maghreb. Source: UNDP’s *Human Development Report 2006*.

This table was compiled by the author:

- *Table 78.2:* History of Regimes in the Maghreb.

In chapter 79, *Zarina Othman* reproduced a map that is in the public domain and compiled three tables based on data that are also in the public domain or a result of her own research:

- *Figure 79.1*: Map of Southeast Asia and of the ASEAN Countries. Source: University of Texas at Austin, Perry-Castañeda Library Map Collection. This map is in the public domain; at: <http://www.lib.utexas.edu/maps/middle_east_and_asia/southeast_asia_pol_2003.jpg>.
- *Table 79.1*: Membership of Southeast Asian countries in regional IGOS and NGOs. Source: Compiled by the author.
- *Table 79.2*: Demographic and Socio-Economic Information of ASEAN States. Source: CIA (2007); at: <<https://www.cia.gov/library/publications/the-world-factbook/>> (15 May 2007); and at: <http://www.aseansec.org> (25 February 2008). Compiled by the author.
- *Table 79.3*: Characteristics of Comprehensive Security and Human Security. Source: Compiled by the author.

In chapter 80, *Nana K. Poku and Bjorg Sandkjaer* in their figures and tables rely on data from the UN and other international organizations that are in the public domain.

- *Figure 80.1*: The increase in proportion of hungry is the greatest in sub-Saharan Africa. Source: United Nations (2005: 8).
- *Figure 80.2*: Undernourished in Africa, estimated and projected, in millions. Source: United Nations (2005) and United Nations Millennium Development Goal Indicators Data Base; at: <<http://mdgs.un.org/unsd/mdg/Default.aspx>> (28 February 2006).
- *Figure 80.3*: Gender and education in sub-Saharan Africa. Source: UNICEF (2006: 117).
- *Figure 80.4*: Children not enrolled in school, sub-Saharan Africa, per cent. Source: UNESCO Data Base on Millennium Development Goal Attainment; at: <http://www.uis.unesco.org/ev.php?URL_ID=5261&URL_DO=DO_TOPIC&URL_SECTION=201> (28 February 2006).
- *Figure 80.5*: Infant Mortality Rate. Source: United Nations World Population Prospects Data Base; at <<http://http://esa.un.org/unpp/>> (27 February 2006).
- *Figure 80.6*: Maternal mortality, SSA countries with rates higher than 1000 in 2000. Source: UN Statistics Division MDG indicators data base.
- *Figure 80.7*: Women in Parliament in 2004. Source: Population Reference Bureau (2005); United Nations (2005).
- *Table 80.1*: GDP growth under adjustment - agriculture growth rate (median) sub-Saharan Africa, 1981-1983, 1987-1991 and 1992-1997. Source: ADB and IMF databases.
- *Table 80.2*: Summary of poverty indicators for Africa (figures have been rounded). Source: CPRC (2005) and World Bank (2003).
- *Table 80.3*: African poverty 1980 - 2003 (Figures have been rounded). Source: CPRC (2005) and World Bank (2003).
- *Table 80.4*: The Millennium Development Goals (MDGs) and targets. Source: UN Millennium Project (2005).

In chapter 81, *Philippe De Lombaerde and Matthew Norton* relied in their tables on sources that are in the public domain on which they based their own calculations.

- *Table 81.1*: Perceptions of threats to human security ranked by sub-region. Source: Rojas (2004: 10).
- *Table 81.2*: Inter-state militarized conflicts in the Americas, 1990-2001. Source: Own calculations based on Mares (2003).
- *Table 81.3*: Selected development indicators for Central America. Source: <<http://hdr.undp.org/statistics>> and own calculations.
- *Table 81.4*: Stock of Natural Disasters Affecting Central American Countries. Source: OFDA/CRED International Disaster Database (EM-DAT); at: <www.em-dat.net> own calculations.

In chapter 82, *Francisco Rojas Aravena* reproduced a map that is in the public domain and obtained permission from the copyright holder to reproduce a table:

- *Figure 82.1*: Map of South America. Source: © 2005-2007 Map-Of-South-America.us. All rights reserved. Download at: <<http://www.map-of-south-america.us/south-america-map.gif>>.
- *Table 82.1*: Conceptualization of National, International and Human Security Dimensions. Source: Gurtov (1999: 25-26). Permission was obtained from Rienner Publishers.

The box and other two tables are based on a previous publication and were compiled for this chapter:

- *Box 83.1*: South American Presidential Summits.
- *Table 82.2*: The five variables of human security and mutual vulnerability. Source: Goucha/Rojas Aravena (2003: 22).
- *Table 82.3*: South American Data. Source: prepared by author.

In chapter 85, *Max Schott* supplied a figure and two tables for which he holds the rights:

- *Figure 85.1*: Interview Situation in the Village Tienfala, Mali, 2003. Source: photo by Max Schott.
- *Table 85.1*: Perception of causes/effects related to the seven human security dimensions by the local population of Mali in urban, pre-urban and rural areas. Source: Compiled by the author.
- *Table 85.2*: Ranking of the seven human security dimensions by local populations. Source: Author.

In chapter 88, *Surichai Wun'Gaeo* reproduced the following maps and satellite images by UN and humanitarian agencies that are in the public domain.

- *Figure 88.1*: Map of Southeast Asia. Source: University of Texas at Austin, Perry-Castañeda Library Map Collection. This map is in the public domain; at: <http://www.lib.utexas.edu/maps/middle_east_and_asia/southeast_asia_ref_2007.jpg>.
- *Figure 88.2*: Impact of the Tsunami in the Indian Ocean on 26 December 2004. Source: UNOCHA Situation Report No. 18 (14 January 2005), ReliefWeb Map Centre; at: http://www.reliefweb.int/rw/fullMaps_Sa.nsf/luFullMap/.
- *Figure 88.4*: Satellite images of the Northern Kho Lak Bay (Thailand) before and after the Tsunami. Source: UNOSAT, International Charter Space and Major Disasters Product ID: 325 - 14 Jan, 2005; at: <<http://unosat.web.cern.ch/unosat/>>.

United Nations Convention to Combat Desertification

Social Consequences of Environmental Degradation

Environmental deterioration includes a long and expanding list of major and multiple dysfunctions that feed on each other (White 1993), increasing the chain of vulnerabilities. In the specific case of land degradation and desertification, its huge economic and social costs, and ultimately, implications for peace and security, have not been given adequate recognition. There is also a common misperception that desertification is a 'natural' problem of advancing deserts in faraway developing countries. In reality, it is about the loss of the land's biological productivity. In terms of its global reach, the drylands include approximately one third of the Earth's surface and more than one hundred countries. Over 250 million people are directly affected by desertification, while one billion are at risk.

With regard to the causal chain that leads to desertification, this has been analysed at length and with different findings. The suggested causes include drought and climate change as well as human-induced factors such as over-cultivation, over-grazing and deforestation, which have to be seen in the broader context of population dynamic, poverty and external constraints imposed by the global economy. None of these causes can explain the process by itself. However, there is a strong correlation between food insecurity, poverty, population dynamic, and land degradation.

A Challenge for Survival: Food Insecurity and Famines

The phenomenon of land degradation, desertification and drought has major bearing on the potential of the arable lands to produce adequate food for human consumption. Depending on the source or the method of calculation, it is estimated that between 40 million and 115 million people are directly affected by food insecurity. Under nourishment, however, is a much wider problem. Although the proportion of the world population affected has steadily declined, the total number of people going hungry has actually increased and is currently above 500 million persons.

The recent world food crisis has brought into the spotlights another important aspect of natural resource scarcity, namely that of endangering human rights. Many of the ongoing conflicts and crises have been considered also as results of the impact of serious drought, desertification and land degradation with rising conflict over deteriorating resources. Together with the Special UN Rapporteur on the Right to Food, the secretariat of the *United Nations Convention to Combat Desertification* (UNCCD) released a study at the 16th session of the CSD in May 2008 in New York (Ziegler/UNCCD 2008).

In several countries there is difficulty to access food due to unprecedented price hikes for commodities, but also due to emerging impacts climate change resulting in frequent and severe *desertification, land degradation and drought* (DLDD). Inflated international food prices have already led to food riots in some countries, while the most vulnerable are also seeing the food aid process being threatened by this economic context. However, available information indicates that occurrences of food shortages, hunger and malnutrition are prevalent in those regions of the

world, in South Asia and Sub-Saharan Africa, where people are least dependent on imports from the world markets. Hunger is caused in these countries not only by high international food prices, but often by local level conditions, especially rural poverty, arable land degradation, desertification and frequent droughts that result in low agricultural productivity. Most of the actual hunger takes place in the villages and in the countryside, and it persists even when international food prices are low. Food crisis grows primarily out of the low productivity of the practiced subsistence farming, mostly undertaken in inherently marginal and degraded lands, with highly unreliable rainfall, remotely located from the markets and public services and infrastructures, without improved seeds, nitrogen fertilizers and irrigation in the event of a drought.

Water availability plays a major role in determining the production and availability of food in developing countries and regions, where crop production is mostly dependent on the rainfall. Inadequate water resources availability, more often than not tends to lead to food shortages and food insecurity owing to a drop in agricultural production and famine that in turn lead to forced human migration and loss of life.

The international community should face this crisis through structural actions. Subsidizing agricultural inputs or food aid will not last. Measures on sustainable land management and soil protection must be implemented under a clear strategy of returning investments to rural areas. Developing countries, particularly those affected by drought and desertification should be encouraged and supported, to propel the expansion of domestic agricultural production through effectively reversing the processes of land degradation and desertification and returning degraded arable land to crop production, improving local level infrastructure and distribution and storage systems and removing policy distortions that discourage food production.

Desertification and Poverty

Also contributing to the exacerbation of desertification is poverty, which is most prevalent among rural populations. According to the World Bank, nearly 75 per cent of the poorest populations live in rural areas, and a large majority of them depend on agriculture for daily subsistence and income. In drylands, the fragile ecosystems make it hard to accumulate a surplus in agricultural production, and poor households

are forced to extract more from their lands than can be sustained in the long term. Overexploitation and burdening of land results in the impoverishment of soils, leading to the vicious downward spiral of increasing desertification and rising poverty. Thus the poor become both the agent and the victims of land degradation and desertification.

The shrinking availability of arable land for food production, a reduced supply of safe water, a growing number of forced migrants, and conflicts induced by scarcity of natural resources or the aggravated impact of national catastrophes are all factors that shed a sharper light on the combined effects of poverty and land degradation.

Desertification and Migration

The loss of livelihoods and natural resources sets in motion a train of events leading from poverty to migration to conflict, to disastrous effects. Traditional ways of life are eroded; disputes over land and natural resources arise. Sometimes, the affected populations have no choice but to leave their homes to make a living elsewhere. Uncontrolled, large-scale rural to urban migration can strain the social order in towns and cities, particularly by swelling the ranks of the urban unemployed or underemployed. Such a mass displacement of people, particularly in cases of severe food shortage, can place enormous strain on the existing social structures in recipient areas, leading to social unrest.

Desertification as a Threat to Security

Increased environmental degradation, meanwhile, has enhanced the destructive potential of natural disasters and in some cases hastened their occurrence. The dramatic increase in major disasters witnessed in the last 50 years provides worrying evidence of this trend. More than two billion people were affected by such disasters in the last decade, and in the same period the economic toll surpassed that of the previous four decades combined. If climate change produces more acute flooding, heat waves, droughts and storms, this pace may accelerate. However, rarely are environmental concerns factored into security, development or humanitarian strategies.

The United Nations has a role to play in this regard. It remains the most universal institution of multilateralism and provides a forum where sovereign states can come together to share burdens, address

common problems, and seize common opportunities. Conflicts resulting from competition over scarce resources also have the potential to escalate into interstate violence. From this viewpoint, desertification is seen as a threat to national security. The perception of national security must therefore be enlarged, so as to include awareness of mounting threats to the global environment. Environmental strains that transcend national borders are already beginning to break down the boundaries of national sovereignty.

Desertification, according to the report of the Millennium Ecosystem Assessment (2005a) is one of the greatest environmental challenges and a major impediment to meeting basic human needs in drylands. With 90 per cent of the drylands population of almost two billion people living in developing countries, the report also cites desertification as “potentially the most threatening ecosystem change impacting the livelihoods of the poor.”

The *United Nations Convention to Combat Desertification* (UNCCD) has been acknowledged as a major player in achieving the MDGs, particularly with regard to the eradication of poverty. Moreover, with desertification having played a role in sparking off 10 of the last armed conflicts in arid lands (Baechler 1995), it is an example of an international treaty, which addresses a global challenge that could pose a steadily increasing threat to international security and geopolitical stability.

In a concerted effort to combat desertification and thus ensure the long-term productivity of inhabited drylands, 193 parties have now joined the UNCCD. Its aim is to promote effective action through innovative action programmes and supportive international partnerships.

Adopted in 1994, the Convention is moving towards implementation, with affected countries beginning to carry out national, sub-regional, and regional action programmes. Criteria for preparing these programmes are detailed in the treaty’s five “regional implementation annexes”: Africa, Asia, Latin America and the Caribbean, the Northern Mediterranean, and Central and Eastern Europe. Drawing on past lessons, the Convention states that these programmes must adopt a bottom-up approach. They should emphasize participation processes and the creation of an ‘enabling environment’ designed to allow local people to help themselves to reverse land degradation.

Governments remain responsible for creating this enabling environment, however, by making politically sensitive changes, such as decentralizing authority, improving land tenure systems, and empowering

women, farmers, and pastoralists. They should also closely collaborate with relevant non-governmental organizations and community based organizations in the UNCCD implementation processes. In contrast to many past efforts, these action programmes are to be fully integrated into national policies for sustainable development. They should be flexible and modified as circumstances change. Desertification can only be reversed through profound changes in local and international behaviour. Step by step, these changes will ultimately lead to sustainable land use and food security. Combating desertification, then, is really just part of a much broader objective: the promotion of sustainable development in fragile ecosystems, and the positive implications for national and international security.

Reducing the risk to security by confidence-building desertification, land degradation and drought are amongst the main threats to ecosystem change. The potential of including desertification within the security debate does not lie in merely identifying how desertification acts as a cause for instability and conflicts. Rather, the focus on desertification brings forward a new type of confidence-building measures that can effectively reduce the risks to security. A more holistic defence concept would involve supporting international agencies in focusing on food security and poverty eradication within the context of drought and scarcity of resources, as they make an important contribution in preventing conflicts. The development of a global political coalition, which abandons traditional assumptions and combines security, energy, and sustainable environmental development as well as poverty alleviation, can contribute significantly to our common objective of peace and stability.

Desertification and Climate Change

Synergies between the UNCCD National Action Programmes, which are building bridges between development and environment policies, and the United Nations Framework Convention on Climate Change National Adaptation Programmes of Action, present a unique yet still untapped - opportunity to establish comprehensive policy instruments. Such an integrated approach to tackling desertification and climate change will have multiple benefits, especially for the poor in the world’s drylands, who are suffering most from the double blow of desertification and climate change.

Linking the activities of the two conventions rather than designing, implementing and managing climate policy separately from combating desertification makes sense from an efficiency and mainstreaming perspective. In countries with scarce financial and human resources this is particularly true. Indeed, coordinating mitigation and adaptation strategies to address aspects of climate change and desertification in one stroke is needed to facilitate the development of innovative poverty reduction strategies, strengthen the adaptation capacities of vulnerable lower income groups, and fight climate change through carbon sequestration and emission reductions.

Carbon sequestration projects in the wide expanses of dryland agro ecosystems, for example, could have significantly greater benefits than expected through soils conservation. The sequestration of carbon in these soils has the potential to counter degradation and increase the productivity and sustainability of these ecosystems. These projects could also provide significant social benefits by increasing food security, which in turn would promote better habitat conservation. Local population could therefore mitigate climate change while combating desertification and protecting biological diversity.

The Ten-Year Strategic Plan: Framework for Implementation of the UNCCD (2008 - 2018)

The Ten-Year Strategic Plan and framework to enhance the implementation of the *United Nations Convention to Combat Desertification* (UNCCD) (2008–2018), adopted by its Parties at the *Conference of the Parties* (COP 8) in Madrid in September 2007, is the latest manifestation of the international community's resolve to address the problem of land degradation and desertification as a major barrier in the fight against poverty in many parts of the globe.

This UNCCD Strategy recognizes that combating *desertification, land degradation and drought* (DLDD) is a global environmental challenge, which deserves a specific momentum and strong international mobilization. This new UNCCD Strategy is to provide a global framework to support the development and implementation of action programmes and policies to prevent, control and reverse deserta-

tion/land degradation and mitigate the effects of drought.

The main objectives of the Strategy include actions to improve both the living conditions of affected populations and the conditions of affected ecosystems; to generate global benefits through effective implementation of the Convention, and to mobilize resources to support the implementation process through building effective partnerships between national and international actors.

Facing Environmental Change by Combating Desertification

Desertification is a major factor contributing to global environmental change in arid and semi arid regions. It contributes to the degradation of agricultural land that becomes also scarcer due to the population dynamic. Both often result in environmental stress. Desertification is also closely linked with several human-induced natural hazards, such as drought, that often trigger famines. In some cases, both the cause (desertification) and the impact (drought, famine) have posed complex threats, challenges, vulnerabilities and risks to human and national security, confronting the affected people often with a "survival dilemma" (Brauch 2004, 2005, 2006, 2008c), either to stay on their degraded land or to move to the urban centres or to emigrate to other countries and supporting the families left behind with remittances. In a few cases these complex interactions may have contributed to conflicts with low levels of violence, in others they may have fostered cooperation within and between countries.

The UNCCD operates today in an environment, which has evolved considerably since the Convention was first negotiated and faces different opportunities and constraints. The policy environment has changed since Rio as a result of the outcome of the *World Summit on Sustainable Development* (WSSD) and the adoption of the *Millennium Development Goals* (MDGs). The newly adopted UNCCD Ten-Year strategic plan offers an historical opportunity to make a lasting contribution to the achievement of sustainable development, particularly goal number one regarding the eradication of extreme poverty and hunger.

Box: Background information on UNCCD and on the UNCCD Secretariat in Bonn

The Convention

In 1977 the United Nations Conference on Desertification (UNCOD) adopted a Plan of Action to Combat Desertification (PACD). The United Nations Environment Programme (UNEP) concluded in 1991 that the problem of land degradation in arid, semi-arid and dry sub-humid areas had intensified, although there were "local examples of success".

The United Nations Conference on Environment and Development (UNCED) in Rio de Janeiro in 1992 supported an integrated approach to the problem, emphasizing action to promote sustainable development at the community level. It also called on the United Nations General Assembly to establish an Intergovernmental Negotiating Committee (INC) to prepare, by June 1994, a Convention to Combat Desertification, particularly in Africa. In December 1992, the General Assembly agreed and adopted resolution 47/188.

The Convention was adopted in Paris on 17 June 1994 and entered into force on 26 December 1996. It is the only international legal instrument to address the issue of desertification and now counts 193 country Parties.

The UNCCD Secretariat

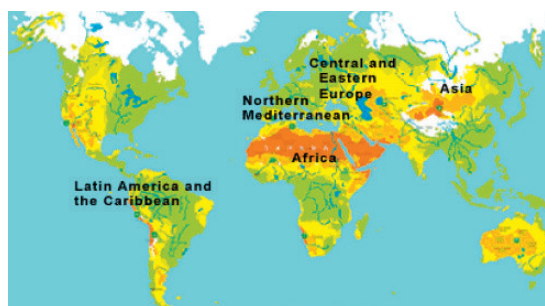

The permanent Secretariat of the UNCCD was established in 1997. It has been located in Bonn, Germany, since January 1999, and moved to the new UN campus in July 2006.

The functions of the secretariat are to make arrangements for sessions of the Conference of the Parties (COP) and its subsidiary bodies established under the Convention and to provide them with services as required. One key task of the secretariat is to compile and transmit reports submitted to it.

Pursuant to the adoption of the UNCCD Ten-Year Strategic Plan (2008–2018), the Secretariat undertook a comprehensive process of corporate review and structural adjustment, which aims not only at providing enhanced substantive services to the Conference of the Parties and its subsidiary bodies, but also upgrading its analytical and knowledge-brokering functions. In this regard, the Secretariat encourages coalition building and system-wide cooperation to enhance support at all levels. It further facilitates the treatment of emerging issues, new mechanisms or legislative tools to support sustainable land management. Support to the strengthening of the scientific basis of the UNCCD process is amongst the main areas of work of the secretariat, with focus on assisting the Committee on Science and Technology to bring forth scientific and technological excellence and standard setting.

UNCCD activities are coordinated with the secretariats of other relevant international bodies and conventions, such as the UN Framework Convention on Climate Change (UNFCCC) and the Convention on Biological Diversity (CBD).

Desertification in the world

Access to regional and country overviews at:
<http://www.unccd.int/regional/menu.php>

National, Sub-regional and Regional Action Programmes

National Action Programmes (NAP) are one of the key instruments in the implementation of the Convention and are strengthened by Action Programmes at Sub-regional (SRAP) and Regional (RAP) levels. National Action Programmes take a participatory approach, with direct involvement of the affected local communities. They spell out the practical steps and measures to be taken to combat desertification and to promote sustainable development in arid ecosystems.

Youth in the UNCCD implementation processes

The UNCCD has facilitated a number of initiatives in recent years in the fight against desertification. Significant among these are 'youth and environment' projects in different parts of the world. These are seen as particularly valuable, because as the future generation, young people will manage the scarce natural resources as well as suffer the severe consequences of environmental degradation, including poverty and unemployment.

Reforestation projects undertaken by Argentina, China and Mozambique, for example, accomplish a number of objectives. While helping to preserve the environment, they also create income-generating activities for young people in areas of high unemployment. The projects also increase the capacity of these communities to implement sustainable development policies in the framework of the UNCCD National Action Programmes.

In addition, the projects have been implemented in areas where they can address the issues of poverty, land degradation, carbon sequestration and loss of biodiversity at the same time, thus strengthening synergies between the Rio Conventions on Desertification, Climate change and Biodiversity.

Facing Global Environment Change and Disaster Risk Reduction

Salvano Briceño¹

Environmental disruptions are generally recognized as an increasingly important factor of migration. The linkage between population displacement, environmental change and vulnerability to natural hazards has been a topic of growing concern to the international community. Environmental disruption is recognized as both a cause and a consequence of population movements. It is a cause when people can no longer gain a secure livelihood in their homelands and are obliged to flee, having no other alternative. It is a consequence when environmental degradation results from the mass movement of people, both in the departure and the receiving areas.

This environmental disruption can take many forms: brutal or slow-onset, natural or man-made, due to a single or cumulative change. For example, the projected impacts of drought and global warming in the drylands of Africa are overwhelmingly negative and it will have significant impacts on human livelihoods, health, water resources, agricultural production and food security, as well as nature-based tourism. If we are to succeed in ensuring environmental security in the face of great challenges to the sustainability of our planet, the United States and the European Union must firmly commit to serving as international leaders in devising and abiding by practical and appropriate multilateral approaches for preserving the environment.

People affected by well-publicized environmental disasters like the 8 October 2006 earthquake in Pakistan, the 2004 Indian Ocean tsunami or the U.S. Gulf Coast hurricanes benefit from the mobilization of private and public sector generosity and humanitarian relief. Countless millions of others around the world,

however, are uprooted by gradual environmental change like desertification, land degradation and sea level rise. Forced to move elsewhere, these displaced people receive comparatively little support such as food, tools, shelter, medical care and grants, and are not even recognized as “refugees”. There are international mechanisms to assist those fleeing wars or conflicts but there is nothing right now to deal with environmental refugees. We should prepare now, to define, accept and accommodate this new breed of ‘refugee’ within international frameworks. The term ‘environmental refugee’ must be carefully defined and distinguished from economic migrants, who depart voluntarily to find a better life but may return home without persecution. But defining an environmental refugee is a contentious issue.

People often believe that nearly all environmental disasters are disasters caused by natural hazards when in fact they are the result of human actions, such as unsustainable use of natural resources, unplanned urban growth, lack of awareness and institutional capacities, insufficient land use planning, housing, infrastructures located in hazard prone areas, ecosystem degradation, and so on. Even in the case of natural events like hurricanes, building a city like New Orleans below sea level in a known hurricane zone was a human decision that led to an environmental and human catastrophe. Worries about toxins in the environment and the costs of rebuilding will likely mean that a large percentage of people displaced from New Orleans will never move back.

Chief among the slow-moving disasters is land degradation or desertification, where croplands and pastures - because of mismanagement enhanced by

¹ The copyright holder for the photo is National Geographic, Natalie Biraben and Tom Wagner SM from whom the permission has been obtained.

changing climate, - can no longer support the people that live there. Millions of people in Africa and Asia have been forced off their land, and where states cannot cope, the international community has to step in.

On the issue of environmental security, migration and disasters resulting from increased vulnerability, like so many global challenges, my duty as Director of the United Nations International Strategy for Disaster Reduction (UN/ISDR) is to ensure that those countries experiencing disasters due to vulnerability to natural hazards, particularly in the developing world, find their voice, and that their voice is heard. During the second World Conference on Disaster Reduction (WCDR, Kobe, Hyogo, Japan, 18-22 January 2005), more than 160 governments agreed on the *Hyogo Framework for Action 2005-2015: Building the Resilience of Nations and Communities to Disasters*. The *Hyogo Framework* carries a strong commitment and ownership of governments and regional, international and non-governmental organizations to reduce the vulnerability to hazards by 2015. All relevant actors coming from different development sectors (health, education, agriculture, tourism, etc.), national disaster management systems, business sector, academic, scientific and technical support organizations have now proceeded to ensure effectiveness in translating the hopeful expectations of the *Hyogo Framework* into the practical measures at international, regional, national, and community levels, and tangible activities by which progress in disaster reduction must be measured.

The *Hyogo Framework* puts forward three strategic goals which may serve as guiding principles in any efforts to advance future education for disaster reduction. It calls for the integration of disaster risk reduction into sustainable development policies and plan-

ning; the need to develop and strengthen institutions and capacities to build resilience to hazards; and the systematic incorporation of risk reduction practices into emergency preparedness, response and recovery programmes.

Most importantly, it provides a basis that commits governments as well as regional, international, and non-governmental organizations to reduce disaster risks through a range of possible approaches and activities presented in five priority areas for action:

1. *Governance* - to ensure that disaster risk reduction is a national and local priority with strong institutional basis for implementation;
2. *Risk identification* - to identify, assess and monitor disaster risks and enhance early warning;
3. *Knowledge* - use knowledge, innovation and education to build a culture of safety and resilience at all levels;
4. Reduce underlying risk factors that increase the likelihood of disasters by involving ('mainstreaming') disaster risk awareness
5. Strengthen disaster preparedness for effective response.

To be sure, the challenges we face are vast. Today, there are millions of so-called eco-migrants who leave their homes every year because of the creeping reach of the world's deserts or the destruction of natural resources that once guaranteed jobs and a way of life. The potential for political instability from drought, famine or forced migrations as a result of desertification is enormous. Millions could be forced to flee their homes and seek new lands for agricultural production. Only by embracing global approaches in team efforts can we solve the global problems that threaten the planet and our future.

Climate Change and Security: A Destablizing Fact of Life

Michael Zammit Cutajar
Former Executive Secretary, UNFCCC
Honorary Ambassador for Climate Change, Malta

In his 2004 apocalyptic fiction movie *The Day After Tomorrow*, director Roland Emmerich included a touch of humour, showing inhabitants of the U.S. of a reversing of the usual migratory flow and crossing the Rio Grande southwards as they flee their freezing homeland. In his award-winning documentary *An Inconvenient Truth*, Al Gore shows a 20-foot sea-level rise sweeping in tsunami-like and engulfing Manhattan, as well as Shanghai and other mega-cities. Tongue-in-cheek humour in the one case, dramatic licence in the other no doubt – but both sending the same message: climate change will destabilize life as we know it and spread a new insecurity around the globe.

Climate change is an unequivocal fact. Human activity has been destabilizing the global climate. The resulting changes, mostly negative in their impacts on society and on ecology, are taking place faster than expected. There is an urgent need for action to contain this trend over the next two or three decades if it is to remain within manageable limits this century. Even within those limits, societies everywhere will have to take stock of the expected changes and adapt to them. Those, in a nutshell, are the messages coming to us from the world's scientists, with ever-greater force and confidence, in the fourth assessment of the Intergovernmental Panel on Climate Change (IPCC AR4 2007). That is the source of the political furore that breaks out from time to time over what is to be done, when and by whom.

Climate change has made it to Hollywood. Not only through a politician turned media star, but also through a media star turned politician: Governor Arnold Schwarzenegger has placed California where it likes to be, at the cutting edge of a new trend, in this case a political one. Indeed, the impacts of climate change and the responsibility for doing something about them are entering the strategic vision of politi-

cal leaders around the world. The effects of climate change fall preponderantly on the supply of food and water, the mainstays of life. The response to climate change is intertwined with the secure supply of energy, the heartbeat of the economy on which a decent and hopeful life depends. Sea-level rise induced by global warming will eat away at living space on low-lying islands and mega-deltas. Climate change will exacerbate natural disasters – hurricanes, floods, droughts – that disturb life, sometimes snatching it away prematurely.

How does this look in the eye of the ordinary family, living way below the political heights? It depends essentially on that family's wealth or poverty. Rich people – like rich countries – tend to believe they can buy their way out of most problems, although the altruistic among them seek to do well. For poor people, problems accumulate beyond their control. Climate change is one of these – an additional factor of stress and vulnerability in their already precarious lives. In areas of existing food and water stress – the Sahel, the Horn of Africa for example – the effect of global warming gives another push towards the decision to make the dangerous migration to the hope of a better life in distant lands. Globally, hundreds of millions of people will face that decision on account of their changing climate.

Adding all this up, climate change has come to be recognized as yet another threat to the prospect of a peaceful and relatively stable world, aggravating tensions over access to food, water and energy and over population movements. Addressing climate change is now an unavoidable part of the continuing struggle by governments and people to make our world a better place.

What is the cause of the problem? We all are. From the exhaust of the luxury limousine to the wood fire inside an impoverished hut, from the rotting

waste of the consumer society to the exhalations of a subsistence rice paddy, much of human activity contributes to the accumulation of gases in the atmosphere that have kicked off a warming trend, departing from the temperature pattern of the previous millennia. This human impact – known as the greenhouse effect – has been a by-product of demographic and economic growth since the start of the industrial era. But clearly an ethical distinction needs to be drawn between the emissions of plenty and those of poverty.

Thus, the historical responsibility for human-induced climate change is not evenly distributed. The countries now riding high on global prosperity account for the bulk of accumulated emissions of greenhouse gases, in aggregate and per capita, with the U.S.A. at the top of the heap. It is they that have the responsibility and the capacity to take the lead in changing technologies and consumption patterns so that prosperity may be enjoyed with less damage to the environment.

But reality is not black-and-white. Even if the presently rich countries were to wave their technological wands and conjure up 'zero emission' life-styles, climate change would continue to be fuelled by the economic growth of the developing world unless technological change is wrought there too. The populous powerhouses of the emerging world – notably China and India – run on dirty fuels using old technologies. The avarice of power combines with the desperation of poverty to strip tropical forests that could otherwise serve to absorb greenhouse gases naturally. In showing the climate-friendly way ahead, the rich world must also provide financial and technological

incentives for the rest to follow. And support must be provided, in a spirit of solidarity, to the vulnerable people and countries least able to cope with and adapt to the impacts of climate change.

For 20 years, the protection of the global climate has been on the international agenda. It was my country, Malta, that brought the issue to the United Nations in 1988. Since that time, the IPCC has been working to provide regular assessments of the science of climate change and its impacts. The world's governments have set up a framework for cooperation: the 1992 UN Framework Convention on Climate Change (UNFCCC) and its 1997 Kyoto Protocol. The latter, aiming to start off the reduction of greenhouse gas emissions by the industrialized countries, has been hindered by its rejection by the current President of the USA.

But the year 2007 has brought new encouraging signs. The confirmation of the Stern Review that prevention is better than cure – the finding that investing now in curbing greenhouse emissions will cost much less than repairing climatic impacts *ex post* – has sent a very strong and positive message around the world's capitals and boardrooms. This has been reinforced by the vigour of the IPCC's latest findings. With the European Union in the vanguard, the year 2007 has seen a resurgence of efforts to launch a multilateral attack on climate change with all the major players on board, developed and developing. There are now high hopes of a new global deal by 2009. Although negotiated with other concerns in mind, this will make an important contribution to enhancing global security.

Facing and Coping with Globalization: How Ten Years of WTO have Created an Agrarian Crisis in India

Vandana Shiva¹

WTO: An anti-democratic Agenda Beyond Trade

The *World Trade Organization* (WTO) came into existence as an outcome of the Uruguay Round of the *General Agreement on Trade and Tariffs* (GATT). The Uruguay Round changed the definition of trade dramatically. In the pre-WTO period, international trade rules governed trade in goods outside national borders. The WTO became an undemocratic instrument for interference into domestic economies, and it did not just change the nature of trade but the nature of production, and social and political patterns through which societies govern themselves. Trade and commerce were disembodied from society and democracy. New issues introduced in the Uruguay Round such as intellectual property, food and agriculture, services and investment are actually redesigning society to suit corporate interests without the consent of the people.

Global trade rules, as enshrined in the WTO's *Agreement on Agriculture* (AOA) and in the *Trade Related Intellectual Property Rights* (TRIPs) agreement, are primarily rules of robbery, camouflaged by arithmetic and in legal terms. In this economic hijack, the corporations gain, and people and nature loose. During the Uruguay Round, India led the resistance against the introduction of new issues. The Uruguay Round was concluded through a non-negotiated, take-it-or-leave-it text drafted by Arthur Dunkel, the then Director General of WTO.

The global reach of corporations to take over the resources of the poor of the Third World is made possible not just by reduction and removal of tariffs, one of the goals of the WTO. It is facilitated by the re-

moval of ethical and ecological limits on what can be owned as private property and what can be traded. The WTO's overall goal of promoting 'market competition' serves two functions. Firstly, it transforms all aspects of life into commodities for sale. Culture, biodiversity, food, water, livelihoods, needs and rights are all transformed and reduced to markets. In this way, globalization is completing the project of colonization that led to the conquest and ownership of land and territory. Biological resources and water, the very basis of life's processes, are being colonized, privatized, and commoditized.

Agriculture, which is still the primary livelihood for three quarters of humanity and two thirds of India, and which is as much a cultural activity as an economic one, is also threatened by 'trade liberalization', driven both by the structural adjustment programmes of the World Bank and the IMF, and by the WTO's *Agreement on Agriculture*. The globalization of food and agriculture systems, in effect, means the corporate take-over of the food chain, the erosion of food rights, the destruction of the cultural diversity of food and the biological diversity of crops, and the displacement of million from land-based, rural livelihoods.

WTO Disputes: Dismantling People's Rights to Seeds and Food

Two of the earliest WTO disputes were brought by the U.S against India. The first was the TRIPs dispute which forced India to change its patent laws, the second was the QR (quantitative restrictions on imports) dispute, which forced India to remove its protection against dumping and cheap imports.

1 The copyright holder for the photo is Nic Paget-Clarke <<http://www.inmotionmagazine.com/shiva.html>>.

TRIPS and Seed Monopolies

To understand the flaws of TRIPS, it is important to know that this agreement is essentially the globalization of Western patent laws that historically have been used as instruments of conquest. The word 'patents' derives from 'letters patent' – the open letters granted by European sovereigns to conquer foreign lands or to obtain import monopolies. Christopher Columbus derived his right to the conquest of the Americas through the letter patent granted to him by Queen Isabel and King Ferdinand of Spain.

The US Patent Laws are based on the takeover of knowledge. One outcome was that broad patents were granted in the US for steamboats – in spite of the steam engine having been invented and patented by James Watt in Scotland fifteen years before.

The US has continued to ignore the pre-existence and use of inventions in other countries when granting patents. Thus, paradoxically, a legal system aimed at preventing 'intellectual piracy' is itself based on legitimizing piracy. This system is codified in Section 102 of the US Patent Act of 1952, which denies patents for inventions that are in use in the US but allows patents for inventions in use in other countries unless they have been described in a publication. If somebody in Europe was operating a machine and you, in good faith, independently and without knowledge of its existence, developed your own invention of essentially the same machine, that fact would not prevent you from obtaining a patent in the US.

In addition, the US has created unilateral instruments such as clause Special 301 in its Trade Act to force other countries to follow its patent laws. Thus, a country that depended on borrowed knowledge for its own development of industrial power has acted to block such transfer of knowledge and technology to other countries.

Introduction of TRIPS

During the Uruguay Round of the GATT, the US introduced its flawed patent system into the WTO, and thus imposed it on the rest of the world. U.S corporations have admitted that they drafted and lobbied on behalf of TRIPS. As a Monsanto spokesman said "The industries and traders of world commerce have played simultaneously the role of patients, the diagnosticians, and prescribing physicians."

TRIPS not only made *Intellectual Property Rights* (IPR) laws global geographically, but also removed ethical boundaries by including life forms and biodi-

versity into patentable subject matter. Living organisms and life forms that are self-creating were thus re-defined as machines and artefacts made and invented by the patentee. IPRs and patents then give the patent holder a monopolistic right to prevent others from making, using or selling seeds. Seed saving by farmers has now been redefined from a sacred duty to a criminal offence of stealing 'property'. Article 27.3 (b) of the TRIPS agreement, which relates to patents on living resources, was basically pushed by the 'Life Science' companies to establish themselves as 'lords of life'.

The chemical companies of the world have bought up seed and biotechnology companies and reorganized themselves as life science corporations, claiming patents on genes, seeds, plants and animals. Ciba Geigy and Sandoz have combined to form Novartis, Hoechst has joined with Rhone Poulenc to form Aventis, Zeneca has merged with Astia, Dupont has bought up Pioneer HiBred, and Monsanto now owns Cargill seeds, DeKalb, Calgene, Agracetus, Delta and Pine Land, Holden and Asgrow. Eighty per cent of all genetically engineered seeds planted are Monsanto's 'intellectual property'. And Monsanto owns broad species patents on cotton, mustard, soya bean – crops that were not 'invented' or 'created' by Monsanto but have been evolved over centuries of innovation by farmers of India and East Asia working in close partnership with biodiversity gifted by nature.

The disastrous impact of WTO in creating seed monopolies has already been felt in India. India's 1970 patent act has been amended three times and there is an attempt to introduce a new seed law which would destroy biodiversity and farmers rights. The epidemic of farmer's suicide is the real barometer of the stress under which Indian agriculture and Indian farmers have been put by globalization of agriculture. Growing indebtedness and increasing crop failure are the main reasons that the farmers have committed suicide across the length and breadth of rural India. The suicides by farmers highlights these high social and ecological costs of the globalization of non-sustainable agriculture which are not restricted to the cotton growing areas of these states but have been experienced in all commercially grown and chemically farmed crop in all regions. While the benefits of globalization go to the seeds and chemical corporation through expanding markets, the cost and risks are exclusively born by the small farmers and landless peasants.

Globalization and privatization of the seed sector have eroded farmers seed supply and seed supplied by

the public sector. While the entry of private seed companies is justified on grounds of increasing farmers options and choices, by making farmers look down on their own varieties as inferior and by eroding the capacity of the public sector, globalization has in effect created a seed famine. Monopolies have contributed to farmers suicides as we analyse in our report *Seeds of Suicides*. As a consequence of the farmers' suicides and high seed costs, the Andhra Pradesh Government brought a case against Monsanto / Mahyco before the *Monopolies and Restrictive Trade Practises Commission* (MRTPC).

Monsanto enjoys a monopoly on production, supply and marketing of Bt. Cotton seed in India. The firm operates through its subsidiary - Mahyco. From the last few years, the company has been charging a 'trait value' (price fixed for research and development on Bt. Cotton seed, which can resist local pests) at Rs. 1750 per pack of 450 grams of seed. The multinational corporation (MNC) gets the seed for Rs. 300 per pack of 750 grams from the farmers who grow it under the company's supervision. The government has challenged the validity of the 'trait value' in the court and demanded its abolition. The government has also demanded Rs. 400 crore from the company, which it collected from the farmers.

The MRTPC directed the Mahyco-Monsanto to reduce the 'trait value' to a reasonable extent. The MNC tried to approach the Supreme Court to stay the order of the MRTPC. But, the apex court refused to grant a stay. Meanwhile, the Andhra Pradesh Government had convened a meeting of the seven other states - Orissa, Karnataka, Maharashtra, Tamil Nadu, Madhya Pradesh, Punjab and Haryana. It was decided in the meeting to bring pressure on Monsanto to reduce the price of Bt. Cotton seed so that farmers are not overburdened by the exorbitant price. The Andhra Pradesh Government's contention is that the high price of the Bt. Cotton seed is one of the reasons for distress among farmers. More than 2000 farmers committed suicide in the last eight years in Andhra Pradesh alone and most of them were cotton growers.

In a parliamentary debate the government admitted the more than 100,000 farmers had committed suicide in the last decade. Rising costs of seeds and other inputs, combined with falling prices of agricultural commodities are the primary cause of indebtedness and indebtedness is the primary cause of farmer's suicide. Both the rise in costs of production and decline in prices of farm produce are driven by the trade liberalization rules of WTO.

AOA, Renewal of QR's and Falling Farm Prices

All over the world, structural adjustment and trade liberalization have already driven millions of farmers off the land because of rising costs of production and collapsing prices of commodities. Instead of supporting policies that help farmers survive, WTO rules are driving small farmers to extinction and ensuring that agriculture is controlled by global corporations.

The AOA of the WTO is a rule-based system for trade liberalization of agriculture that was pushed by the US in the Uruguay Round of the GATT. However, these rules are the wrong rules for protecting food security, nature and culture. Instead, they are perfectly shaped for the objective of corporate rule over our food and agriculture systems. The AOA rules apply to countries, even though it is not countries for their farmers that engage in global trade in agriculture but global corporations like Cargill. These firms gain from every rule that marginalizes farmers by removing support from agriculture. They gain from every rule that deregulates international trade, liberalizes exports and imports, and make restrictions of exports and imports illegal. Market openings through the AOA are therefore market openings for the Cargills and Monsantos.

The outcome of negotiations for the AOA should not be surprising, because global agribusiness corporations had tremendous influence on the negotiations. In fact, the U.S delegation was led by Clayton Yeutter, a former Cargill employee. There are three components to the AOA

- Domestic Support
- Market Access
- Export Competition

The WTO dispute to remove QR's was the means to get across to India's markets. However, since the rich countries subsidize their agriculture up to \$ 400 billion annually, removal of import restrictions amounts to removing the protection against cheap imports and dumping. As a result of subsidies, prices of agricultural commodities have been falling worldwide.

The crisis in cotton is an example of the agrarian crisis created by globalization. The worst suicides are taking place in the cotton belts of Vidharbha, Andhra Pradesh, Karnataka and Punjab. More than 70 countries globally produce and export cotton. Of these, eight countries are responsible for almost 80 per cent of global output. The world's cotton market is dominated by the US, - which is the second largest pro-

Commodity	1988	1995	1997	2000	2001 (Jan.)	Percent Change 2001 over 1995
Wheat (US HW)	167	216	142	130	133	-38.2
Wheat (US RSW)	160	198	129	102	106	-46.5
Wheat (Argentina)	145	218	129	112	118	-45.9
Maize (Argentina)	116	160	133	88	80	-50.0
Maize (U.S)	118	159	112	97	92	-22.0
Rice (U.S)	265.7	-	439	271	291	-33.7
Rice (Thai)	284	226	316	207	179	-46.7
Cotton	63.5	98.2	77.5	66	49.1	-50.0
Groundnut Oil	590	991	1010	788	-	-20.5
Palm Oil	437	626	93.5	74.7	-	-88.1
Soya bean Oil	464	479	625	71.4	-	-85.1
Soya bean Seed	297	273	262	199	178	-
Soya bean Seed	110	156	111	102	99	-36.5
Sugar	10.2	13.3	11.4	10.2	9.2	-30.8
Jute	370	366	302	276	-	-24.6

ducer. Support to the cotton sector is greatest in the US, followed by China and the EU. The combined support (domestic and export subsidy) provided by the US government to cotton producers is pegged at US\$ 4 billion. The US subsidy system is based on direct payments to farmers who can sell cotton in world markets at prices well below the cost of production. Production costs are US\$ 1.70 per kg but its cotton is sold at US\$ 1.18 per kg. Export subsidies for 2005-2006 amount to US\$ 360 million.

The worst losers are farmers in the least developed countries. This subsidy is helping only a few thousand farmers in the developed nations but is putting millions of poor Africans and Indians into a death trap. For example the \$ 4 billion subsidy that the US gives is only meant for 20,000 farmers who cultivate cotton. Meantime, falling cotton prices are creating US\$ 250 million increased poverty in several central African countries such as Burkina Faso, Chad, Mali and Togo.

In India falling cotton prices driven by the removal of import restrictions are killing our farmers. Before 1990 cotton import and export was totally controlled by the central government. After the formation of WTO in 1995, cotton import and export has been free. But we could not export cotton as prices in international market had fallen to one third from what was it was in 1994. The cost of production in America of

1 kg of cotton lint is not less than US\$ 1.8. But it is sold in international market at US\$ 1.0 per kg. This is why cotton farmers in India are committing suicide.

Traditionally, India has been a net cotton exporter. But by 1998, it emerged as a major importer due to policy changes. Imports were liberalized when the Cotton Corporation of India's import monopoly was terminated in 1991. Now imports are subject to the Open General License, allowing unrestricted imports by private traders.

The story of falling prices is repeated in spices, edible oil, and dairy products. Suicides of Wynad farmers are directly connected to imports of spices. According to the Government of Kerala, falling prices have led to losses of Rs. 2958 crores for coconut farmers, Rs. 695 crores for pepper farmers, Rs. 924 crores for arecanut farmers, Rs. 388 crore for coffee growers and Rs. 178 crore for tea grower and Rs. 70 crore for cardamom growers in 2000-2001. In India, agricultural imports have gone up by 300 per cent during the last decade. While edible oil imports have increased by 398 per cent, cotton imports have multiplied by a whopping 13,153 per cent. Sugar, fruits and vegetables and spices are some other commodities that have poured in unchecked. For all agricultural commodities, our study *The Mirage of Market Access* assesses that falling prices due to imports have led to annual losses of Rs. 116200 crores of Indian farmers.

Changing the Trade Rules

The growing agrarian crisis India is experiencing, with farmers suicides as the most tragic expression of the crisis, is a direct result of WTO rules and the trade liberalization paradigm. It is an imperative to change these rules to allow for the protection of Indian farmers against cheap imports. This requires re-introducing QR's. We also need to be able to promote national and local food security policies. Food and agriculture are issues of livelihood and basic needs, not mere matters of trade. Across the world, people are calling for removing agriculture from the WTO.

Similarly, WTO is the wrong place to create rules for intellectual property. TRIPS must also be removed from WTO. This is the suggestion from experts and the call of the movements like the '*Indian People's campaign against WTO*' convened by Mr. S.P. Shukla, who was Ambassador to GATT during the Uruguay Round.

The WTO is in deep crisis because it imposed unjust and asymmetric rules on the South. The Seattle ministerial (1999) failed because of people's resistance. The Doha Round (since 2001) was negotiated in the shadow of 9/11. Cancun (2003) failed because the South organized under the G-20, with India as a leading player, and the G-90 the group of least development countries. Hong Kong (2005) too would have failed, but this time India and Brazil joined the rich countries to produce a disastrous draft. The emptiness of the promises made in Hong Kong were born out by the failure of the WTO negotiations in July 2006.

The Doha round negotiations collapsed once again at the Mini Ministerial in Geneva on 23rd July 2006. Martin Khor of Third World Network reported from Geneva that when asked of the Doha Round is dead or in intensive care, Mr. Kamal Nath, India's Commerce Minister, said it is somewhere between intensive care in hospital and the crematorium. Peter Mandelson, the EU Trade Commissioner, told the press following suspension of WTO negotiations, "we have missed the last exit on the motorway."

The US is being identified by all as responsible for the collapse of talks, by its refusal to reduce its agricultural subsidies. The US and its corporations were the driving force behind two agreements of the Uruguay Round, which have the highest impact on the poor of the Third World. The TRIPS Agreement has increased the cost of seeds and medicine by promoting monopolies. Thousands of Indian farmers have committed suicide due to debts resulting from a new

dependence on costly yet unreliable hybrid and Bt cotton sold by Monsanto and its Indian partners. The *Agreement on Agriculture* (AoA) has destroyed agricultural livelihoods of millions of peasants and food security of the world's poor. The Deputy Chairman of the Planning Commission wants to see an "exit policy for farmers of India, which in effect means planning for the destruction of their livelihoods.

The willingness of the US to allow the Doha Round negotiations to grind to a halt by showing inflexibility in offering to reduce distorting farm subsidies in exchange for increased market access is not because agricultural market access is no longer of interest to the US. The US does not have to give up anything multilaterally because it is getting market access bilaterally, often with 'non-agreements' like the US - India Knowledge Initiative in Agriculture, which is promoting GMOs, agricultural imports and the entry of the US giant Walmart into the Indian retail. Monsanto, Walmart and ADM are on the board of the US India Agriculture Initiative.

USAid is interfering directly in India's gene modification (GM) policies and has financed the push to commercialize Bt Brinjal, which would be the first GM food crop approved for large scale commercial trials and seed production in India. While India's biosafety assessment framework has no reference to the unscientific 'substantial equivalence' principle, (a principle promoted in the US to avoid looking for the unique biological impacts of GM foods), the 'substantial equivalence' is the basis of Bt Brinjal data submitted by Monsanto-Mahyco to the *Genetic Engineering Approval Committee* (GEAC), the statutory body for granting approvals for *gene modified organism* (GMOs). The virus of biosafety deregulation is thus being subtly introduced into India. GMOs are spreading bilaterally without the WTO, which had to be used against Europe in the US - EU GMO dispute.

The US biotech agenda is also being internalized into India's agricultural policy. The Planning Commission, India's highest planning body, headed by Montek Singh Ahluwalia is appointing a non-resident, the US based Dr. Deshpal Verma, Professor of Genetics and Biotechnology at Ohio, to head a cell to promote GMOs in agriculture and to increase the role of global corporations like Monsanto in the farm sector. Bilateral deals are thus mutilating into unilateral policies referred to an 'autonomous liberalization'.

US agribusiness like Cargill and ADM do not need WTO's market access rules anymore to capture India's markets. As part of the Bush-Singh agreement, India has been influenced to import wheat, even

though there was enough wheat produced in India. And domestic markets too have been captured by MNC's like Cargill, Canagra, Lever, and ITC. India's food security is being systematically dismantled. Food prices have increased dramatically, and with it, hunger and malnutrition. While being presented as an economic power and the new poster child of globalization, India now is the home of one third of the world's malnourished children. And the problem of hunger will grow as peasants are pushed off the land and food prices increase.

Meantime, corporations like Walmart are trying to grab India's retail market, which consists of the small-scale informal sector employing more than 200 million people. Walmart is trying to get into capturing this large market and has succeeded in getting FDI pushed through in retail. It is also trying to partner with Reliance Industry Ltd (RIL), which is planning to

build new super stores in 784 Indian towns, 1600 farm supply hubs, and move the produce with a 40-plane air cargo fleet. The Reliance group has also become the largest land grabber in India, using governments to forcefully acquire hundreds of thousands of acres of fertile farmland at 1/1000th the market price. These are the subsidies Walmart is seeking through partnerships. And Walmart does not need a *General Agreement on Trade in Services* (GATS) to take over retail services in India. Bilateral and unilateral policies are opening up India's markets for Walmart. WTO might be on life support, but 'free trade' is alive and kicking.

Bilateral and unilateral, initiatives are the new avatars of globalization and free trade. And it is these avatars we must challenge to stop corporate rule, while WTO hangs between intensive care and the crematorium.

1 Introduction: Facing Global Environmental Change and Sectorialization of Security

Hans Günter Brauch

1.1 Introductory Remark¹

This second volume of the *Global Security Handbook for the Anthropocene*² focuses on issues of *Global Environmental Change* (Young/Demko/Ramakrishna 1996; Munn 2002; Oldfield 2005, Ehlers 2008) that have contributed to a *reconceptualization of security in the 21st century*. This has evolved since the end of the Cold War and has significantly been influenced by the globalization process (Brauch 2008, 2008a).

This reconceptualization of security has resulted in a ‘*widening*’ of the dimensions of security from the narrow political and military focus during the Cold War era towards an inclusion of economic, societal and environmental dimensions, a ‘*deepening*’ of the referent objects from the nation state (or ‘national security’) to the international realm (international, regional, and global security), as well as to the sub-state level (of societal, communal, and human and gender security) and a ‘*sectorialization*’ of the applications of

security to different issue areas (energy, water, health, livelihood security concepts).

Three stages of *Global Environmental Change* (GEC) can be distinguished:

1. The emergence as a new multidisciplinary scientific field of study since the 1970’s and 1980’s that has focused on climate change, desertification, water and biodiversity, as well as on the depletion of the ozone layer. Since the 1990’s global change scientific networks, programmes (IGBP, IHDP, DIVERSITAS, WCRP), and projects as well as policy focused scientific epistemic communities (Haas 1989, 1990, 1992, 1993) as the IPCC (Bolin 2007) have evolved that assess and interpret scientific research results, and explain them to the global policy community and via the media to a global attentive public (*scientific agenda setting*).
2. The development of a new major policy field of international (environment) policy since the Earth Summit (UN Conference on Environment and Development) in Rio de Janeiro in 1992 has resulted in new forms of international governance (climate change, biodiversity, desertification, water regimes) that have moved to the centre of political concerns (*politicization*³ through major global governmental conferences in the framework of the annual *conference of parties* (COPs) of UNFCCC⁴, CBD⁵, UNCCD⁶, and the triennial World Water Fora (I: 1997 in Marrakesh; II: 2000 in The Hague; III: 2003 in Kyoto; IV: 2006 in Mexico City; V: 2009 in Istanbul).⁷
3. Since the early 21st century this process of *politicization* has been complemented by a process of

1 The author is grateful to two reviewers for their useful comments and suggestions.

2 The term ‘Anthropocene’ was coined by the Nobel Laureate Paul Crutzen (2002, Crutzen/Stoermer 2001, Clark/Crutzen/Schellnhuber 2004, 2005, Ehlers 2008; see chap. 98 by Oswald Spring/Brauch/Dalby). It refers to an evolving transition in Earth history from the Holocene, the present interglacial period that followed the last glacial period of the Pleistocene about 10,000 years ago (Goudie 1996: 48–66), to a new period that has been increasingly influenced by human or ‘anthropogenic’ interferences of humankind since the start of the Industrial Revolution (about 1750) due to the extensive burning of hydrocarbon energy sources (coal, oil, natural gas) that have resulted in an increase of greenhouse gases from 280 ppm (parts per million) in the atmosphere in 1750 to 379 ppm in 2005 (IPCC 2007: 2). The atmospheric concentration of CO₂ in 2005 exceeds by far the natural range over the last 650,000 years (180 to 300 ppm) as determined from ice cores.

3 An extensive scientific and political literature is available on these issues that have also contributed to this process of politicization especially of climate change issues. For a brief guide to the guide to this debate see Dessler/Parson (2006, 2008).

declaring selected global challenges (especially climate change) as political issues of utmost importance that require extraordinary means, and by addressing these global dangers and concerns as key security issues (*securitization*).

The year 2007 has been a turning point in this process of *securitization* of questions of global environmental change, and especially of climate change when the highest national policymakers (G-8, European Council) and high-level fora (UN Security Council) and officials of international organizations (UN Secretary-General) addressed global warming (often in relationship with desertification and water scarcity) as key political and security issues that may lead to internal displacements, forced distress migration, as well as crises and conflicts. This emerging *securitization* of global environmental change focuses on the environ-

-
- 4 The *UN Framework Convention on Climate Change* (UNFCCC) was signed in 1992 at the Earth Summit and entered into force in 1994; its Kyoto Protocol (1997) entered into force on 16 February 2005 with the ratification by Russia and it will expire in 2012. Until April 2008 the USA and Turkey did not ratify the Kyoto Protocol. See the documentation at: <http://unfccc.int/essential_background/items/2877.php>.
 - 5 The *Convention on Biological Diversity* (CBD) was signed in 1992 at the Earth Summit and until April 2008 it was ratified by 187 countries. Its Cartagena Protocol on Biosafety was adopted in 2000 and entered into force in 2003 and by April 2008 147 countries had deposited their ratification. The USA did so far neither sign nor ratify this protocol. See the documentation at: <<http://www.cbd.int/>>.
 - 6 The UNCCD was signed in 1994 and entered into force on 26 December 1996. As of March 2002 over 179 countries were parties. See the documentation at: <<http://www.unccd.int/>>.
 - 7 The world water fora have been organized by the World Water Council, “an international multi-stakeholder platform that was established in 1996 in response to an increasing concern about world water issues from the global community. Its mission is ‘to promote awareness, build political commitment and trigger action on critical water issues at all levels, including the highest decision-making level, to facilitate the efficient conservation, protection, development, planning, management and use of water in all its dimensions on an environmentally sustainable basis for the benefit of all life on earth.’ The Council aims to reach a common strategic vision on water resources and water services management amongst all stakeholders in the water community. In the process, the Council also catalyses initiatives and activities, whose results converge toward its flagship product, the World Water Forum.” See at: <<http://worldwater-council.org/index.php?id=92&L=0>>.

mental dimension of security, and on the complex interaction between human beings and humankind as causes, triggers, and victims of the societal consequences of this process.

Below the first two stages of the global environmental change debate will be briefly reviewed: the emerging scientific research on global environmental and climate change since the 1970’s, and the political agenda-setting since the late 1980’s (1.2), and the *politicization* of global environmental change issues since the Earth Summit of 1992 (1.3.). The third stage of the emerging *securitization* of GEC issues that is closely linked to the environmental dimension of human, national, and international security will be examined separately (chap. 4 by Brauch). After a brief overview of the themes covered in this security handbook on the global rethinking on security (1.4.), the *sectorialization* of security and the sectoral security concepts (1.5.) as well as the structure and contributions of this book will be introduced (1.6.), and a few remarks will be offered on its multidisciplinary perspectives for a global audience (1.7.).

1.2 Scientific Research on Global Environmental and Climate Change and Political Agenda-Setting

Since the 1970’s, *global environmental change* (GEC) has focused on “human-induced perturbations in the environment” that encompass “a full range of globally significant issues relating to both natural and human-induced changes in the Earth’s environment, as well as their socioeconomic drivers.” According to Munn (2002: xi) “changes greater than humankind has experienced in its history are in progress and are likely to accelerate.” Dealing with future environmental trajectories requires more than a prediction of a single future path. It requires to “map a broad range of future environmental trajectories” that may confirm “that the changes of the 21st century could be far greater than experienced in the last several millennia” (Munn 2002: xii). Scientists, but also decision-makers and administrators are challenged to think the unthinkable; to minimize ‘surprise’ should nature manifest itself.

Since the 1990’s, the *International Geosphere-Biosphere Programme* (IGBP), the *International Human Dimensions Programme* (IHDP), the *World Climate Research Programme* (WCRP), and *DIVERSITAS* were instrumental for rallying a global environmental change research community around coordinated sci-

entific projects, and sensitizing policymakers and the public alike. In response to the Amsterdam Declaration on Global Change (2001), these four international GEC research programmes formed the *Earth System Science Partnership* (ESSP). Their work will be examined in the subsequent volume (Brauch/Oswald Spring/Mesjasz/Grin/Kameri-Mbote/Chourou/Dunay/Birkmann 2009)⁸.

The human dimension of global environmental change covers both the contribution and adaptation of societies to these changes. Wilson (1998) noted a growing *consilience* (the interlocking of causal explanations across disciplines) in which the “interfaces between disciplines become as important as the disciplines themselves” that would “touch the borders of the social sciences and humanities”.

As a topic of environmental history (Simmons 2002: 62–72; Radkau 2002, 2008) GEC analyses the human impact on nature during the past 10,000 years of the Holocene: 1) as hunters and gatherers from 10,000–8000 BCE (solar energy; localized impact on species and habitats); 2) agriculturalist period from 8000 BCE to CE 1750 (solar energy; impacts on soils, water, landforms); 3) industrialist era from 1750 to 1950 (fossil energy; intensification of impact and spatial extension); and 4) post-industrialist phase from 1950 to the present (fossil, nuclear, renewable energy; new chemicals, genetics create large-scale uncertainties). Since the Industrial Revolution (CE 1750) and especially since 1950 the massive use of fossil energy (coal, oil, natural gas) has contributed to an intensifying anthropogenic global environmental and climate change.

Global change combines and affects the ecosystem and the anthroposphere. The *ecosphere* comprises the *atmosphere* (climate system), the *hydrosphere* (water), the *lithosphere* (earth crust, fossil fuels), the *pedosphere* (soil), and the *biosphere* (life), while the *anthroposphere* deals with populations, social organizations, knowledge, economy and transport, and other human-related systems (WBGU 1993) such as culture (MA 2005) and cosmovisions.

Steffen, Sanderson, Tyson, Jäger, Matson, Moore, Oldfield, Richardson, Schellnhuber, Turner, and Wasson (2004: 1) have argued that a global perspective on

the interactions between environmental change and human societies has evolved. This led to an awareness of two aspects of Earth System functioning: “that the Earth is a single system within which the biosphere is an active, essential component; that human activities are now so pervasive and profound in their consequences that they affect the Earth at a global scale in complex, interactive and apparently accelerating ways”. They have further argued “that humans now have the capacity to alter the Earth System in ways that threaten the very processes and components, both biotic and abiotic, upon which the human species depends.” Oldfield (2005: 1) argued that the changes during the past 50 years were greater than those since the opening of the interglacial period of the Holocene some 10,000 years ago due to three developments:

- The rate of change in atmospheric CO₂ concentrations exceeds the mean rate during glacial-interglacial transitions by one to two orders of magnitude.
- The human population is now many orders of magnitude greater than it was at the opening of the Holocene.
- The degree to which the full range of human activities has transformed the world and the way it functions, especially over the past 50 years, has created a biosphere with no past analogues. Humans have become agents of change with diverse and increasing impacts on almost every aspect of the Earth System.

Oldfield (2005: 152–189) examined the changes that could be observed in the Anthropocene with regard to the changing atmosphere, land and aquatic environments, and ecosystems. In his conclusions he “outlined the need to bridge three methodological gaps, between contemporary and paleo-research, between empirical and modelling approaches, and between biophysical and socioeconomic perspectives ... [and] ... between well-validated research and policy-making” (Oldfield 2005: 295).

In the social sciences, the analysis of GEC and the human-nature relationship is polarized between epistemological idealism and realism (Glaeser 2002: 11–24), or between *social constructivism* and *neo-realism*. The *neo-idealist orientation* has highlighted two aspects: a) the uncertainty of scientific knowledge and claims; and b) the attempt to explain the scientific and public recognition of environmental change influenced by political and historical forces (Rosa/Dietz

8 The early activities of these programmes until 2001 are covered in the five volumes of the *Encyclopedia of Global Environmental Change* (Munn 2002); *Diversitas* (II: Mooney/Canadell 2002: 268–271); *IGBP* (II: Mooney/Canadell 2002: 350–357); *IHDP* (IV: Tolba 2002: 245); *WCRP* (I: MacCracken/Perry 2002: 753–754).

Table 1.1: Worldviews on Security and Standpoints on Environmental Issues: **Source:** Brauch 2003, 2005, 2005a).

Worldviews/Traditions on security (→)	Hobbes, Morgenthau, Waltz (neo)realist (pessimist) Power matters	Grotius liberal pragmatist Cooperation matters	Kant Neo-liberal institutionalist (optimist) International law matters and prevails
Standpoints on environmental issues (↓)			
Neo-Malthusian pessimist Resource scarcity	I	II	III
Equity-oriented pragmatist <i>Cooperation will solve problems</i>	IV	V International organizations and regimes	VI
Cornucopian neo-liberal optimist. <i>Technological ingenuity will solve problems</i>	VII	VIII	IX

1998). Two opposite scientific standpoints exist on environmental issues (Gleditsch 2003):

- the *pessimist* or *Neo-Malthusian view* (Malthus 1798) stresses the limited carrying-capacity of the Earth to feed the growing population;
- while the *optimist* or *Cornucopian view* believes that an increase in knowledge, human progress, and breakthroughs in science and technology could cope with these challenges.

These two opposite positions have dominated the environmental debate since the Club of Rome's *Limits of Growth* (Meadows/Meadows/Randers/Behrens 1972; Meadows/Meadows/Randers 1992), and Lomborg's (2001, 2004) *Skeptical Environmentalist*. Homer-Dixon (1999: 28-46) distinguished among *neo-Malthusians* (biologists, ecologists); *economic optimists* (economic historians, neoclassic economists, agricultural economists), and *distributionists* (poverty, inequality, misdistribution of resources). Brauch (2002, 2003) suggested an *equity-oriented pragmatism* as a middle ground between the two opposite views. Table 1.1 combines

- three worldviews on security of the English school (Bull 1977; Wight 1991; Brauch 2008a) represented by Hobbes (realism), Grotius (pragmatism), and Kant (idealism) with
- three ideal-type standpoints on the environment (Neo-Malthusian, Cornucopian, Pragmatist).

This leads to nine combined ideal type positions on security and environmental issues. Our perception of and policy response to the new challenges posed by global environmental change depends on the specific combination of the prevailing worldviews and stand-

points that influence the mindset of policymakers. At least three ideal type positions can be distinguished:

- I: the (neo)realist and Neo-Malthusian pessimist for whom only military, economic, and political power matters to face and cope with resource scarcity, and who often acts unilaterally;
- V: the liberal and equity-oriented pragmatist for whom multilateral cooperation (in international organizations, regimes) matters and can solve challenges.
- IX: the combination of Kantian ideas and Cornucopian optimism that democracies, the rule of law and international law, but also new technologies, can solve the new global environmental challenges.

The (neo)realist and Neo-Malthusian pessimist position is often pursued by major military powers, while the centrist position is often advocated by smaller countries and middle powers and by the multilateral United Nations system, and the optimist perspective is probably best represented by the Wilsonian tradition to international affairs. The pessimist position is reflected in many studies that analysed climate change as a threat to US national security, while the centrist standpoint has been dominant in many contributions that examined climate change as a challenge for international security. In the political realm, these three ideal type perspectives may be rare, and often issue specific responses prevail that are influenced by the political forces (parties, coalitions) and political mindsets or ideologies of decision-makers.

During the past two decades *global environmental challenges* (Brauch/Oswald Spring/Mesjasz/Grin/Dunay/Behera/Chourou/Kameri-Mbote/Liotta 2008) have created an intensive public awareness to *face* the impacts of GEC and to *cope* with its consequences

(Brauch/Oswald Spring/Mesjasz/Grin/Kameri-Mbote/Chourou/Dunay/Birkmann 2009). How policymakers, the media, and the public perceive, interpret, and convey scientific knowledge on the new global environmental dangers depends on the specific combination of the worldviews and ecological standpoints that differ both within and among countries.

Since the start of the scientific discourse on global environmental change in the 1980's and the initially policy-driven debate on environmental (Brundtland 1987; Myers 1989; Mathews 1989) or ecological security (Gorbachev 1987, 1988) in the social sciences since the global turn, there was little interchange between the natural scientists in the global change research community and the social scientists and policymakers and advisers who dominated the debate on the reconceptualization of security. Both discourses and debates were pursued in parallel by different scientific and policy communities with a limited exchange between natural and social scientists or between scientists and policymakers, environmental and security experts, international and national officials, diplomats and military officers. So far there has also been little debate between the environmental and the human security school in the social sciences and in diplomacy, with few exceptions.

In the framework of IHDP, its GECHS (*Global Environmental Change and Human Security*) project has argued since the late 1990's that these GEC impacts affect *human security*: natural disasters, cumulative changes or slow-onset changes, accidental disruptions or industrial accidents, development projects, and conflict and warfare (GECHS 1999). Authors associated with GECHS (Barnett/Matthew/O'Brien 2008) and UNU-EHS (2008) have addressed both the input factors and the often extreme societal outcomes from a people-centred human security approach. But the emerging policy debate has focused so far primarily on challenges posed by *climate change* primarily for *international* (regional and global) and *national security*. But in May 2008, the *Human Security Network* (HSN) has for the first time addressed the political impacts of climate change on human security.

1.3 Politicization of Global Environmental Change

Two parallel policy debates on a reconceptualization of security and on problems of global environmental change have gradually emerged since 1990. In the

security realm four conceptual policy debates can be distinguished:

- an initially *Northern debate* where a state-centred security concept has been extended by developing an *environmental dimension of national and international security* (in the US, Western Europe, NATO, OSCE, UNEP, UNDP, ENVSEC et al., part VIII, chap. 59–73);
- an initially *Southern debate* on a human-centred security concept that was launched by Mahbub-ul Haq⁹ with the *Human Development Report 1994* (UNDP 1994) that was promoted by UNESCO (Part IX, chap. 74–96);
- since 2000 a growing debate on *water security* (chap. 11 by Oswald/Brauch and part VII, chap. 41–58), on the *securitization of climate change* (chap. 4 by Brauch), and on desertification as a security issue (Kepner/Rubio/Mouat/Pedrazzini 2006; Brauch 2003, 2006; chap. 8 by Boulharouf/Pattie; chap. 9 by Rechkemmer); and finally
- since 2004 an emerging debate on the environmental dimension of human security and since 2007/2008 on climate change as a human security challenge that focuses on the most vulnerable and affected people that daily *face* the impacts of global environmental change.

Since the 1990's, the widening of the security concept has progressed and concepts of 'environmental security' (UNEP, OSCE, OECD, UNU, EU), 'human security' (UNDP, UNESCO, UNU), 'food security' (WHO, World Bank), 'energy security' (World Bank, IEA), 'health security' (WHO), and 'livelihood security' (UNEP, OECD) have been widely used.

1.3.1 Global Policy Debate on Environmental Security

In 1987 Soviet President Gorbachev "proposed ecological security as a top priority". The Brandt-Report (1980) noted that "few threats to peace and survival of the human community are greater than those posed by the prospects of cumulative and irreversible degradation of the biosphere on which human life depends." The Brundtland Commission (1987: 19) ar-

9 Mahbub ul Haq (1934–1998) was a Pakistani economist who in 1990 created the Human Development Index, which the UNDP used in its annual reports on people's standards of living to determine their countries' wealth. He had served as the World Bank's director of policy planning and Pakistan's finance minister.

gued that the security concept “must be expanded to include the growing impacts of environmental stress”. The Commission on Global Governance (1995) called for a broader concept of global security for states, people, and the planet. It claimed a linkage between environmental deterioration, poverty, and underdevelopment as causes of conflict. These reports put the linkage between environmental stress, conflicts, and conflict resolution on the political agenda of international organizations.¹⁰

1.3.1.1 Environmental Security Debate within the United Nations System

The *Millennium Report of the Secretary-General* (Annan 2000) mentioned several international organizations that have addressed the linkages between environmental stress and conflicts. The *World Summit on Sustainable Development* (WSSD) in Johannesburg (2002) in its political declaration and plan of implementation referred only to ‘food security’, while ‘environmental’ and ‘human security’ were not explicitly mentioned. Former UN Secretary-General Kofi Annan (2003) pointed to the potential threats posed by environmental problems. In January 2004 UNEP identified a “need for scientific assessments of the link between environment and conflict to promote conflict prevention and peace building” (Töpfer 2004: 1). UNEP’s *Division of Early Warning and Assessment* (DEWA) launched an “Environment and Conflict Prevention” initiative to stimulate “international efforts to promote conflict prevention, peace, and cooperation through activities, policies, and actions related to environmental protection, restoration and resources” (Lonergan 2004: 2). In November 2008 an UNEP Advisory Group on Environment, Conflict and Peacebuilding was launched.¹¹

10 The scientific debate on the first three phases of environmental security research is discussed below in chap. 59 by Dalby/Brauch/Oswald and proposals for the fourth phase are offered by Oswald/Brauch/Dalby (chap. 98). For a review of the political debate on environmental security in international organizations until 2002 (see Brauch 2003) and until 2004/2005 (Brauch 2005, 2007, 2007a, 2007b, 2007c). This reviews focuses primarily on the political developments between January 2003 and April 2008 within the UN, OSCE, NATO, OECD, and the EU.

11 See: “New Advisory Group on Environment, Conflict and Peacebuilding”, in: *Environment, Conflict and Cooperation Newsletter*, April 2008; at: <http://www.ecc-platform.org/index.php?option=com_content&task=view&id=1377>.

The Secretary-General’s High-level Panel on Threats, Challenges and Change (UN 2004) identified six ‘threat clusters’: 1) socioeconomic threats, including poverty, infectious diseases, and environmental degradation; 2) classic inter-state wars; 3) intrastate violence, including civil wars and genocide; 4) weapons of mass destruction; 5) terrorism; and 6) organized crime. In a succinct analysis of this document and of the policy debate within the UN about it, von Einsiedel, Nitzschke, and Chhabra (2008: 635–636) argued that “in the absence of a coherent security concept”, the UN “has dichotomized ‘hard’ security threats to ‘state security’, such as armed conflict, terrorism, and weapons of mass destruction, versus ‘soft’ threats to ‘human security’, such as poverty, infectious disease, and environmental degradation”. Furthermore, “in arguing that threats to human and state security are a threat to all states, the Panel has reaffirmed the importance of sovereignty to safeguard human security, but it has also qualified sovereignty to reaffirm the objectives of the ‘human security’ agenda.” While environmental degradation was repeatedly noted among the ‘soft’ and socioeconomic threats, the environmental security debate itself was not taken up by the SG’s High-level Panel (2004).

1.3.1.2 Environmental Security Debate of OSCE

The *Organization for Security and Co-operation in Europe* (OSCE) has dealt with security risks from environmental stress. Among the non-traditional security risks confronting OSCE countries in Central, Eastern and South-Eastern Europe, in the Caucasus, in Central Asia, and other parts of the former Soviet Union are transboundary pollution, shortage of drinking water, disposal of radioactive waste, reduction of human losses in man-made disasters and natural catastrophes. The Ministerial Council meeting in Maas-tricht in December 2003 adopted the *OSCE Strategy Document for the Economic and Environmental Dimension*, thus committing themselves

‘to cooperate on economic, good governance, sustainable development and environmental protection issues in order to tackle the threats and challenges to security that had emerged over the previous decade. In the Strategy Document, the participating States recognized that ‘environmental degradation, unsustainable uses of natural resources and mismanagement in the processing and disposal of wastes have a substantial impact on the health, welfare, stability and security of our countries.’

On 30 November 2007 the Foreign Ministers of the OESCE countries adopted the ‘*Madrid Declaration on Environment and Security*’¹² that addresses “the

issue of climate change, ... [where] the OSCE ... has a complementary role to play within its mandate in addressing this challenge in its specific region".¹³ Spain also tabled an *Action Plan on the Threats and Opportunities in the Area of Environment and Security* that was not endorsed.¹⁴ It contained specific recommendations in five areas:

- Refocusing OSCE institutions and mechanisms on environmental matters;
- Raising awareness on environmental challenges, including climate change and its security implications;
- Promoting environmental cooperation as a tool for conflict prevention and confidence building;
- Improving environmental governance; and
- Addressing social economic aspects of environmental security.

At the 15th OSCE Economic and Environmental Forum on "Environmental Security and Sustainable Development" two key issues were addressed: "land degradation, soil contamination and water management" in two meetings in Vienna on 22-23 January 2007 and in Prague on 21-23 May 2007 that were prepared by two preparatory expert conferences in Bishkek, Kyrgyzstan on 16-17 November 2006 on "Land Degradation and Soil Contamination", and in Zaragoza, Spain on 12-13 March 2007 on water management. The OSCE Chairman-in-Office, Spanish Foreign Minister Miguel Ángel Moratinos, argued that global security

'will be increasingly at risk because of man-made environmental threats. ... It is important ... to include environmental security issues in political agendas by fostering the participation of national, international, public and private actors. ... Environmental cooperation can be an effective catalyst for reducing tensions, broadening cooperation and promoting peace'.

12 Resolution on Environment and Security adopted by the Ministerial Council of the OSCE in Madrid on 30 November 2007 as "Madrid Declaration on Environment and Security", in: Organization for Security and Co-operation in Europe. MC.DOC/4/07; at: <http://www.osce.org/documents/mcs/2007/12/28657_en.pdf>.

13 See the speech by Bernard Snoy, coordinator of OSCE Economic and Environmental Activities, on 12 March 2008 at a NATO meeting, at: <http://www.nato.int/docu/comm/2008/0803-science/pdf/bernard_snoy.pdf>.

14 In his speech of 12 March 2008, Bernard Snoy also reviewed the OSCE activities in the framework of the ENVSEC Initiative and the 15th OSCE Economic and Environmental Forum on "Environmental Security and Sustainable Development" and its follow-up activities.

The OSCE launched several initiatives supporting regional cooperation:

- by establishing a *Regional Drought Management Center in Central Asia* by the countries of Central Asia to implement the UN *Convention to Combat Desertification* (UNCCD);
- by organizing a follow-up conference concentrating on degradation of land and pollution as well as on water management in Central Asia in Tashkent on 30-31 October 2007.
- by holding a workshop in Valencia on 10-11 December 2007, on "Water Scarcity, Land Degradation and Desertification in the Mediterranean Region: Environment and Security Aspects" under the joint auspices of the Spanish OSCE Chairmanship and of the NATO Science for Peace and Security Programme.¹⁵

Based on the *Madrid Declaration on Environment and Security* more attention will be given to environmental security issues and to links between the economy, environment, and security.

1.3.1.3 Applying Environmental Security: The ENVSEC Initiative

In late 2002, OSCE, UNEP, and UNDP launched a joint initiative to promote the use of environmental

15 See the conference programme at: <http://www.osce.org/documents/eea/2007/11/27982_en.pdf>. Henri-Luc Thibault, the director of the Blue Plan, which is the Regional Activity Center of the UNEP/Mediterranean Action Plan presented possible future scenarios for environmental conditions in the Mediterranean region arguing "that trends projected for water and energy demand for the next 20 years in the 21 Mediterranean-rim countries ... are simply not compatible with the objectives of sustainable development and that, compounded with the effects of climate change, they risk being associated with irreversible land and other environmental degradations, loss of livelihoods, increased migration, and ultimately serious threats to security and stability in the region. It is crucially important to improve the management of water scarcity, to save energy, to increase the share of renewable energy and to decouple economic growth from overexploitation of natural resources and excessive pressure on the environment." See this author's background study for the Blue Plan of November 2007 in English at: <http://www.planbleu.org/publications/energaia/RAPPORT_Brauch_EN.pdf> and in French at: <http://www.planbleu.org/publications/energaia/RAPPORT_Brauch_FR.pdf> and his PowerPoint presentation at: <http://www.afes-press.de/pdf/Brauch_porjected_climate_change.pdf>.

management as a strategy for reducing insecurity in South-Eastern Europe, in the Caucasus, and Central Asia. A ministerial conference in Kiev in May 2003 adopted an environmental strategy for the countries of these sub-regions. After Kiev, the *Environment and Security Initiative* (ENVSEC) has focused on:

1. vulnerability assessment and on monitoring environment and security linkages,
2. policy development and implementation,
3. institutional development, capacity building, and advocacy.¹⁶

Since 2004 many reports have been published in this framework (chap. 71 by Cheterian) on environment and security problems. In 2004 NATO became an associate, and since 2006 the *United Nations Economic Commission for Europe* (UN-ECE) and the *Regional Environment Center for Central and Eastern Europe* (REC) joined.

1.3.1.4 Environmental Security Research and Dialogue supported by NATO

Since the mid-1990's, NATO's Science Committee has supported Advanced Research Workshops on environmental security and conflict involving scientists from former Warsaw Pact and from Mediterranean dialogue partner countries (Gleditsch 1997; Brauch 2003).¹⁷ The final report of the NATO-CCMS (1999) pilot study on *'Environment and Security in an International Context'* assessed the links between environment and security, examined the consequences of economic stress and their potential impact on conflict escalation, offered a typology of environmental conflict cases, provided an integrated risk assessment, dealt with indicators, data and decision support systems, and presented an integrated approach of policy responses for environmental, development, foreign, and security policy (Lietzmann 1999: 35) that covered

early warning, preventive diplomacy, permanent mechanisms for dispute settlement, crisis and post-crisis management (NATO/CCMS 1999: 164-167). Based on its 1999 Strategic Concept, NATO's *Public Diplomacy Division* (PDD) has supported workshops and collaborative research projects on environmental security issues, facilitating cooperation with scientists from Mediterranean Dialogue and Partnership for Peace countries.

In February 2008, NATO's *Science Security Forum* (SSF) organized a high-level Forum on environmental security with experts from the natural sciences and defence establishments from NATO member, Partner, and Mediterranean Dialogue countries.¹⁸ Jean-François Bureau, NATO Assistant Secretary-General for Public Diplomacy, argued "that the number of circumstances where our defence and security policies have to take into account the environmental factor is obviously developing in the same way" which is why it "becomes a key factor of military efficiency". Environmental concerns should be integrated into NATO's operational concepts:

- Major developments in military observations and surveillance capabilities (like satellites and UAVs) also provide capabilities to monitor environmental issues; those examples show that when we look at the relationship between environment and security we mainly deal with dual technologies, those which can be applied to civil as well as military purposes;
- when NATO develops its partnership programmes, environmental security is a major item: many examples will show that NATO and its members have developed a wide spectrum of activities with Caucasus, Central Asia, Western Balkans, and Mediterranean nations.¹⁹

The environment and security issues should ... also

fit the NATO priorities when dealing with future challenges. Terrorism, proliferation of weapons of mass destruction, cyber-defence, maritime awareness, and energy security are among the most challenging. NATO nations are deciding whether and how NATO should be a key contributor in these fields which will shape our future security.

16 See at: <http://www.iisd.org/pdf/2003/envsec_post_kiev.pdf>.

17 NATO's scientific and Environmental Affairs Division financed several Advanced Research Workshops (ARWs) including on: "Conflict and the Environment" (Gleditsch 1997); on: "Environmental Change, Adaptation and Security" (Loneragan 1999); on: "Responding to Environmental Conflicts: Implications for Theory and Practice" (Petzold-Bradley/Carius/Vincze 2002); on "The Caspian Sea: a Quest for Environmental Security" (Asher/Mirovitskaya 2000); and on: "Soil Quality, Sustainable Agriculture and Environmental Security in Central and Eastern Europe" (Wilson/Maliszewska-Kordybach 2000).

18 See the NATO website on environmental security; at: <<http://www.nato.int/issues/science-environmental-security/index.html>>. This meeting and all presentations are documented at: <<http://www.nato.int/docu/comm/2008/0803-science/0803-science.htm>>.

19 See the speech by Jean-François Bureau, at: <<http://www.nato.int/docu/speech/2008/so80312a.html>>.

Jean-François Bureau wanted the security science forum “to cover key environmental issues which are also global security concerns (such as transboundary water issues, global climate change or natural catastrophes) in order to play a forward-looking, horizon-scanning role to propose a road map for future projects that will contribute to security and stability in the Euro-Atlantic zone and beyond.”

1.3.1.5 Environmental Security Debate in OECD Documents

The *Organization for Economic Co-operation and Development* (OECD) has addressed the linkages between development, environment, and conflicts in several policy statements, such as “Development Assistance, Peace and Development Co-operation of the 21st Century” (OECD/DAC 1997, 2000), and in a scoping paper on the economic dimension of environmental security which are reflected in the “Guidelines on Conflict, Peace and Development Co-operation” (OECD/DAC 2001: 89).²⁰ In February 2000, the OECD’s DAC Working Party on Development Co-operation and Environment (WP/ENV) published a *State-of-the-Art Review of Environment, Security and Development Co-operation* that was compiled by the *World Conservation Union* (IUCN) together with a group of experts.²¹

20 An overview of the activities and resources material of OECD on ‘conflict and peace’ and on the DAC Network on Conflict, Peace and Development Co-operation (CPDC, <www.oecd.org/dac/conflict) that brings together conflict prevention and peacebuilding experts from bilateral and multilateral development agencies, including from the UN system, EC, IMF and World Bank is at: <http://www.oecd.org/department/0,3355,en_2649_34567_1_1_1_1_1,00.html>. The CPDC is a subsidiary group of the OECD Development Assistance Committee (DAC).

21 For a “State-of-the Art Review on Environment, Security and Development Co-operation” by IUCN for the Working Party on Development Co-operation and Environment OECD Development Assistance (OECD 2000), see at: http://www.iisd.org/pdf/2002/envsec_oecd_summary.pdf, and the full report at: <<http://www.oecd.org/dataoecd/8/51/2446676.pdf>>. For a more recent North American review see Brown (2005); See also the documentation of a conference during the German EU presidency on: “Integrating Environment, Development, and Conflict Prevention – European and National Approaches and Challenges”, Berlin, 29–30 March 2007; at: <http://www.adelphi-consult.com/ECC2007/Downloads/Programme_ECC_Conference_2007_FINAL.pdf>.

Between 2001 and 2004, the *Working Party on Global and Structural Policies* (WPGSP) of the Environment Directorate, and the *Network on Environment and Development Co-operation* (Environet) conducted the OECD’s ‘Development and Climate Change’ project with the goal “to provide guidance on how to mainstream responses to climate change within economic development planning and assistance”. In this context several country case studies were carried through that focused at the socioeconomic and political impact of climate change for Bangladesh, Egypt, Fiji, Nepal, and Tanzania that are relevant for the environmental security debate without being directly framed in a security context.²² The OECD assumed that these insights would have implications for the development assistance community in OECD countries, and for national and regional planners in developing countries.

The *OECD Environmental Outlook to 2030* offered a baseline projection of environmental change based on the underlying economic and social factors that drive these changes. Simulations were done for specific policies to address the main environmental challenges identified, and their economic costs and environmental benefits until 2030, and in some areas up to 2050 (OECD 2008). The key environmental pressures include “climate change, biodiversity loss and water scarcity, and the key sectors exerting pressure on the environment (agriculture, energy and transport).” An OECD Policy Brief highlighted its “work on the likely impact of various courses of action to mitigate climate change, and the costs of inaction.”²³ Both publications did not reflect OECD’s previous work on environmental security.

1.3.1.6 Environmental Security Concerns and the EU’s Green Diplomacy

Since the 1990’s, the *European Union* (EU) has pursued two strategies for ‘environmental security’: a) integrating environmental goals into all sectoral policies (*Cardiff process*), including development, foreign,

22 On Bangladesh: Agrawala/Ota/Ahmed/Smith/van Aalst (2003); on Egypt: Agrawala/Moehner/El Raey/Conwa/van Aalst/Hagenstad/Smith (2004); on Fiji: Agrawala/Ota/Risbey/Hagenstad/Smith/van Aalst/Koshy/Prasad (2003); on Nepal: Agrawala/Raksakulthai/van Aalst/Larsen/Smith/Reynolds (2003); and on Tanzania: Agrawala/Moehner/Hemp/van Aalst/Hitz/Smith/Meena/Mwakifwamba/Hyera/Mwaipopo (2003).

23 OECD Policy Brief: “Climate Change: Meeting the Challenge to 2050”, Paris, February 2008; at: <<http://www.oecd.org/dataoecd/6/21/39762914.pdf>>.

and security policies; and b) stressing conflict prevention and management in its activities in international organizations (UN, OSCE) and for specific regions (Brauch 2003: 86–89).

At the meeting of the European Council held in Barcelona in March 2002, a sustainable development strategy was adopted that emphasized the integration of environmental concerns into sectoral policies. The European Council in Seville (June 2002) approved a conflict prevention programme that aimed both at short-term prevention and at the root causes of conflict, in its development cooperation with poverty reduction. The European Council in Thessaloniki in June 2003 approved a green strategy of the EU.

In spring 2008, the approach of the European Union towards environmental security issues has evolved within the framework of its *Common Foreign and Security Policy* (CFSP), the *European Security and Defence Policy* (ESDP), the *European Security Strategy* (ESS) and its *Conflict Prevention and Crisis Management* programme, its *country and regional strategy papers*, and the policies of the EU with Neighbouring States through the *Stability Pact for the Balkans*, the *Euro-Mediterranean Partnership* (EMP) and the *EU Neighbourhood Policy* (ENP).²⁴ Goals of environmental security have also been part of the EU's environment and development policies and practices through a) the *Kimberley process*, the *EU Water Initiative* (EUWI), the *EU Action Plan for Forest Law Enforcement, Governance and Trade* (FLEGT), the *EU Energy Initiative for Poverty Eradication and Sustainable Development* and the *Global Monitoring for Environment and Security* (GMES).

As part of the Cardiff process environmental considerations must be mainstreamed into sectoral policies, which is being achieved with regard to EU development cooperation through its *Country Environment Profile* (CEF), in the *Country Strategy Paper* (CSP). For its preparation a tool box has been made available through the *Environmental Mainstreaming in EC Development Cooperation Support and Resource Panel* (Kingham 2006: 136–137).

According to Article 6 of the *EC Treaty*, “environmental protection requirements must be integrated into the definition and implementation of the Community policies and activities”... “in particular with a view to promoting sustainable development”. In im-

plementation of the EU Council decision of Thessaloniki (2003), the *Green Development Network* (GDN) of representatives of the foreign ministries dealing with international environment and sustainable development issues of the 27 EU member countries was set up to enhance the integration of environmental concerns into foreign policy.²⁵ The GDN focuses on the following themes: a) climate change; b) biodiversity; c) desertification; d) cooperation with third countries; e) sustainable development; f) forests; g) water; h) energy; i) waste management; and j) fisheries and marine resources. Among the tasks of the network are: “increasing the coherence, consistency and effectiveness of European actions in the field of environment”.

The EU's *Sustainable Development Strategy*, adopted in June 2006, lists among its goals the need for the EU to “actively promote sustainable development worldwide and ensure that the European Union's internal and external policies are consistent with global sustainable development and its international commitments.” The GDN performs these functions:

- To promote the use of the EU's extensive diplomatic resources (diplomatic missions, delegations, development cooperation offices) in support of environmental objectives, orchestrating campaigns and demarches....
- To exchange views and share experiences on how Member States (in particular Foreign Ministries) are integrating environmental concerns into their diplomatic efforts.

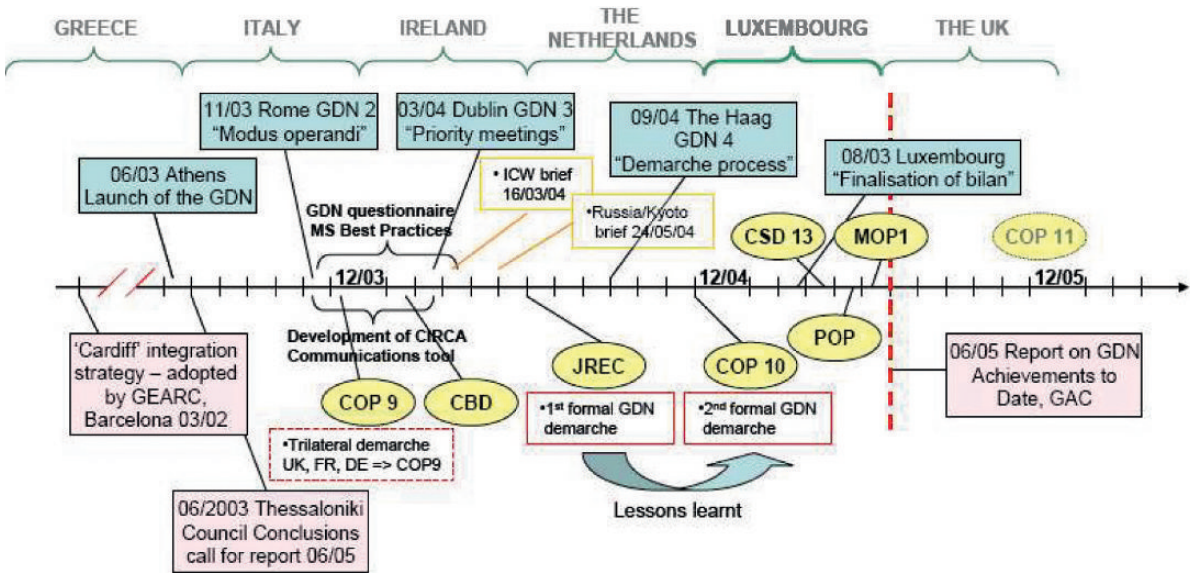

The Network started during the Greek presidency with the adoption of an initial action plan and work programme. Until December 2005 (under the Greek, Italian, Luxembourg, Dutch, and UK presidencies of the EU) several milestones were achieved (figure 1.1).

During the Austrian, Portuguese (2006), German, Finnish (2007), and Slovenian presidencies (2008), the *Green Diplomacy Network* (GDN) addressed an improved international environmental governance through a reform of UNEP; the implementation of several environmental conventions (CBD), the coordination of climate change negotiations prior to COP 12 and COP 13 of the UNFCCC and MOP_{2/3} of the Kyoto Protocol; and carried out demarches on climate change for the post-2012 climate architecture. The German presidency (2007) organized a conference on

24 See the chapters in vol. III of the Hexagon book series by: Mosca Moschini (2008); Hintermeier (2008); Maurer/Parkes (2008); Ekengren (2008); Katseli (2008); Biscop (2008) and Aydın/Kaptanolu (2008).

25 See the GDN website at: <http://ec.europa.eu/external_relations/env/gdn/index.htm>.

Figure 1.1: Green Diplomacy Milestones June 2003-June 2005. **Source:** European Commission; at: <http://ec.europa.eu/external_relations/env/milestones.pdf>.

Integrating Environment, Development and Conflict Prevention, highlighting the key role that the GDN can play in linking environmental concerns with matters of foreign policy, while the presidency of Portugal (2007) emphasized "Climate Change and Development Cooperation". Furthermore, it was agreed in July 2007 in Lisbon:

to further develop the Network by strengthening cooperation on the ground in third countries between environment correspondents in Commission delegations and Member State embassies. These Local Green Diplomacy Networks will act as in-country forums to share information, experiences and approaches and ensure close EU coordination on international environment policy priorities. In its pilot phase this process will commence in 5 key emerging economies (Brazil, Russia, India, China and South Africa).

On the future GDN objectives the Commission argued that GDN should amplify "consistency and effectiveness of the EU's line on International Environmental Matters" by: 1) organizing demarches; 2) further exchange of good practices for integrating environment and sustainable development in the external policies at European and national levels; 3) better information on positions of non member-countries; and 4) proactive dissemination of accurate and up-to-date environmental information.

At the operational level, the European Commission in cooperation with the *European Space Agency* (ESA) launched the joint programme on *Global Monitoring for Environment and Security* (GMES) that

aims at "combined ground and space-based observations to develop an integrated environmental and security monitoring capability" to provide with these data "a better understanding of the earth's land surface, its atmosphere and its oceans, and support emergency and security services" and thus to "allow for a better management of environmental and security crises".²⁶

But neither the GDN nor the GMES documents have referred to the environmental security concept although many issues of the EU's green diplomacy have addressed environmental security concerns. In the conceptual, analytical, and operational efforts of these international organizations on environmental security, so far human security concerns have played no role.

1.3.1.7 Environmental Security Initiatives in Latin America, Africa, and the Asia Pacific

Several developing countries interpreted the environmental security debate with suspicion, and repeatedly

²⁶ See European Commission, IP/08/346, 28 February 2008: "Security and the environment: new satellites to spur earth observation", at: <<http://europa.eu/rapid/pressReleasesAction.do?reference=IP/08/346&format=HTML&caged=0&language=EN&guiLanguage=en>>. More information on GMES, see at: <<http://www.gmes.info/>> and on ESA, at: <<http://www.esa.int/esaCP/index.html>>.

members of the Group of 77 (G 77) prevented references to environmental security issues in UN documents. Irrespective of these policy concerns, there has been a conceptual debate on environmental security concepts and issues by scholars from these regions (part VIII).

But this is changing. In Latin America the Committee on Hemispheric Security of the OAS Council in a “Framework Treaty on Democratic Security in Central America” of April 2008 emphasized that:

the Central American Democratic Security Model is based on the supremacy and strengthening of civil power, the reasonable balance of forces, the security of persons and of their property, the elimination of poverty and extreme poverty, the promotion of sustainable development, the protection of the environment, the elimination of violence, corruption, impunity, terrorism, drug trafficking, and arms trafficking. Also, the Central American Security Model will increasingly devote resources to social investments.²⁷

This Committee discussed on 12 February 2007 environmental security concerns of Small Island States with regard to the shipment of nuclear waste through the Caribbean.²⁸ While several references to environmental and ecological security in OAS documents exist, no specific operational project has been launched such as the ENVSEC initiative.

While environmental security issues have been discussed by African scholars (see chap. 68 by Ejigu and 69 by Moyo), no references to these themes could be found in the security debate of the African Union. But in several policy papers environmental degradation has been listed as a structural cause of conflict in discussions of the EU with ECOWAS.²⁹

Socio-ecological and environmental security concerns have been discussed in South Asia (chap. 62 by Ramakrishnan; Behera 2008), for North East Asia (chap. 63 Schreurs; Lee 2008; Hunter/Cheng 2008) and for the Asia Pacific (chap. 72 by Barnett; Clements/Foley 2008), but they have not resulted in multilateral environmental security initiatives.

27 See: Committee on Hemispheric Security of the Permanent OAS Council: “Framework Treaty on Democratic Security in Central America” (5 April 2008); at: <<http://www.oas.org/csh/english/docc&t%20CenAm.asp>>.

1.3.2 The Global Policy Debate on Human Security

The human security concept used by UNDP (1994) triggered a global scientific debate where the persons affected by environmental stress and its outcomes (hazards, migration, crises, conflicts) are the referent object (chap. 74 by Brauch).³⁰ For many states and the security studies community the ‘nation state’ remains the major referent object that is to be secured while the human security concepts deal with the protection of the individual, the citizen or humankind. Bogardi and Brauch (2005) suggested that human security should rest on four pillars:

- ‘*Freedom from want*’ (economic and societal security dimensions) by enhancing the implementation of the millennium development goals through active development and environment policies aiming at sustainable development by reducing *social vulnerability* through poverty eradication programmes (UNDP 1994; CHS 2003);
- ‘*freedom from fear*’ (political and military security dimension) by reducing the probability that people become victims of violence and conflict and by enhancing human rights;
- ‘*freedom to live in dignity*’ (human rights agenda; Annan 2005);
- ‘*freedom from hazard impacts*’ (environmental security dimension) by reducing vulnerability of societies confronted with natural and human-induced hazards and by enhancing resilience, disaster preparedness, and response (UNU-EHS 2005; Brauch 2005, 2005a).

Since the mid-1990’s several UN institutions (General Assembly, Security Council, UNDP, UNESCO, UNU) have widely used the human security concept. But so far only few researchers and policy initiatives have conceptually explored and politically developed the environmental dimension of human security (Barnett 2001; Brauch 2005, 2005a, 2006, 2008; chap. 98 by Oswald/Brauch/Dalby). Among them GECHS and the *United Nations University Institute on Environment and Human Security* (UNU-EHS 2005, 2008) have been most prominent.

30 See for a list of definitions of human security in the scientific literature at: <http://www.hsph.harvard.edu/hpcr/events/hsworkshop/list_definitions.pdf>; and at: <http://www.uncrd.or.jp/hs/doc/04a_10jun_mani_concept.pdf> for threats to human security, see at: <http://www.hsph.harvard.edu/hpcr/events/hsworkshop/comparison_definitions.pdf>.

According to the initial GECHS definition: “Human security is achieved when and where individuals and communities: have the options necessary to end, mitigate, or adapt to threats to their human, environmental, and social rights; actively participate in attaining these options; and have the capacity and freedom to exercise these options” (GECHS 1999: 29). Barnett, Matthew, and O’Brien (2008: 360) noted that “there has been little emphasis on the broader implications of global environmental change for human security, including how increased human security can potentially mitigate environmental change,” and they concluded that “despite growing international concern about climate change, biodiversity loss, ... these issues have not been identified as priority areas for human security research.” While both considerations “are central to the *Millennium Development Goals* (MDG), there is no explicit recognition of the implications of global environmental change for these goals,” the only “MDG that addresses the environment (Goal 7: ensure environmental sustainability) does not consider the challenges posed by environmental change.”

While GECHS has initially focused on the causes and impacts of GEC, UNU-EHS has focused on the *response* to its extreme outcomes, especially to floods and droughts aiming at ‘freedom from hazard impacts’, by reducing social vulnerability and enhancing the coping capabilities of societies confronted with environmental and human induced hazards. For UNU-EHS ‘human security as freedom from hazard impact’ is achieved when people who are vulnerable to and at risk of these manifold environmental hazards and disasters that are often intensified by other associated societal threats (poverty), challenges (food insecurity), vulnerabilities and risks (improper housing in highly vulnerable flood-prone and coastal areas) are better warned of impending hazards, prepared, and protected against these impacts and are empowered to prepare themselves effectively to cope with the ‘survival dilemma’ (Brauch 2004, 2005, 2008c). During the Greek presidency (2007/2008) the *Human Security Network* (HSN) explored the environmental dimension of human security (chap. 75 by Fuentes/Brauch).

While there has been an academic and policy-focused scientific debate on human security in Africa (chap. 80 by Poku/Sandkjær), Latin America (chap. 81 by De Lombaerde/Norton; chap. 82 by Rojas) and in Central, South, South East Asia, as well as in the Far East and Asia Pacific (see chap. 74 by Brauch; chap. 79 by Othman; chap. 88 by Wun’Gaeo), only two African

countries (Mali, South Africa), two Latin American countries (Chile, Costa Rica) and two Asian countries (Thailand, Jordan) have joined the *Human Security Network* (HSN). Except in Thailand where a Ministry on Human Security was set up that focuses on human development, the conceptual debate had so far few operational impacts on the bilateral, sub-regional, and regional security policies of Asian countries.

1.4 Mapping the Global Reconceptualization of Security and Environment Linkages in the Anthropocene

As a result of the emerging securitization of problems related to global environmental change and specifically of climate change, water, and soil these issues became problems of utmost importance that require extraordinary policy efforts by the international community (international organizations, societal groups and business organizations) where the use of both traditional and modern scientific and technological knowledge is needed to face these manifold new security dangers and concerns posed by the challenges of GEC (chap. 4 by Brauch).

This global scientific mapping project on the *reconceptualization of security* is designed as a multi-disciplinary and global ‘Security Handbook for the Anthropocene’ in three volumes:

- The first volume on: *Globalization and Environmental Challenges: Reconceptualizing Security in the 21st Century* (Brauch/Oswald Spring/Mesjasz/Grin/Dunay/Behera/Chourou/Kameri-Mbote/Liotta 2008) offered a conceptual assessment of the ‘widening’ and ‘deepening’ of security since the end of the Cold War.
- This volume on: *Facing Global Environmental Change: Environmental, Human, Energy, Food, Health and Water Security Concepts* reviews the application of the ‘widening’ (environmental security), ‘deepening’ (human and gender security) and ‘sectorialization’ (energy, food, health, and water security) during the transition to the Anthropocene.
- The third volume on: *Coping with Global Environmental Change, Disasters and Security – Threats, Challenges, Vulnerabilities and Risks* (Brauch/Oswald Spring/Mesjasz/Grin/Kameri-Mbote/Chourou/Dunay/Birkmann) conceptualizes the terms threats, challenges, vulnerabilities

Table 1.2: Vertical Levels and Horizontal Dimensions of Security in North and South

Regional security					
Global/Planetary security					

and risks with regard to global environmental change, natural hazards and disasters, as well as security. It also reviews emerging policy responses for coping with these new security issues.

The debate on the reconceptualization of the security concept and the review of the securitization of global environmental change issues provide the conceptual and empirical context for this volume that breaks new ground by offering a comprehensive overview of the global, regional, and national conceptual debates and policy applications. These three volumes differ from the debates in political science, international relations, security studies and peace research literature³¹ by offering:

- a plurality of disciplinary approaches, aiming at *trans-* and *multidisciplinarity*;
- manifold national, regional and global perspectives from scholars from all five continents representing different cultures, religions, and scientific

traditions thus diversifying and enriching Northern approaches to security issues;

- overcoming the separation between the academic ivory tower and the political arena of international global and regional organizations and national, regional, and local governments.

These three volumes offer a comprehensive and innovative handbook mapping the global reconceptualization of security thinking and policy applications in the early 21st century.

1.5 Sectorialization of Security and Sectoral Security Concepts

While the Copenhagen school (Buzan/Waever/de Wilde 1998) has introduced the horizontal ‘widening’ (in five sectors or dimension) and the vertical ‘deepening’ (referring to different actors or referent objects), this volume includes a third process of ‘sectorialization’ of security that is linked to policy problems (e.g. energy, food, water, health and livelihood, and more recently also to climate) and that have been used by international organizations (e.g. the IEA, FAO, WHO) to describe and justify their policy mission and budgetary requests.

These sectoral security concepts of energy, food, health, and water security refer to and can be analysed for different dimensions and with different referent objects in mind (table 1.2).

Energy security has different meanings for the supplier (e.g. oil producing and exporting countries and oil companies are interested in good prices and in a steady demand, i.e. in energy demand security) while the consumers are interested in an uninterrupted supply at affordable prices (energy supply security). Energy security applies to all five dimensions and to all referent objects. Energy supply security is a precondition of military, political, and economic secu-

31 See e.g.: Kolodziej (2005) adhered to a narrow perspective of political and military security and did neither discuss environmental and human security concepts nor the process of securitization. Booth (2007: 321–336) offered a critical review of both concepts but he avoided a securitization of global environmental change issues, although he noted the impact of climate change. Thakur (2006, 2007: 71–155) offered four soft security perspectives on human security, human rights, international criminal justice, and international sanctions, but he ignored the environmental security debate and the environmental dimension of human security, and did not address global environmental change as a new security issue. Loader and Walker (2007) in “civilizing security” reviewed the role of the state as meddler, partisan, cultural monolith, and idiot with regard to the good and global public good of security, but they did not discuss the new security dangers posed by GEC.

ity, and it has impacts on the environmental and societal security dimensions.

A national or international energy security strategy that relies heavily on biofuels may have direct negative impacts on food security of food importing countries by reducing food supplies and thus increasing food prices. During 2007 and 2008 the declining food supplies in major crops (e.g. in cereals) and products (milk, butter, cheese, etc.) has resulted in food shortages and global food price increases that have resulted in spring 2008 in several countries (e.g. in Haiti, Egypt) both in peaceful protests, but also in an eruption of violence. Food security is a human, a societal, and a national security issue, and during natural hazards and in periods of food shortage it can become an international political and security problem.

Health security problems can be analysed both as issues of international security (e.g. major pandemics, SARS, Asian flu etc.) but also of national security (e.g. in the USA in the framework of the 'war on terror') but health security is foremost a problem of human security as it affects both the individual human being but may also face humankind. These different dimensions and referent objects will be addressed in chapters 23–59 in parts IV (energy), V (food), VI (health and livelihood), and VII (water) of this book.

1.6 Focus and Contribution of this Book

This volume is organized in ten parts that address these key themes of:

- global environmental change (part I: chap. 2–3) and its securitization (part II: chap. 4–14) and the securitization of extreme outcomes of GEC (part III: chap. 15–22);
- four sectoral concepts of energy security (part IV: chap. 23–32), food security (part V: chap. 33–35), livelihood and health security (part VI: chap. 36–40) as well as water security (part VII: chap. 41–58);
- the environmental dimension (part VIII: chap. 59–73) of a widened security concept;
- human and gender security approaches of a deepened security concept to many new security dangers and concerns (part IX: chap. 74–96); and
- concluding remarks and a policy outlook that offers a brief overview of the contribution of remote sensing to security analysis, a research manifesto for the fourth phase of environmental security re-

search and policy conclusions (part X: chap. 97–100).

1.6.1 Part I: Contextualization of Global Environmental Change

In the following two chapters the historian *John McNeill* (USA), School of Foreign Service at Georgetown University in Washington, DC, reviews the evolution of “The International System, Great Powers, and Environmental Change since 1900” (chap. 2), while *Rik Leemans* (The Netherlands), an environmental systems analyst at Wageningen University and chair of the international *Earth System Science Partnership* (ESSP), summarizes the results of “The Millennium Ecosystem Assessment: Securing Interactions between Ecosystems, Ecosystem Services and Human Wellbeing” (chap. 3).

1.6.2 Part II: Securitization of Global Environmental Change

The next eleven chapters start with a review of the emerging policy debate on securitizing GEC (chap. 4), address issues of climate history (chap. 5–6) and the impact of climate change for small island states (chap. 7), review security connotations of desertification (chap. 8–10), discuss the securitization of water (chap. 11), assess demographic trends and ageing as a security concern (chap. 12), and examine the linkages between urbanization and security (chap. 13–14).

Hans Günter Brauch (Germany), a political scientist who teaches at the Free University of Berlin and a fellow at UNU-EHS in Bonn, examines the conceptual discussion and policy debate on securitizing climate change, water, and desertification (chap. 4). *Wolf Dieter Blümel* (Germany), a physical geographer at the University of Stuttgart, offers an overview on: “Natural Climatic Variations in the Holocene: Past Impacts on Cultural History, Human Welfare and Crisis” (chap. 5), while *Arie S. Issar* (Israel), a hydrogeologist at the J. Blaustein Institute for Desert Research of the Ben Gurion University of the Negev, and *Mattanyah Zohar* (Israel), an archaeologist and assyriologist, summarize the results of a study on: “Climate Change Impacts on the Environment and Civilization in the Near East” (chap. 6). *Yannis Kinnas* (Greece), a former diplomat and international relations specialist from Athens, reviews the linkages between: “Human Security, Climate Change and Small Islands” (chap. 7).

The first of the three chapters on linkages between desertification and security that is co-authored by *Rajeb Boulharouf* (Algeria), the external relations and public information coordinator of the Secretariat of United Nations Convention to Combat Desertification (UNCCD) in Bonn, and *Douglas Pattie* (USA), coordinator of the Platform for the Promotion of Early Warning, United Nations International Strategy for Disaster Reduction (UN/ISDR) in Bonn, focuses on: “Redefining Sustainability: A Policy Tool for Environmental Security and Desertification” (chap. 8). *Andreas Rechkemmer* (Germany), the Executive Director of the International Human Dimensions Programme on Global Environmental Change (IHDP), discusses the “Societal Impacts of Desertification: Migration and Environmental Refugees?” (chap. 9), while *Ali Ghazi* (Algeria), Ministry of Town and Country Planning, Environment and Tourism in Algiers, examines “Desertification in Algeria: Policies and Measures for the Protection of Natural Resources” (chap. 10).

Úrsula Oswald Spring (Mexico), *Center for Multi-disciplinary Studies* (CRIM) of the National University of Mexico (UNAM) in Cuernavaca and MunichRE chairholder on social vulnerability at UNU-EHS in Bonn, and *Hans Günter Brauch* (Germany), review the conceptual and policy efforts of: “Securitizing Water” (chap. 11), while *Wolfgang Lutz* (Austria), who leads the World Population Programme of the International Institute for Applied Systems Analysis (IIASA) and directs the Vienna Institute of Demography (VID) of the Austrian Academy of Sciences, assesses the: “Changing Population Size and Distribution as a Security Concern” (chap. 12).

Ben Wisner (USA), Oberlin College, Ohio and research fellow at DESTIN, London School of Economics, and at the Benfield Hazard Research Centre, University College London, and *Juha I. Uitto* (Finland), United Nations Development Programme (UNDP), analyse: “Life on the Edge: Urban Social Vulnerability and Decentralized, Citizen-Based Disaster Risk Reduction in Four Large Cities of the Pacific Rim” (chap. 13). *Isabelle Milbert* (France/ Switzerland), Graduate Institute for International and Development Studies, who teaches development studies at the University of Geneva, discusses “Policy Dimensions of Human Security and Vulnerability Challenges: The Case of Urban India” (chap. 14).

1.6.3 Part III: Securitization of Extreme Natural and Societal Outcomes

The following eight chapters link the peace research with the hazard community (chap. 15), focus on HIV/AIDS (chap. 16, 17), deal with natural hazards (chap. 18) and environment-induced migration (chap. 19), summarize the results of the Toronto and the Swiss schools on environmental security (chap. 20 and 21), and deal with environmental conflict resolution (chap. 22).

Ben Wisner (USA) in his contribution on: “Interactions between Conflict and Natural Hazards: Swords, Ploughshares, Earthquakes, Floods and Storms” (chap. 15) suggests a cooperation between the peace and conflict research and the hazard communities. *Nana K. Poku* (Ghana/UK), University of Bradford, and *Bjorg Sandkjær* (Norway), African Centre for Gender and Social Development at the United Nations Economic Commission for Africa (UNECA in Ethiopia), co-authored: “AIDS as a Human Security Challenge” (chap. 16), while *Sophia Benz* (Germany), Institute of Political Science, University of Tübingen writes on: “Conflict and HIV/AIDS: Quantitative Analysis” (chap. 17).

This is followed by a co-authored chapter by *János J. Bogardi*, Vice-Rector of UNU in Europe and director of UNU-EHS in Bonn, *Jörn Birkmann*, *Niklas Gebert* (all from Germany), and *Neysa Jacqueline Setiadi* (Indonesia/Germany) on: “Preparing for Low-Frequency, Extreme Natural Hazards: Contributing to Human Security by Enhancing ‘Freedom from Hazard Impact’” (chap. 18). *Imtiaz Ahmed* (Bangladesh), University of Dhaka and executive director of the Centre for Alternatives, offers an empirical analysis of: “Environmental Refugees and Environmental Distress Migration as a Security Challenge for India and Bangladesh” (chap. 19).

Thomas Homer-Dixon (Canada), Chair of Global Systems at the University of Waterloo (Canada), and *Tom Deligiannis* (Canada), Department of Environment, Peace and Security at the University for Peace in Costa Rica, provide a succinct summary of the results on environmental security by the Toronto school on: “Environmental Scarcities and Civil Violence” (chap. 20). A team of five co-authors, representing a second generation of the Swiss school on environmental security studies: *Simon A. Mason* (Switzerland), Center for Security Studies (CSS), ETH Zürich, *Tobias Hagmann* (Switzerland), Department of Geography, University of Zürich, *Christine Bichsel* (Switzerland), Department of Geography, University

of Berne, *Eva Ludi* (Switzerland/UK), Rural Policy and Governance Group, *Overseas Development Institute* (ODI) in London, and *Yacob Arsano* (Ethiopia), Political Science and International Relations Department at Addis Ababa University, analyse the “Linkages between sub-national and international water conflicts: the Eastern Nile Basin” (chap. 21). Last but not least, *Saleem Ali* (USA), University of Vermont’s Rubenstein School of Natural Resources and Environmental Conflict Resolution, deals with: “Extractive Industries and the Environmental Aspects of International Security” (chap. 22).

1.6.4 Part IV: Energy Security for the 21st Century

Eleven chapters review the conceptual aspects and concrete policy problems of energy security with a special focus on renewable energy sources. *Klaus-Dietmar Jacoby* (Germany), a seconded national expert in the EU Commission, starts with a contribution on: “Energy Security: Conceptualization of the International Energy Agency (IEA)” (chap. 23). This is followed by two scenario analyses by *Leo Schrattenholzer* (Austria), International Resource Management (Vienna), on: “Scenarios of Energy Demand and Supply until 2100: Implications for Energy Security” (chap. 24); and by *Jörg Schindler* (Germany), *Ludwig-Bölkow-Systemtechnik* (LBST) and his colleague *Werner Zittel* (Germany) who analyse: “Projections of Fossil Energy Reserves and Supply until 2050 (2100): Implications for Longer-term Energy Supply Security” (chap. 25).

This is followed by three chapters on renewable energy sources by *Andre Faaj* (The Netherlands), Copernicus Institute for Sustainable Development of Utrecht University, who writes on: “Technical and Economic Potentials of Biomass until 2050: Regional Relevance for Energy Security” (chap. 26). *David Faiman* (Israel), Department of Solar Energy and Environmental Physics at Ben Gurion University’s Jacob Blaustein Institutes for Desert Research, in Sede Boqer, and director of Israel’s National Solar Energy Center, discusses the potential of: “Solar Energy on a Global Scale: Its Impact on Security” (chap. 27). *Franz Trieb*, *Wolfram Krewitt* from the Department of Systems Analysis and Technology Assessment, German Aerospace Center (DLR); and *Nadine May* (all from Germany), VDI/VDE-IT GmbH, write on: “Solar Energy as a Key for Power and Water in the Middle East and North Africa” (chap. 28).

Two chapters deal with oil in the Middle East. *Mohammad El-Sayed Selim* (Egypt), a political scientist from Cairo University and presently at Kuwait University, and *Abdullah Sabar Mohammad* (Kuwait), Political Science Department in Kuwait University, write on: “Energy Security in the Arab World” (chap. 29), while *Gareth Winrow* (United Kingdom), formerly with Bilgi University in Istanbul, analyses: “Turkey: Energy Security and Central Asia: The Politics and Economics of the So-called Great Game” (chap. 30).

Nogoye Thiam (Senegal), Energy, Environment and Development Programme of the NGO Enda-TM, offers an analysis on “Towards a Sustainable Energy System for Africa: An African Perspective on Energy Security” (chap. 31). *Rolf Linkohr* (Germany), president of CERES (Centre for European Energy Strategy) in Brussels and a former member of the European Parliament (1979–2004), discusses: “Energy Security: Economic, Environmental, and Societal Opportunity for the North - Potential of Renewables to Avoid Conflicts?” (chap. 32).

1.6.5 Food Security for the 21st Century

This part provides three analyses and case studies on food security from Latin American, African, and Asian perspectives. *Úrsula Oswald Spring* (Mexico), a social anthropologist and environmentalist, starts with a critical analysis on: “Food as a new human and livelihood security challenge” (chap. 33). *Mohamed Salih* (Sudan/The Netherlands), Institute of Social Studies, The Hague, and Department of Political Science, University of Leiden (The Netherlands), supplies a succinct analysis on: “Food Security and Democracy: from the perspective of governance” (chap. 34).

A team of five authors from Turkey including *Selim Kapur*, Faculty of Agriculture Department of Archaeometry, *Burcak Kapur*, Department of Agricultural Structures and Irrigation and *Erhan Akca*, Department of Soil Science and Archaeometry from the University of Çukurova in Adana in Turkey as well as *Hari Eswaran* (USA), Natural Resources Conservation Service of the US Department of Agriculture, and *Mustafa Aydin* (Turkey), TOBB-Economics and Technology University and National Security Academy, offer “A Research Strategy to Secure Energy, Water and Food via Developing Sustainable Land and Water Management in Turkey” (chap. 35).

1.6.6 Livelihood and Health Security for the 21st Century

The first chapter introduces the ‘livelihood security concept’ while the remaining four cover the debate on the health security concept and on selected health security problems. *Hans-Georg Bohle* (Germany), Geography Department, University of Bonn and MunichRE chairholder on social vulnerability at UNU-EHS in Bonn, discusses “Sustainable Livelihood Security. Evolution and Application” (chap. 36).

Guenael Rodier (France/Switzerland) and *Mary Kay Kindhauser* (USA/Switzerland) from the *World Health Organization* (WHO), Geneva review: “Global Health Security: The WHO Response to Outbreaks Past and Future” (chap. 37); while *Jennifer Leaning*, Department of Population and International Health, School of Public Health at Harvard University, offers a conceptual analysis of “Health and Human Security in the 21st Century” (chap. 38).

Then a team of four junior researchers offer case studies on Africa and Asia. *Fred Eboko* (France), a political scientist and sociologist with IRD-INSERM-Université de la Méditerranée and the Observatoire Régional de la Santé, and *Teresa Nemeckova* (Czech Republic), an economist with the Department of the World Economy, University of Economics in Prague, write on: “AIDS – Challenge to Health Security in Africa: Politics in Africa and a Case Study of Botswana” (chap. 39). *Isabel Fischer* (Germany), Institute of Agricultural Economics and Social Sciences in the Tropics and Subtropics, University of Stuttgart Hohenheim, and *Mohammad Musfequs Salehin*, Department of Rural Sociology, Bangladesh Agricultural University, examine: “Health and Poverty as Challenges for Human Security: Two Case Studies on Northern Vietnam and Bangladesh” (chap. 40).

1.6.7 Water Security for the 21st Century

This part includes 18 chapters by authors from many disciplines and countries. It starts with a theoretical and conceptual analysis by a geographer and water specialist. Eight chapters deal with water security issues in the international river basins of the Mekong, the Euphrates and Tigris, the Jordan and Nile, the Senegal, Volta and the Zambezi, four chapters deal with problems of water resource management and conflicts in Central Asia, while two review water security issues in India and Jordan, one offers a theoretical analysis for the Middle East, another on Sub-Saharan

Africa, and the last chapter provides a legal analysis of water security in armed conflicts.

J. A. [Tony] Allan (UK), a geographer at King’s College, University of London, introduces into the theme with: “Global trade: balancing existing and future regional water resource deficits” (chap. 41). This is followed by an ecofeminist perspective by *Vandana Shiva* (India), a physicist and environmental activist, on “Water Wars in India” (chap. 42). *Bastien Affentranger* (France), a geographer with the *Institute for Industrial Environment and Risks* (INERIS), writes on: “Sustainability of Environmental Regimes: The Mekong River Commission” (chap. 43), while *Mustafa Aydin* (Turkey) and *Fulya Ereker* (Turkey), Department of International Relations, Ankara University, deal with: “Water Scarcity and Political Wrangling: Security in Euphrates and Tigris Basin” (chap. 44).

The three chapters on water security issues in the Near East start with a country study by *Bassam Ossama Hayek* (Jordan), director of the Environmental Research Center, Royal Scientific Society in Amman, that deals with: “Water Resources in the Arab World: A Case Study on Jordan” (chap. 45). *Jan Selby* (UK), Department of International Relations at the University of Sussex, discusses: “‘New Security Thinking’ in Israeli-Palestinian Water Relations” (chap. 46), while *Anders Jägerskog* (Sweden), *Stockholm International Water Institute* (SIWI), writes on: “Functional Water Cooperation in the Jordan River Basin: Spill-over or Spillover for Political Security?” (chap. 47).

Two chapters deal with the Nile River Basin. *Emad Adly* (Egypt), chairman of the *Arab Office for Youth and Environment* (AOYE), and *Tarek Abdallah Ahmed* (Egypt), a water resource planner, write on “Water and food security in the River Nile Basin: Perspectives of the Government and NGOs in Egypt” (chap. 48), while *Patricia Kameri-Mbote* (Kenya), School of Law, University of Nairobi and Programme Director for Africa, International Environmental Law Research Centre (IELRC), Nairobi, and *Kithure Kindiki* (Kenya), School of Law, University of Nairobi, offer a legal perspective from an upstream country on: “Water and Food Security in the River Nile Basin: The Perspectives of Governments and NGOs of Upstream Countries” (chap. 49). Two senior water specialists from South Africa, *Peter Ashton*, *Council for Scientific and Industrial Research* (CSIR), and *Antony Turton*, CSIR and University of Pretoria, offer a profound theory-guided analysis on: “Water Security in Sub-Saharan Africa: Emerging Concepts and their

Implications for Effective Water Resource Management in the Southern African Region” (chap. 50).

Three chapters emerged from diploma theses from the French-German cycle at the Free University of Berlin by political scientists from Germany and France. *Martin Kipping* (Germany), Free University of Berlin, challenges present wisdom on: “Water Security in the Senegal River Basin: Water Cooperation and Water Conflicts” (chap. 51), while *Maëlis Borghese* (France), *Agence Française de Développement* (AFD), offers a theoretical and empirical analysis on: “The Centrality of Water Regime Formation for Water Security in West Africa: An Analysis of the Volta Basin” (chap. 52), and *Stefan Lindemann* (Germany), London School of Economics and Political Science (LSE), writes on: “Success and Failure in International River Basin Management – The Case of Southern Africa” (chap. 53).

Four chapters deal with water problems in Central Asia. Based on field research in Kyrgyzstan, *Martin Kipping* discusses the question: “Can ‘Integrated Water Resources Management’ Silence Malthusian Concerns? The Case of Central Asia” (chap. 54), while *Eva Patricia Rakel* (Germany), University of Amsterdam, reviews: “Environmental Security in Central Asia and the Caspian Region: Aral and Caspian Seas” (chap. 55), and *Julia Wunderer* (Germany), International Office of Humboldt University of Berlin, analyses: “The Central Asian Water Regime as an Instrument for Crisis Prevention” (chap. 56). *Christopher Martius* (Germany), *Center for Development Research* (ZEF), University of Bonn, *Jochen Froebrich* (Germany), Wageningen University in the Netherlands, and *Ernst-August Nuppenau* (Germany), University of Giessen, write on: “Water Resource Management for Improving Environmental Security and Rural Livelihoods in the Irrigated Amu Darya Lowlands” (chap. 57).

Finally, *Mara Tignino* (Italy), Graduate Institute of International Studies and Law Faculty of Geneva University, contributes a study on: “Water Security in Armed Conflicts” (chap. 58).

1.6.8 Environmental Security Concepts and Debates

Fifteen chapters review the environmental security discourse and environmental security debates in North America, in Russia, Belarus and Ukraine, in India, the Far East and in the Arab World, as well as on Israel and Palestine, on Uganda, Rwanda, Ethiopia and Burundi, in Sub-Sahara Africa, on Amazonia, the

Caucasus, the Asia Pacific, and the Arctic and Antarctic regions.

Simon Dalby (Canada), a geographer, environmental expert and political economist, Carleton University, Ottawa, *Hans Günter Brauch*, and *Úrsula Oswald Spring*, merge their experience from three disciplines on: “Environmental Security Concepts Revisited During the First Three Phases (1983–2007)” (chap. 59). *Richard Matthew* (USA), Schools of Social Ecology and Social Science at the *University of California at Irvine* (UCI), director of the Center for Unconventional Security Affairs, and *Bryan McDonald* (USA), UCI, review: “Environmental Security: Academic and Policy Debates in North America” (chap. 60), while *Alexander Sergunin* (Russia), Department of International Relations Theory and History, St. Petersburg State University, writes on: “The Debate on Ecological Security in Russia, Belarus and Ukraine” (chap. 61).

P. S. Ramakrishnan (India), School of Environmental Sciences, Jawaharlal Nehru University, New Delhi, examines: “Linking Knowledge Systems for Socio-ecological Security” (chap. 62), while *Miranda Schreurs* (USA), Environmental Policy Research Centre, Free University of Berlin, discusses: “Environmental Security in Northeast Asia” (chap. 63).

Mohamad El-Sayed Selim (Egypt) starts the Middle East section with a contribution on: “Environmental security in the Arab World” (chap. 64), while *David Newman* (Israel), Department of Politics and Government at Ben Gurion University and editor of *Geopolitics*, offers a discourse analysis on: “In the Name of Security: In the Name of Peace’ – Environmental Schizophrenia and the Security Discourse in Israel-Palestine” (chap. 65). *Robin Twite* (UK/Israel), *Israel Palestine Center for Research and Information* (IPCRI) in Jerusalem, discusses: “Security and Environment and the Israel-Palestine Conflict” (chap. 66), while *Mohammed S. Dajani Daoudi*, American Studies Institute, Al-Quds University, Jerusalem reviews the: “Conceptualization and Debate on Environmental and Human Security in Palestine” (chap. 67).

In the next two chapters two authors from Africa discuss international and national environmental security issues in Eastern and Central Africa. *Mersie Ejigu* (Ethiopia), *Partnership for African Environmental Sustainability* (PAES) and *Foundation for Environmental Security & Sustainability* (FESS) analyses: “Environmental Scarcity, Insecurity, and Conflict: The Cases of Uganda, Rwanda, Ethiopia, and Burundi” (chap. 68), while *Sam Moyo* (Zimbabwe), executive director of the African Institute for Agrarian Studies

(AIAS) in Harare, discusses: “Environmental Security in Sub-Sahara Africa: Global and Regional Environmental Security Concepts and Debates Revisited” (chap. 69).

Alexander López (Costa Rica), Institute for International Affairs of the Universidad Nacional de Costa Rica, discusses: “The Brazilian Amazon in an Environmental Security and Social Conflict Framework” (chap. 70). This is followed by a contribution by *Vicken Cheterian* (Switzerland), a journalist with CIMERA in Geneva, who reviews the: “Politics of Environment in the Caucasus Conflict Zone: From Nationalizing Politics to Conflict Resolution” (chap. 71).

Jon Barnett (Australia), Department of Resource Management and Geography at the University of Melbourne, analyses: “Environmental Security in the Asia-Pacific Region: Contrasting Problems, Places, and Prospects” (chap. 72), while *Gunhild Hoogensen* (Norway), Department of Political Science at the University of Tromsø, writes on: “Security at the Poles: the Arctic and Antarctic” (chap. 73).

1.6.9 Part IX: Human and Gender Security Concepts and Debates

With 23 chapters, this part offers a conceptual introduction and an overview on the debates on human security in the social sciences and in international organizations (chap. 74-77), before it reviews the human security discourses in the Arab world, in Southeast Asia, in Sub-Saharan Africa, in Central and South America (chap. 78-82) and analyses human security as ‘freedom from fear’, ‘freedom from want’, ‘freedom to live in dignity’, and as ‘freedom from hazard impacts’ (chap. 83-88). This is followed by a controversial discussion on human and gender security approaches (chap. 89-93) and it concludes with three case studies on Afghanistan, Guyana, and on a human security based early warning and response system (chap. 94-96).

Introducing into the scientific and political debate on human security, *Hans Günter Brauch* (Germany) surveys the “Human security concepts in policy and science” (chap. 74), and *Claudia Fuentes Julio* (Chile), Josef Korbel School of International Studies (GSIS) at Denver University, and *Hans Günter Brauch*, discuss the: “Human Security Network: A Global North-South Coalition” (chap. 75).

The next two chapters offer conceptual discussions of the human security concept from a South Asian and European perspective. *A.K.M. Abdus*

Sabur (Bangladesh), International Studies Division at *Bangladesh Institute of International and Strategic Studies* (BIISS) and editor of the *BIISS Journal*, offers a: “Theoretical Perspective on Human Security: A South Asian View” (chap. 76). *Sascha Werthes* (Germany), Institute of Political Science at the University of Duisburg-Essen and fellow at its Institute for Development and Peace (INEF), and *Tobias Debiel* (Germany), Institute of Political Science and director of INEF, discuss the: “Horizontal and Vertical Extension of International Security: A Human Security Approach” (chap. 77).

This is followed by five chapters on the human security debate in the South. *Béchir Chourou* (Tunisia), University of Tunis-Carthage, writes on: “Human Security in the Arab World: A Perspective from the Maghreb” (chap. 78), while *Zarina Othman* (Malaysia), *Universiti Kebangsaan Malaysia* (UKM/National University of Malaysia), covers: “Human Security Concepts, Approaches and Debates in Southeast Asia” (chap. 79). *Nana Poku* (Ghana/UK) and *Bjorg Sandkjær* (Norway) analyse: “Human Security in Sub-Saharan Africa” (chap. 80). *Philippe De Lombaerde* (Belgium), *United Nations University - Comparative Regional Integration Studies* (UNU-CRIS) in Bruges, and *Matthew Norton* (UK), Sociology Department of Yale University, discuss: “Human Security in Central America” (chap. 81), while *Francisco Rojas Aravena* (Chile), Secretary General of the *Latin American Faculty of Social Sciences* (FLACSO), contributes on: “Human Security: a South American Perspective” (chap. 82).

Human security as ‘freedom from fear’ aiming at overcoming violence is discussed by *David Black* (Canada), Department of International Development Studies, Political Science, and International Development Studies at Dalhousie University, and *Larry Swatuk* (Canada), International Development Studies, Dalhousie University, and Departments of International Development Studies and Political Science, St. Mary’s University, Halifax, Nova Scotia, in: “Human Security in North America: A Canadian Perspective” (chap. 83).

Human security as ‘freedom from want’ is covered by *Hideaki Shinoda* (Japan), Institute for Peace Science, Hiroshima University, who reviews: “Human Security Initiatives of Japan” (chap. 84). *Max Schott* (Germany/USA), Human Security Unit at the Office for the Coordination of Humanitarian Affairs (OCHA) of the UN Secretariat in New York, presents a case study on what people in Mali consider as their key human security concerns, in: “Human Security:

International Discourse and Local Reality: The Case of Mali” (chap. 85).

Human security as ‘freedom to live in dignity’ is introduced by *Dieter Senghaas* (Germany), Institute of Intercultural and International Studies, University of Bremen, who writes on: “Enhancing human rights: a contribution to human security” (chap. 86). Human security as ‘freedom from hazard impact’ is conceptually introduced by *Fabien Nathan* (France), *Graduate Institute of Development Studies* (IUED, Geneva), National Centre for Competence in Research, North-South (NCCR/NS), in: “Vulnerability, Disaster and Human Security” (chap. 87). *Surichai Wun’Gaeo* (Thailand), Chulalongkorn University in Bangkok, offers a case study on: “Environment as an Element of Human Security in Southeast Asia: Case Study on the Thai Tsunami” (chap. 88).

Five chapters by seven women from Mexico, Vietnam/Netherlands, the Philippines and Sri Lanka conceptualize different approaches to human and gender security. *Serena Eréndira Serrano Oswald* (Mexico), UNAM, discusses: “The Impossibility of Securitizing Gender vis-à-vis ‘Engendering’ Security” (chap. 89), while *Úrsula Oswald Spring* (Mexico) develops her own concept of: “Human, Gender and Environmental Security: A HUGE Security Concept” (chap. 90). *ThanhDam Truong* (Netherlands/Vietnam), Institute of Social Studies (ISS) in The Hague, offers a theoretical analysis on: “Human Security and the Governmentality of Neo-Liberal Mobility: A Feminist Perspective” (chap. 91). This is followed by an empirical account by *Mary Soledad L. Perpiñan* (Philippines), a former secretary-general of the Asian-Pacific Peace Research Association (APPRA), *Maria Eugenia Villareal* (Mexico/Guatemala), a sociologist working on child protection and human security in Central America, and *Úrsula Oswald Spring* (Mexico) that focuses on: “Gender Security in South East Asia and Trafficking of Children for Sexual Exploitation in Central America: a HUGE Security Challenge” (chap. 92). *Madhavi Matalgoda Ariyabandu* (Sri Lanka), an expert on gender mainstreaming initiatives with UNDP and the *United Nations International Strategy for Disaster Risk Reduction* (UN/ISDR), and *Dilrukshhi Fonseka* (Sri Lanka), a freelance consultant and trainer with several NGOs in peacebuilding, human rights, discuss: “Do Disasters Discriminate? A Human Security Analysis of the impact of the Tsunami in India, Sri Lanka, and of the Kashmir Earthquake in Pakistan” (chap. 93).

The last three chapters offer case studies on specific discourses and issues. *Sharbanou Tadjbaksh*

(USA/France/Iran), director of the Programme for Peace and Human Security at the CERI (*Centre d’Etudes et de Recherches Internationales*), Sciences Po, Paris, offers an empirical case study on: “A Failed Narco-state or a Human Security Failure? Ethical and Methodological Ruptures with a Traditional Read of the Afghan Quagmire” (chap. 94). *Joseph Singh* (Guyana), chief executive officer of the Guyana Telephone and Telegraph Company, reviews the: “Relevance of Human and Environmental Security Concepts for the Military Services: A Perspective of a Former Chief of Staff” (chap. 95). A chapter by *Albrecht Schmabel* (Germany) and *Heinz Krummenacher* (Switzerland), swisspeace, suggests to move: “Towards a Human Security-Based Early Warning and Response System” (chap. 96).

1.6.10 From Knowledge to Action: Policy Outlook

In the concluding part, *Dirk H. Hoekman* (The Netherlands), Wageningen University and general director of SarVision, writes on: “Methods and Techniques of Remote Sensing to Contribute to Security in Tropical Rain Forests” (chap. 97). This is followed by a research manifesto by *Úrsula Oswald Spring*, *Hans Günter Brauch*, and *Simon Dalby* that suggests: “Linking the Anthropocene, HUGE, and HESP in a Fourth Phase of Human, Environmental, and Gender Security and Peace Research” (chap. 98). In a policy outlook on: “Towards Sustainable Peace for the 21st Century”, *Hans Günter Brauch* and *Úrsula Oswald Spring* suggest to move from ‘facing global environmental change’ to ‘coping’ with climate change, water scarcity and desertification in a proactive way. This requires an ‘anticipatory learning’ process to which both the natural and social sciences must contribute to move towards a ‘sustainable peace’ with ‘sustainable development’ strategies. This is a challenge humankind is confronted with in the 21st century. In the concluding chapter 100 *Hans Günter Brauch* summarizes key messages of the previous 99 chapters.

1.7 Multidisciplinary Perspectives for a Global Audience

This book – as the previous and the subsequent volumes – differs from many publications on security by aiming at a fourfold dialogue between the social and the natural sciences, among the different social science disciplines, programmes and schools, between

scholars from North and South, and scientists and policymakers. Therefore the editors pursue three goals:

- a.) to contribute to *problem awareness* for the different security concepts in North and South, on hard and soft security issues, on non-military and primarily environmental challenges and environmental security problems;
- b.) to stimulate and encourage multi-, inter-, and transdisciplinary scientific research and political efforts to resolve, prevent, and avoid that environmental factors may contribute to violent conflicts (both scientific and political *agenda-setting*); and
- c.) to contribute to a better understanding of the complex interactions between natural processes, nature, and human-induced regional environmental changes (*learning*).

While power has once been defined by Karl Deutsch (1963, 1966) as not having to learn, during the 20th century the resistance to any *anticipatory* learning by those who control the resources over outcomes has been significant. In history, it often required severe foreign policy and domestic crises (e.g. in the USA in the 1970's during the Vietnam war and in the former Soviet Union in the 1980's during the Afghanistan war) to stimulate major reassessments of existing foreign and security policies and to launch fundamental revisions.

Several scientists (E.U. von Weizsäcker 1989; E.O. Wilson 1998) have described the 21st century as the century of the environment. For this new century, Edward O. Wilson (1998a) has referred to a growing *consilience*, which implies that the interfaces of disciplines become as important as the disciplines. Ted Munn (2002), in his preface to the *Encyclopedia of Global Environmental Change*, argued based on Wilson:

that this interlocking amongst the natural sciences will in the 21st century also touch 'the borders of the social sciences and humanities'. In the environmental context, environmental scientists in diverse specialties, including human ecology, are more precisely defining the area in which that species arose, and those parts that must be sustained for human survival (Wilson 1998).

Anticipatory learning must acknowledge this need for a growing *consilience* that causal explanations across disciplines may contribute to new understanding and knowledge that will be needed to cope with the challenges of the 'international risk society' (Beck 1992, 1999, 2007).

This book intends to broaden the scope and to sensitize the reader to the thinking in different disciplines, cultures, and global regions, especially on nature and humankind. The editors have worked hard that these three related books on 'reconceptualizing security' will be of relevance for scholars, educators, students, and an academically trained audience in many scientific disciplines, such as: *political science* (international relations, security studies, environmental studies, peace research, conflict and war studies); *sociology* (security conceptualization and risk society); *economics*; *philosophy* and *culture* (security conceptualization); *international law* (water in conflicts), *geosciences* (global environmental change, climate change, desertification, water), *geography* (global environmental change, population, urbanization, food), as well as in *diplomacy* (diplomatic academies) and *military science* and practice (military academies).

The global thinking on security is also of importance for policymakers and their advisers on the national and international level in: a) foreign, defence, development and environment ministries and their policy-oriented think tanks; b) international organizations: NATO, European institutions, UN, UNESCO, FAO, WHO, UNDP, UNEP, IEA, UNU, et al.; c) for the *Human Security Network* as well as for the *Friends of Human Security*; d) for the green development network of the representatives of 27 EU foreign ministries; and in e) nongovernmental organizations in the areas of foreign and defence, development and environment policies; as well as for f) diverse social movements.

The thinking on security and on the specific security policies of countries, alliances, and international organizations, especially a people-centred security approach, may be of interest for educators (at all levels) and media specialists. The editors and authors hope that those colleagues who focus on the broader conceptual context of security will benefit from this unique global, multidisciplinary, and policy focused compendium.

2 The International System, Great Powers, and Environmental Change since 1900

J.R. McNeill

2.1 Introduction

This chapter examines an aspect of the relationship between the international system and environmental change. Political scientists have recently created a new sub-field, called 'environmental security', in which they argue that environmental stresses add to security risks. Without disputing the validity of that literature, indeed complementing it, this chapter puts the matter the other way around: security risks put added stress on the environment, thereby creating something of a vicious circle. In particular, the unusually high security anxiety of the 20th century helped drive unusually rapid and large-scale environmental change since 1900. The evidence offered in support of this argument concerns nuclear weapons programmes, pollution-intensive industrialization efforts, pro-natalism, among others.

One of the major influences upon modern environmental history has been, and remains, the struggle for survival and power in the international system. This chapter argues that historically international struggle has generally selected against ecological prudence in states and societies, and that the rigorous struggle of the 20th century selected rigorously against ecological prudence. Further, it argues that preparation for war and economic mobilization for war had stronger environmental consequences than did combat itself. After brief consideration of the scale and scope of environmental change and its causes (2.2) and of the evolution of the international system (2.3), the chapter focuses on environmental impacts of war and preparation for war (2.4).

2.2 Environmental Change and Its Causes in the 20th Century

Environmental change has always been part of the human experience. Since they first harnessed fire sev-

eral hundred thousand years ago, hominids and humans have changed the world's ecology. But in modern and contemporary times we have done so on a scale unprecedented in human history and with very few analogues in earth history. Humankind undertook a gigantic, uncontrolled experiment on the earth, altering land cover, atmospheric chemistry, biodiversity, biogeochemical flows, and much else (McNeill 2000; Steffen et al 2005, see table 2.1).

Why did this tremendous flux occur when it did and how it did? The reasons are many, complex, and overlapping. Population growth, often cited as the principal driving force behind all manner of environmental change, did indeed matter. The expansion of human numbers from about 1.5 billion in 1900 to about 6.3 billion in 2005 is obviously unprecedented, destined never to be repeated, and replete with environmental consequences. But the energy system mattered even more. First, because it was based on fossil fuels: after 1890 they provided more than half of the energy used around the world. Fossil fuels are dirty. The carbon dioxide they emitted into the atmosphere promoted climate change. The sulphur dioxide they emitted fell as acid rain, damaging the biota of rivers and lakes, and possibly damaging forests as well. But the pollution consequences of burning fossil fuels were only part of the larger picture. Digging coal, drilling for oil, and transporting oil were messy affairs too. Fossil fuels allowed new technologies that exponentially increased the volume and pace of mining, to the point where it became rewarding to shear off mountain tops in search of coal, or to crush millions of tons of rock in quests for a few grams of gold. Fossil fuels allowed the chain saw, without which tropical deforestation, so characteristic of our times, could not have taken place nearly so quickly. And of course fossil fuels are not the only component of the 20th century's energy system: hydroelectricity required dam building, often done on the gigantic scale; and nuclear energy, with its accidents

Table 2.1: Co-efficients of Change, from the 1890's to the 1990's.

Indicator	Coefficient of change
World population	4
Urban proportion of world population	3
Total world urban population	13
World economy	14
Industrial output	40
Energy use	13-15
Coal production	7
Oil production	240
Carbon dioxide emissions to atmosphere	15
Carbon dioxide concentration in atmosphere	1.3
Sulphur dioxide emissions to atmosphere	13
Lead emissions to atmosphere	8
Freshwater use	9
Marine fish catch	35
Cattle population	4
Pig population	9
Goat population	5
Sheep population	1.8
Horse population	1.1
Cropland	2
Pasture area	1.8
Irrigated area	5
Bird and mammal species	0.99 (1 % decrease)
Fin whale population	0.03 (97 % decrease)
Blue whale population (Southern Ocean only)	0.0025 (99.75 % decrease)

and waste storage problems, had significant ecological effects too, although so far rather less calamitous than often feared.

The ideological fixations of modern times have also contributed to the pattern of twentieth-century environmental history. Under the tutelage of the economists, and inspired by routine self-interest, pub-

lic servants and private individuals consistently sought to foment economic growth and secure monetary gain. They regarded the natural world as a storehouse of raw materials, without intrinsic worth. They saw little value in such abstractions as balance, stability, or resilience in ecosystems. The reigning ideas about appropriate individual and state behaviour promoted rapid environmental change, and justified it in the name of various higher goals: economic growth, political stability, social mobility. The environment changed so much because prevailing ideas changed so little.

These were the most important reasons why the 20th century had the environmental history that it did (McNeill 2000: 267-356). But there were others, among which was politics. It was conventional politics, not environmental politics that mattered most. Even after 1966, when countries began to create environmental agencies, departments, and even ministries, real environmental policy was made elsewhere, in the powerful branches of government: e.g. the ministries of finance, trade, industry, and defence. In every country at all times these were more powerful than the environment ministry (or department or agency), and they made de facto environmental policy as accidental by-products of their own affairs. One concern they all shared, to greater or lesser degrees, was 'state security'. It is this I shall focus on here, only a part of the overall picture.

2.3 The International System and Its Imperatives

The quest for 'state security' has been in force, and affecting ecology, since states were first organized.¹ Throughout most of the history of states, however, the rigour of state security concerns has been blunted by the success of large empires. Most people lived in circumstances either of imposed peace managed and maintained by the technocrats of a bureaucratic empire, or else in an anarchic world in which states can scarcely be said to have existed. Enduring systems of competing states – the international anarchy we tend to regard as normal – have been rare. Typically, they quickly collapsed into imperial unification or reunification. Notable and durable exceptions include the era of warring states in China (c. 770 BC to 221 BC) and Greece from the first *poleis* (ca. 800 BC) to Alex-

1 Westing (1980: 14) provides a list of 26 wars with a capsule description of their ecological cost.

under the Great's unification (336 BC). In these times and places interstate struggle doubtless took its toll on landscapes, although details are obscure.² But in these cases the scales of military and bureaucratic operations were comparatively small, and the technologies involved rudimentary. Consider the technology of destruction. Before 1800 the only powerful means of ecological damage were deliberate fire and the capacity to tear apart irrigation works, causing deliberate floods. So the ancient eras of anarchic competition in international systems were limited in their ecological impact. Modern times have seen the resurgence of international anarchy combined with ever-growing scales of operations and technological sophistication.

The current competitive international system has not yet collapsed or unified, but instead has evolved and grown so as to be effectively global. It originally emanated from the stalemate in sixteenth-century Europe among the Hapsburg, Valois, and Ottoman dynasties. None succeeded in re-establishing a pan-European empire, which eccentricity marked Europe off from the rest of the world. This extraordinary failure was codified by the Peace of Westphalia in 1648, and a self-consciously self-regulating system of competing states was born, ratcheting up the rigour of intersocietal and interstate struggle. The constant competition of this system obliged (surviving) European states to evolve ever more formidable political, fiscal, and military capacities, which by the nineteenth century created states more powerful than those anywhere else in the world.

But in the 19th century (1815–1910) the Great Powers managed their competition almost peacefully, thanks to diplomatic skill, a fairly stable balance of power, and British economic and naval hegemony. In effect they almost banished war to Asia and Africa (and various frontiers in the Americas), where it prevailed with heightened regularity in part because of colonial pressures from the Great Powers. These conflicts required minimal mobilization on the part of the Great Powers: colonial wars were cheap, mainly because of technological and organizational edges enjoyed by European states, but also because they often

were fought by colonial troops. But the situation changed with the rise of a united Germany after 1870, and acutely when German industrialization allowed greater German assertiveness after 1890. So the 20th century would be different, an era of high anxiety for great powers, beginning with the run-up to World War I.

In the 20th century the rigour of struggle ratcheted up on account of the mounting requirements of competitiveness and the heavy costs of defeat in an age of total war. By 1914, only an all-out effort gave any chance of survival in the European international system; by 1939–45, losers in the competition risked annihilation. Higher stakes brought forth more strenuous effort and greater disregard for goals other than immediate political and physical survival. By 1945–90 even peacetime seemed to require the utmost preparedness for war. The international system selected for those characteristics that promised power in the present moment: technological sophistication, mass industrial and agricultural production, and ideological conformity (on fundamental questions at least, and in some societies on more than that). The health of soils, waters, and air took a distant back seat.

2.4 International Struggle and Environmental Change

Intersocietal competition affected the environment directly through warfare and less directly through the preoccupation with military power: that is, through war and through preparation for war.

2.4.1 The Deeper Past

Until the 20th century, combat did not produce vast environmental consequences except in extraordinary circumstances. When men fought with clubs, spears, arrows, swords, lances, pikes or muskets, they could do little to landscapes. Indeed, the more destructive wars so disrupted agriculture that they produced a fallowing effect, as in Brittany in the 100 Years' War, or in Germany during the Thirty Years' War.³ Forests and wildlife recovered when and where farmers and herders could not conduct their daily business. So did fisheries when naval war, pirates, or privateers confined fishermen to port. The built environment, of course, has always been vulnerable to destruction in war, usually through fire. Victors have torched countless cities; retreating armies have scorched earth aplenty. The Mongols, in their thirteenth-century

2 In the Second Punic War the Roman efforts to defeat Hannibal led to ecological damage in southern Italy that, according to one observer, was visible more than 2,000 years later (Toynbee 1965, II: 11–35). Caesar's legions energetically burned the forests of Gaul (Demorlaine 1919; Corvol/Amat 1994). For the ecological consequences of political-military struggle in ancient China see Elvin 2004.

conquest of Iraq, devastated a flourishing irrigation network, flooding arable lands, creating (or re-creating) swamps. While the Mongols' efforts edged Iraq more nearly to a state of nature, from the cultivators' point of view – not initially shared by the Mongols – this was environmental damage on a large scale.⁴ From any point of view it amounted to vast and enduring environmental change. But such cases were quite rare, essentially confined to landscapes of irrigation.

Preparation for war, rather than combat, typically provoked more serious environmental changes. In Europe for instance, the navy-building programmes of Venice and Genoa in the 11th through 16th centuries, and then of Britain, France, and Spain in the 17th and 18th centuries severely depleted the supply of tall fir and spruce and stout oak in Mediterranean and Atlantic Europe. All states developed forest conservation programmes so as to save more specialized timber for navies, but this proved inadequate in every case. By the 18th century Europe's wooden navies sought ship timber in Indonesia, India, Brazil, Canada and elsewhere around the world (Appuhn 2000; Merino Navarro 1981: 181–267; Albion 1926; Bamford 1956; Lane 1965; Miller 2000).

2.4.2 Combat's Environmental Consequences in the Twentieth Century

In the 20th century, while the technology of destruction grew vastly more powerful, preparation for war, as in remoter times, wrought greater and more lasting environmental change than did war itself. The direct environmental effects of warfare since 1914 have been vast but usually fleeting. The battle zones of WWI's western front created small deserts, where little but rats, lice, and men could live – and few men lived for long. But these zones are hard to detect today, except where carefully preserved: elsewhere their recovery

and assimilation to the French and Belgian countryside is nearly complete. The more mobile campaigns of WWII produced less concentrated damage to landscapes (except for cities),⁵ although certain episodes were destructive enough. For example, in 1938 Chinese troops, in an effort to forestall Japanese advance, deliberately breached the dikes that held the Hwang Ho in place, flooding broad areas of North China and killing people (almost all Chinese), drowning crops, sweeping away bridges, roads, over 4,000 villages and millions of tons of soil: a disaster to be sure, but one soon made invisible by the careful labour of millions of Chinese peasants.⁶ By 1947 the Hwang Ho dikes were repaired. The 'war erosion' of the Russian and Ukrainian plains (1941–45) is perhaps the next greatest example of combat-derived environmental change (cities excepted) from WWII, and in the grand sweep of Soviet soil history it ought probably to be considered trivial (Sobolev 1947; Alayev/Badenkov/Karavaeva 1990). In general, the theatres of operations in World War I and II involved ecologically, economically, and socially resilient places, so the environmental impacts of combat lasted comparatively briefly. Bomb craters remain here and there, forests are still recovering, and the destabilizing effects of tank tracks on dunes in the North African desert linger, but very little of significance in the way of combat-derived environmental change will prove lasting.

The environmental impact of the 1991 Gulf War, a subject viewed with great alarm at the time because of its conspicuous oil fires and spills, now seems not as great as many first feared. It is too soon to comment on its durability, which for marine ecosystems at least may prove considerable. About 10 million barrels of oil flowed into the Gulf, the equivalent of 40 Exxon Valdez spills. The fires, despite initial alarms, appear to have had a negligible impact on the atmosphere and climate (Westing 2003; Hawley 1992; Hobbs/Radke 1992). In Kuwait the war enriched desert environments. So much lethal ordnance remained amid the shifting sands of the Kuwaiti desert that all prudent Kuwaitis refrained from pre-war pastimes of hunting and joyriding. Bird populations grew

3 See: Cintree (1992: 119–127). Between 1420 and 1440 the Breton marches lost 20–80% of their population, almost all settled land was abandoned for decades and returned to second-growth forest. See also: Duby (1968: 296–302), where he says the 100 Years' War led to a resurgence of forest in wide areas throughout France. On the Thirty Years War, see Makowski and Buderath (1983). I am grateful to David Blackbourn for this reference.

4 The Mongols did rebuild the water system in Baghdad and eventually saw the attractions of higher revenues from irrigated farming. Details can be found in Christensen (1993).

5 Hewitt (1983) reports that about 750 square kilometres of German and Japanese cities were flattened by aerial bombing in WWII.

6 The Dutch used a similar tactic to forestall a French invasion in the 1670's, inflicting great flood damage on their own country, and many marauding or occupying armies have purposely flooded other people's lands.

a hundred-fold after the war. Grasses flourished to the point where they reminded some observers of prairies. Similar, if temporary, consequences arose from the desert campaigns in Libya and Egypt in 1942-3.⁷ Thus, in exceptional cases the heavy use of explosive ordnance in conventional war has permitted more rapid recovery from environmental damage.

One perhaps durable effect of the 1991 Gulf War is the near elimination of the marshes that for several millennia had spread over the lower reaches of the Tigris-Euphrates. These were home to people disloyal to Saddam Hussein in his war with Iran in the 1980's, and who rose in revolt against him in 1991. They were crushed. As a coup-de-grâce, the Iraqi dictator ordered the draining of the marshes beginning in 1993 (based on a plan drawn up in 1989), a form of ecological warfare that destroyed birds, fish, reed beds and a way of life for a few hundred thousand people. Attempting to destroy the ecological and economic basis of life of one's enemies is a practice with a long pedigree. In the twentieth century, energy-intensive machinery made such projects far easier than in times past. In this case, with the fall of Saddam, it is possible that engineers will attempt to create the marshes anew. If they succeed, the episode of the Iraq marshes will be just another case of fleeting environmental damage from war (Nicholson/Clark 2002).

2.4.3 The Impacts of Guerrilla War

As a rule, more enduring environmental change came from the guerrilla wars of the 20th century. They were disproportionately important in environmental change because they invariably involved systematic attempts at habitat destruction, similar to that which Saddam Hussein undertook from 1993. Guerrillas inevitably sought to hide from the firepower of their enemies, and except in urban settings that meant hiding in forest and bush. After the dawn of air reconnaissance and bombing (the 1920's, practically speaking), hiding in remote areas proved insufficient: vegetation cover was required. Those fighting against guerrillas found it expedient to destroy that vegetation.

In some instances, this produced durable consequences for vegetation and soils, notably in drier, mountainous regions with high erosion potential, such as those around the Mediterranean. The anti-guerrilla campaigns in the Rif Mountains of Morocco (1921-26), in the mountains of north-western Greece (1942-49), and in the Algerian Tell (1954-61) all entailed widespread forest burning, often through air power. All these wars left scars still visible today, and reduced both the biomass and the economic potential of these districts (McNeill 1992). The consequences may last for centuries. The numerous wars in Africa since 1970, often intersocietal but not international, have led to heightened rates of desertification and ecological damage of many sorts. These too are likely to be durable in their effects, as for climatic, geological, economic, and social reasons the resilience of the affected ecosystems is weak. Ethiopia is perhaps the saddest example of this, but much the same situation prevails in Mozambique, Angola, Chad, and Somalia (Kreike 2004; Timberlake 1987: 162-173; Rubenson 1991). In Vietnam, where defoliation figured prominently in American tactics, the durable results of war are less conspicuous but no less real: geology, climate, and human agency have combined to permit quick repair of most but not all of the damage. Bomb craters (about 20 million all told) and deforested zones remain throughout the country, testament to the American anti-guerrilla effort (Westing 1976, 1984; De Koninck 1999). Guerrilla wars in Central America in the 1970's and 1980's also accelerated forest clearance and added to the chemical poisoning of waterways (Rice 1989; Faber 1992).

2.4.4 Impacts of War Refugees

Additionally, both conventional and guerrilla warfare routinely disrupted local ecologies through the mass migration of refugees. As thousands or millions left war zones, their impact in disturbing or managing their home environments was lost. This at times proved ecologically helpful, but in some cases, such as terraced mountains, mass emigration led to accelerated erosion because terraces fall apart without constant upkeep. Whatever the consequence of war refugees' departure, their arrival somewhere else almost always proved stressful, ecologically as well as in other respects. A careful study of the environmental effects of 3.5 million Afghan refugees in northwest Pakistan in the 1980's provides a grim picture. Suddenly heightened demand for arable land and fuel wood, and the Afghans' inevitable ignorance of local ecol-

7 Reported anonymously in *Environment* (35,4, May 1993: 22); on Egypt and Libya: Said 2003, who recounts tragic consequences of lingering landmines in Egypt; and Westing (1980: 110). Westing (1980: 154) also reports parallel events in the North Atlantic fisheries, where WWII temporarily halted harvesting, and so stocks flourished until peace permitted renewed fishing.

ogy, combined to devastate Pakistan's largest remaining forest zone (Allan 1987). Africa's decolonization and postcolonial conflicts since the 1950's created refugees in their millions, obliged to occupy landscapes which they often understood poorly and in which they hoped to have no long-term stake.

Previous centuries of course featured war refugees. But the twentieth century was distinctive for the number of refugees (~30 million in the 1990's), greater than in the past because human numbers grew so much greater, and because warfare became much more dangerous. Moreover, only rarely in the 20th century could war refugees find unoccupied lands into which to move; much more often they had to crowd into landscapes already thickly settled. Thus their impacts were probably greater because ecological buffers had already been worn thin in the lands obliged to accept them (Jacobsen 1994; Westing 1994).

2.4.5 Impacts of Preparation for War

Combat in general, whether guerrilla or conventional, even including refugee impacts, had a lesser impact than the business of war production and preparing for war. This was because more societies prepared for war than actually fought wars; because many societies saw fit to maintain their preparedness for decades on end, while wars themselves were (usually) comparatively brief; and because most of the big economies and populous societies were deeply involved in the geopolitical turmoil of the 20th century. It was also true because, with the transportation systems and integrated markets that had developed since 1870 or so, the demand for war materiel, and thus the impacts of economic mobilization for war, reached into nearly every nook and cranny of the globe.

Preparedness for war implied maximizing immediate production, putting much of it at the disposal of the state, and mobilizing as much labour as quickly as possible. Powers great and small sacrificed the quality of their soils, waters, and urban air in concentrated efforts to maximize production and stockpiles of food, rubber, oil, steel, uranium, soldiers, and other strategic substances. In the First World War the British government encouraged farmers to plough every imaginable acre. Labour shortage prevented farmers from caring for their lands as they would have wished. British grain production increased by 30 per cent in the course of the war, but much marginal land was damaged in the process (Horn 1984). Britain's

war efforts of course extended to the Empire, to Australian wheat fields, Canadian forests, and South African mines. During WWII in colonial Southern Rhodesia (now Zimbabwe), for example, the British revived the practice of forced African labour on white settlers' farms, trying to maximize production of food and tobacco, and bled the African farms of their labour supply. African farms thus lacked the labour needed to manage soils and wildlife, while settlers' farms extended cultivation at the expense of surrounding bush (Johnson 2000).

Fascist states regarded preparation for war during peaceful interludes as a sacred duty. In the 1920's, Mussolini, well informed about food shortages in Germany and Austria in the latter stages of World War I, thought that Italy needed to be self-sufficient in grain. He launched a 'Battle for Wheat', and did not care that this policy promoted forest clearance of sloping and otherwise marginal lands, accelerating the erosion of Italian soils over subsequent decades.⁸ He also tried, with scant success, to make Italy energy-independent, which involved promoting dam-building in the Alps for hydropower.

Crash programmes of economic mobilization proliferated in wartime and in times when war loomed on the horizon. Such programmes often amounted to a form of environmental roulette, but societies, whether fascist and militarist in orientation or merely anxious about war, played willingly because the ecological bills fell due much later than the political and military ones did.

2.4.6 Military Pro-natalism

International competition encouraged maximization not merely of food and energy harvests, but of the human crop as well. Emperors and kings for many centuries typically encouraged reproduction, in part because they wanted to ensure a ready supply of army recruits. Modern states sometimes made it a staple of policy. Fascist Italy, Third Republic France, Ceausescu's Romania, Mao's China and the Syria of Hafez al-Assad all sought to raise birth rates in order to provide more troops to fight possible enemies: military pro-natalism. Normally populations have responded desultorily to their leaders' efforts to get them to re-

8 Mussolini may have had an equally unintended impact, this time beneficial, upon Italian landscapes, by his campaign to reduce the populations of Italian goats. He regarded the goat as an unfascist animal (McNeill 1992).

produce more exuberantly. Romanians under the dictator Nicolae Ceausescu were the great exception, a product of special circumstances. In 1965 Romania was very much a Soviet satellite, but Ceausescu had in mind a rather more independent foreign policy than Moscow wished. He concluded that Romania needed more people, preferably 30 million by the year 2000, so he banned all forms of birth control and abortion. He set his secret police the task of ensuring that Romanian women were not shirking their reproductive duties. Romania's birth rate doubled in 1966, before tapering off. After Ceausescu's overthrow in 1989, women went on a reproduction strike, so Romanians fell well short of the population target he set (Kligman 1998; Chesnais 1995: 171-8).

Mao, like Ceausescu, usually thought more people meant more security. From the time of the Korean War (1950-53) he anticipated a nuclear attack by the Americans, which was not a far-fetched fantasy since General Douglas MacArthur in 1951 recommended just that. After the Sino-Soviet split in 1958, Mao also feared nuclear attack from the Soviets. He concluded that China's best defence lay in raising its population so that it could better withstand nuclear war. For Mao, a large population was China's way to combat technologically more advanced enemies. He surprised Nikita Khrushchev in 1957 with his views:

We shouldn't be afraid of atomic missiles. No matter what kind of war breaks out - conventional or thermo-nuclear - we'll win. As for China, if the imperialists unleash war on us, we may lose more than 300 million people. So what? War is war. The years will pass and we'll get to work producing more babies than ever before (Khrushchev 1974: 255 quoted in Shapiro 2001: 32).

Mao's successors were horrified by the rapid population growth Mao encouraged, and in 1976 turned to the most restrictive birth control programme ever implemented. The 20th century witnessed many other cases of military pro-natalism, a policy which, when successful, could lead to imbalance between population and environment, over-intensive resource exploitation, environmental degradation, and perhaps a higher probability of war.

2.4.7 Military Industrialization

Most states, however, recognized early in the 20th century that military power rested on industrial might more than upon massive population. Several shuffled their priorities accordingly, building military-industrial complexes. The British and Germans began this

policy in the 19th century, and were soon imitated by the Japanese. The lessons of WWI, in which the Russian army lacked the necessary armament to fight the Germans effectively, drove home the importance of having one's own heavy industry. So from WWI onwards all great powers, and some not-so-great, encouraged the emergence of metallurgical and armaments industries within their national territories, and their empires. These industries, inevitably, involved heightened levels of air and water pollution. Further, they intensified resource use, especially of coal and iron, with attendant environmental effects from mining.

The most dramatic examples came where the state enjoyed maximal latitude to direct economic development, as in Stalin's USSR and Mao's China. In both cases security anxiety helped to motivate heroic, overnight industrialization campaigns (which in both cases had other motives as well). The dirty industrialization of the USSR beginning in 1929 reflected Stalin's fear that his country would be crushed by its enemies if it did not become an industrial power within ten years. He was correct in this assessment, although it is certain that sufficient industrialization to resist Hitler could have been achieved at lower environmental (and human) cost than Stalin was prepared to exact.

After the defeat of the Germans in 1945 the Soviets embarked on grand plans for the harnessing of nature in the service of the state, formalized in the 1948 "Plan for the Transformation of Nature" (Josephson 2002: 28). The deepening Cold War made it seem necessary that no drop of water should flow to the sea unused; no forest should be left unharvested. Giant hydroelectric dams served as the centrepiece of this plan, but it involved a comprehensive restructuring of the USSR's ecology. Cost constraints prevented Stalin and his successors from realizing their most grandiose ambitions: The Soviets never managed to divert the Siberian Rivers to Central Asia, or reroute the Pacific Ocean's Japan Cold Current. But they built a sprawling military-industrial complex with very few checks on pollution, and kept secret the environmental and health consequences of their efforts (Josephson 2002; Weiner 1999; Feshbach/Friendly 1992).

In 1958 the Chinese embarked on an industrialization that was even dirtier than the Soviet effort. Mao had become fixated on the idea of surpassing British steel production, and encouraged Chinese peasants to make steel in their backyards. They made plenty of steel, most of it useless, and in the process acceler-

ated the deforestation of China in their quest for fuel for their tiny smelters (Shapiro 2001). After Mao's death in 1976, China continued its industrialization programme, although in more conventional forms.

Meanwhile, South Korea and Taiwan proceeded apace with their own pollution-intensive industrializations, nurtured by the Americans, whose interest in economic development in East Asia was mainly geopolitical. The American security agenda required the rapid industrialization of its East Asian allies to counter the emergence of China. All of these efforts, capitalist or communist, were notably successful except for Mao's Great Leap Forward. In every case, pollution levels and other environmental concerns carried a very low priority until about 1990. And in every case, especially the Great Leap Forward, the environmental consequences proved unfortunate.

In the United States a military-industrial complex emerged in the 20th century too, although there top-down state planning played a much smaller role. And domestic, non-military demand was so strong that the steel mills of Pittsburgh and Gary, along with the coalmines of West Virginia and Wyoming would have thrived even without security anxiety. Nonetheless, tentatively and temporarily in WWI, and exuberantly from 1942 onward, the American state subsidised and otherwise encouraged military industry, adding a filip to the demand for steel, coal, bauxite, nickel, electricity and other enterprises, all of which carried profound ecological consequences.

2.4.8 Militarily Useful Transportation Infrastructure

Beyond the more or less direct environmental impacts of industrialization and weapons programmes, there are indirect environmental consequences of state actions driven, at least in part, by security anxiety. Consider transport infrastructure. German railroads, the trans-Siberian railroad, Brazilian Amazonian highways, the Karakoram Highway connecting Pakistan and China, and even the U.S. Interstate system were built partly or entirely for military reasons.⁹ Each investment in rails or roads led to rapid economic change (generally regarded as beneficial),

9 See: The Economist, 10 October 1992, recounts the story of Eisenhower's 1919 cross-country convoy drive and his role in establishing the federal interstate highway programme in 1956. He also admired the military potential of Germany's autobahns in the campaigns of 1945.

rapid social change (often controversial), and unanticipated environmental change (normally ignored). People and businesses flocked to the new roads and railroads, almost like iron filings to a magnet. The U.S. Interstate system strongly affected land use, population distribution and densities, and, through promoting trucking and automobile travel at the expense of rail transport, air quality and energy use. It is true, of course, that highways and railroads also exist in places where military motives played no role in their construction. In light of this it is fair to say that, in contrast to nuclear weapons, the world's networks of roads and railroads would exist approximately as it is even absent security anxiety. The point here is a limited one: the extent, location, and timing (of construction) of much of the 20th century's transport infrastructure had military motives, and that in myriad ways transport infrastructure affects the environment.

2.4.9 Nuclear Weapons Industry

The starkest illustration of how security anxiety propelled the great powers to indulge in reckless environmental change comes from the nuclear weapons programmes of the U.S. and USSR. No component of the world's military-industrial complexes could rival nuclear weapons for state support, for freedom of action with respect to environmental consequences, and for protection from public and press scrutiny.

The American nuclear weapons complex was born in 1942 and by 1990 involved some 3,000 sites in all. The U.S. built some 70,000 nuclear warheads, and tested more than a thousand of them, mainly in Nevada and on small Pacific atolls.¹⁰ The jewel in the nuclear weapons crown was the Hanford Engineering Works, a sprawling bomb factory on the Columbia River in the bone-dry steppe of south-central Washington State. It built the bomb that flattened Nagasaki in 1945. Over the next 50 years, Hanford engineers intentionally released billions of gallons of low-level radioactive wastes into the Columbia River, and accidentally leaked some more into groundwater. In 1949, shortly after the Soviets had exploded their first atomic bomb, the Americans conducted a secret experiment at Hanford. The fallout detected from the Soviet test prompted questions about how quickly the Soviets were able to process plutonium. In response, American officials decided to use 'green' uranium, less than 20 days out of the reactor, to test their hy-

10 Figures from: Brookings Institution, see at: <<http://www.brook.edu/FP/PROJECTS/NUCW/COST/50.HTM>>.

potheses about Soviet activities. The 'Green Run', as it was known to those in on the secret, released nearly 8,000 curies of iodine-131, dousing the downwind region with radiation at levels varying between 80 and 1,000 times the limit then thought tolerable. The officially tolerable limit has been lowered since then. The local populace learned of these events in 1986, when Hanford became the first of the US nuclear weapons complexes to release documents concerning the environmental effects of weapons production. The 'Green Run' shows the environmental liberties the Americans took under the influence of Cold War security anxiety.¹¹

That was the tip of the iceberg. More environmentally serious were the wastes, which in the heat of the Cold War were left for the future to worry about. A half century of weapons production around the U.S. left an archipelago of contamination, including tens of millions of cubic meters of long-lived nuclear waste. More than half a ton of plutonium is buried around Hanford alone. No one has yet devised a technically feasible and politically acceptable solution to the environmental problems posed by the American nuclear weapons industry (Fioravanti/Makhijani 1997; US Department of Energy 1995).

The Soviet nuclear program began with Stalin, who wanted atomic weapons as fast as possible, whatever the human and environmental cost. The Soviet command economy was good at such things: a large nuclear weapons complex arose from nothing in only a few years. Soviet engineers built about 45,000 warheads and exploded about 715 between 1949 and 1991, mostly at Semipalatinsk (in Kazakhstan) and on the Arctic island of Novaya Zemlya. They also used nuclear explosions to create reservoirs and canals, and to open mine shafts. In 1972 and 1984 they detonated nuclear bombs to try to loosen ores from which phosphate (for fertilizer) was derived. They experimented with nuclear explosions as a means of salt mining. They dumped much of their nuclear wastes at sea, mostly in the Arctic Ocean, some of it in shallow water. They scuttled defunct nuclear sub-

marines at sea. Most of the world's known reactor accidents befell the USSR's Northern Fleet, based at Archangel.

The Soviets had only one centre for reprocessing used nuclear fuel, at Mayak in the upper Ob basin of south-western Siberia, now easily the most radioactive place on earth. It accumulated 26 metric tons of plutonium, 50 times Hanford's total. From 1948 to 1956 the Mayak complex dumped liquid radioactive waste into the Techa River, an Ob tributary, and the sole source of drinking water for 10,000–20,000 people. Some 124,000 people in all were exposed to heightened radiation in this way. After 1952, storage tanks held some of Mayak's most dangerous wastes, but in 1957 one exploded, raining 20 million curies down onto the neighbourhood – equivalent to about 40 per cent of the radiation released at Chernobyl. About 270,000 people lived in the contaminated territory. After 1958 liquid wastes were stored in Lake Karachay, a shallow pond some 45 hectares in area. In 1967 a drought exposed the lakebed's radioactive sediments to the steppe winds, sprinkling dangerous dust, with 3,000 times the radioactivity released in the 1945 bombing of Hiroshima, over an area the size of Belgium and onto a half million unsuspecting people. By the 1980's, anyone standing at the lakeshore for an hour received a lethal dose of radiation (600 roentgens/hour). A former chairman of the USSR's Supreme Soviet's Subcommittee on Nuclear Safety, Alexander Penyagin, likened the situation at Mayak to 100 Chernobyls. No one knows the extent of contamination in the former USSR because the nuclear complex was so large and so secret. Much of the complex was shut down in the last years of the USSR, but the mess remained and post-Soviet Russia and Kazakhstan could not afford to clean it up even if the technical and political obstacles to doing so were overcome (Egorov/Novikov/Parker/Popov 2000; Yablokov 1995; Bradley 1997; Josephson 2000; Cochran/Norris/Suokko 1993).¹² The lethal residues of the British, French, Chinese, Indian, Pakistani, Israeli, South African (and perhaps a few other) nuclear weapons programmes were, mercifully, not on the superpower scale (Danielsson/Danielsson 1986; Makhijani/Hu/Yih 1995).

Taken as a whole, the nuclear programmes of the great powers left a remarkable legacy. They burdened

11 Details of this episode are in Caufield (1990) and Gerber (2002). In arguing that the U.S. ought not to adhere to radiation guidelines approved by the International Commission on Radiological Protection, one American nuclear mandarin in 1958 said, "the nation's security may demand the exposure of people to higher levels of radiation than those just established by the International Commission" (Caufield 1990: 130). See also Gephart (2003) for a detailed discussion of Hanford.

12 A useful general study of the Soviet nuclear weapons program to 1956 is Holloway (1994). The latest general report on Russian nuclear issues is Kurdrik, Digges, Nikitin, Bohmer, Kuznetsov and Larin (2004)

posterity with an apparently intractable long-term waste-management obligation. They exploded about 400 atomic devices above ground after 1945, sprinkling some 200 million tons of radioactive material around the earth. Underground testing irradiated chambers in the earth's crust. Moreover, undersea testing, practiced by the French in Polynesia, leaked plutonium into the Pacific (Danielsson/Danielsson 1986). The magnitude of these leaks remains secret, but their durability is well-known: plutonium's half-life is 24,000 years. Nuclear weapons programmes also gobbled up nearly a tenth of the commercial energy deployed worldwide after 1940 (Smil 1994: 185). The environmental changes resulting from nuclear weapons production and testing, which will persist long after the wars and tensions of the 20th century are forgotten, were driven exclusively by international security concerns.

2.5 Conclusion

In most societies, politics, institutions, and mentalities have evolved so as to provide security as their foremost goal. This has been truer since about 1910 than at most times in the deeper past. Hence, our politics and institutions are ill-adapted to the complex demands of ecological prudence, in which everything is connected to everything, and everything is always in flux. In Darwinian terms, the international security anxiety of the 20th century selected for states and societies that emphasized military power and industrial strength over all else: survival of the dirtiest.

When the ecology movement gathered force, in the 1970's, it did so in a moment of detente, which provided an opening for other items on political agendas. Since then it has flourished best in societies with minimal risks of war. Ecological concern on the part of states remained hostage to fortune.¹³

In 1990 when the war clouds were gathering over the Persian Gulf, President George Bush asked the American Congress to exempt the military from all environmental laws, and Congress complied. After 2001, his son asked that oil companies be allowed to drill for oil in the Arctic National Wildlife Refuge in Alaska, on the grounds that in time of war Americans cannot let caribou get in the way of strategic require-

ments. And in March 2003, as the U.S. prepared to attack Iraq, the President and Secretary of Defense pressed Congress for a permanent, blanket exemption from environmental regulations for the American military. The 20th century's pattern, in which great power security anxiety put a ceiling on environmental preservation and actively fomented ecological change, bids fair to hold in the 21st as well.

13 Britain relaxed its air and water pollution regulations during WWII in hopes of spurring industry to greater production levels; indeed coal smoke over cities served military purposes because it made it harder for German bombers to see their targets.

3 The Millennium Ecosystem Assessment: Securing Interactions between Ecosystems, Ecosystem Services and Human Well-being

Rik Leemans

3.1 Introduction

During the past millennia the human impact on natural systems has only gradually increased. In the 20th century the impacts have accelerated and increased exponentially. For example, humans now appropriate about 20 per cent of global Net Primary Production (NPP). In Western Europe and south Central Asia, humans consume even more than 70 per cent of their regional NPP (Imhoff/Bounoua/Ricketts/Loucks/Harriss/Lawrence 2004). Up to 50 per cent of the land surface is in some way modified by humans. This fragmented the habitats of many species. For an even larger area, humans are altering the functioning of ecosystems through emissions and deposition of nitrogen and other substances (Vitousek/Aber/Howarth/Likens/Matson/Schindler/Schlesinger/Tilman 1997). Additionally, through emissions of greenhouse gases due to the burning of fossil fuels, cement production and land-use change, humans are altering the composition of the atmosphere and changing the climate (IPCC 2001). The consequent climate change is illustrated by the observed rise in the global-mean surface-air temperature by 0.8 °C since the late 19th century (e.g. Moberg/Sonechkin/Holmgren/Datsenko/Karlén 2005).

Ecologists have shown that all these environmental changes together (depicted by the term 'global change') have a noticeable impact on present-day ecosystems in widely dispersed ecological zones (e.g. Parmesan/Yohe 2003, Root/Price/Hall/Schneider/Rosenzweig/Pounds 2003, van Vliet/Leemans 2006). Species extinction levels are estimated to be a magnitude larger than natural background levels (e.g. Jablonski 2004), coral bleaching by the increased pollution and frequency of high-temperature events in surface waters are abundant (Knowlton 2001), and glaciers and permafrost disappear rapidly all over the world (Arctic Climate Impact Assessment 2004).

These increasing human pressures on the Earth's functioning have been studied intensively over the last few decades (e.g. Steffen/Sanderson/Tyson/Jäger/Matson/Moore/Oldfield/Richardson/Schellnhuber/Turner/Wasson 2004). Many now recognize that we live in an era that for the first time in the Earth's history is dominated by one single species: *homo sapiens*. Crutzen (2002) therefore named the current era the 'Anthropocene'. All these studies indicate one important feature. The biosphere and the ecosystems, landscapes and species (including humans) that are part of it, play an important role in the functioning of the Earth. This role involves the cycling of water, energy and nutrients, it involves the provision of many different ecosystems, goods, and services to humanity, and it ultimately regulates many parts of the earth system (Lovelock 1992). The diversity of life or biodiversity (e.g. Wilson 1989, e.g. Wilson/Peter 1988) strongly supports this role and emphasizes that ecosystems thus are capital assets. Threats to ecosystems and biodiversity are thus direct threats to the functioning of ecosystems and (indirectly) human well-being.

Although the changes that have been made to ecosystems have contributed to large gains in human well-being and economic development, the corresponding degradation of ecosystems and their services limit the benefits that future generations obtain from ecosystems. This can cause significant harm to human well-being and represents a loss of a natural asset or wealth of a country. Global environmental change has therefore become a major issue in discussions on environmental security (O'Brien 2006). I use the term 'environmental security' in the broadest possible sense, similar to the pragmatic definitions promoted elsewhere (e.g. the Copenhagen School: Buzan/Wæver/De Wilde 1997; Wæver/Buzan/De Wilde 2008; De Wilde 2008 and Dalby 2002, 2008).

Global environmental change, together with the concerns about the socio-economic consequences of these changes and the costs associated with the pro-

Box 3.1: The Millennium Ecosystem Assessment. **Source:** Millennium Ecosystem Assessment (2005).

The Millennium Ecosystem Assessment (MA) is an international work programme designed to meet the needs of decision-makers and the public for scientific information concerning the consequences of ecosystem change for human well-being and options for responding to those changes. The MA was launched by U.N. Secretary-General Kofi Annan in June 2001 and was completed in June 2005. It will help to meet assessment needs of the Convention on Biological Diversity, the Convention to Combat Desertification, the Ramsar Convention on Wetlands, and the Convention on Migratory Species, as well as needs of other users in the private sector and civil society. If the MA proves to be useful to its stakeholders, it is anticipated that it will be repeated every 5–10 years and also that such integrated ecosystem assessments will be regularly conducted at national or sub-national scales.

The MA focuses on ecosystem services, how changes in ecosystem services have affected human well-being, how ecosystem changes may affect people in future decades, and response options that might be adopted at local, national, or global scales to improve ecosystem management

and thereby contribute to human well-being and poverty alleviation. The specific issues being addressed by the assessment have been defined through consultation with the MA users.

The MA synthesizes information from the scientific literature, datasets, and scientific models, and includes knowledge held by the private sector, practitioners, local communities, and indigenous peoples. All of the MA findings undergo rigorous peer review. More than 1,350 authors from 95 countries have been involved in four expert working groups preparing the global assessment, and hundreds more continue to undertake more than 20 sub-global assessments.

The MA was conducted as a "multi-scale" integrated assessment, consisting of interlinked assessments undertaken at local, watershed, national, regional and global scales. The MA sub-global assessments were designed to meet needs of decision-makers at the scale at which they are undertaken, strengthen the global findings with on-the-ground reality, and strengthen the local findings with global perspectives, data, and models.

posed measures to cope with them, have attracted the attention of the general public, decision-makers, the press, and interest groups from industry and NGOs (non-governmental organizations). Concerns about global change have already led to national and international actions. Several international treaties and conventions deal with ecosystems, biodiversity, and species. The *Convention on Biological Diversity* (CBD) that originated at the second UN *Conference on Environment and Development* (UNCED) in Rio de Janeiro in 1992, for example, directly targets biodiversity. Its objective is to “conserve biodiversity, the sustainable use of its components, and the fair and equitable sharing of the benefits arising out of its utilization”. This objective does clearly recognize that humans are dependent on the sustainable use of biodiversity. It therefore does not solely focus on conservation. Additionally, the equitable or fair sharing of benefits is a strong political statement targeting (sustainable) development. Much scientific and policy attention has already focused at the conservation of biodiversity (Heywood/Watson 1995), but little on how to manage the use of biodiversity.

This chapter reports on the background and findings of an international assessment, the *Millennium Ecosystem Assessment* (MA)¹, which was concluded

in 2005 (box 3.1). This MA explicitly linked ecosystems and biodiversity through ecosystem services to human well-being. The MA also evaluated the biodiversity target “to significantly reduce the decline of biodiversity by 2010”, and the *Millennium Development Goals* (MDGs) to eradicate extreme poverty and hunger, to achieve universal primary education; to promote gender equality and empower women; to reduce child mortality; to improve maternal health; to combat HIV/AIDS, malaria and other diseases; to ensure environmental sustainability; and to develop a global partnership for development. These were agreed upon by the world’s leaders at the *World Summit on Sustainable Development* (WSSD) in Johannesburg in 2002.

3.2 Defining Important Concepts

3.2.1 Ecosystems and Biodiversity

Central in the discussion on biodiversity is the *ecosystem* concept. An ecosystem is a complex of communities, consisting of plants, animals and micro-organisms and their non-living environment. Ecosystems exhibit different kinds of dynamics: the species involved are important in the cycling of energy (e.g. CO₂ and carbohydrates), water, and nutrients. Through time species can replace each other as a response to changes in the environment or succession. All these

1 Reports and additional information can be found at: <<http://www.maweb.org>>.

processes interact and make the ecosystem a functional unit. Humans are an integral part of ecosystems. Ecosystems are often defined broadly and range from coarse biomes (large-scale landscapes determined by major climate patterns, such as boreal, temperate and tropical forests, grasslands and deserts) to relatively small patches (e.g. bogs and forests groves). A well-defined ecosystem has strong interactions among its own components and weak interactions across its boundaries. Summarizing, an ecosystem is not a well-defined unit but behaves as a functional unit integrating the living and non-living environment.

Biodiversity is the variability among living organisms. It includes diversity within and among species, within populations of a single species and communities of multiple species, and of populations and communities within landscapes. The levels involved thus ranges from genes, through species to landscapes. However, in defining biodiversity, the non-living environment is never considered.

3.2.2 Ecosystem Services

Biodiversity contributes to the way that we explore, use, and manage ecosystems. Different species or combinations of species, for example, are used to provide products (e.g. milk from cows transformed by bacteria to yoghurt or the fermentation of barley by yeasts for beer), rich wildlife in a landscape provides value for tourism (e.g. bird watching: Wall 1998), wetlands species provide clean water (e.g. Catskills Mountains: Sagoff 2002) and mangrove forests protect coastal areas (e.g. Sundarbans in India: Singh 2003). Biodiversity is thus a source of many ecosystem services. *Ecosystem services* are the benefits people obtain from ecosystems (Millennium Ecosystem Assessment 2003). These include (figure 3.1):

- provisioning services such as food, fuel, fibre, and fresh water;
- regulating services such as slope stabilization, flood protection, detoxification, and disease control;
- cultural services such as spiritual, aesthetic, recreational, educational or cultural benefits; and
- supporting services such as pollination and nutrient cycling.

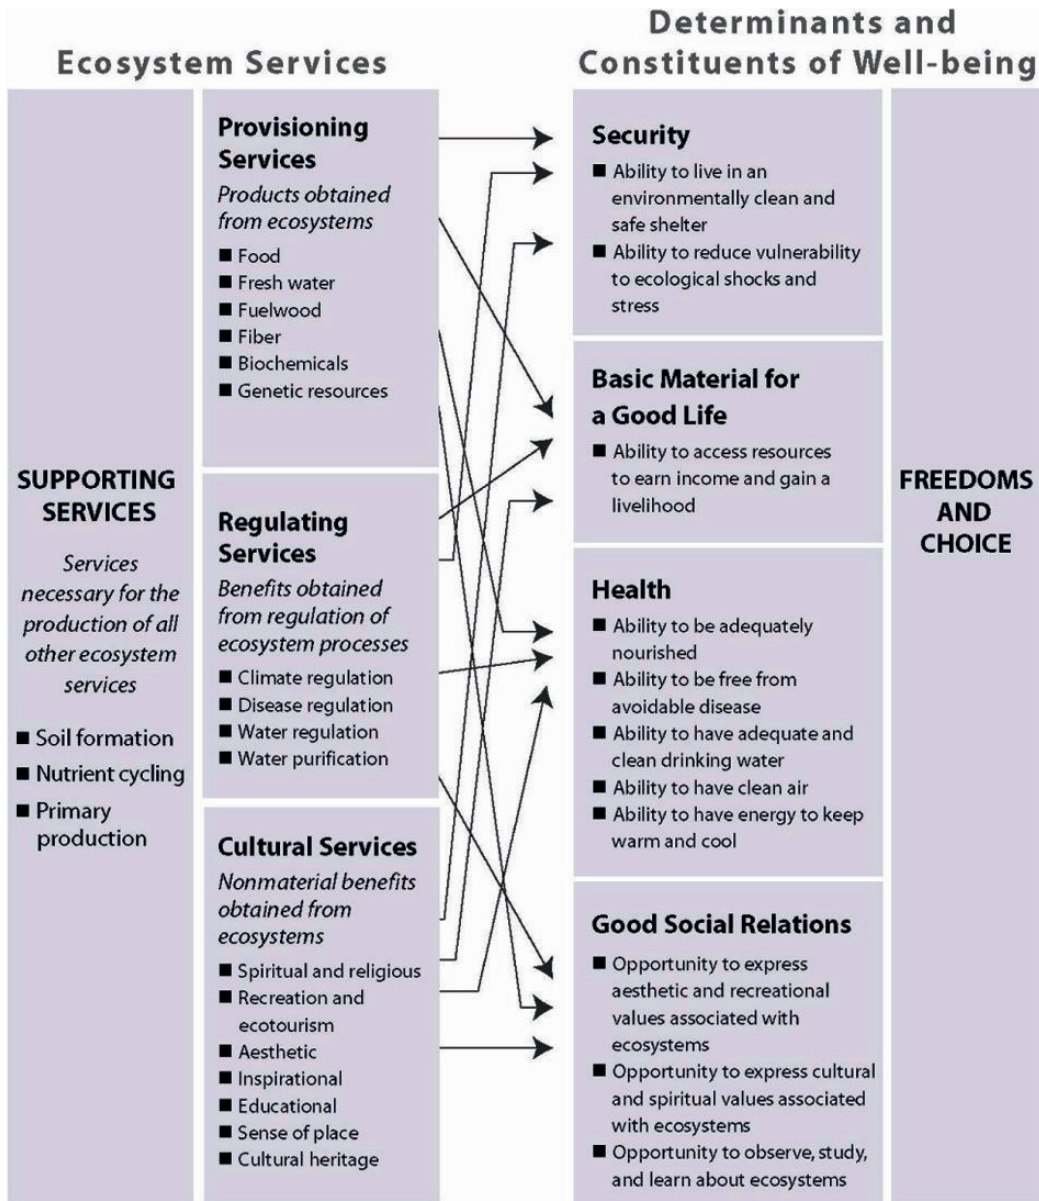

The first three types of services all provide direct utility to humans. Provisioning services consists of all different goods that are generally traded in local and international markets. They are priced and therefore often carefully managed by their owners. The regulat-

ing services are the benefits of regulation of ecosystem processes, while the cultural services involve the non-material benefits obtained from ecosystems. Both are still of direct use to people and society, but rarely traded with proper market prices. They are part of the commons, sometimes strongly regulated but often not regulated at all. The supporting services are rarely of direct utility to people and society, but maintain the conditions for life (e.g. soil formation and pollination).

The dependence of humans on ecosystem services reflects directly the profound co-evolutionary processes that underlie the origins of the Earth's biosphere and human society. The effects of adverse ecosystem changes on human well-being can be classed as direct and indirect. *Direct effects* occur with some immediacy, through locally identifiable biological or ecological pathways. For example, impairment of the water-cleansing capacity of wetlands may adversely affect those who drink that water. Building dams can increase mosquito-breeding and thus the transmission of malaria. The deforestation of hillsides can expose downstream communities to the hazards of flooding. *Indirect effects* take a toll on well-being through more complex chains of causation, including through social, economic, and political routes. Some may take decades to have an impact. For example, where farmlands under irrigation become saline, crop yields are reduced; this in turn may affect human nutritional security, child growth and development, and susceptibility to infectious diseases. Beyond threshold points, limited or degraded supplies of fresh water may exacerbate political tensions and impair local economic activity and livelihoods. These dynamic, interacting processes can jeopardize various aspects of human well-being.

The impacts of adverse ecosystem change do not fall evenly on human populations. Indigent, poorly resourced, and otherwise disadvantaged communities are generally the most vulnerable. Further, many poor rural populations rely disproportionately on the integrity and functions of local ecosystems, and are likely to lack the means to import ecosystem services. Impoverishment as a result of adverse ecosystem change may sometimes lead to a downward spiral for such people. In all instances, the ability to achieve well-being is reduced by the diminished availability of ecosystem services.

Figure 3.1: The linkages between ecosystem services and human well-being. **Source:** Millennium Ecosystem Assessment (2005). Reprinted with permission of WRI.

3.2.3 Human Well-being

There have been many formulations and definitions of human well-being (Alkire 2002). There is widespread agreement that well-being and poverty are the two extremes of a multidimensional continuum. The World Bank, for example, defined poverty as “the pronounced deprivation of well-being” (World Bank 2002).

Most agree that the constituents and determinants of human well-being includes a necessary material

minimum for a good life (i.e. having access to resources and gaining a livelihood), the experience of freedom, personal and societal security, good social relations, good health, and the conditions for physical, social, psychological, and spiritual fulfilment. The determinants of human well-being are sometimes expressed as commodities, many of which are provided by ecosystem services. Enabling physical, environmental, and social conditions and access to resources and space are also relevant as means to well-being.

How well-being or poverty are expressed and experienced is context- and situation-dependent, reflecting local social and personal factors such as geography, ecology, age, gender, and culture (Prescott-Allen 2001). Although these concepts are recognized as complex and value-laden, some elements are nevertheless widespread – if not universal. This was evident in the ‘voices of the poor’ research (Narayan/Chambers/Shah/Petesch 2000), in which poor people from many countries were asked to reflect, analyse, and express their ideas of the bad and the good life. The respondents stressed many aspects, including the importance of secure and adequate livelihoods, cultural and spiritual activities, and the ability to raise their children. They stressed five components (figure 3.1):

- *security*, including safety of person and possessions, secure access to natural and other resources, and living in a predictable and controllable environment with security from natural and human-made disasters. This means security in the broadest sense and in a very pragmatic interpretation;
- *a basic material minimum for a good life*, including secure and adequate livelihoods, income and assets, enough food at all times, shelter, furniture, clothing, and access to goods;
- *health*, including being strong, feeling well and looking good, and having a healthy physical environment;
- *good social relations*, including social cohesion, mutual respect, good gender and family relations, and the ability to help others and provide for children;
- *freedom and choice*, including having control over what happens and being able to achieve what a person values doing or being.

These five dimensions reinforce each other, either positively or negatively. A change in one often brings about changes in the others. In this multidimensional formulation, there are many webs of interactions. For example, poor people are vulnerable to sickness, which in turn makes them poorer; bad social relations make people vulnerable to shocks, which in turn deepen material poverty and so on; and all of these contribute to powerlessness. On the side of well-being and the good life, having materially enough facilitates physical strength, enabling a better livelihood, while good social relations can provide security against stresses and shocks. In turn, security is likely to increase material well-being and so on. And all of these enhance freedom of choice and action.

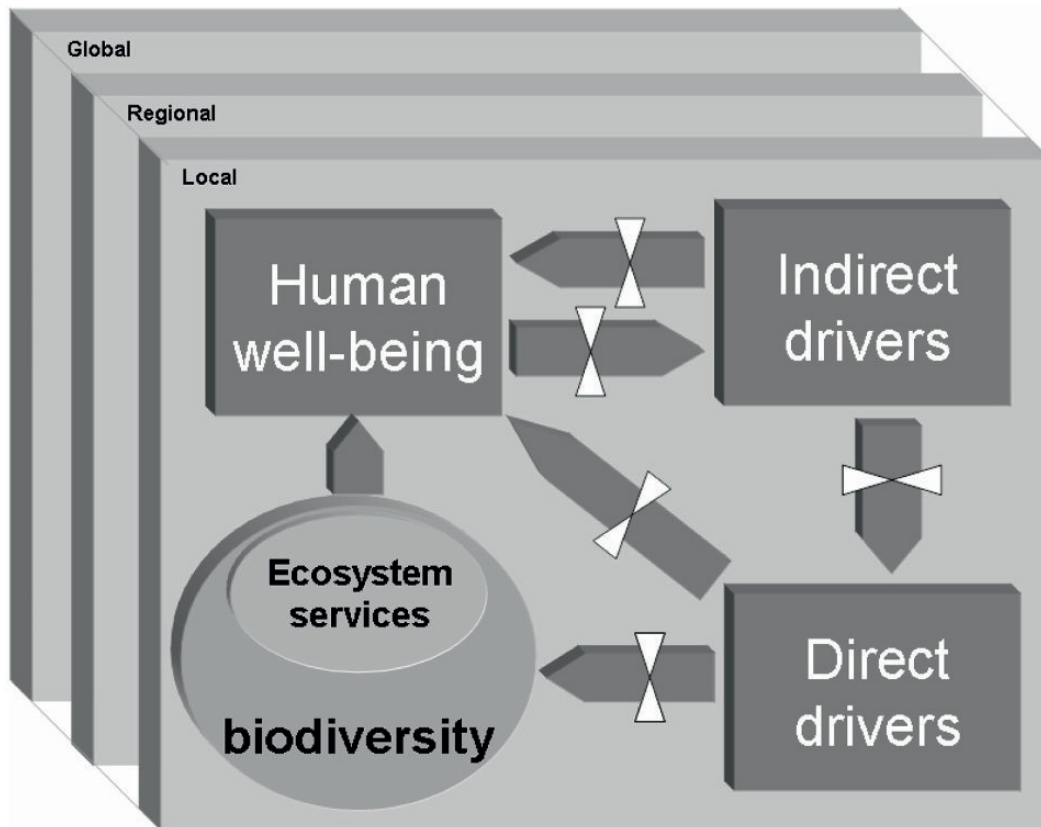

The well-being of present and future human populations depends on ecologically sustainable and socially equitable ways of living in the world (Figure 3.1). Distinguishing ecosystem services and their obvious link to human well-being helps to communicate the role of ecosystems and biodiversity to policymakers and the broader public (Millennium Ecosystem Assessment 2003).

Security is thus a major constituent of human well-being but it has not been a major focus of the assessment. The conventions that asked for the assessment (e.g. box 3.1) stressed the need for a clear assessment of the consequences of ecosystem change for the MDGs (and thus poverty). In the final synthesis reports, social and environmental security was therefore not separately addressed. However, security issues became a major issue in developing the scenarios (Carpenter/Pingali/Bennett/Zurek 2005). Differences in equity and security were major drivers in differentiating the four scenarios. In one of the scenarios, the lack of equity and security (in the broadest meaning) led to major barriers between regions and conflict, resulting in additional degradation of ecosystem services.

3.2.4 Assessments

The ability of ecosystems to deliver services and contribute to human well-being can be assessed by a variety of qualitative and quantitative methods, developed by different natural, economic, and social science disciplines. Such assessments thus require integrated approaches. All assessments mine scientific information and synthesize it into policy relevant information. Assessments are not just consensus reports because they clearly report on uncertainties, ongoing debates, and controversies. They also are responsive to changing policy needs and do not prescribe solutions. Assessments help decision-makers to determine which service or set of services is valued most highly, which trade-offs emerge in developing or selecting specific services, and how to develop approaches for sustainable management of all the necessary services. Selecting and implementing appropriate response strategies is the responsibility of the policymakers. An assessment thus can only provide guidance.

Figure 3.2: The conceptual framework of the Millennium Ecosystem Assessment. **Source:** Millennium Ecosystem Assessment (2005). Reprinted with permission from WRI.

3.3 Guiding Questions and Concepts of the MA

The goal of the MA was stimulating and guiding action to conserve ecosystems and enhance their contribution to human well-being, and simultaneously build the necessary capacity to undertake integrated ecosystem assessments and to act on their information. Core questions, which are all addressed in detail in the MA reports, to the assessment were:

- What are the current conditions and trends of ecosystems and their associated human well-being?
- What are the plausible future changes in ecosystems, ecosystem services, and the associated human well-being?
- What can we do to enhance well-being and conserve ecosystems?
- What are the most robust findings and key uncertainties?
- What tools and methodologies can strengthen capacity to undertake integrated assessments of ecosystems and human well-being?

These questions stress understanding change. This means that the underlying causes of these changes have to be identified and quantified. Additionally, the assessment should also provide an evaluation of possible responses and response strategies.

The integrated approach that was developed by the MA recognized the importance of dynamically linking biodiversity, ecosystem services, and human well-being on local, regional, and global levels (as explained in much more detail in: Millennium Ecosystem Assessment 2003: #15200). These links were illustrated by elaborating on the different types of ecosystem services and constituents of human well-being as depicted in figure 3.1. The linkages, however, do not emphasize the changes over time or space. To depict this, a comprehensive Conceptual Framework (CF, figure 3.2) was developed early in the assessment

process. The function of this CF was to ease communication of cause and effect, and to illustrate that policies mainly influence drivers, which are factors that alter the behaviour or dynamics of the elements of the CF (biodiversity, services, human well-being and drivers). Policies targeted at one element (e.g. biodiversity) will have (unintended) impacts on other elements (e.g. drivers, services or human well-being).

The CF uses broad definitions of ecosystems and biodiversity, which represents life on earth that provides all the ecosystem services required to sustain human well-being. Changes in biodiversity, ecosystem services, and human well-being are caused or triggered by one or more drivers. Responses (e.g. measures or policy strategies) try to influence these drivers. Two different types of drivers are distinguished in the CF: *direct* and *indirect drivers*. The indirect drivers operate from a distance (exogenous) and involve the larger scale causes of change. The direct (endogenous) drivers influence the system in an explicit way. Indirect drivers are, for example, increased food demand because of growing population. This leads to expansion or intensification of agricultural land activities, which involve a series of direct drivers.

Such a classification of drivers is not rigid. Actually, drivers are scale dependent. At local scales, many drivers are indirect and can only be influenced by larger scale actors (e.g. trade policies by national governments), but the consequences of the direct drivers and those that govern them can be assessed much more easily and precisely. One of the major challenges was not only to include cause and effect but also decision-making processes into the framework. As an economist stated during the discussion on the CF: "People are not driven, they make choices". By recognizing the actual actor or institution (e.g. an individual, a municipal, a nation, an international company, or a multilateral agreement) that can influence a driver and its specific domain of influence, decision-making processes were accommodated in the CF as well. The CF was therefore a major harmonizing effort to facilitate integration across the many disciplines involved in the assessment.

3.4 Main Findings of the Millennium Assessment

The main finding of the MA is that over the past 50 years humans have changed ecosystems more rapidly and extensively than in any comparable period of time in human history, largely to meet rapidly growing

demands for food, fresh water, timber, fibre, and fuel. This has resulted in a substantial and largely irreversible loss in the diversity of life on Earth.

The changes that have been made to ecosystems have contributed to substantial net gains in human well-being and economic development, but these gains have been achieved at growing costs in the form of the degradation of many ecosystem services, increased risks of nonlinear changes, and the exacerbation of poverty for some groups of people. These problems, unless addressed, will substantially diminish the benefits that future generations obtain from ecosystems. The degradation of ecosystem services could grow significantly worse during the first half of this century and is a barrier to achieving the biodiversity target and the Millennium Development Goals.

The challenge of reversing the degradation of the ecosystem while meeting increasing demands for services can be partially met under some scenarios considered by the MA, but will involve significant changes in policies, institutions, and practices that are not currently under way. Many options exist to conserve or enhance specific ecosystem services in ways that reduce negative trade-offs or that provide positive synergies with other ecosystem services.

The bottom line of the MA findings is that human actions are depleting the Earth's natural capital, putting such strain on the environment that the ability of the planet's ecosystems to sustain future generations can no longer be taken for granted. At the same time, the assessment shows that with appropriate actions it is possible to reverse the degradation of many ecosystem services over the next 50 years, but the changes in policy and practice required are substantial and not currently underway.

The MA synthesized at the most basic level information that has previously been available, and do not present new research findings. Nevertheless, three aspects of the MA do represent important new contributions. *First*, the findings of this assessment are the consensus view of the largest body of social and natural scientists ever assembled to assess knowledge in this area. Like the IPCC, the availability of this broad view of scientists from multiple disciplines is an important 'value added' part of the process and an important contribution to decision-makers. The assessment identifies not only where broad consensus exists on findings, but also where the information is insufficient to reach firm conclusions.

Second, the focus of this assessment on ecosystem services and their link to human well-being and development needs is unique. By examining the environ-

ment through the framework of ecosystem services, it becomes much easier to identify how changes in ecosystems influence human well-being and to provide information in a form that decision-makers can weigh alongside other social and economic information. The MA framework of ecosystem services and links to human well-being is already being adopted by other institutions and incorporated into other processes.

Third, the assessment identified a number of ‘emergent’ findings, conclusions that can only be reached when a large body of existing information is examined together. Four of them stand out:

- *The balance sheet.* Although individual ecosystem services have been assessed previously, the finding that 60 per cent of a group of 24 ecosystem services examined by the MA are being degraded is the first comprehensive audit of the status of the Earth’s natural capital.
- *Nonlinear changes.* Nonlinear (accelerating or abrupt) changes have been previously identified by a number of individual studies of ecosystems. Examples of such changes include disease emergence, abrupt alterations in water quality, the creation of ‘dead zones’ in coastal waters, the collapse of fisheries, and shifts in regional climate. The MA is the first assessment to conclude that ecosystem changes are increasing the likelihood of nonlinear changes in ecosystems, and the first to note the important consequences of this finding for human well-being.
- *Drylands.* Because the assessment focuses on the linkages between ecosystems and human well-being, a somewhat different set of priorities emerge from it. While the MA does confirm that major problems exist with tropical forests and coral reefs, from the standpoint of linkages between ecosystems and people, the most significant challenges involve dryland ecosystems. These ecosystems are particularly fragile, but they are also the places where human population is growing most rapidly, biological productivity is least, and poverty is highest.
- *Nutrient loading.* The MA confirms the emphasis that decision-makers are already giving to addressing important drivers of ecosystem change such as climate change and habitat loss. But the MA finds that excessive nutrient loading of ecosystems is one of the major drivers today and will grow significantly worse in the coming decades unless action is taken. The issue of excessive nutrient loading, although well studied, is not yet receiving

significant policy attention in many countries or internationally.

The MA further established that progress towards achieving the 2015 MDG targets will need to be accelerated dramatically. In particular sub-Saharan Africa, Central Asia, parts of South and South-East Asia, as well as some regions in Latin America, are currently off track with respect to meeting these goals. Here human well-being and thus security is jeopardized by the degradation and loss of ecosystems and ecosystem services that can be slowed or reversed through improved ecosystem management. In many places the sustainability and continuity of particularly agro-ecosystems is threatened by structural shortage of measures to maintain their services and productivity. By restoring those functions there is more room for other less productive systems, but that requires clear choices at the local, regional, national, and international level. Particular emphasis needs thus to be placed on the sustainable intensification of existing cultivated ecosystems to satisfy growing demand for food and other ecosystem services.

The evidence synthesized by the MA underlines that ecosystem services can only be sustained in the long term if the integrity and completeness of ecosystems are maintained or restored. This information and the tools for improved management of ecosystems need to be integrated more systematically into development strategies, such as poverty and hunger reduction strategies. This is a particularly important prerequisite for achieving the targets relating to poverty, hunger, gender equality, water and sanitation and health.

Finally, modified ecosystem management as part of a strategy to achieve the MDGs in 2015 has to consider that many drivers effect ecosystems and their services (figure 3.2). Therefore policies, institutions, and reorientation acting at local, regional, and global scales need to address several drivers at the same time. Particular attention needs to be placed on improving ecosystem management and the capacity for policymaking at the national and local level, as well as addressing global challenges including long-term climate change, nutrient depositions, and the depletion of international fisheries.

3.5 Concluding Remarks

Sufficient information now exists to enhance decision-making in support of biodiversity conservation and sustainable development at all scales. However,

many research needs and information gaps were identified in the MA, and actions to address those needs could yield substantial benefits in the form of improved information for policy and action. For example, relatively limited information exists about the status of many ecosystem services, and even less information is available about the economic value of non-marketed services. The costs associated with the depletion of these services are rarely tracked in national accounts. As a consequence, models used to project future environmental and economic conditions have also limited capability for incorporating ecological and societal feedbacks, such as nonlinear changes in ecosystems, or behavioural feedbacks such as learning that may take place through adaptive management of ecosystems.

Assessments also play a useful role in clarifying where scientific uncertainties remain. While uncertainties can be used to argue for a 'wait and see' approach, they can equally well be used to argue for a precautionary approach. Among the MA findings, the certainty or robustness of the global findings is generally high. Perhaps the greatest uncertainty associated with a critically important feature of ecosystem change surrounds the knowledge of the extent of land degradation in drylands. Even so, using relatively conservative estimates of land degradation (10–20 per cent degraded), the area and the number of people involved is still large. Here, and in many other places, there is typically insufficient information on the full economic costs and benefits of alternate uses of ecosystems to fully inform decisions.

While the MA findings do identify significant problems related to the management of ecosystems, these problems need to be viewed in the context of the MA finding that *the changes people have made to ecosystems have contributed to substantial net gains in human well-being* (including many aspects of security; see figure 3.1) and economic development. The problems identified in the MA – including growing costs in the form of degradation of ecosystem services, increased risks of nonlinear changes, and the exacerbation of poverty and security for some groups of people – are serious, and the MA shows that these problems could grow much more serious in the coming decades. At the same time, the assessment shows that the future really is in our hands. People can reverse the degradation of many ecosystem services and improve human well-being further over the next 50 years, but the changes in policy and practice required are substantial and not currently under way.

4 Securitizing Global Environmental Change

Hans Günter Brauch

4.1 Introduction¹

The thesis of this chapter is that the year 2007 has been a turning point in the process of *securitization*² of questions of *global environmental change* (GEC) and especially of *global climate change* (GCC) when several of the highest national policy-makers and high-level fora (UN Security Council) and officials of international organizations addressed global warming (cause) and climate change (effect) as a major objective security danger and subjective security concern that may lead to internal displacements, forced distress migration, as well as crises and conflicts. Other elements of GEC, such as water, have previously been sectorialized (as ‘water security’) or discussed as security issues (desertification, drought, famine) resulting from ‘water’ insecurity and leading to ‘food’ and ‘health’ insecurity.

This emerging scientific discourse, policy debate and political process of *securitization* of GEC and GCC focuses on the environmental dimension of security, especially on the complex interaction between human beings and humankind as causes, triggers, and victims of the societal consequences of this anthropogenic change. Thus, the *securitization* of GEC and GCC issues is also closely linked to different referent objects of international, national, and human security.

With the *securitization* of GEC and GCC the focus of analysis is on the process of scientific and political agenda-setting, and prioritization of nature-societal issues during the past 20 years. While in 1987, both GEC and GCC were still primarily emerging scientific problems for a small group of water, soil, and

climate specialists, by 2007 after intensive processes of *politicization* and *securitization* global warming and climate change have moved to the top of the policy agenda as the most urgent security dangers and concerns that require both urgent, stringent, and long-lasting policy responses with a fundamental transformation of the global energy system (decarbonization), but also of human values and consumer patterns.

Why has this turning point towards a securitization of GEC and GCC occurred in 2007? Why did the most important and influential policy-makers, e.g. the heads of states and governments of the G-8 and the European Union, in key policy statements (‘speech acts’), declare climate change as an international and national security issue? What purpose is this securitization of climate change to achieve, and who will be empowered to address and to respond to this new urgent security concern?³

In responding to these questions, this chapter will first introduce GEC and GCC as a security issue in the Anthropocene, and briefly outline the theory and method to be used below in the context of different models on the complex nature-society interactions (4.2) before the emerging process of securitization of water, climate change, and desertification (4.3), and the indirect role of the IPCC as a new ‘securitizing actor’ (4.4.) are examined. It will then review the emerging policy debates on GEC and especially GCC issues since 1990 that have resulted first in a *politicization* and in the early 21st century in a progressive *securitization* that are addressed for climate change in the context of international, national, and human security scientific discourses and policy debates (4.5.). So far this *securitization* of GEC and GCC has been largely policy driven. (4.6).

1 The author is grateful to two reviewers for their useful comments and suggestions that have been implemented in this text and have helped the author to condense the empirical evidence.

2 The theory of securitization has been developed by Ole Wæver (1995, 2008, 2008a) and the Copenhagen school (Buzan/Wæver/de Wilde 1998; Wæver/Buzan/de Wilde 2008). For details see below in part 4.2.2.

3 The author is grateful to Ole Wæver, University of Copenhagen, for his useful comments to a presentation of an earlier version at the 49th ISA convention in San Francisco on 26 March 2008.

The analysis of the *securitization* of GEC and GCC does not imply a causal analysis of the complex interrelationship of these factors in the past (climate, environmental history), presence and future (in the 21st century) nor a probability assessment of the relevant importance of these factors as causes, drivers, triggers or as independent, intervening or depending variables.

4.2 Global Environmental Change as a Security Issue in the Anthropocene: Theory, Methods, and Models

The securitization of GEC issues occurs on the background of a third major cause for a reconceptualization of security that fundamentally challenges the prevailing Hobbesian security thinking in international relations and in security studies, and the contending security theories of (neo)realism, liberal institutionalism, economic liberalism or Marxism (Kolodziej 2005), and also of some representatives of critical security studies (Booth 2007; Booth/Wheeler 2008) but also of people-centred approaches (Thakur 2006; Picciotto/Olonisakin/Clarke 2007) that have either ignored or downgraded the environmental dimension of international, national, and human security. The causes of GEC and GCC pose fundamentally different security threats, challenges, vulnerabilities, and risks for the international community, the nation state, and humankind (Brauch 2005, 2005a).

The enemy is us, not ‘they’ (the rival social class, religious or ethnic group, nation or alliance), it is ‘us’, ‘our consumptive behaviour’ and ‘our use of fossil fuels’ (coal, oil, gas) and that of previous generations since the outset of the Industrial Revolution (ca. 1750) that has been accumulated in the atmosphere and has become the cause of a rapid anthropogenic climate change (figure 4.1, 4.2). For this new security issue traditional military strategies and power as well as armaments offer no credible policy response. As it is impossible to declare a ‘war against climate change’, in analogy to the ‘war on terror’, a ‘militarization’ of GEC and GCC to maintain ‘our way of life’ and indirectly to prevent others to achieve our per capita greenhouse gas emission levels or to enforce emission reduction targets with military means will be counterproductive. Booth (2007: 412–413) warned “unless the rogue states that constitute the axis of pollution agree collectively, then the tipping point will surely have arrived by mid century. ... The outcome for world secu-

rity would then be highly unpredictable”. While the ‘Hobbesian fear’ (Butterfield 1950) of global warming may generate the “constraints and incentives for collective action” in order to diminish “fear and insecurity and receiving increased cooperation and international aid” (Cerutti 2007: 202), the Hobbesian logic of power to enforce the goals and strategies of the Leviathan offers no solution for a proactive security policy in the Anthropocene to cope with the impacts of GEC and GCC. The new security dangers in the Anthropocene posed by GEC and GCC differ fundamentally from that posed by nuclear weapons during the Cold War (Cerutti 2007), although there have been similarities in both worst case analyses with authors who operate with the same mindset (Sunstein 2007). But the Hobbesian logic of ‘mutual assured destruction’ (MAD) doctrines has become totally obsolete for a new security and peace policy for the Anthropocene era.

According to the IPCC (2007: 2) greenhouse gases have increased from 280 ppm (parts per million) in the atmosphere in the year 1750 to 379 ppm in 2005. The projected increase until the year 2100 for six scenarios (SRES B1, AIT, B2, A1B, A2 and A1FI) is according to the Synthesis Report of the IPCC’s (2007: 45) Fourth Assessment Report (AR4) “about 600, 700, 850, 1250 and 1550 ppm, respectively.” This projected increase is far above the natural variation in temperature changes that has been measured for the changes in climate for the past ten millennia. The IPCC (2007c: 72) lists as robust findings on the observed changes in climate and their effects, and their causes:

Warming of the climate system is unequivocal, as is now evident from observations of increases in global average air and ocean temperatures, widespread melting of snow and ice and rising global average sea level. {WGI 3.9, SPM}

Many natural systems, on all continents and in some oceans, are being affected by regional climate changes. Observed changes in many physical and biological systems are consistent with warming.

As a result of the uptake of anthropogenic CO₂ since 1750, the acidity of the surface ocean has increased. {WGI 5.4, WGII 1.3}

Global total annual anthropogenic GHG emissions, weighted by their 100-year GWPs, have grown by 70 per cent between 1970 and 2004. As a result of anthropogenic emissions, atmospheric concentrations of N₂O now far exceed pre-industrial values spanning many thousands of years, and those of CH₄ and CO₂ now far exceed the natural range over the last 650,000 years. {WGI SPM; WGIII 1.3}

Figure 4.1: The new security danger in the Anthropocene posed by changes in atmospheric CO₂ measured at the Mauna Loa Observatory in Hawaii (1958-2007). **Source:** Pieter Tans, NOAA/ESRL, 12 May 2008; at: <http://www.esrl.noaa.gov/gmd/ccgg/trends/co2_data_mlo.html>. Reprinted with permission.

Most of the global average warming over the past 50 years is *very likely* due to anthropogenic GHG increases and it is *likely* that there is a discernible human-induced warming averaged over each continent (except Antarctica). {WGI 9.4, SPM}

Anthropogenic warming over the last three decades has *likely* had a discernible influence at the global scale on observed changes in many physical and biological systems. {WGII 1.4, SPM}

The US *National Oceanic and Atmospheric Administration* (NOAA) has compiled the measurements at the Mauna Loa Observatory in Hawaii for the past fifty years. Figure 4.1 documents that two thirds of the increase since 1750 has occurred since 1958, and that the average increase in global warming has further accelerated since the year 2000.⁴ According to the IPCC this has resulted in an increase of the average temperature over land during the 20th century of 0.8 °C (figure 4.2).

The security danger posed by hydro-meteorological hazards has killed ca. 1.5 million people and affected more than 5 billion people between 1974 and 2003 (Guha-Sapir/Hargitt/Hoyois 2004), and the trend has been rising both in number and intensity, although not exclusively due to anthropogenic climate change, and it has been projected that such events will

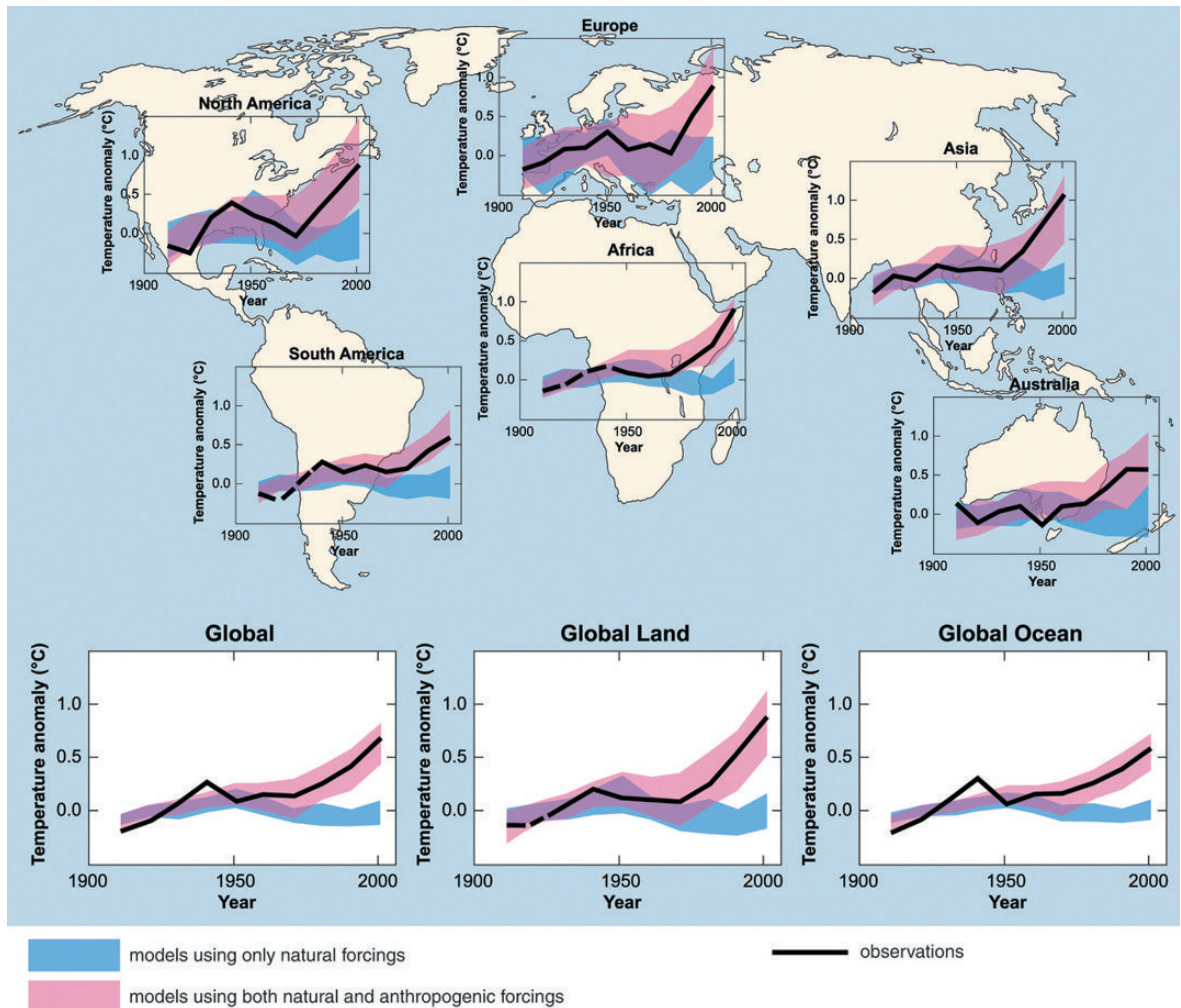

be very likely during the 21st century (IPCC 2007: 8). In Bangladesh between 1947 and 2001 about 1 million people died due to cyclones, floods, and drought (Brauch 2002: 83).⁵

But these hazards have also caused severe damages in OECD countries. The heat wave that hit Western Eu-

4 According to the US *National Oceanic and Atmospheric Administration* (NOAA) the annual mean growth of CO₂ based on measurements at the Mauna Loa Observatory in Hawaii for 2005 was 2.53 ppm, for 2006, 1.76 ppm, and for 2007 2.14 ppm (figure 4.1), reaching 387 ppm in May 2008. “From 1970 to 2000, the concentration rose by about 1.5 ppm, but since 2000 the annual rise has leapt to an average of 2.1 mm.” See: David Adam: “World CO₂ level at record high, scientists warn”, in: *Guardian*, 12 May 2008; at: <<http://www.guardian.co.uk/environment/2008/may/12/climate-change.carbonemissions>>. Most of this growth has occurred during the past 50 years since 1958 when it rose from 315 ppm (1958) to 387 ppm at the end of 2007 according to NOAA measurements, or twice as fast than during the previous 200 years.

5 These data have been displayed in many presentations by this author, e.g. in a talk to the Union of Concerned Scientists in Washington, on 21 April 2008; at: <http://www.afes-press.de/pdf/Brauch_UCS_a.pdf>.

Figure 4.2: Global and continental temperature change (1900-2000). **Source:** IPCC (2007: 11); at: <<http://www.ipcc.ch/graphics/graphics/ar4-wg1/ppt/spm.ppt#262,5>, Figure SPM.4>. Reprinted with permission under IPCC rules.

Explanation by the IPCC. Comparison of observed continental- and global-scale changes in surface temperature with results simulated by climate models using either natural or both natural and anthropogenic forcings. Decadal averages of observations are shown for the period 1906–2005 (black line) plotted against the centre of the decade and relative to the corresponding average for the 1901–1950. Lines are dashed where spatial coverage is less than 50%. Blue shaded bands show the 5 to 95% range for 19 simulations from five climate models using only the natural forcings due to solar activity and volcanoes. Red shaded bands show the 5 to 95% range for 58 simulations from 14 climate models using both natural and anthropogenic forcings. Source: IPCC (2007c: 40),

rope in August 2003 killed more than 72,210 persons⁶ and caused an economic damage of ca. 10 billion Euros for agriculture due to a major decline in food yield (Scheffran 2008: 19 based on Stern 2007: 151). Hurri-

cane Katrina that touched land on 29 August 2005, killed according to official statistics some 1,833 persons, and became thus the fourth most deadly hazard in the USA since 1900. It affected about 500,000 people and caused economic damages amounting to about US\$ 125 billion, thus becoming the most costly natural hazard in US history until 2008 (Brauch 2008d).

However, in many contemporary security analyses (e.g. Kolodziej 2005; Thakur 2006), the environment,

⁶ See: CRED: “Extreme temperature disasters”, in: *CRED Crunch*, No. 9, June 2007; at: <<http://www.em-dat.net/documents/Cred%20Crunch%209.pdf>>. According to Munich Re 35,000 people died and agricultural losses reached 15 billion (Stern 2006: 150–151).

GEC issues, and hydro-meteorological hazards have not been discussed as security dangers and concerns, and have thus been excluded from 'securitization'.

4.2.1 Security Policy in and for the Anthropocene

According to Clark, Crutzen, and Schellnhuber (2004: 1): "we live today in what may appropriately be called the 'Anthropocene' - a new geologic epoch in which humankind has emerged as a globally significant - and potentially intelligent - force capable of reshaping the face of the planet" (Crutzen 2002). The recognition of the role of humans as global transformers of the earth has gradually evolved since Alexander von Humboldt (1808) and was systematically developed by the Russian geochemist, V. I. Vernadsky (1926, 1945, 1998) in his lectures on the 'biosphere' delivered at the Sorbonne in the 1920's.

Clark, Crutzen, and Schellnhuber (2004: 2) argued that "the last half century witnessed an accelerating program of scientific studies (e.g. Thomas 1956; Steffen/Sanderson/Tyson/Jäger/Matson/Moore/Oldfield/Richardson/Schellnhuber/Turner/Wasson 2004) that have broadened and deepened our understanding of what Turner, Clark, and Kates et al. (1990) have convincingly characterized as an 'Earth transformed by human action'." In response to the gradual understanding of the anthropogenic contribution to GEC and climate change in the Anthropocene the normative concept of 'sustainable development' (Brundtland 1987) has been adopted in Rio de Janeiro in 1992 at UNCED and become a key policy goal of UN Secretary-General Kofi Annan's *Millennium Report* (2000), and at the WSSD in Johannesburg (2002) where "the need for harnessing science and technology in support of efforts to achieve the goal of environmentally sustainable human development in the Anthropocene was generally recognized" (Clark/Crutzen/Schellnhuber 2004: 3).

At the Dahlem Conference in May 2003 these three scientists assessed the state of this transformation and called for an 'earth system science' that requires a second Copernican revolution or a new scientific paradigm of a 'science for global sustainability'. The Amsterdam Declaration (2001) that established the *Earth System Science Partnership* (ESSP) contributed to a comprehensive earth system science research programme by formulating 23 basic analytical, normative, operational, and strategic questions (Leemans/Rice 2009).⁷ Clark, Crutzen, and Schellnhuber (2004: 19) argued that efforts to synthesize the work

on the resilience of ecological systems and on the vulnerability of social systems

have highlighted the importance of incorporating multiple stresses, teleconnections, explicit pathways of exposure, the possibility of threshold responses, explicit treatment of scale, and attention to the components of adaptive capacity in frameworks for the analysis of vulnerability and resilience (Turner/Kasperson/Matson et al. 2003). ... Needed now for management is problem-driven research that utilizes these conceptual vulnerability/resilience framework to illuminate the kinds, rates, and magnitudes of specific disturbances beyond which the 'ability of society to advance human well-being' can no longer be sustained.

Therefore, a proactive security policy in the Anthropocene that addresses the *Global Challenges for Leviathan* (Cerutti 2007) must be science- and knowledge-based, and requires a different knowledge from what national intelligence agencies and the military establishment have offered policy-makers, and it calls also for different goals, strategies, and means than traditional security experts trained in the Hobbesian tradition of security studies can offer.

Such a new security policy in and for the Anthropocene necessitates for the new security dangers posed by GEC a new policy framework that integrates both the experience of past nature-human interactions as well as the scenario- and model-based projections of the probable societal outcomes of future trends. This emerging security policy makes a conceptual thinking for a new peace policy in the early 21st century necessary that combines the goals of 'sustainable development' with a 'sustainable peace' to cope with the 'survival dilemma' of humankind (Brauch 2008c; Oswald 2008; chap. 100 by Brauch/Oswald).

4.2.2 Securitization Theory

So far, the emerging policy debate on the security implication of GEC has not been guided by these fundamental scientific considerations on a sustainability science for the Anthropocene. The 'securitization theory'⁸ developed by Wæver (1995, 1997) and the Copenhagen school (Buzan/Wæver/de Wilde 1998) of

7 Thereof four are relevant for security studies, as e.g. 7: Which are the most vulnerable regions under global change? 8: How are abrupt and extreme events processed through nature-society interactions? 14: What are the most appropriate methodologies for integrating natural science and social science knowledge? and 23: What is the structure of an effective and efficient system of global environment and development institutions?

fers a theoretical approach for a conceptual mapping and analysis of the policy declarations ('speech acts') on the security impacts of climate change.

Wæver (1995; 1997: 221) argued that by declaring a development a security problem, or as an existential threat to sovereignty, the 'state' has been the major securitizing actor. "By saying 'security' a state-representative moves the particular case into a specific area; claiming a special right to use the means necessary to block this development." Wæver (1997: 224) suggested

"that a major focus of 'security studies' should be the process of securitization and de-securitization: when, why and how do elites label issues and developments as 'security problems'? when, why and how do they succeed and fail respectively? What attempts are made by other groups to press securitization on the agenda? And what are the cases of attempts to keep issues off the security agenda, to move below the security threshold or even to securitize issues that have been securitized?"

This first presentation was further developed by Buzan, Wæver and de Wilde (1998: 23-26) when they introduced 'securitization' as being "above politics" and as a "more extreme version of politicization." They argue that any public issue could be located in a spectrum between *nonpoliticized* (no state action is needed), *politicized* (requiring government decision and resources), and *securitized* (existential threat that requires emergency measures). They state that the *securitization* e.g. of environmental issues could also be enacted by non-state actors in declaring an issue as an existential threat that requires utmost priority that entitles an actor to use extraordinary means. "'Security' is thus a self-referential practice, because it is in this practice that this issue becomes a security issue - not necessarily because a real existential threat exists because the issue is presented as such a threat." They argue that 'securitization' is the result of an "intersubjective establishment of an existential threat with a saliency sufficient to have substantial political effects." This could be studied by focusing on "discourse and political constellations." But a discourse that presents "something as an existential threat to a referent object does not by itself create securitization - this is a securitizing move, but the issue is securitized only if and

when the audience accepts it as such." Securitization is fulfilled "by existential threats that legitimize the breaking of rules."

According to Buzan, Wæver, and de Wilde (1998: 26) a "successful securitization thus has three components: existential threats, emergency action, and effects on interunit relations by breaking free of rules." This implies for the analyst not "to assess some objective threats" but to "understand the shared processes of constructing a shared understanding of what is to be considered and collectively responded to as a threat." More recently, Wæver (2008a: 582) summarized securitization as:

the discursive and political process through which an intersubjective understanding is constructed within a political community to treat something as an existential threat to a valued referent object, and to enable a call for urgent and exceptional measures to deal with the threat. Other central concepts in the theory are 'referent object', 'securitizing actor', and 'audience'. The central idea of the theory is, that it is not up to analysts to try to settle the 'what is security?' question - widening to include the environment or narrowing to only military security - but more usefully one can study this as an open, empirical, political and historical question: who manages to securitize what under what conditions and how? And not least: what are the effects of this? How does the politics of a given issue change when it shifts from being a normal political issue to becoming ascribed the urgency, priority and drama of 'a matter of security'.

This securitization theory and the approach of the Copenhagen school on the widening of the security agenda and the deepening of the referent objects and actors has either been totally ignored (Kolodziej 2005) or critiqued by both representatives of narrow traditionalist and critical schools.

Booth (2007: 163-169) considered the concept of securitization "seriously flawed" and he described it as a "curious theoretical mixture of liberal, poststructural, and neorealist assumptions." He considered the approach of the Copenhagen school primarily state-centric and elitist and conservative with its emphasis on the audience that has to be convinced by a speech act. Booth (2007: 269) concludes that these ideas "do not advance the cause of a more progressive security studies," and he conceived security instead "as political theory, and understood in relation to emancipation." Contrary to Booth, Dannreuther (2007: 42-44) applauds the "implicit democratization of the field of security studies" by the Copenhagen school by analysing "how the general public, and their leaders, 'construct' security threats and challenges." He argues that "the securitization approach has provided the new 'se-

8 Much of the elaboration of this theory (Wæver/Buzan/Kelstrup/Lemaitre 1993; Buzan/Wæver/de Wilde 1998; Wæver/Buzan/de Wilde 2008) has occurred through exploring the particular dynamics and characteristics of security within different 'sectors' of security: economic, environmental, political, military, and societal. Brief introductions to the theory can be found at: <<http://polforsk.dk/download/securitytheory2006/homepage>>."

curity agenda' with a good potential theoretical base." But he also pointed to several shortcomings of the securitization approach, its subjective epistemology, its separation of the realism of politics and security, and the Eurocentric focus of its research agenda.

Below the 'securitization approach' will be used to structure and analyse the emerging policy debate on global environmental and climate change as a new subjective international, national, and human security concern whereby the 'securitizing actor' that produces the 'speech act' is not solely the nation state (government representatives, politicians) but also a transnational epistemic community of primarily natural scientists (IPCC). The referent objects are not only the state and the international community but primarily individual human beings and humankind who are both the cause of global warming and the victims of climate change. However, both actors are not identical, what has created major new equity problems (Adger/Paavola/ Huq/Mace 2006).

From a narrow and 'state-centred' national security perspective the 'securitizing actor' and the 'referent object' remains the nation state (its top government officials, policy-makers and the political elite), while from a wider environmental and deeper 'people-centred' societal or human security outlook the scientific community has become a new securitizing actor, and the referent object are not any longer the state but the vulnerable people that will be hurt most by these newly emerging security issues.

4.2.3 Conceptual Mapping

Three methods for the analysis of the word, term and concept of security, and for its 'reconceptualization' have been distinguished: a) *etymology* (word, term, concept) of security, b) *conceptual history* (Koselleck 2006), and c) *conceptual mapping* (Brauch 2008: 34; 2008a: 65-67). The third method of a 'conceptual mapping' was introduced as "the use of the concept of security in different countries, political systems, cultures and religions and scientific disciplines, in national political processes, within civil society and social movements, but also as a guiding and legitimating instrument within international organizations. Any conceptual mapping has to reflect the specific context in time and space that influence the meaning and the use of concepts." It was further argued that "in the social sciences, especially ... in security studies, the meaning of the concept of security is theory-driven." Therefore, "the 'conceptual mapping' of security ... is a task of political science that requires the knowledge

of other disciplines (linguistics, history, philosophy) with a specific focus on the theoretical approaches prevailing in the social and political sciences" (Brauch 2008a: 67).

In this chapter, this method is not used to 'map' the diversity of the manifold contemporary uses of this contested concept but to document how this concept has been applied - both in scientific discourses and policy debates - to issues of GEC and GCC to 'move' a scientific issue to the top policy agenda thereby legitimating extraordinary measures for coping with this new danger, and to document how this 'securitizing move' has been convincing a rapidly growing global audience to recognize and to approve the high costs of proactive adaptation and mitigation measures. Thus, this method is used to analyse the evolution of policy declarations (or 'speech acts') by scientists, policy analysts, and representatives of states and international organizations that have referred to the regional security impacts of GEC and global climate change (GCC), especially in highly vulnerable regions (hotspots) with a high exposure, high social vulnerability, and a limited coping capacity being confronted with three impacts of global climate change: i) temperature increase, ii) sea level rise, and iii) increase in the number and intensity of natural hazards.

With this *securitization* of GEC and GCC, these security dangers and concerns have been given highest priority on the policy and security agenda to legitimate extraordinary and costly measures that require a progressive increase in energy efficiency and a decarbonization of the energy system by increasing renewable energy sources but without creating serious food security challenges that have already resulted in spring 2008 in several poor and food importing countries in violent food riots (e.g. in April 2008 in Haiti). The *securitization* of issues of GEC and GCC has thus become a policy tool for the justification of the allocation of significant public funds in terms of 'international' (in most EU countries), or 'national security' (primarily in the USA) but also of 'human security' (in countries of the Human Security Network, see chap. 75 by Fuentes/Brauch).

4.2.4 Models for Nature – Human Interactions

The conceptual mapping of the *securitization* of issues of GEC and GCC documents the scientific discourse and the policy debate on the security impacts of climate change. It does not argue whether past cli-

mate history reflecting the impacts of natural variability and not yet of anthropogenic climate change (chap. 5 by Blümel; chap. 6 by Issar/Zohar) resulted in violent conflicts and in the climate-induced collapse of civilizations, nor does it assess the probability of extreme societal outcomes: internal displacements, forced migration, crises and conflict constellations from anthropogenic climate change in the 21st century (Fagan 2000; 2004; Diamond 2005; Linden 2006; Zhang/Brecke/Lee/He/Zhang 2007; Scheffran 2008).

Various models have been developed to analyse the nature-human interactions. Below five such models will be briefly introduced. *First*, three pressure-state-response models will be sketched for the analysis of environmental issues (e.g. of pollution); *second*, the models used by the Toronto and Swiss schools on linking environmental scarcity, degradation, and stress with potentially violent societal outcomes will be noted (4.2.4.2), and *third*, this author's PEISOR model⁹ will be outlined (4.2.4.3) that integrates elements of the two previous models; *fourth*, different vulnerability frameworks for dealing with natural hazards and societal disasters will be reviewed (4.2.4.4), and *fifth* a model for analysing the linkages between climate change and armed conflicts as a new security danger will be reproduced (4.2.4.5).

4.2.4.1 Pressure-State-Response Models of OECD, UNCSO, and EEA

Instead of a simple stress-response model that claims direct links between stress factors and societal responses, the *Pressure-State-Response* (PSR) model of OECD (1994; 1998; 1999; 2001; 2001a) assumes that human activities put pressure on nature that leads to environmental changes (climate change, water and soil degradation, biodiversity loss) to which the government and society respond with ecological and economic measures and programmes.

The OECD's PSR model distinguished between 'pressure' (P), 'state of the environment' (S), and 'response' (R) indicators. Among 'pressure' key factors are listed (population growth, consumption, poverty), while 'state' refers to the environmental conditions that emerge from this pressure (air pollution, defor-

estation, degradation) that influence human health and well-being, and 'response' points to the manifold activities of society to avoid, prevent, and reduce negative impacts on the environment, and to protect natural resources from these effects. Among the *pressures* are human activities in the energy, transport, industry, and agricultural sector on natural resources (air, water, soil, organisms) to which the state, society, business, and international actors respond. Between these three elements of the PSR model there are many complex interactions (resource transfers, information, decisions)¹⁰.

The UN Commission for Sustainable Development (UN-CSD) used with its DSR (*Driving Force-State-Response*) model a slightly modified framework.¹¹ The *European Environment Agency* (EEA 1998) has developed a framework that distinguishes "Driving Force - Pressure - State - Impact - Response (DPSIR)"¹² that offers a mechanism for the analysis of environmental problems and for the development of environmental indicators (figure 4.3).¹³

A different model was used as a framework for the *Millennium Ecosystem Assessment* (MA 2003, 2005) that distinguished between direct and indirect drivers of change that directly affect human well-being and ecosystem services. In this framework besides the material minimum for a good life, health, and good social relations, security is considered as one of the key elements of human well-being that influence freedom of choice (figure 3.1). Security has been defined as: a) the ability to live in an environmentally clean and safe shelter, and b) the ability to reduce vulnerability to ecological shocks and stress (MA 2005; chap. 3 by Lee-mans). In the words of the *Human Security Commission* (CHS 2003) this refers to two basic principles: 'protection' and 'empowerment'. These four models have served a specific purpose: to develop environ-

9 The PEISOR model is still in the process of development and has been discussed for the first time at the 6th Open meeting of IHDP in Bonn in October 2005 (Brauch 2005b). The evolution is documented in this author's download section at: <http://www.afes-press.de/html/download_hgb.html>. This section draws on Brauch (2007h: 26–29).

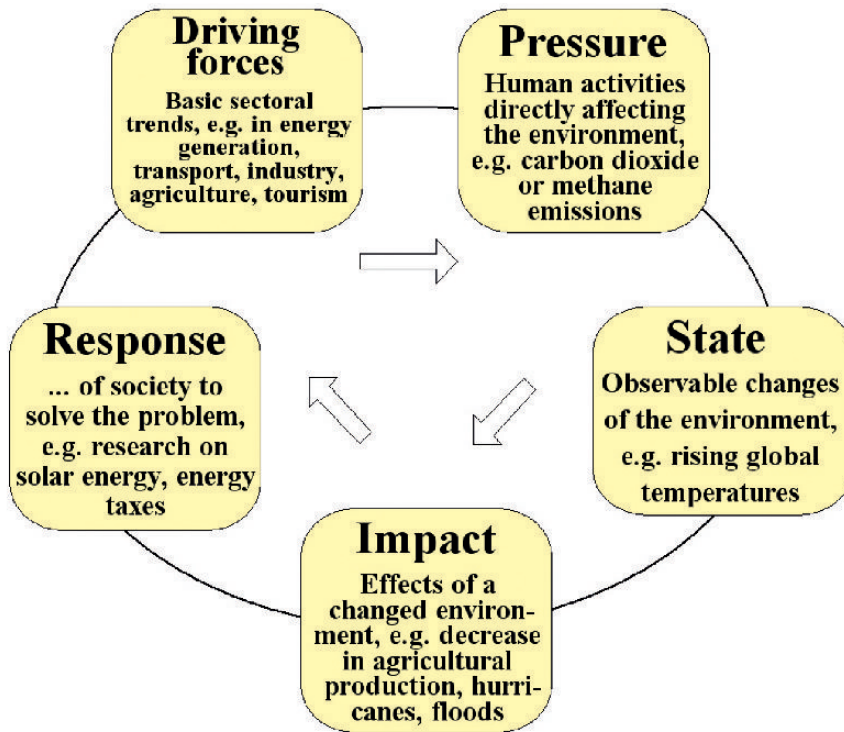

10 Jesinghaus (n.d.), at: <http://esl.jrc.it/envind/theory/handb_03.htm>: The PSR model was developed in the 1970's by the Canadian statistician Anthony Friend, and subsequently adopted by the OECD's *State of the Environment* (SOE) group; for an illustration see at: <<http://www.virtualcentre.org/en/dec/toolbox/Refer/EnvIndi.htm>>.

mental indicators and to guide the ecosystem assessment. But they did not focus - from a security perspective - on the linkages between processes of GEC, GCC and natural hazards and their socio-political consequences.

4.2.4.2 The Models on Environmental Scarcity, Degradation, and Stress

The Toronto Group analysed assumed linkages between environmental stress factors and conflicts (Homer-Dixon 1991, 1994). Homer-Dixon (1994: 39) argued: “that environmental scarcity causes violent conflict. This conflict tends to be persistent, diffuse, and sub-national.” He assumed that “global warming will probably not have a major effect for several decades, and then mainly by interacting with already existing scarcities” (see figure in Homer-Dixon, 1994: 31). Levy (1995: 35-62) commented that it “is of very little importance” that environmental problems constitute security risks for the USA, and he argued “that ozone depletion and climate change are the only significant environmental problems that currently pose a direct physical harm to US interests” (61-62). In reply, Homer Dixon (1995: 189) argued that climate change “could endanger core American values” and thus

could become “direct threats to US security interests,” but not in the near-term.

A second project analysed the links between environment, population, and security based on case studies (Homer-Dixon/Blitt 1998) that focus on the social consequences of renewable resource scarcity. They argued that under certain circumstances scarcity of these resources may cause violent conflict. They focused on six types of environmental change: water and land degradation, deforestation, decline in fisheries, and to a lesser extent global warming and ozone depletion that can produce scarcities of vital renewable resources. They distinguished among “supply-induced” (environmental change), “demand-induced” (population growth, per capita consumption); and “structural” scarcity (unequal social distribution of a resource).

They discussed two patterns of interaction among these three types: *resource capture* by powerful groups, and *ecological marginalization* resulting in a lack of access for the poor segments of the society that are often forced to migrate to ecologically fragile and vulnerable regions. Such environmental scarcity is not determined to result in social disruption and violent conflict. But different adaptation failures, such as market failure, social friction, and the lack of capital

availability may produce five types of social effects: “constrained agricultural productivity, constrained economic productivity, migration, social segmentation, and disruption of legitimate institutions.” They considered environmental scarcity as a cause that interacts with various contextual factors ranging “from the nature of relations among ethnic groups to the state’s degree of autonomy from outside pressure groups.”

Homer-Dixon (1999: 5) pursued the linkages between environment, scarcity, and violence, looking to five future types of likely violent conflicts that third world countries will be less able to prevent: 1) disputes from local environmental degradation; 2) ethnic clashes arising from population migration and deepened social cleavages; 3) civil strife (insurgency, banditry, coups d’état); 4) interstate war (on water), and 5) North-South conflicts over global environmental problems (global warming, ozone depletion, biodiversity). He considers the first and last type unlikely, and interstate scarcity wars as least likely. He discussed the scarcity’s causal role between: *Environmental Scarcity* → *Social Effects* → *Violent Conflict*. While he admits that scarcity as such is neither a necessary nor a sufficient cause of conflict, he claims “that environmental scarcity is an important cause of these conflicts” (Homer-Dixon 1999: 8). Among the major determinants of supply-induced environmental scarcity that contribute to the depletion and degradation of renewable resources, Homer-Dixon (1999: 50) referred to a) *ideational factors* (social relations, preferences and beliefs), b) *physical availability* of natural resources, and c) *ecosystem sensitivity* that impact on population and resource consumption (energy → global warming; cropland scarcity → deforestation; fresh water). With continued population growth, the decrease in quality of renewable resources can either result in a) *resource capture* (via unequal resource access) or b) *unequal resource access* (figure 20.4).

After a decade of research, Homer-Dixon (1999: 177) concluded: “that scarcity of renewable resources ... can contribute to civil violence, including insurgencies and ethnic clashes” and he predicted that in the future “such violence will probably increase as scarcities of cropland, freshwater, and forests worsen in many parts of the developing world,” where the role of scarcity will be “often obscure and indirect,” interacting with political, economic, and many other factors. He further predicted that continued population growth and rising resource demand and persistent inequalities will affect environmentally sensitive regions.

The *Environment and Conflicts Project* (ENCOP), co-directed by Günther Bächler and Kurt R. Spillmann (Bern and Zürich group), started from the premise that environmental transformation does not directly result in conflicts but that it impacts on existing socio-economic conflict potentials that violently escalate. According to its working definition:

environmental conflicts manifest themselves as political, social, economic, ethnic, religious or territorial conflicts over resources or national interests, or any other type of conflict. They are traditional conflicts *induced by environmental degradation*. Environmental conflicts are characterized by the principal importance of degradation in one or more of the following fields: a) overuse of renewable resources; b) overstrain of the environment’s sink capacity (pollution); c) improvement of the space of living (Libiszewski 1992: 13; Bächler 1998: 24).

According to ENCOP’s analytical framework (Bächler 1993; Libiszewski 1992, 1996: 339–340) the analysis of environmental conflict followed four steps: 1) to describe the environmental situation on the background of human activities; 2) to deduce the social and economic effects of environmental transformation and degradation; 3) to analyse the political implications of these socio-economic effects and conflicts arising from them; and 4) to evaluate approaches to peaceful management and resolution on different levels of analysis. ENCOP concluded that besides resource degradation other contextual factors were decisive for conflicts,¹⁴ and “while conflict and environmental change are related in many ways, conflict is more likely to be linked directly to the disruptions of modernity” (Dalby 2002a: 97). In a study on Rwanda, Bächler (1999) clarified the ENCOP model and stressed “that violence was to occur in more remote areas, mountain locations, and grasslands – places where environmental stress coincides with political tensions and unjust access to resources” (Dalby 2002: 97).¹⁵

Bächler (1998: 24–44) examined “the critical role of transformation regarding causation on environmental conflicts in certain areas of developing countries.” To do so one has “to build on prepared empirical ground to highlight the different patterns of causation, to select types of environmental conflicts in terms of different pathways leading to violence, as well as to stress the socio-political characteristics of environmental conflicts”. Bächler (1998: 24) concluded

14 Bächler 1998, 1999. For reviews at: <<http://www.uni-bonn.de/iwdp/gechssp.htm>>: 13–14; Dalby 2002: 97.

that neither apocalyptic scenarios of environmental catastrophes nor alarmist prognoses of world environmental wars are tenable. Environmentally-caused conflicts escalate across the violence threshold only under certain conditions. Human-induced environmental change can be either a contributing or a necessary factor for both the emergence and/or the intensification of violent conflicts. On one hand, violent conflicts triggered by environmental disruption are due in part to socio-economic and political developments. On the other, social and political maldevelopment, due in part to degradation of natural resources, has become an international peace and security challenge. *Development and security dilemmas* are connected to a syndrome of problems which produces environmental conflicts of varying intensity and nature.

Bächler (1998: 40–44) provided a typology of 40 environmental conflicts with different conflict intensity he categorized as: 1) *intrastate* a) ethnopolitical, b) centre-periphery, and c) regionalist migration/displacement conflicts; 2) *intrastate* conflicts with a trans-boundary dimension, caused by a) migration, b) demographic pressure, and c) water/river basin conflicts (28–39); and 3) *international* global environmental conflicts.

Both approaches had a significant impact by developing an empirical basis for the primarily policy-oriented discourse that added an environmental dimension to the US national security agenda in the post-Cold War era which succeeded during the Clinton administration but was discontinued during the administration of George W. Bush (chap. 60 by Matthew/McDonald).

Why a critical socio-economic constellation escalated into violent conflict, and when and why they could be avoided by bilateral and multilateral cooperation of states, experts, and representatives of civil society could not yet be explained by these studies.¹⁵ After a decade of research a consensus emerged that

“environmental stress is rarely considered to be the sole factor in precipitating conflict” both within and between nations. Schwartz (2002: 137) stated:

In many cases environmental stress is a relatively distant factor, acting in combination with other economic and social factors such as poverty and weak governments. In other cases, conflict breaks out when rival nations, or rival groups within a nation, battle for diminishing supplies of environmental resources. Although environmental stress is usually only one cause of conflict among many, the evidence suggests that it can play an important role, and that violence may be avoided by addressing environmental problems.

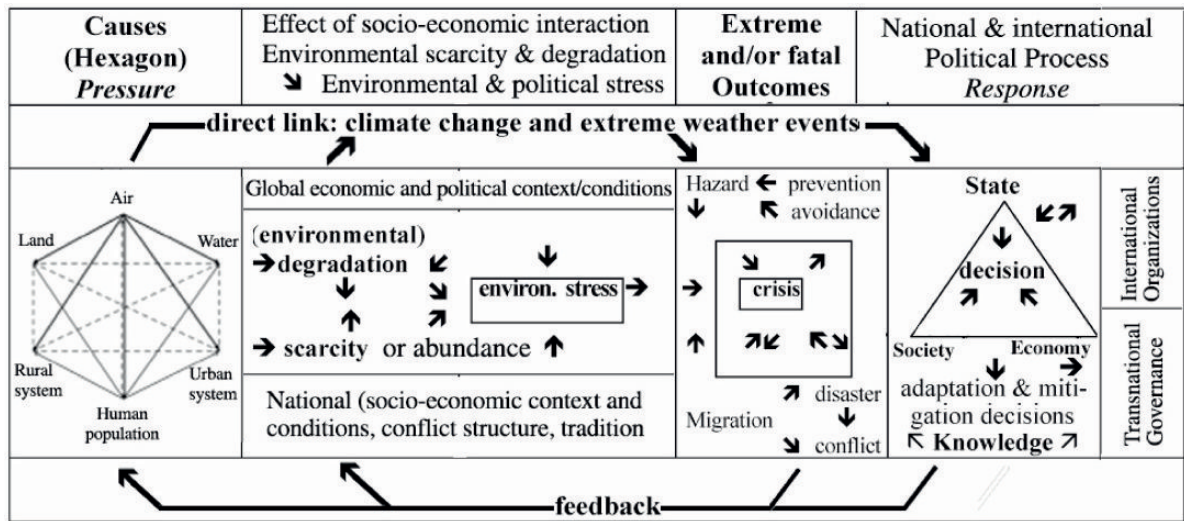

Schwartz considers population growth as closely linked with environmental stress. Among the wide-ranging environmental factors he includes ozone depletion and global warming, and among the localized ones those environmental factors that affect small areas at different times (desertification, water pollution). He points to “five pathways to indirect internal conflict that involve environmental stress: economic decline, migrations, social fragmentation, erosion of civil society, and curtailment of the state.” A major effect of several types of environmental stress is economic decline that will affect the poor more than the rich strata of society and countries. A second pathway from environmental stress to conflict is through migration that may be caused by floods, droughts or locusts, or by a lack of arable land that again is often the result of environmental stress, but also by water and air pollution, or shortage of fuel wood. The complex interaction of environmental stress and its social, economic, and political ramifications has often resulted in increasing urban violence.

Global and localized environmental stress may in some cases contribute to conflicts. Gleick (1989) noted that global warming could affect freshwater availability and food productivity, and that this would have severe impacts on poorer nations. Some argued that environmental stress coupled with rapid population growth could induce large-scale migration pressures from South to North, and that this may increase tensions between host countries and immigrants. Direct internal conflict has occurred as a result of environmental stress, e.g. in the Sahel (due to drought) where many nomads clashed with farmers in less affected zones. Schwartz argues that causal linkages be-

15 The results of the ENCOP project were published in three volumes, of which the first volume (Bächler/Böge/ Klötzli/Libiszewski/Spillmann 1996) examined the environment as a topic of conflict research, environmental degradation through over-development (*wealth-driven*) and underdevelopment (*poverty-driven*) focusing on actors, on key environmental factors of soil, rivers, and mining. It offered a synthesis on environmental degradation as a cause of war and how environmental conflicts can be solved peacefully. The second volume contains eight case studies on Bangladesh, Sudan and Darfur, Nigeria, Central Asia, the Jordan Basin, Rwanda and on mining in the South Pacific (Bächler/Spillmann 1996a). The third volume includes thirteen country studies by external experts (Bächler/Spillmann 1996b).

16 This approach was criticized by Diehl/Gleditsch (2001); Peluso/Watts (2001); Hartmann (2001: 39–62); Bannon/Collier (2003); see overview in Brauch (2003, 2007) EOLSS [Four Phases of Research].

Figure 4.4: PEISOR-Model. Source: Brauch (2005a: 16, 2007h: 28).

tween environmental stress and conflict could be shown in individual case studies, but that future research is needed “to estimate the causal effects of environmental stress.” Kawashima and Akino (2001), Strippel (2002), and Brauch (2002) discussed possible longer-term security implications of climate change.

Hauge and Ellingsen (1998) integrated environmental degradation (soil erosion, deforestation) into a model of civil war. They concluded: “that environmental degradation does stimulate the incidence of conflict, but less so than political, economic, and cultural factors, or previous conflict history.” Saltnes (1998) found that “there was indeed a bivariate relationship between the spread of deserts and internal armed conflicts in the period 1980–1990”, Gleditsch (2002) suggested that resource and environmental aspects of conflict “should be examined within the context of a broader view of armed conflict” with a special focus on politics, economics, cultural factors, and the conflict history.

4.2.4.3 The Emerging PEISOR Model

The PEISOR model was stimulated by the pressure and response models and by the debates on environmental security (chap. 20: by Homer-Dixon/Deligianis; chap. 21 by Mason/Hagmann/Bichsel/Ludi/Arsano) and on natural hazards. The PEISOR model (Brauch 2005, 2006) combines five stages:

- P (pressure) refers to six drivers of global environmental change (survival hexagon);
- E to the effects of the linear, non-linear or chaotic interactions within the ‘hexagon’ on environmental scarcity, degradation, and stress;

- I to extreme or fatal impacts of human-induced and climate-related natural hazards (storms, flash floods, flooding, landslides, drought);
- SO to societal outcomes: internal displacement, migration, urbanization, crises, conflicts, state failure, and
- R to response by the society, the business community, the state where both traditional and modern technological knowledge can make a difference.

While hazards cannot be prevented, their impact in terms of deaths, affected people, economic and insured damages can be reduced by a combination of policies and measures that link protection with empowerment of the people to become more resilient.

Figure 4.4 refers in the first column under causes or pressure to six key factors contributing to GEC, three supply or environmental factors (land, air, and water) and three demand or human factors (population living and working in rural or urban systems). These six factors interact in a non-linear or sometimes chaotic way, and pose pressure on the political and societal context where they may trigger, impact or affect socio-economic interactions either causing or contributing to anthropogenic environmental degradation (of water, soil, air) or scarcity (of water and soil). The interaction among these two processes may result in environmental stress that can cause various extreme and in a few cases even fatal impacts.

However, there may also be a direct impact of climate change resulting in an increase in hydro-meteorological hazards. This aspect has only marginally been addressed in the initial stages of environmental security research (chap. 59 by Dalby/Brauch/Oswald) but

it is key to the debate on the *securitization* of climate change. Environmental stress may increase the impact of hazards (especially for those with a high degree of social vulnerability) and cause or contribute (with natural hazards and conflicts) to internal displacement, urbanization, and to transboundary forced migration.

Whether these factors result in domestic crises, disasters, and in a few worst cases in violent conflicts, or whether these can be avoided, depends on many specific factors and activities resulting from the interaction between the three actors representing the state, the society, and the business community, but also on the use of both traditional and modern technical and organizational knowledge and knowledge-based response strategies by governments and international organizations and transnational societal and economic organizations (governance).¹⁷

4.2.4.4 Vulnerability Frameworks for Hazards and Disasters

For natural hazards and societal outcomes, complex vulnerability frameworks were developed. Bohle (2001) distinguished a dual structure of vulnerability by referring to ‘external’ or ‘environmental vulnerability’ that points to exposure and is influenced by political economy approaches, human ecology perspectives and theories of entitlement, and to ‘internal’ or ‘social vulnerability’ that highlights coping and is dealt with in crisis and conflict theory and influenced by approaches from action theory and models of access to assets. On this conceptual background Bohle (2002) illustrated the conceptual relationship between globalization, contributing to social vulnerability, and GEC resulting in environmental vulnerability, and how both impact on human security.¹⁸ Clark, Crutzen, and Schellnhuber (2004: 18–19) relied on a framework for vulnerability analysis in sustainability science (figure 4.5)

whose basic architecture consists of:

(i) linkages to the broader human and biophysical (environmental) conditions and processes operating on the coupled system in question; (ii) perturbations and stressors/stress that emerge from these conditions and processes; (iii) the coupled human-environment system of concern in which vulnerability resides, including exposure and responses (i.e., coping, impacts, adjustments, and adaptation). These elements are interactive and scale dependent, such that analysis is affected by the way in which the coupled system is conceptualized and bounded for study. The full framework is illustrated in figure [4.5] by way of spatial scale, linking place (blue) to region (yellow) to globe (green). ... The coupled human-environment system ... constitutes the place of analysis.

These two vulnerability frameworks and the BBC model (chap 18 by Bogardi, Birkmann, Gebert, and Setiadi, figure 18.1) cannot be used for the analysis of the causal path of the security issues posed by GEC and GCC via (i) temperature increase, (ii) sea-level rise, and (iii) growth in the number and intensity of hydro-meteorological hazards and the manifold extreme and in some cases even fatal societal outcomes, such as internal displacements, forced migration, as well as domestic and transborder small-scale conflicts, and in the least likely event even wars (Brauch 2002, 2002a).

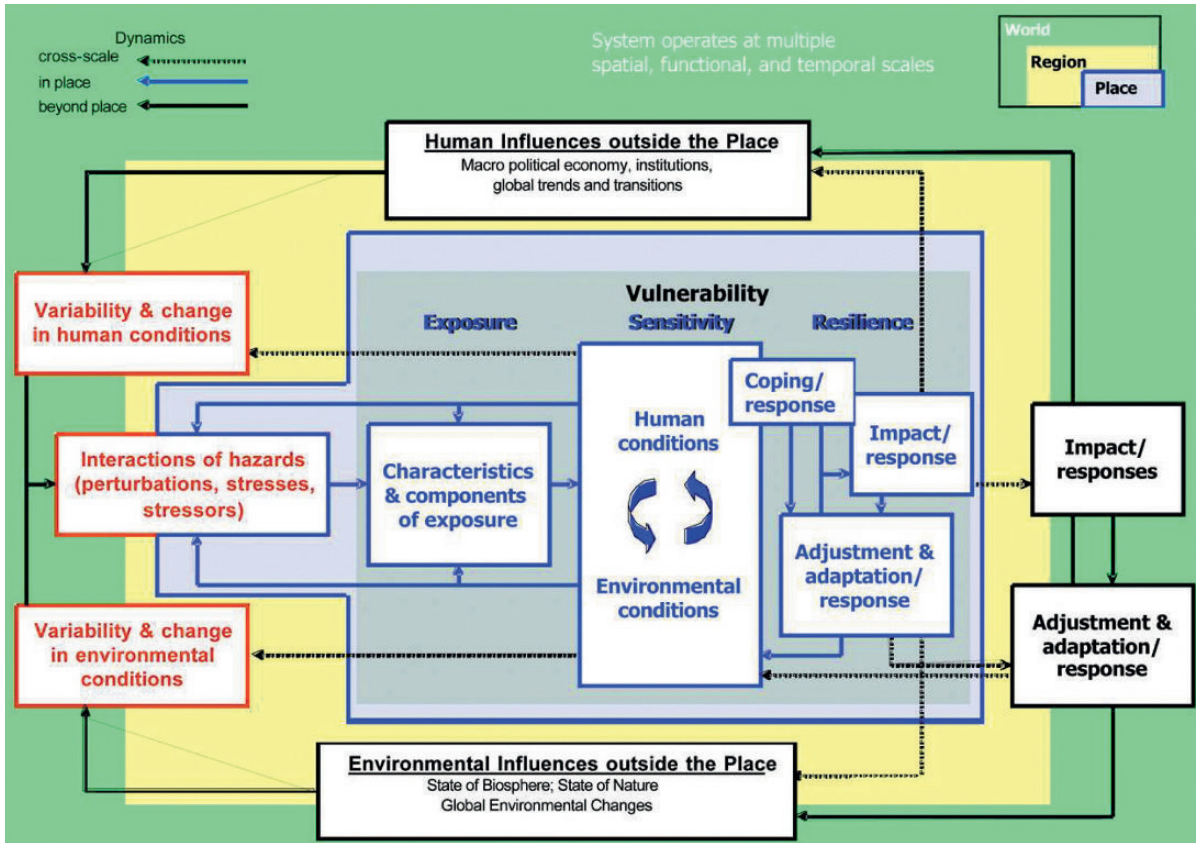

4.2.4.5 Model for the Analysis of Climate Change and Armed Conflict

For a World Bank conference, Bulhaug, Gleditsch, and Theisen (2008) assessed the peer-reviewed primarily statistical literature on “Implications of Climate Change for Armed Conflict.” They distinguished among three physical effects causing a reduction in livelihood and several catalysts (migration, political and economic instability, social fragmentation, and inappropriate response) that may lead to armed conflict. They point to possible pathways to conflict, referring to migration as the first outcome that is influenced by population pressure, political (bad governance, societal inequalities, bad neighbours) and economic factors (food insecurity, reduction of livelihood) that lead to five intermediary factors of political and economic instability, social fragmentation, inappropriate response (policy failure), and to migration. These factors may offer an increased opportunity for organizing and instigating violence resulting in armed conflict where at least one party is the government of a state and at least 25 battle related deaths occur within a year. This conflict definition excludes small-scale violence, e.g. tribal clashes between

17 The PEISOR model was illustrated for the impacts of the six factors of global environmental change on the environmental dimension of human security for the Mediterranean space during the 20th and 21st century with regard to the repercussions on landscape ecology by posing new challenges to environmental and human security. See especially: Brauch (2001; 2006; 2007h); see also for speeches by the author in Lecce (2004), Bonn (2005), Israel, Mexico and Thailand (2006), at: <http://www.afes-press.de/html/download_hgb.html>.

18 This argument by Bohle (2001, 2002) has been summarized in Brauch (2003: 132–133) where the figure on the conceptual linkages between globalization, GEC and human security is reproduced.

Figure 4.5: Vulnerability framework. Components of vulnerability identified and linked to factors beyond the system of study and operating at various scales. **Source:** Turner/ Kasperson/Matson/McCarthy/Coell/Christensen/Eckley/Kasperson/Luerse/Martello/ Polsky/Pulsiphera/Schiller 2003: 8076). Reprinted with permission.

herders and resident farmers, mass protests, and food riots.

Bulhaug, Gleditsch, and Theisen (2008: 30) concluded that “in contrast to the rich causal stories presented in the case literature, statistical comparative studies on the subject tend to model the scarcity-conflict relationship in rather simplistic ways.” They claim that the available statistical literature has so far produced little convincing evidence of a direct link between climate change and armed conflict, and that no study has tested links between natural hazards and conflicts. A major limitation of previous research has been that it addressed only the most severe forms of organized violence, and has excluded violent clashes between herders and resident farmers, e.g. in the Sahel zone to which many case studies refer (Kahl 1988, 2002, 2003, 2006; Martin 2005; Suliman 1993, 1999, 1999a).

At the same conference Raleigh, Jordan, and Salehyan (2008) addressed the impact of climate change on migration and conflict by analysing the migration potential of droughts and famines, floods and land-

slides, cyclones, hurricanes and waves, extreme temperature and sea level rise. They offered a typology of direct and indirect environmentally induced migrants leading to internal and distress migration resulting in local displacement, in some cases in permanent relocation and resettlement. They argued that government policies can influence the vulnerability and coping through resilience building. This paper dismissed the ‘securitization’ of the issue and called for “a focus on the development component of vulnerability to climate change” (Raleigh/Jordan/Salehyan 2008: 40). They based their judgement on previous comments (Levy 1995; Gleditsch 1998; Barnett 2000) on the environmental security debate that had not addressed climate change as a cause of conflicts.

In their extensive bibliography, Bulhaug, Gleditsch, and Theisen (2008: 41–49) did not include scientific reports commissioned by governments (BMU 2002), by scientific advisory groups of governments (Stern 2006; WBGU 2007, 2008), and by international organizations (IPCC 2001a, 2007; UNDP 2007/2008; OECD 2008) that according to the IPCC

rules may be included in its assessment along with peer-reviewed research. They argued that “the public debate on the security implications of climate change have been dominated by NGO reports, national security, and statements by national and international public officials”. They noted an overlap between present conflict-ridden countries and regions with serious projected climate change impacts (figure 4.7) that also partly overlap with the hotspots with projected climate change impacts on conflict constellations (WBGU 2008: 4; figure 4.7).

Given the lack of both structured, focused, and comparable cases studies (George/Bennett 2005) addressing the complex causal chain (figures 4.4) and non-existing statistical research based on a large number of cases, it is premature to conclude whether and which causal linkages have existed between physical and social effects of climate change and their impacts on internal displacement, distress migration, domestic crises, and conflicts.

But neither comparative case studies nor statistical research can analyse potential conflict constellations in vulnerable hotspots and in a world where the average annual temperature has increased by 2 °C (virtually certain), or 4 °C (still probable) or even 6 °C (possible under business as usual scenarios) by the end of this century.

This requires both different methods (modelling, simulation, and scenario analysis) of nonlinear interactions that may lead to tipping points of the climate system.¹⁹ “In response to anthropogenic climate forcing, a small perturbation at a critical point could qualitatively alter the future fate of the system. Such changes could be triggered this century and would undergo a qualitative change within this millennium.” Lenton, Held, Kriegler, Hall, Lucht, Ramstorf, and Schellnhuber (2008: 1186) pointed to the melting of

the Arctic sea-ice, rapid changes in the Greenland and in the West Antarctic ice sheet, a shutoff of the Gulf Stream (Atlantic Thermohaline Circulation), changes in the El Niño-Southern Oscillation (ENSO), in the Indian summer monsoon, in the Sahara/Sahel and West African monsoon, a drying of the Amazon basin and changes in boreal forests. These possible abrupt climate changes could trigger serious consequences for international and national security (Schwartz/Randall 2003).

While the regions where presently conflicts cluster (figure 4.7) and the hotspots with significant security impacts of climate change (figure 4.9) partly overlap, the regional impacts of possible tipping points (figure 4.8) in the climate system may seriously affect all parts of the globe, especially also the North Atlantic region, including Northern and Central Europe.

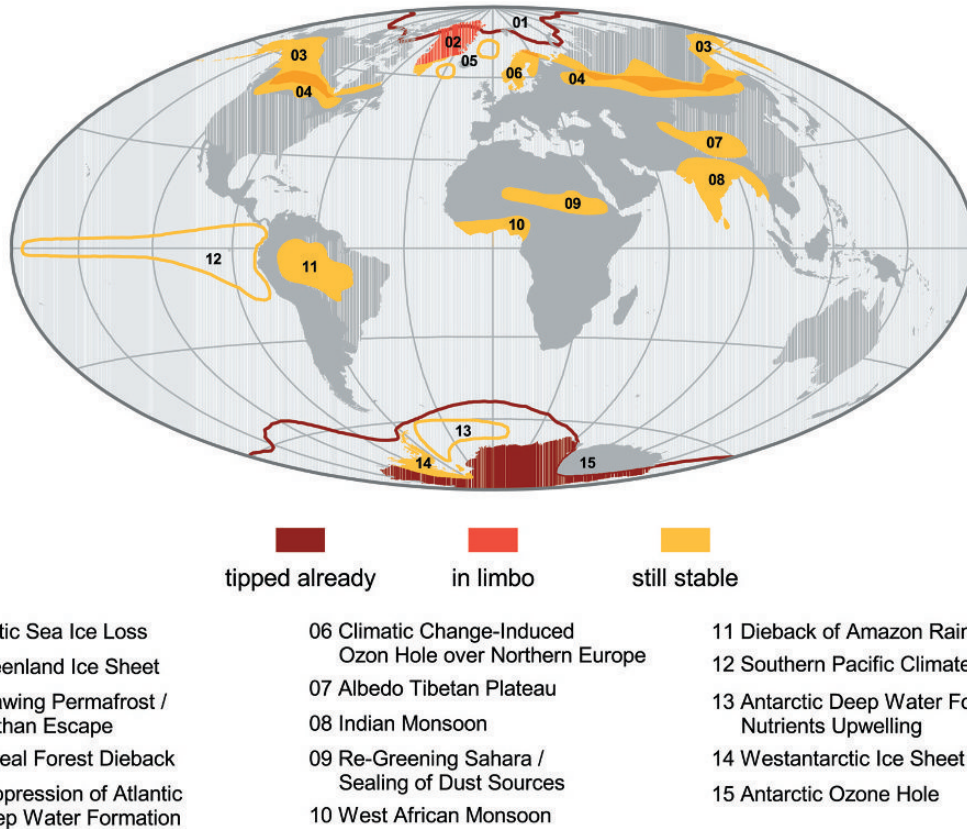

4.2.5 Securitization of Societal Outcomes and Policy Response

While the PEISOR model (figure 4.4) focuses on a sequence of *pressures* resulting from the interaction of natural and social system components, their *effects* on the socio-economic-political context, as well as on their *impacts*, *societal outcomes* and *policy responses*, the vulnerability framework (figures 4.5) systematically couples the nature-society systems from the perspective of hazard impacts (relationship between exposure, vulnerability, and resilience). In the interaction between the state, society, and the economic sector, multidisciplinary knowledge creation and application for sustainability and for coping with climate change impacts plays a key role for supporting the coping activities of state, societal, and economic decision-makers.

The model suggested by Bulhaug, Gleditsch, and Theisen (2008) on possible pathways between climate change impacts and an increased risk of armed conflict reduces the analysis of GEC and GCC to two physical effects of sea level rise and increase in hydro-meteorological hazards, and it includes an increasing resource scarcity. Their model does not discuss the security impacts of different temperature increase scenarios, of different climate conflict constellations (WBGU 2008), and nor does it reflect on geographic hotspots and tipping points. The complex interactions between the six components of the ‘survival hexagon’ (figure 4.4) are beyond the scope of their analysis, nor are the complex interactions between climate change, desertification, and biodiversity loss (MA 2005) being addressed.

19 Lenton, Held, Kriegler, Hall, Lucht, Ramsdorf, and Schellnhuber (2008: 1186) argued that the term ‘tipping point’ has been used in discussions of global change “to describe a variety of phenomena, including the appearance of a positive feedback, reversible phase transitions, phase transitions with hysteresis effects, and bifurcations where the transition is smooth but the future path of the system depends on the noise at a critical point”. They offered “a formal definition, introducing the term ‘tipping element’ to describe subsystems of the Earth system that are at least subcontinental in scale and can be switched - under certain circumstances - into a qualitatively different state by small perturbations. The tipping point is the corresponding critical point - in forcing and a feature of the system - at which the future state of the system is qualitatively altered”.

Figure 4.6: Map of potential policy-relevant tipping elements in the climate system. **Source:** Lenton, Held, Kriegler, Hall, Lucht, Ramstorf and Schellnhuber (2008: 1187). Reprinted with permission.

According to Clark, Crutzen, and Schellnhuber (2004: 19) the synthetic efforts of the vulnerability framework:

have also drawn attention to the parallels between climatic and chemical ‘life-support systems’ long discussed by Earth science researchers, the elements of ‘livelihood security’ (e.g. access to and use of resources) stressed by development practitioners, and the newer emphasis by ecologists and resource economists on ‘ecosystem services’.

In their view “management systems for a sustainability transition need to be systems for adaptive management and social learning that require information, incentives, and institutions that must mobilize the right knowledge, integrate different sources of knowledge, balance flexibility and stability, and to build up an infrastructure and capacity.” To achieve this ambitious goal they suggested a “new contract for planetary stewardship” between the scientific and political sector (Clark/Crutzen/Schellnhuber 2004: 19–24).

For the analysis of the process of *securitization* of GEC and GCC, the models reviewed above are not of less importance, nor had the claims that were made

during the ‘securitizing move’ to be supported by peer-reviewed social science research. But the *securitization* of GEC and GCC has already triggered a political demand for systematic multi-, inter-, and transdisciplinary research, and monitoring of these claimed causal or probabilistic linkages to build up knowledge that will support policies to recognize (early warning of climate related security risks) and to cope with these security dangers in a proactive way before they lead to violent conflicts. Thus, the claimed linkage between climate change and conflicts has been an additional legitimating component or the ‘securitizing move’ with regard to GEC and GCC.

4.3 Securitizing Global Environmental Change

The year 2007 was a turning point in the reconceptualization of security debate when the *Intergovernmental Panel on Climate Change* (IPCC) released its *Fourth Assessment Report* (AR4) in four parts in February in Paris (WG I on the *Physical Science Basis*,

IPCC 2007), in April in Brussels (WG II on the *Impacts, Adaptation and Vulnerability*, IPCC 2007a), in May in Bangkok (WG III report on *Mitigation of Climate Change*, IPCC 2007b), and in November in Valencia (*AR4 Synthesis Report*, IPCC 2007c).²⁰

These four reports – whose ‘Summary for Policy-makers’ had to be approved by government representatives – set the stage for a global debate on the security implications of three different climate-induced worlds: a) of a global average increase of temperature up to 2°C by 2100 which the European Union hopes to achieve; b) of a global average increase of temperature up to 4°C by 2100; or c) of a global average increase of temperature up to 6°C by the end of this century which would seriously impact on the well-being and survival of humankind, and thus also on security policy. In addition, the projected increase in the sea level will seriously threaten delta and coastal regions, while the projected increase in the number and intensity of hydro-meteorological hazards may result in an increase of human victims, persons affected, and in economic damages. The projected impacts of temperature increase, sea level rise, and natural hazards will pose severe societal and political challenges for the affected regions and countries that can possibly lead to multiple security threats, challenges, vulnerabilities, and risks that can force people to migrate, to protest and rebel, and in the worst cases may lead to small-scale violence and possibly also to armed resource conflicts.²¹

On 17 April 2007, the United Nations Security Council addressed for the first time climate change as an international security issue²² and from 29 July to 2 August 2007 the UN General Assembly held a special thematic debate on *Climate Change as a Global*

Challenge.²³ In June 2007, at the G-8 meeting in Heiligendamm (Germany) the heads of states and/or governments agreed ... “in setting a global goal for emissions reductions” that they will “consider seriously the decisions made by the European Union, Canada and Japan which include at least a halving of global emission by 2050.”²⁴ Thus, climate change, as an aspect of global environmental change, was increasingly addressed as a new objective security danger and subjective security concern for the livelihood and survival of humankind in this century.

On 12 October 2007, the Norwegian Nobel Committee awarded the Nobel Peace Prize to both the IPCC and to Al Gore “for their efforts to build up and disseminate greater knowledge about man-made climate change, and to lay the foundations for the measures that are needed to counteract such change” (figures 1.1). In a press release the Committee justified its choice:

Extensive climate changes may alter and threaten the living conditions of much of mankind. They may induce large-scale migration and lead to greater competition for the earth’s resources. Such changes will place particularly heavy burdens on the world’s most vulnerable countries. There may be increased danger of violent conflicts and wars, within and between states. ... By awarding the Nobel Peace Prize for 2007 to the IPCC and Al Gore, the Norwegian Nobel Committee is seeking to contribute to a sharper focus on the processes and decisions that appear to be necessary to protect the world’s future climate, and thereby to reduce the *threat to the security of mankind*. Action is necessary now, before climate change moves beyond man’s control.

On 10 December 2007, in his acceptance speech for the IPCC, its chairman, Rajendra Pachauri noted that this award is

an acknowledgement of three important realities, which can be summed up as:

1. The power and promise of collective scientific endeavour, ...

2. The importance of the role of knowledge in shaping public policy and guiding global affairs for the sustainable development of human society.
3. An acknowledgement of the threats to stability and human security inherent in the impacts of a changing climate and, therefore, the need for developing an effective rationale for timely and adequate action to avoid such threats in the future.

He referred to the complex linkage between climate change and its severe impacts on some of “the poorest and the most vulnerable communities in the world” that “see a decline in their economic condition, with a loss of livelihoods and opportunities to maintain even subsistence levels of existence.” But due to its mandate, the IPCC did not assess “how conflicts inherent in the social implications of the impacts of climate change could be avoided or contained.” Pachauri suggested that “it would be particularly relevant to conduct in-depth analysis of risks to security among the most vulnerable sectors and communities impacted by climate change across the globe.” He defined peace “as security and the secure access to resources that are essential for living” where climate change affects some populations to access a) clean water (*water security*), b) sufficient food (*food security*), c) stable health conditions (*health security*), d) ecosystem resources (*environmental* or *ecological security*), and e) security of settlements (*urban security*). The knowledge – assessed by the IPCC – provides a basis for the analysis in the social sciences as to how “climate change will affect peace” and whether its impacts could become a source of conflict. Pachauri argued that “human ingenuity and strength are capable of meeting this challenge” by acknowledging “the importance of sustainable development as the path to peace and prosperity.”

These three related events: a) the publication of the fourth IPCC Assessment Reports, b) the debates in the United Nations (Security Council and General Assembly), and the c) awarding of the Nobel Peace Prize to the IPCC have given climate change and its impacts a high political visibility to which Germany actively responded during its dual presidency of the EU and of the G-8, while the UK took the lead in putting this challenge on the agenda of the UN Security Council. Based on a report on *Security Risk Climate Change of the German Advisory Council on Global Change* (WBGU 2007, 2008) that was released to the G-8 summit, the German government proposed an EU strategy paper on the security impacts of climate change. In June 2007 the European Council instructed Javier Solana and the European Commission

to draw up a report on the security side of climate change that was submitted on 10 March 2008 to the EU Council of Ministers, and to the European Council on 13–14 March 2008.

Thus, during 2007 climate change has been addressed by a few governments and experts as a major security issue, and in this process of ‘*securitization*’ of problems of GEC the IPCC has indirectly become a major ‘*securitizing actor*’ by upgrading climate change to an ‘*existential threat*’ to different referent objects from the international community (*global, international* and *regional security*), the state (*state* or *national security*), and humankind (*human* and *gender security*). Addressing GEC and GCC as a new security danger and concern reflects the fundamental reconceptualization of security in the Anthropocene.

4.4 IPCC: Epistemic Community and Securitizing Actor?

A theoretical linkage between the burning of hydrocarbons and global warming was first postulated in 1896 by the Swedish physicist and chemist Svante Arrhenius (v. Weizsäcker/LovinsLovins 1995: 249; Bolin 2007: 3–8). But it took the scientific community until 1979 to recognize this linkage when the first world climate conference was organized by the *World Meteorological Organization* (WMO). Several scientific meetings followed in 1983, 1985, and 1987 in Villach (Austria) and Bellagio (Italy) that were carried out by the WMO in cooperation with the *United Nations Environment Programme* (UNEP) and the *International Council of Scientific Unions* (ICSU), and in 1985 participants from 29 countries warned for the first time of the danger of an anthropogenic climate change. After the publication of the Brundtland Commission Report (WCED 1987) UNEP and WMO added climate change to the agenda of the UN General Assembly (Bolin 2007: 40).

In the autumn of 1988, the US Reagan Administration put climate change on the policy agenda of the G-7 in Toronto where in June 1988 some 300 scientists and policy-makers at the “World Conference on the Changing Atmosphere, Implications for Global Security” suggested in their final declaration a reduction of CO₂ emissions by 20 per cent between 1988 and 2005 (Oberthür 1993). In November 1988, UNEP and WMO established the *Intergovernmental Panel on Climate Change* (IPCC) and in December 1988, at the suggestion of Malta (Bolin 2007: 49–51), the UN General Assembly declared the atmosphere as being “a

common heritage of mankind” (GA/43/53), and two years later on 21 December 1990 the General Assembly set up the *International Negotiating Committee on Climate Change* (INC) with a mandate to negotiate the *United Nations Framework Convention on Climate Change* (UNFCCC) that was approved in June 1992 at the Rio Earth summit (UNCED). Five years later with the adoption of the *Kyoto Protocol* (KP), the first binding quantitative emissions reductions were adopted that will be replaced by an emerging post-2012 climate change regime (Ott 2007; Aldy/Stavins 2007; Zedillo 2008).

Thus, since 1988 climate change has increasingly become an urgent policy issue and was thus ‘politicized’, and since the turn of the century climate change has gradually been perceived and discussed as an international (BMU 2002; WBGU 2007/2008), national (Schwartz/Randall 2003), and human security issue (Adger/Barnett 2005; Wisner/Fordham/Kelman/Johnston/Simon/Lavell/Brauch/Oswald Spring/Wilches-Chaux/Moench/Weiner 2007). In a similar vein, issues of water scarcity, degradation, stress, soil degradation, and desertification have first been politicized and then also securitized. Thus, facing global environmental change has increasingly been perceived and addressed as an emerging soft security issue.

During the past two decades, *global environmental challenges* have created an intensive public awareness to *face* this global environmental change and to *cope* with its consequences (Brauch/Oswald Spring/Mesjasz/Grin/Kameri-Mbote/Chourou/Dunay/Birkmann 2009). Since then, both the scientific discourse and the policy debates on GEC and on the reconceptualization of security were pursued by different scientific and policy communities.

4.5 Securitizing Global Environmental and Climate Change

Since the *UN Conference on Environment and Development* (UNCED) in Rio de Janeiro (1992) and the *World Summit on Sustainable Development* (WSSD) in Johannesburg (2002) the GEC posed by climate change, water stress, and soil erosion and desertification have been added to the international policy agenda, and since the turn of the millennium they have increasingly been addressed and perceived as new security issues.

4.5.1 Securitizing Water or ‘Water Security’

The concept of ‘water security’ was introduced in the Ministerial Declarations of the second *World Water Forum* (WWF) in The Hague (2000), and developed further at the third WWF in Kyoto (2003) and at the fourth WWF in Mexico City (2006).²⁵ The meeting in The Hague launched the *The African Water Vision* that “seeks to address the water paradox of the continent (floods and droughts, water scarcity and under-exploited water resources).”²⁶ The ‘Mexico Ministerial Declaration on Water’ of 17 March 2006 emphasized the goal of achieving water security stating that “African countries need to invest in water infrastructure ..., in order to achieve a self-sustaining auto-induced growth to eradicate poverty and achieve sustainable development.” Among the water security challenges the first *African Water Week* in March 2008 addressed the sanitation gap and the strategies for closing it, as well as the infrastructure for water security. Similar strategies have been developed for Latin American and Asian countries. Since 2000, the water security concept has been widely used by water specialists in the natural and social sciences, by policymakers and international organizations (chap. 11 by Oswald/Brauch, 18 chapters in part VII).

4.5.2 Securitizing Climate Change

Since the early 21st century climate change has increasingly been perceived as a security problem. Climate change has gradually been ‘securitized’ in government reports and in statements of government officials in the UK, in Germany, in the USA, and in many other countries.²⁷ It got on the US national policy agenda in February 2004 when a Pentagon contract study by Schwartz and Randall (2003) was leaked that stimulated a policy discussion that was further fuelled by a documentary “The Day After Tomorrow: Could it Really Happen” on a very dramatized impact of an abrupt climate change (NRC 2001). Since 2007 many

26 See the African Development Bank; at: <http://www.afdb.org/pls/portal/docs/PAGE/ADB_ADMIN_PG/DOCUMENTS/NEWS/CONCEPT%20NOTE-ENG.PDF>.

policy studies have securitized climate change as: a) an *international security* issue (4.5.2.1); b) a *national security* threat for the United States (4.5.2.2), and c) as a *human security* challenge affecting socially vulnerable and poor population groups (4.5.2.3).

4.5.2.1 Climate Change as an International Security Danger and Concern

At the “World Conference on the Changing Atmosphere – Implications for Global Security” in June 1988 in Toronto, the Norwegian Prime Minister Brundtland stated that “the impact of world climate change may be greater than any challenge mankind has faced, with the exception of preventing nuclear war.”²⁸ She thus launched the process of *politicization* and *securitization* of climate change that reached a political criticality during the year 2007.

In autumn of 1988, during its 30th anniversary meeting in Brighton, the IISS addressed non-military aspects of strategy and invited Neville Brown to explore potential avenues for future research on “climate, ecology and international security.” Brown (1989, 2001)²⁹, a trained meteorologist and historian and a professor of international security affairs, reviewed the growing ecological awareness, climate history and its impact on politics, and the possible impacts of the greenhouse effect. He argued that “the challenge begins to look like ‘the moral equivalent of war’, not least because a failure to meet it would have catastrophic consequences for international security.” Brown (1989: 531) called for a paradigmatic shift in strategy and the “adoption of a new corpus of knowledge and ideas,” and that strategists will find themselves confronted “with a large, diverse and unfamiliar

agenda. But it will be one informed by the precept that if doom can be foreseen, it may be thwarted. Such a self-defeating prophecy is what good strategy has always been about.”

In the United States, Peter Gleick (1989, 1989a) addressed the links between climate and international security arguing that “global climate change will potentially alter agricultural productivity, freshwater availability and quality, access to vital minerals, coastal and island flooding, and more.” These impacts “will be challenges to political relationships, realignment of energy markets and regional economies, and threats to security.” When the national security discussion on the environment started in the United States (Mathews 1989, 1991, 1992, 1993; Myers 1989), Gleick pointed to a

debate about the extent to which resource constraints or environmental problems alone can lead to conflict. However, it is widely acknowledged that resource constraints can lead to economic pressures and tensions or as triggers to conflicts when other tensions exist between states or political actors. These challenges, together with the long history of political frictions and disputes worsened by environmental stresses, suggests that global climatic changes have the potential to exacerbate international and subnational tensions and conflicts.³⁰

27 The first conceptual and empirical studies addressed “climate change, worst-case scenarios of climate change in the Southwest Pacific” (Edwards 1996, 1999), “climate change and world food security” (Parry/Rosenzweig/Iglesias/Fischer/Livemore 1999), “climate change and violent conflicts” (Rahman 1999), “linking climate change research with food security and poverty reduction in the tropics” (Sanchez 2000), “from climate risk to climate security” (Wiman/Stripple/Chong 2000), “security and climate change” (Barnett 2001), “climate change as a security issue” (Stripple 2002), and “climate change, environmental stress and conflict” (Brauch 2002).

28 Philip Shabecoff, “Norway and Canada Call for Pact to Protect Atmosphere”, in: *New York Times*, 28 June 1988; at: <<http://query.nytimes.com/gst/fullpage.html?res=940DE0DA163BF93BA15755C0A96E948260&sec=&spn=&pagewanted=print>>.

29 In his book on *History and Climate Change. A Eurocentric perspective*, Brown (2001) analysed major turning points of European history on the background of climate history. He carefully reviewed the intellectual debate among historians on the opposite views of the climate determinist Huntington and the climate sceptic Gibbon, pointing to the persisting uncertainties and to short-term climate fluctuations. He suggests that during the next two to three decades “a combination of research fieldwork and modelling should reveal considerably more about historical climatology on these last two millennia.” For the 21st century he argued that it cannot be ruled out that climate change could well become “a prime generator of instability and conflict.” Brown sees several reasons “that a climate crisis could induce a fundamentally irrational response.” He concluded with a critique of the “poverty of strategy” that failed “to adapt to the strategic revolution of 1989–91.” In his balanced assessment Brown argued that the impact of climate change appeared more local and regional than continental.

30 See the testimony of Peter H. Gleick to the United States Congress, Committee on Government Reform Subcommittee on National Security, Emerging Threats, and International Relations, Hearing on Energy as a Weapon: Implications for U.S. Security: “The Implications of Global Climatic Changes for International Security”, 16 May 2006.

Thirteen years later, a report for the German environment ministry (BMU) focused on the causes of climate change and their complex interactions with other drivers of GEC, on those environmental factors that contribute to environmental stress as a driver that may cause or trigger potential conflictual or cooperative outcomes. This BMU-study discussed the results of these considerations in five case studies on small island states, Mexico, Bangladesh, Egypt, and for the Mediterranean, and drew conceptual conclusions for scientific considerations and strategies aiming at conflict prevention (Brauch 2002).

From a state-centred international security perspective, the *German Advisory Council on Global Change* (WBGU 2007/2008) reviewed *Climate Change as a Security Risk* arguing that “without resolute counteraction, climate change will overstretch many societies’ adaptive capacities within the coming decades. This could result in destabilization and violence, jeopardizing national and international security to a new degree.” But also a positive development is possible if the international community “recognizes climate change as a threat to humankind and soon sets the course for the avoidance of dangerous anthropogenic climate change by adopting a dynamic and globally coordinated climate policy.”³¹

The report refers to probable new conflict constellations due to sea level rise, storms, and floods that may threaten coastal cities and industrial regions. The melting of the glaciers may jeopardize water supply in the Andean and Himalayan regions. The disappearance of the Amazon Forest and the loss of the Asian monsoon “could cause large-scale changes in the Earth System” and “incalculable consequences for the societies concerned.” While the WBGU considered “climate-induced inter-state wars” unlikely, it argued that “climate change could trigger national and international distributional conflicts and intensify problems already hard to manage such as state failure, the erosion of social order, and rising violence. In the worst-affected regions, this could lead to the proliferation of destabilization processes with diffuse conflict structures. These dynamics threaten to overstretch the established global governance system, thus jeopardizing international stability and security.”

The WBGU identified four conflict constellations “as typical causal linkages at the interface of environment and society, whose dynamic can lead to social destabilization and, in the end, to violence:” a) Climate-induced degradation of freshwater resources; b) Climate-induced decline in food production; c) Climate-induced increase in storm and flood disasters; and d) Environmentally-induced migration. The WBGU identified several regional hotspots in North Africa, the Sahel zone, in Southern Africa, in Central Asia, India, Pakistan and Bangladesh, in China, Caribbean and the Gulf of Mexico and in the Andean region and Amazonia (figure 4.7).

The WBGU referred to “six key threats to international security and stability which will arise if climate change mitigation fails”: 1) possible increase in the number of weak and fragile states as a result of climate change; 2) risks for global economic development; 3) risks of growing international distributional conflicts between the main drivers of climate change and those most affected; 4) the risk to human rights and the industrialized countries’ legitimacy as global governance actors; 5) triggering and intensification of migration; and 6) overstretching of classic security policy.

Whether these conflict constellations and social crises will occur depends on the increase of global average temperature by the end of this century. Thus, in the WBGU’s view, “climate policy ... becomes preventive security policy, for if climate policy is successful in limiting the rise in globally averaged surface temperatures to no more than 2°C relative to the pre-industrial value, the climate-induced threat to international security would likely be averted.”

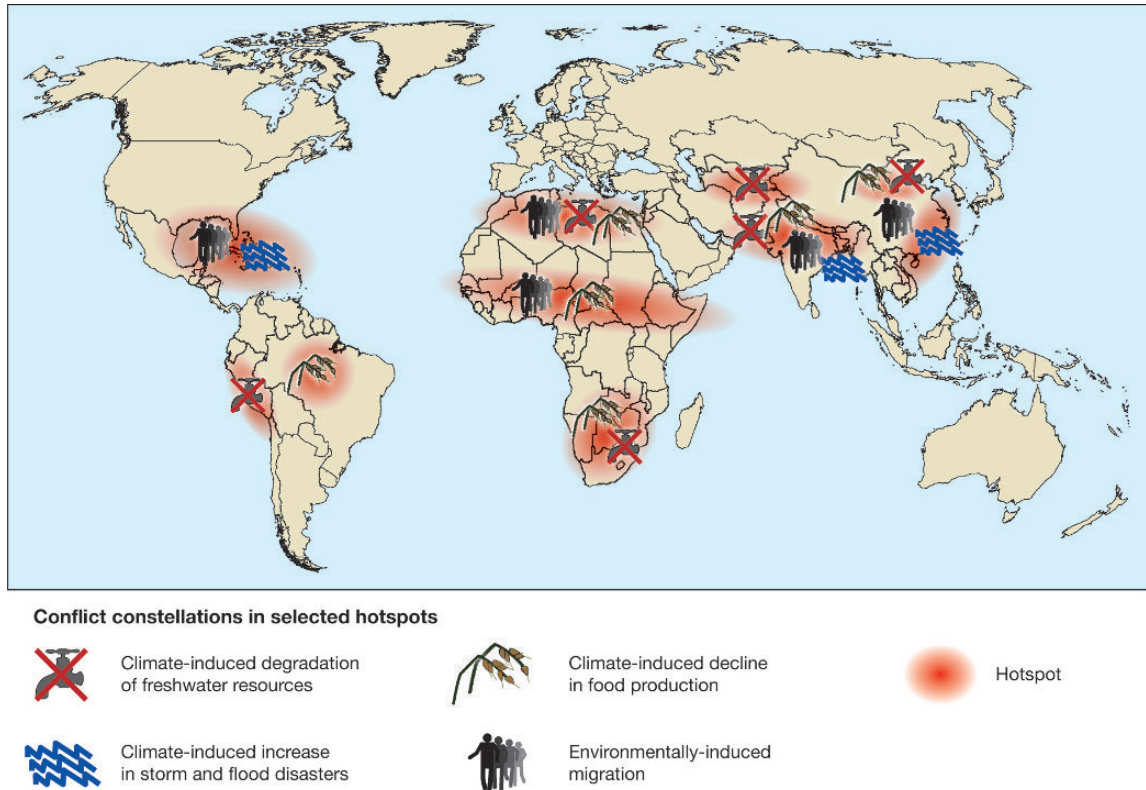

But – the WBGU Report further argued – if the mitigation efforts fail,

climate-induced security risks will begin to manifest themselves in various regions of the world from around 2025–2040. The key challenge is to take resolute climate policy action within the next 10–15 years, in order to avert the socio-economic distortions and implications for international security that will otherwise intensify in subsequent decades.

A week after the G-8 summit in Heiligendamm (Germany), the WBGU report was discussed in the German Foreign Office with representatives of civil society. In his concluding remarks Foreign Minister Steinmeier argued that an effective global climate policy is “decisive for stability and peace in the world.” The German foreign minister called for a preventive environmental diplomacy and a resource-oriented industrial policy also in the Near and Middle East

31 See for details the WBGU website at: <http://www.wbgu.de/wbgu_jg2007_engl.html>, where several expert studies are also available for download at: <http://www.wbgu.de/wbgu_jg2007_kurz_engl.html> and the full report is at: <http://www.wbgu.de/wbgu_jg2007_engl.pdf>.

Figure 4.7: Regional hotspots and security risks associated with climate change. **Source:** WBGU (2008: 4). Reprinted with permission.

“where ecological questions have become issues of survival and security.” He called for a European diplomacy to cope with the security challenges posed by climate change, and he announced that this preventive approach would be discussed in a meeting of foreign ministers of the G-8 and G-5 in late 2007 in Berlin.³²

Key arguments of this study are reflected in a paper of the European Commission and of the Secretary-General of the European Council that was approved by the European Council on 14 March 2008. Thus this scientific agenda setting has resulted within nine months in a policy document of the 27 countries of the European Union. The book was introduced to COP 13 of UNFCCC in December 2007 in Bali in a joint side event by UNEP and the WBGU³³.

A background paper for the ‘International Women Leaders Global Security Summit’ in November 2007 in New York³⁴ put forward “a new security agenda that views the safety of people as inseparable from the security of the state” focusing on “four important themes of global security: climate change, the respon-

sibility to protect, the economics of insecurity, and preventing terrorism(s).” This report stated that:

Climate change poses significant security risks due to an increased occurrence of severe weather patterns, degradation of vital natural resources and threats to the livelihoods and safety of populations on every continent. Pressure on resources, natural disasters and humanitarian crises - including flooding, drought, desertification and loss of arable land, massive and rapid migration and refugee flows - have the potential to threaten economic, political and social stability while increasing the risk of internal civil unrest.

33 At the 13th conference of parties to the UNFCCC in Bali on 10 December 2007, the security links of climate change were addressed in a side event by UNEP and WBGU; see: UNEP News Centre: “Climate Change and Conflict - New Report Weighs the Risks and Pinpoints Likely Hotspots”; at: <<http://www.unep.org/Documents.Multilingual/Default.asp?DocumentID=523&ArticleID=5720&cl=en>>.

34 See for details at: <<http://womenandglobalsecurity.org>>. A summary report of this event is at: <<http://womenandglobalsecurity.org/docs/IWLGSS%20Report.pdf>>.

32 This meeting on “Sicherheitsrisiko Klimawandel” is fully documented in German in: Auswärtiges Amt (2007).

The report of the International Women Leaders Global Security Summit further argued that

Women's leadership must help increase political will at the national and global level, guide the private sector away from voluntary initiatives and toward legally required changes in practice, give voice to affected communities in setting priority targets and legal standards, and identify and prioritize the communities most in need of assistance to mitigate and cope with the effects of climate change.

The report suggested that "an integrated human, gender and environmental security approach is needed for dealing with the growing threat of climate change, in order to develop appropriate adaptation and mitigation strategies."³⁵ This summit concluded that "the road to real security requires women leaders to integrate state, global and human security in a mutually reinforcing way that builds upon currently existing theoretical frameworks of security policy". Women leaders must "use existing mechanisms to enforce global standards and existing international law, and create new methods where needed." It argued that "women leaders bring a new perspective to the security policy dialogue ... that can make a difference in both government and civil society. Building an inclusive process, persistence, consensus-building, considerations of short- and long-term implications and a talent for negotiation are some of the cornerstones of traditional women's leadership". Women leaders can "create practical change and apply a human face to security".

These national and international efforts to securitize climate change and its projected societal impacts have been complemented by many reports for NGOs and national governments (e.g. in Sweden for SIDA and FOI) that share the goal of making climate change an issue of utmost political importance that requires extraordinary policy responses and coping measures.

The links between climate change, peace and war were analysed in a report by International Alert (Smith/Vivekananda 2007) that highlighted four key

elements of risk - political instability, economic weakness, food insecurity, and large-scale migration, and it made twelve recommendations for addressing climate change in fragile states. It discussed the climate change impacts for Algeria, Darfur, Peru, Bangladesh, and for Karachi, governance matters for Mali and Chad, as well as linking for Liberia peacebuilding and climate adaptation efforts and developing social resilience for Nepal. The report supplied two lists of states at risk: a) facing a high risk of armed conflict as a consequence of climate change (46 states); and b) states facing a high risk of political instability as a consequence of climate change (56 states). An extended version of *A Climate of Conflict* was published by SIDA (Smith/Vivekananda 2008) that offers case studies on Kenya, Bangladesh, Mali and Chad, as well as on Sudan and Darfur, Liberia, Nepal, Colombia and Rwanda.³⁶

In a study for the *Swedish Defence Research Agency* (FOI), Peter Haldén (December 2007: 4) analysed "The Geopolitics of Climate Change" by focusing on: "whether and in what way climate change may alter the conditions of international security." He argues that "organized violence is more likely in regions with weak states and conflictual inter-state dynamics than in those characterized by co-operative relations," and he concludes that "in the short- to medium term, climate change is unlikely to alter the constitutive structures of international security," but that "a long-term development marked by unmitigated climate change could very well have serious consequences for international security."³⁷

In December 2007 Ecopeace/Friends of the Earth Middle East in a report on *Climate Change: A New Threat to Middle East Security* (Freimuth/Bromberg/Mehyar/Alkahteb 2007) argued that "the climate crisis and its potential physical and socio-economic impacts are likely to exacerbate this cross-border instability" and that "climate change is likely to act as a 'threat multiplier' - exacerbating water scarcity and tensions over water within and between nations linked by hydrological resources; geography; and shared political boundaries". However, this crisis of

fers opportunities “for local, cross-border and international cooperation to ameliorate the problems that are already occurring and that are projected to intensify.”³⁸

The impacts of “climate change as the ‘new’ security threat for Africa” (Brown/Hammill/McLeman 2007) have been discussed since 2007 and several contract studies for European ministries of development also for subregions (e.g. for West Africa) and countries (Ghana, Burkina Faso, e.g. by Brown/Crawford 2008) and provinces (Darfur, e.g., by UNEP 2007). Several African leaders have called climate change as an ‘act of aggression’ (President Museveni of Uganda in 2007).

For the *securitization* of climate change impacts by policy-makers in North and South, Brown, Hammill and McLeman (2007: 1143–1154) pointed to two reasons a) that climate change “threatens to exacerbate drivers of conflict in a way that could roll back development across many countries,” and b) that this debate is “part of a clear process to invest the international debate with a greater sense of urgency.” They argue that this debate presents both risks (if it creates a sense of hopelessness, search for military solutions, and results in a distraction of resources from development) and opportunities if it encourages politicians to reduce emissions, to invest in adaptation, and speed efforts for implementing both climate and conflict resolution policies.

The security aspects and implications of climate change have been considered by government representatives within the environment directorate of the OECD, and informally discussed between the British Foreign Office (FCO) and the German Environment Ministry (BMU) since 2001. The public policy debate on the *securitization* of climate change has been most intensive in the UK since 2004 in which successive secretaries of defence and foreign affairs, as well as high level policy advisers, leading scientists, and retired diplomats actively participated at conferences and in the media.

Sir Crispin Tickell (2003), a former UK diplomat, pointed to environmental factors behind societal collapse. John Mitchell, chief scientist at the UK Met Office, forecasted that the coming decades will see a 30

per cent increase in severe drought, and that Africa will experience increased desertification, water stress, and disease. On 9 January 2004, David King, the UK Government’s chief scientific adviser, was quoted as saying that climate change is a far greater threat to the world than international terrorism.³⁹ In February 2004, John Reid MP, then British Secretary of State for Defence and later Home Secretary, argued that climate change may spark conflict between nations. He claimed that violence and political conflict would become more likely in the next 20 to 30 years with climate change, he listed among the major threats in future decades, “uncertainty about the geopolitical and human consequences of climate change. ... Impacts such as flooding, melting permafrost and desertification could lead to loss of agricultural land, poisoning of water supplies and destruction of economic infrastructure. ... More than 300 million people in Africa currently lack access to safe water; climate change will worsen this dire situation.”⁴⁰

In October 2006, the *Stern Review* on the *Economics of Climate Change* by the Prime Minister’s Special Adviser, Sir Nicholas Stern (2006), reviewed the scientific basis, impacts of climate change on growth and development, the economics of stabilization, the policy responses for mitigation and adaptation and international collective action to cope with the consequences of GCC. The *Stern Review* notes among the societal impacts of GCC:

- Greater resource scarcity, desertification, risks of drought and floods, and rising sea levels could drive many millions of people to migrate – a last-resort adaptation for individuals that could be costly to them and to the world.
- Drought and other climate-related shocks may spark conflict and violence, as they have done already in many parts of Africa.

Stern (2006: 128–131) listed both future risks in West Africa and in the Nile River Basin, and past national

and cross-border conflicts. This report assessed the costs of climate change and the economic benefits of proactive climate policies: It contributed to a further *politicization* of GCC, and enhanced the perception of ‘urgency’ and of a need for ‘extraordinary measures’ to cope with GCC, two essential components of Britain’s political strategy of *securitization*.

In October 2006, then Foreign Secretary Margaret Beckett considered climate change as a “serious threat to international security” that “must not be dealt with using guns and tanks, but through dialogue and the sharing of new technologies between developed and developing countries”.⁴¹ John Ashton, her Special Representative for Climate Change, repeatedly argued: “Climate change is a security issue because if we don’t deal with it, people will die and states will fail.” And he added that “there is no hard power solution to climate change – you cannot force your neighbour to change its carbon emissions at the barrel of a gun.”⁴²

This British ‘*securitization move*’ culminated in April 2007 in a debate in the UN Security Council. This followed UNSC Res. 1625 of 14 September 2005 that called for promoting sustainable development as part of a broad strategy of conflict prevention. This linkage was explicitly stressed in the UK concept paper that put climate change on the agenda of the UN Security Council on 17 April 2007, when this body addressed for the first time climate change as a security issue.⁴³ In her opening statement UK Foreign Secretary Margaret Beckett listed among new causes of conflicts: “fights over water, changing patterns of rainfall, fights over food production, land use.”⁴⁴ She ar-

gued that “an unstable climate will exacerbate some of the core drivers of conflict, such as migratory pressures and competition for resources.” Japan’s Ambassador Kenzo Oshima said that “it is clear that climate change can pose threats to national security ... [and] in the foreseeable future climate change may well create conditions or induce circumstances that could precipitate or aggravate international conflicts.” On behalf of the EU countries, the German Development Minister, Heidemarie Wiecek-Zeul, argued:⁴⁵

that the scarcity of water, food and fertile land can be a contributing factor to drive conflict, [and] the vulnerability of people ... can increase the potential for instability and conflict. ... A wide range of interacting factors such as ethnic tensions, trans-border disputes, inequalities in societies, population movements and failed states can contribute to armed conflict. But climate change will become an ever more important factor among root causes for conflict as the climate will continue to change at a faster rate.

From this political analysis, the representative of the EU presidency argued that

we are in need of a global framework of risk management to address the challenge of climate change. ... The security dimension should be duly reflected in future research and reports on the effects of climate change. ... An overall framework of preventive diplomacy is needed in order to alleviate the worst consequences.... As other challenges to humankind like hunger, disease, poverty, water scarcity or migration, climate change should be addressed in a holistic and preventive manner.

Among the countries that supported this ‘*securitizing move*’ Sindico (2007) distinguished three groups, a) those wanting to raise global awareness for climate change (UK), b) those focusing on conflict prevention (Germany, France), and c) the most vulnerable small island states. The opponents argued that climate change as a sustainable development issue should not be considered by the UNSC (China, Russia, India, South Africa, Brazil, Indonesia, and Qatar) but by the UNGA, ECOSOC, and UNCSD, while Mexico and Singapore acknowledged that climate change could lead to future security concerns but that the UNSC should not interfere into state energy policies. For UN Secretary General, Ban Ki-moon “projected changes in the earth’s climate are thus not only an environmental concern. ... Issues of energy and climate

change can have implications for peace and security.”⁴⁶ By taking climate change to the UNSC, it has been upgraded from an environmental and development to a security issue. But the debate on climate change at the UNSC has also shown two different approaches to security. A broad concept of international security promoted by developed countries that embraces climate change, and a narrow concept favoured by developing countries, which tends to exclude climate change from the global security agenda. ... Developing countries rightly fear that some developed countries wish to securitize climate change in order to impose their own climate policy (Sindico 2007: 34).

In May 2007, in a speech at RUSI on “the case for climate security,” Foreign Secretary Margaret Beckett argued that climate security “requires a whole new approach to how we analyse and act on security. The threat to our climate security comes not from outside but from within: we are all our own enemies. And what is at stake is not the relatively narrow national security of individual states but our collective security in an interdependent world.” She further stressed that “the traditional tools of hard security – in simple terms bombs and bullets – are not going to be able to solve that problem.” Guaranteeing this new security requires a “commitment to non-military options: to international diplomacy; to leveraging international finance and markets; to building coalitions between governments, business and consumers.” The new objective “in the fight against climate change ... is not to defend a way of life but to change it.” This implies “nothing less than to shift the foundations upon which the global economy is built.”⁴⁷ But Ms. Beckett also hinted to a tactical component of her *securitization move*:

Flagging up the security aspects of climate change has a role in galvanizing those governments who have yet to act. And, for all of us, it has a role in setting the level of ambition – the political and financial commitment – that is needed. Second, the security community has a very direct role to play. The analytical framework – the sce-

nario building – ... was developed ... in the security community. ... For a problem with the complexity of climate change, that ability to construct a vision of the future and to draw the links between a wide variety of physical impacts and possible consequences to our security is invaluable.

Since January 2004, when Sir David King claimed that climate change was a more urgent security threat than terrorism, in many interviews, speeches, and reports (‘speech acts’) high British government officials launched a ‘securitizing move’ addressing GCC as a new danger for global, international, and collective security that succeeded to stir a public debate in the UK that rapidly proliferated abroad, and to put climate change on the agenda of the UNSC. Already in 2001, officials in the German Environment Ministry commissioned a report on *Climate Change and Conflict* (BMU 2002) that was intended to put the security dimension of GCC on the agenda of the IPCC for its fourth Assessment Report, and on the agenda of OECD. In 2007, the *German Advisory Council on Global Change* (WBGU)⁴⁸ focused its flagship report on *Climate Change as a Security Risk* (WBGU 2007/2008) that was tabled in June 2007, just prior to the G-8 meeting in Heiligendamm (Germany).

The climate change issue has been discussed at the G-8 meetings in August 2005 in Gleneagles⁴⁹ in the UK and in June 2007 in Heiligendamm in Germany where the heads of states and/or governments of the G-8 agreed ... “in setting a global goal for emissions reductions” that they will “consider seriously the decisions made by the European Union, Canada and Ja-

Lederer: “Security Council Tackles Climate Change”, in: *Washington Post*, 18 April 2007.

47 See text at: <<http://www.fco.gov.uk/en/newsroom/latest-news/?view=Speech&cid=1892973>>.

48 See on the mission of the WBGU, at: <http://www.wbgu.de/wbgu_auftrag_en.html>. Among the WBGU’s tasks are to: a) analyse global environment and development problems and report on these, b) review and evaluate national and international research in the field of global change, c) provide early warning of new issue areas, d) identify gaps in research and to initiate new research, e) monitor and assess national and international policies for the achievement of sustainable development, f) elaborate recommendations for action and research, and g) raise public awareness and heighten the media profile of global change issues. Its nine members are jointly appointed by the Federal Ministry for Education and Research and the Federal Ministry for Environment, Nature Conservation, and Nuclear Safety, in agreement with other ministries for a period of four years.

49 At the G-8 meeting in Gleneagles the *Gleneagles Plan of Action* on “Climate Change, Clean Energy and Sustainable Development” was adopted; see at: <http://www.fco.gov.uk/Files/kfile/PostG8_Gleneagles_CCChangePlanofAction.pdf>.

pan which include at least a halving of global emission by 2050.”⁵⁰ In a joint statement of the German G-8 presidency with the heads of states and/or governments of Brazil, China, India, Mexico and South Africa, the goal of fighting climate change was endorsed, including the “crucial role of economic incentives,” “climate friendly investments in large scale,” and improved means of adaptation for developing countries “with enhanced technology cooperation and financing.”

On 31 July to 2 August 2007, the UN General Assembly held an “informal thematic debate” on “climate change as a global challenge” (Spence/Chasek 2007). On 24 September 2007, United Nations Secretary-General Ban Ki-moon convened a high-level event on climate change “to advance the global agenda on climate change when he me[t] with heads of state and other top officials from more than 150 countries at United Nations Headquarters.”⁵¹

In November 2007 the *Human Development Report 2007/2008: Fighting climate change: Human solidarity in a divided world* (UNDP 2007/2008) suggested that the world should focus on the development impact of climate change. The *Human Development Report 2007/2008* argues that climate change poses challenges for political leaders and people in rich nations to acknowledge their historic responsibility and to initiate significant cuts in greenhouse gas emissions, and for the entire human community to undertake prompt and strong collective action. Climate change also poses major obstacles to progress in meeting the MDGs and maintaining progress raising the HDI.⁵²

On 14 March 2008, the Council of the European Union released a paper on “Climate change and international security” (SII3/08)⁵³ from the High Representative and the European Commission to the European Council that reflected key arguments of the 2007 WBGU report. This EU policy paper sees “Cli-

mate change ... as a threat multiplier which exacerbates existing trends, tensions and instability” that “threatens to overburden states and regions which are already fragile and conflict prone.” They include “political and security risks that directly affect European interests.” It further claims that “in line with the concept of human security, it is clear that many issues related to the impact of climate change on international security are interlinked requiring comprehensive policy responses.” It “focuses on the impact of climate change on international security and considers the impact of these international security consequences for Europe’s own security, and how the EU should respond”. And it “concludes that it is in Europe’s self interest to address the security implications of climate change with a series of measures: at the level of the EU, in bilateral relations and at the multilateral level, in mutually supportive ways”.

The EU paper lists seven major international security threats posed by climate change: i) conflict over resources; ii) economic damage and risk to coastal cities and critical infrastructure; iii) loss of territory and border disputes; iv) environmentally-induced migration; v) situations of fragility and radicalization; vi) tension over energy supply; and vii) pressure on international governance. It discusses several geographical examples where these threats may materialize: a) Africa, b) Middle East, c) South Asia, d) Central Asia, e) Latin America and Caribbean, and f) Arctic. Based on this analysis the EU policy paper concluded that:

The active role of the EU in the international climate change negotiations is vital and must continue. The EU has demonstrated leadership both in international negotiations ... with its far-reaching decisions on domestic climate and energy policies. ... In the EU’s response, special consideration needs to be given to the US, China and India and what the implications mean for the EU’s long-term relations with Russia. The recommendations below should be complemented by further studies and followed up by coherent EU action plans, aiming at addressing the different dimensions of the responses required to address the impact of climate change on international security in a comprehensive and effective manner. The upcoming examination of the implementation of the European Security Strategy ... should take account of the security dimension of climate change.

53 Joint paper by the Commission and the Secretary-General/High Representative concerning “Climate change and international security” to the European Council, Brussels, 3 March 2008; Source: <http://euractiv.com/29/images/SolanaCCsecurity%20reportpdf_tcm29-170886.pdf>.

The report recommended specifically: a) *to enhance capacities at the EU level* (build up knowledge, assess the EU's own capacities, improvement in the prevention of, and preparedness for early responses to, disasters and conflicts). Possible actions could include:

- To intensify EU capacities for research, analysis, monitoring and early warning and Watch Lists including the Institute for Security Studies, the EU Satellite Centre (EUSC), the EU Joint Situation Centre (SITCEN), the EU Network of Energy Correspondents (NESCO), the Global Monitoring for Environment and Security and Joint Research Centres. Monitoring and early warning needs to include in particular situations of state fragility and political radicalization, tensions over resources and energy supplies, environmental and socio-economic stresses, threats to critical infrastructures and economic assets, border disputes, impact on human rights and potential migratory movements.
- To further build up EU and Member State planning and capabilities including civil protection and the use of crisis management and disaster response instruments (civil and military) to contribute to the response to the security risks posed by climate change.
- To commission further work to look, region-by-region, in more detail at what the security implications are likely to be and how they will affect EU interests.

For the international level the EU should use its “*multilateral leadership to promote global climate security*”, what may “become a positive driver for improving and reforming global governance.” It lists among possible actions:

- Focus attention on the security risks related to climate change in the multilateral arena; in particular within the UN Security Council, the G-8 as well as the UN specialized bodies (among others by addressing a possible need to strengthen certain rules of international law, including the Law of the Sea).
- Enhance international cooperation on the detection and monitoring of the security threats related to climate change, and on prevention, preparedness, mitigation, and response capacities. Promote the development of regional security scenarios for different levels of climate change and their implications for international security.
- Consider environmentally-triggered additional migratory stress in the further development of a comprehensive European migration policy, in liaison with all relevant international bodies.

With regard to the “*cooperation with third countries*” the paper calls for “revisiting and reinforcing EU cooperation and political dialogue instruments, giving

more attention to the impact of climate change on security.” The paper argued that “this could lead to greater prioritization and enhanced support for climate change mitigation and adaptation, good governance, natural resource management, technology transfer, trans-boundary environmental cooperation (inter alia water and land), institutional strengthening and capacity building for crisis management.” The paper recommends as possible actions:

- Further integrate adaptation and resilience to climate change into EU regional strategies (for example Northern Dimension, European Neighbourhood Policy, EU-Africa Strategy, Barcelona Process, Black Sea Synergy, EU-Central Asia Strategy, Middle East action plan). Special attention should be given to the most vulnerable regions and potential climate security hot-spots. The Global Climate Change Alliance between the EU and the most vulnerable developing countries should be built upon.
- Develop an EU Arctic policy based on the evolving geo-strategy of the Arctic region, taking into account i.a. access to resources and the opening of new trade routes.
- Examine the security implications of climate change in dialogue with third countries including through the sharing of analyses.

Thus, the European Union has taken up the conceptual and political debate on the *securitization* of climate change in the UK and in Germany, and thus the European Council has become a major *securitizing actor* in translating the scientific messages into concrete policy proposals that will lead to action in the years to come.⁵⁴

During the meeting of the European Council, on 13 March 2008 the British Foreign Secretary David Miliband and the German Foreign Minister Frank-Walter Steinmeier argued in a joint article that climate change “threatens our prosperity and well-being, not just in Europe but beyond. Moreover, it will reshape the geopolitics of the world in which we live, with important consequences for peace and security.”⁵⁵ They diagnosed:

54 Andrew Bounds: “Climate change poses ‘security risk’”, in: *FT.Com.* 3 March 2008; Ian Traynor: “EU told to prepare for flood of climate change migrants”, in: *The Guardian*, 10 March 2008.

55 British Embassy Berlin: “Europe has to rise to the security challenges of climate change. Joint contribution by Foreign Secretary David Miliband and German Foreign Minister Frank-Walter Steinmeier, 13 March 2008”; at: <<http://www.britischesbotschaft.de/en/news/items/080313a.htm>>.

Climate change will act as a stress multiplier. ... Competition for scarce resources threatens to fuel migration. The impact is likely to be most acute in regions such as the Sahel, the Middle East and South and Central Asia, where people are already socially and economically vulnerable and which are prone to instability. Rising sea-levels and melting ice caps also risk triggering new conflicts over shifting maritime borders. This is not an apocalyptic scenario. It is the assessment of increasing numbers of security experts based on the findings of climate scientists. Their conclusions demand a clear and coherent foreign and security policy response.

Both foreign ministers referred to their joint and coordinated efforts to securitize climate change by putting

the security implications of climate change on top of the international agenda. In 2007, the UK initiated a debate in the UN Security Council on the impacts of climate change on peace and security. During her EU Presidency in 2007, Germany initiated a report on a European response to the new security risks. ... Both UK and Germany support a European response to the emerging security challenges of climate change. We want to help implement an effective European and multilateral strategy to address the new threats. What are the important elements of such a strategy?

They pointed in this regard to three key initiatives within the EU and globally:

First, we should intensify our efforts to meet the new security risks triggered by climate change. With the European Union's strategy for Central Asia and the new EU-Africa partnership, we have groundbreaking policy frameworks which will allow us to mainstream climate security into the EU's regional policies. In Central Asia, transboundary water management is an important pillar within our strategy. By helping build capacity, fostering regional dialogue, and setting up more efficient water infrastructure we are promoting water as focus of regional co-operation ... The same is true for Africa, where the effects of food insecurity, water shortages and extreme weather are likely to be severe. The EU-Africa Partnership gives priority to more cooperation to address land degradation and increase aridity. Promoting food security through initiatives like the "Green Wall for the Sahara" is a key element for political stability and crisis prevention in Africa.

Second, we will have to address an increasing number of global natural disasters such as storms, floods, and droughts in the future. There is a strong case for closer monitoring of climate related developments in crisis-prone areas. But we also need to prepare for increased demand for European-led disaster management and humanitarian relief.

Third, we need to consider now how climate change will affect the strategic context of European foreign and security policy in the years to come. For instance the shrinking Arctic ice cap could raise questions about

resources, delimitation of maritime zones and sea lanes in the far North. To avoid new tensions, the EU report on climate security proposes a European Arctic policy. It is vitally important for European security to implement governance structures for the Arctic region based on international law, aiming at a cooperative and peaceful management of resources and preserving the ecological heritage of mankind.

In the view of the British and German Foreign Ministers:

Anticipating new foreign policy challenges and reinforcing the climate security and conflict prevention aspects of our regional strategies are important steps in defining a joint EU response. These efforts will help us to avoid growing resentment between those most responsible for climate change and those most affected by it. A potential stand-off between 'polluters' - both in the North and among the emerging economies - and 'victims', who will be predominantly in the South, would put the already burdened international security architecture under increasing pressure.

Ultimately, there is no hard power option for tackling the causes of the climate threat or for dealing with its direct impacts. You cannot use military force to build a low carbon global economy; no weapon system can halt the advance of a hurricane bearing down on a city, or hold back the rising sea. But what the emerging analysis on climate and security tells us is that we can be sure that there will be hard power consequences if we fail to rise to the challenge.

Since 2007, many international organizations have made climate change a priority of their activities. Several divisions of the World Bank are now working on climate change issues. In March 2008 the Division on Social Development in a workshop addressed the "Social Dimensions of Climate Change."⁵⁶ On 27 March 2008, the Environmental Division released a concept and issues paper on: "Addressing a Strategic Framework on Climate Change and Development for the World Bank Group." The World Bank plans a *World Development Report 2010 on Climate Change*.

While many of these policy studies for government agencies and NGOs discuss a variety of potential security dangers and concerns posed by climate change impacts, many high-level policy-makers and policy ad-

56 See for the workshop programme, presentations and background papers; at: <<http://web.worldbank.org/WBSITE/EXTERNAL/TOPICS/EXTSOCIALDEVELOPMENT/0,,contentMDK:21659919~pagePK:210058~piPK:210062~theSitePK:244363,00.html>>. Bulhaug/Gleditsch/Theisen (2008: 41-42) recommended to assess also the security effects of countermeasures to climate change and to include security issues in the next round of IPCC assessments.

visers have also claimed such links between climate change and conflict. These policy documents and statements ('speech acts') illustrate the manifold policy efforts, especially since 2007, to securitize climate change by addressing it as a key security concern for the survival of humankind and for the affected states that require proactive extraordinary measures to reduce the probability that the impacts of political baseline scenarios become a conflictual reality.

Thus, the year 2007 has been the turning point in the *securitization* of problems of global environmental change, and especially of climate change. During 2007, the IPCC, as a knowledge-based epistemic community, has indirectly become a major *securitizing actor* although its mandate has so far excluded security issues, and in the fourth assessment report no single reference to security can be found in the index of the first three volumes. But the scientific messages of the IPCC, due to its high scientific and political reputation and their instant and wide global coverage and dissemination, have reached a global audience that has increasingly become receptive to the sense of urgency what again has made it attractive for national policy makers to stress the need for proactive and massive action even though the lobbyists of affected industrial sectors have tried to delay and to weaken responses that would be costly for them.

Both Britain and Germany – during its dual presidency of the G-8 and the EU – have taken the lead in putting the security implications of climate change impacts on the agenda of the UN Security Council, on the agenda of the meetings of the G-8 and of the G-5 in June 2007 in Germany and tabling this question on the agenda of the European Union. Two women leaders who were trained in the natural sciences (physics and metallurgy) played a key political role in the *securitization* of climate change, German Chancellor Angela Merkel and UK Foreign Secretary Margaret Beckett, who both had previously been engaged in climate change policies and negotiations as former environment ministers (Merkel 1994–1998; Beckett 2001–2006).

In the meantime, the *securitization* of climate change has also reached the traditional *securitizing actors*, the national defence ministries, the military establishments, and the intelligence community that have started to address climate change as a new national security threat.

4.5.2.2 Climate Change as a National Security Danger and Concern

The *securitization* of climate change as a national security issue has started in the USA in February 2004 when a contract study by Schwartz and Randall (2004) for the US Department of Defense on the impact of *Abrupt Climate Change on US National Security* was leaked to the press. Three years later, Gilman, Randall, and Schwartz (2007) discussed the *Impacts of Climate Change on US National Security* as did a report on *National Security and the Threat of Climate Change* by the US Center of Naval Analysis (CNA 2007).

This study addressed three questions: a) on the conditions climate change is likely to produce globally that represent security risks for the USA; b) how they may affect the US national security interests; and c) what actions should the USA launch to address its national security consequences. The study concluded that the predicted consequences of climate change include: “extreme weather events, drought, flooding, sea level rise, retreating glaciers, habitat shifts, and the increased spread of life-threatening diseases,” that may add “new hostile and stressing factors” and that have the potential “to create sustained natural and humanitarian disasters” whose consequences “will likely foster political instability where societal demands exceed the capacity of governments to cope” and it “will add to the tensions even in stable regions of the world.”⁵⁷

The study suggested that the climate change impacts “should be fully integrated into national security and national defense strategies,” that the USA should help “stabilize climate changes at levels that will avoid significant disruption to global security and stability,” and “help less developed nations build the capacity and resiliency to better manage climate impacts.” It proposed that the US Department of Defense should “enhance its operational capability by accelerating the adoption of improved business processes and innovative technologies that result in improved US combat power through energy efficiency,” and “conduct an assessment of the impact on US military installations worldwide of rising sea levels, extreme weather events and other projected climate change impacts over the next 30 to 40 years.”

⁵⁷ This report was discussed at a meeting on “National Security and the Threat of Climate Change”, by the *Environmental Change and Security Program* (ECSP) of the Wilson Center on 14 May 2007.

On 29–31 March 2007, the Strategic Studies Institute and the Triangle Institute for Security Studies conducted a colloquium on “Global Climate Change: National Security Implications,”⁵⁸ that reached the following key insights that climate change is underway and that its national security implications “are proportional both to the speed of change and the extent,” that “threats to national survival stemming from catastrophic change must be anticipated, evaluated, and neutralized to the greatest degree possible,” and that this will “require multinational, multi-agency cooperation on a scale heretofore unimaginable and could provide no-fault ground for global cooperation.” The first impact would come from displaced people and their malnutrition and disease that “could aggravate or spark displacement and border security issues.”⁵⁹

In November 2007, the *Center for Strategic and International Studies* (CSIS) and the *Center for a New American Security* (CNAS) released a report on: *The Age of Consequences: The Foreign Policy and National Security Implications of Global Climate Change* (Campbell/Lennon/Smith 2007) by a group of high-level US security experts and climate specialists that discussed three future worlds with climate change impacts during the next 30 and 100 years that

are based on *expected*, *severe*, and *catastrophic* climate cases. The first scenario projects the effects in the next 30 years with the *expected* level of climate change. The *severe* scenario, which posits that the climate responds much more strongly to continued carbon loading over the next few decades than predicted by current scientific models, foresees profound and potentially destabilizing global effects over the course of the next generation or more. Finally, the *catastrophic* scenario is characterized by a devastating ‘tipping point’ in the climate system, perhaps 50 or 100 years hence. In this future world, global climate conditions have changed radically, including the rapid loss of the land-based polar ice sheets, an associated dramatic rise in global sea levels, and the destruction beyond repair of the existing natural order.

58 Other co-organizers included the Army Environmental Policy Institute, The Center for Global Change (Duke University), Creative Associates, The Nicholas Institute for Environmental Policy Solutions (Duke University), The Environmental Change and Security Program (The Woodrow Wilson International Center for Scholars), and the Department of Environmental Sciences at the University of North Carolina-Chapel Hill.

59 U.S. Army War College and Triangle Institute for Security Studies, Strategic Studies Institute, Colloquium Brief, compiled by Douglas V. Johnson II; at: <<http://www.strategicstudiesinstitute.army.mil/pdffiles/PUB779.pdf>>.

The authors drew several policy conclusions from the discussion of these three scenarios:

- Historical comparisons from previous civilizations and national experiences of such natural phenomena as floods, earthquakes, and disease may be of help in understanding how societies will deal with unchecked climate change.
- Poor and underdeveloped areas are likely to have fewer resources and less stamina to deal with climate change – in even its very modest – and early manifestations.
- Perhaps the most worrisome problems associated with rising temperatures and sea levels are from large-scale migrations of people – both inside nations and across existing national borders.
- The term ‘global climate change’ is misleading in that many of the effects will vary dramatically from region to region. A few countries may benefit from climate change in the short term, but there will be no ‘winners’.
- Climate change effects will aggravate existing international crises and problems.
- We lack rigorously tested data or reliable modelling to determine with any sense of certainty the ultimate path and pace of temperature increase or sea level rise associated with climate change in the decades ahead.
- Any future international agreement to limit carbon emissions will have considerable geopolitical as well as economic consequences.
- The scale of the potential consequences associated with climate change – particularly in more dire and distant scenarios – made it difficult to grasp the extent and magnitude of the possible changes ahead.
- At a definitional level, a narrow interpretation of the term ‘national security’ may be woefully inadequate to convey the ways in which state authorities might break down in a worst case climate change scenario.

Also in November 2007, the *Council on Foreign Relations* (CFR) released a report on: *Climate Change and National Security* that proposed several policy options to reduce the vulnerability of the United States and other countries to the predictable effects of climate change. Bushby (2007) argued that sharp GHG reductions in the long run are essential to avoid unmanageable security problems.

These studies were picked up by members of the US Congress. In March 2007, Senators Richard J. Durbin (D-IL) and Chuck Hagel (R-NE) introduced the “Global Climate Change Security Oversight Act” (S.1018) requesting a national intelligence estimate to assess whether and how climate change might pose a

national security threat (Scheffran 2008: 22). A similar “Global Climate Change Security Oversight Act” (H.R.1961) was submitted in the House by Congressman Edward Markey (D-MA).⁶⁰ However, none has so far been adopted by both Houses of the US Congress.

While the CIA had ignored climate change in its projection of the world by 2020 (CIA 2004), it would now have to pinpoint “the regions at highest risk of humanitarian suffering” and assess the “likelihood of wars erupting over diminishing water and other resources.” Furthermore, the Pentagon would have to determine how global climate change could affect US security, including “direct physical threats to the United States posed by extreme weather events such as hurricanes.”

The securitization of climate change as a US national security threat followed the example of AIDS “that was long seen as exclusively a health issue until intelligence officials warned that it could ravage military forces across Africa and draw the United States into conflict.” Retired Air Force General Charles Wald voiced support for bringing the national security bureaucracy into the debate over global warming and John J. Hamre, a deputy secretary of defence in the Clinton administration, said “global warming couched in security terms would make it far more difficult for politicians to ignore.”⁶¹

In the framework of the Quadrennial Defense Review of 2006, Ackerman (2008) argued that in response to climate change, the US “must recognize this long-term threat, operationalize a new strategy, reorient capabilities and forces, reshape the defense enterprise, develop a twenty-first-century total force, achieve unity of effort, and create a roadmap to victory aimed at coping with climate change.” He analysed the long-term traditional, irregular, disruptive and catastrophic threats posed by climate change.

61 Bryan Bender: “Bill ties climate to national security seeks assessments by CIA, Pentagon”, in: *The Boston Globe*, 9 April 2007.

Ackerman (2008: 75) argued that the simultaneous occurrence of these climate change threats could lead to a perfect storm that “would overwhelm the ability of US forces to respond in a timely and effective manner.” As part of a new sustainable national security strategy he suggested a fundamental reorientation of US military capabilities and forces that should be oriented at the triple goals of “economics, equity, and environment.”

In the aftermath of Hurricane Katrina (2005), the most costly natural hazard in US history, US public opinion and the sentiment in the US Congress on climate change have been changing since 2007 when the Democrats regained the majority in both houses. The high scientific reputation of the IPCC’s Fourth Assessment Report (2007, 2007a, 2007b, 2007c) and the self-discrediting of the military threats used by the Bush Administration for the justification of its intervention into Iraq⁶² have created a credibility gap, the IPCC could temporarily fill as an alternative *securitizing actor* supplementing the Pentagon as the single most important national *securitizing actor*. On the background of these international developments, for the USA the year 2007 has also become a turning point when climate change was increasingly perceived as an urgent security concern for US national security and its military establishment.

Since 2006 climate change has also become an urgent security issue in Australia. In *Heating up the Planet* Alan Dupont and Graeme Pearman (2006) analysed the linkages between climate change and security, arguing that climate change will complicate Australia’s security environment due to temperature increase, sea level rise, and an increase in natural hazards by exacerbating “food, water and energy scarcities in a relatively short time span,” by contributing to “destabilizing, unregulated population movements in Asia and the Pacific,” by triggering “short-term disease spikes but also have more enduring health security consequences.” The cumulative effect of these causes and consequences on:

agriculture, fresh water and energy could threaten the security of states in Australia’s neighbourhood by reducing their carrying capacity below a minimum threshold, thereby undermining the legitimacy and response capabilities of their governments and jeopardizing the security of their citizens. Where climate change coincides

62 See: “Commission on the Intelligence Capabilities of the United States Regarding Weapons of Mass Destruction” (Washington: White House, 31 March 2005); at: <<http://www.wmd.gov/report/index.html>> .

with other transnational challenges to security, such as terrorism or pandemic diseases, or adds to pre-existing ethnic and social tensions, then the impact will be magnified. However, state collapse and destabilizing internal conflicts is a more likely outcome than interstate war. For a handful of small, low-lying Pacific nations, climate change is the ultimate security threat, since rising sea levels will eventually make their countries uninhabitable.

Dupont and Pearman argued that climate change poses fundamental questions of “human security, survival and the stability of nation-states” that must dictate fresh judgments about political and strategic risk as well as economic cost. In October 2007, an opinion survey – conducted by the US Studies Center at the University of Sydney in July 2007 – “showed that 40 per cent of Australians thought that global warming was a greater threat to security than Islamic fundamentalism. Only 20 per cent thought it was less serious.” According to Alan Dupont, “climate change has moved from the environmental field to the security sphere.” Also the Australian Police Commissioner Mick Keelty argued that climate was a growing security concern. “We could see a catastrophic decline in the availability of fresh water. ... Crops could fail, disease could be rampant and flooding might be so frequent that people, en masse, would be on the move. Even if only some and not all of this occurs, climate change is going to be the security issue of the 21st century.”⁶³ In this emerging debate the implications for Australian internal and external security were discussed.⁶⁴

In the UK, the British Ministry of Defence (MoD) and its Development, Concepts and Doctrine Centre have identified climate change as a key strategic trend.⁶⁵ The UK’s Chief of Defence Staff suggested in a speech on 25 June 2007 that climate change is a threat to global security that military planners must in-

clude into their calculations.⁶⁶ In September 2007, the MoD awarded a £12 million research contract to the UK Met Office, Hadley Centre that calls for identifying those world regions “where global warming could spark conflict and security threats, as well as predict the likely conditions in which British forces may have to deploy in the future.”⁶⁷ In Germany, the link between ‘climate change and security’ was discussed at a workshop by the German Command and Staff College (FüAk) in cooperation with the Centre for Transformation of the German Armed Forces (*Bundeswehr*) and the German Development Institute (GDI) in Hamburg in autumn 2006 (Jopp/Kaestner 2008).

4.5.2.3 Climate Change as a Human Security Danger and Concern

Climate change also poses severe security impacts for human security and its referent objects: human beings and humankind. From a human security perspective, climate change has been addressed by the GECHS programme of IHDP in June 2005⁶⁸ and was the focus of the Greek Presidency of the Human Security Network (2007–2008)⁶⁹ that aimed “to raise the international community’s awareness of the impact of climate change and global warming on human security, with regard to vulnerable groups, particularly women, children and persons fleeing their homes due to climate change.”⁷⁰

ston/Simon/Lavell/Brauch/OswaldSpring/Wilches-Chaux/Moench/Weiner 2007) pointed to manifold impacts for international, national, and human security for selected direct, indirect, and slow-onset linkages. Some effects are already evident and will become very clear in the short run (2007–2020). They will increase and others will manifest themselves in the medium term (2021–2050); whilst in the long run (2051–2100), they will all be active and interacting strongly with other major trends. Africa is very likely to suffer very damaging impacts and has the least resources for coping and adapting to these stresses (IPCC 2007: 10). Livelihood and human security interact with ‘hard’ security issues because of the national and regional upheavals that climate stress may put on livelihood systems already vulnerable and incapable of adapting.⁷² The rural and urban poor are already under stress, and for some groups such as women-headed households in Africa, adaptation to climate-induced stress will be very difficult indeed. Some major climate changes may actually occur rapidly.

Besides the *Human Security Network* (HSN), the *Friends of Human Security* (FHS) that are coordinated by Japan and Mexico also discussed issues of climate change and human security based on a symposium on 31 July 2007 that reviewed the impact of climate change in developing countries, the challenges of disaster risk reduction, and the linkages between development and security.⁷³ For the Mexican co-chair

human security should be understood as a multidimensional concept, which would overcome the existing polarization among the three pillars of the UN: peace and security, development, and human rights.

The conceptual debate on climate change and human security is just starting. Barnett and Adger (2005: 1) discussed how climate change may undermine human security, and how human insecurity may increase the risk of violent conflict as well as the role of states in human security and peace building. Schnabel (2007) addressed the linkages between climate change, human (in-)security and stability because anthropogenic “climate change ... poses a risk to economic development and social and political stability” but will also act as a “powerful amplifier of existing threats.”

4.5.2.4 Impact of the Securizing Move on the Audience

The framing of climate change impacts in terms of international, national, and human security has succeeded to raise public awareness and to reach a global audience. With the presentation of the Fourth Assessment Report in 2007 the IPCC – as a scientific epistemic community – has evolved as an undeclared *securizing actor*. Several EU countries (UK, Germany, Sweden) took the lead in declaring climate change an existential threat to international security and survival that required urgent and exceptional measures to deal with this threat to which policy-makers and international organizations have responded (G-8, EU, UNFCCC, UNDP, UNEP, World Bank, OECD). These manifold *securizing moves* have convinced a majority of the people in many countries (‘the audience’) that climate change has become a major threat or challenge to their own security and survival.⁷⁴

In Britain, in 2006 in an Ipsos MORI poll, 48 per cent of all respondents named climate change as the most serious threat to the planet, compared with 20 per cent who said terrorism, what has been a fundamental change since 2004 when terrorism topped the list. In late 2007, in the wide-ranging global analysis of threats and challenges published by the Swedish Defence Commission, climate change and environmental impact were referred to as the most serious global threat to people’s security.

According to a poll conducted by GlobeScan Inc. between October 2005 and January 2006 with 33,237

Climate change, and the natural hazards and extreme weather events that are associated with it, are not some distant, future threat. The threat to human security is here, it’s real, and it’s today.”

74 See: Goska Romanowicz: “Climate change is biggest global threat, say Britons” (14 September 2006); at: http://www.edie.net/news/news_story_printable.asp?id=11993;

Figure 4.8: Poll by GlobeScan Incorporated: “Climate change: A serious problem or not?” 25 April 2006. **Source:** <<http://www.worldpublicopinion.org/pipa/articles/btenvironmentra/187.php?nid=&id=&pnt=187>>. Reprinted with permission.

people from 30 countries, majorities in every country said that climate change is a problem. In 24 countries the problem was seen as very serious by a majority (in 23 countries). Eighty per cent of the Chinese rated the problem as serious, with 39 per cent calling it very serious. Eighty per cent of Americans said the problem was serious, with 49 per cent calling it very serious (figure 4.8). According to a Pew poll published on 27 June 2007 (figure 4.9)

majorities in all 37 countries named ‘global warming’ as a serious problem. Majorities in 25 and pluralities in 6 rated the problem as ‘very serious’. With just a few exceptions the percentage saying that the problem is ‘not too serious’ fell under one in five. The two largest

producers of greenhouse gases - the United States and China - had large majorities saying the problem was serious but relatively lower numbers saying that it was very serious. Seventy-five per cent of Americans rated the problem as serious with 47 per cent rating it very serious. In China, 88 per cent considered global warming a very serious problem, while 42 per cent called it very serious.⁷⁵

75 For a list of opinion polls on climate change as a security threat or concern; see at: <<http://www.worldpublicopinion.org/pipa/articles/btenvironmentra/435.php?nid=&cid=&pnt=435>>.

The *Chicago Council on Global Affairs* (CCGA) in a poll published in 2007 asked respondents in 10 countries to evaluate the threat posed by 'global warming' in the next 10 years. In six of the ten countries majorities called it a critical threat, as did pluralities in another three. Pluralities saw the threat as critical in China (47–33 per cent important) and the United States (46–39 per cent important). Only small minorities in all countries called it unimportant. In 2007 the *German Marshall Fund* (GMF) found that majorities in 12 European countries plus the United States believed they would probably "be personally affected by the effects of global warming." On average across the 12 European countries, 85 per cent said it was likely (very likely 54 per cent, somewhat 31 per cent); and in no country did less than 77 per cent say this. Slightly fewer believed this in the United States; 70 per cent said it was likely (very likely 43 per cent, somewhat 27 per cent).

In an analysis published on 5 December 2007, the World Public Opinion.Org stated that the the "concern about climate change appears to be growing":

GlobeScan surveys have documented the world's increasing concern about climate change. In polls conducted across 16 countries in 2006 and 2003, the percentages calling climate change/global warming a 'very serious' problem increased an average of 16 points. In only one country was there a significant decline in the perceived severity of the problem of climate change. GMF has also found signs of increasing concern. In 10 European countries polled in 2005 and 2007, the average percentage saying that global warming is an extremely important threat went up 5 points (from 51 to 56 per cent). In the United States, this number went up 5 points (from 41 to 46 per cent). In most countries, majorities say that they have heard a significant amount about climate change. Not surprisingly, willingness to take action in regard to climate change rises with greater awareness.⁷⁶

Thus, by the end of 2007, climate change was not only addressed by scientists, governments, and international organizations as an urgent security danger, it was also perceived by a majority of the people in many countries as a major new international, national, and human security concern. Since 2008, the impact of climate change on security in developing countries is also increasingly being addressed by the

security community both for national security (e.g. by IDSA⁷⁷ in India) and from a human security perspective (by ISS in Pretoria).⁷⁸

4.5.3 Securitizing Soil Erosion and Desertification

While the linkage between problems of soil erosion and degradation and desertification with food security has been addressed since the 1990's, the systematic securitization of desertification started with a NATO-sponsored conference on 'desertification as a security issue in the Mediterranean' in December 2003 in Valencia (Kepner/Rubio/Mouat/Pedrazzini 2006).⁷⁹ Subsequent meetings in Almería (2006) discussed the links between desertification and migration as a major national and regional security issue for the states of North and West Africa and Southern Europe.⁸⁰ These links have also been addressed by UNCCD during the CRIC 3 meeting in Bonn in May 2005.⁸¹

On 26 June 2007, in a workshop on "Desertification: A security threat? - Analysis of risks and challenges", the German development (BMZ) and foreign ministries (AA) in cooperation with the UNCCD Secretariat tried "to facilitate debate about the linkages between security and the degradation of land resources." The state secretary of the foreign ministry,

78 See the workshop by ISS (Pretoria) with IDRC (Canada) on: "Climate change and human security in Africa" (Pretoria, South Africa, 27–28 February 2008);

79 At the Valencia conference Brauch (2003a, 2006) provided a systematic overview of the manifold conceptual linkages between processes of desertification and their impacts in terms of water, food, and health security that may have repercussions for national and regional security. Other contributions by Kepner (2006), Rubio/Recatala (2006); Yousef/Hegazi (2006); Safriel (2006) discussed security aspects from the perspective of the natural sciences, while López-Bermúdez/García-Gómez (2006) referred to the links with food security.

80 See for the conference documents at: <http://www.sidym2006.org/eng/eng_ponencias_conclusiones.asp>.

81 See for a brief report at: <http://www.afes-press.de/pdf/UNCCD_journal_050511.pdf> and a documentation of the CRIC-meeting at: <http://www.afes-press.de/pdf/Earth_negot_bulletin_04_175.pdf>; see also the speech by Oswald/Brauch; at: <http://www.afes-press.de/pdf/Oswald_Brauch_lang.pdf>.

Georg Boomgaarden, used an extended security concept for discussing environmental threats:

'If we ask ourselves who the enemy is in climate change, using the concepts of classic security policy, we must conclude that we are turning nature itself into an enemy'. ... 'And with this enemy, neither deception nor deterrence is going to be of any use. The later we adapt, the greater the cost will be'. ... Avoiding security-relevant cataclysms of global extent required the course to be set today. The time window for possibly irreversible processes to occur as a result of global temperatures rising by more than two degrees compared to pre-industrial days was about to close.

Pekka Haavisto, a former Finnish Minister for the Environment and Development and a former EU Special Representative for Darfur, referred to the manifold linkages of desertification to global, regional, national, and human security:

Desertification and security has many aspects, and indeed there are many securities. ... When we speak about climate change and desertification, we are referring to global security instead of only looking at security from a regional or national point of view. Climate change and desertification have local and regional security aspects as well as international ones. Then there is the issue of human security, affecting individual people and their human rights. First of all, people must have security in those places that they have traditionally been living in. If they have to go elsewhere for reasons of security, we have to provide security to those people under new circumstances. Human security is linked to the risks of migration.

Michelle Leighton referred to the dual security aspects with regard to migration triggered by desertification that "International migration can raise security issues in countries of origin, transit and destination, both in terms of human security and national security." Fausto Pedrazzini argued that "environmental security, food security, and desertification are very much related to the overall concept of security because they affect human and societal dynamics, they may lead to migration, and they have a strong influence on political stability and possible conflicts at all levels." During the *International Year to Combat Desertification* (2006) the security linkage was occasionally addressed⁸², but contrary to the intensive securitization of climate change no similar policy debate has so far emerged on desertification.

4.6 Conclusions

Environmental issues have also been framed as security issues since the Brandt (1980) and Brundtland Commission Reports (WCED 1987). A chapter in *Our Common Future* on the conceptual quartet of "Peace, Security, Development, and the Environment" set the stage for a policy debate on the widening of the security concept and agenda during the past two decades (Dabelko 2008). In June 1988, at the first world conference on climate change and global security in Toronto, as the first political leader, Norwegian Prime Minister Gro Harlem Brundtland addressed the linkage between both issues. In the scientific world, Neville Brown (1989) and Peter Gleick (1989, 1989a) were among the pioneers of the *securitization* of climate change during the global turn (Oberdorfer 1992).

In this chapter, Wæver's theory of *securitization* and the approach of the Copenhagen school of critical security studies was applied to selected GEC issues, in particular to GCC. For this *securitization move* many *speech acts* have been conceptually mapped that have convinced a growing 'audience', especially in Europe, that climate change along with water stress and desertification pose existential security dangers in the framework of international, national, and human security. Extraordinary measures are needed to respond to these new security issues in a proactive and timely way, and to prevent that the projected policy consequences will become a catastrophic reality during the 21st century.

Especially since the year 2000 the above review has documented a progressive *securitization* of major issues of GEC, starting with the adoption of the 'water security' concept at The Hague in spring 2000. But the turning point in the *securitization* of climate change has occurred in 2007. UK Foreign Secretary Margaret Becket and the the German state secretary in the foreign office, Georg Boomgaarden, argued that the nature of security threats have fundamentally changed. The threat analysis focuses no longer on missiles and nuclear weapons of the other bloc but on the growing concentration of greenhouse gases in the atmosphere (figure 4.1), on the increase in average global and regional temperature (figure 4.2), and on the increase in the number, intensity, and economic damage from climate related hydro-meteorological hazards.

The response to this new security danger is no longer provided by the Hobbesian logic guiding military establishments, but it relies on a common concerted global effort based on the ingenuity of engi-

82 See the presentations of this author in Cairo and in Rome in 2006, in Florence and Fuerteventura in 2007 that can be accessed at: <http://www.afes-press.de/html/download_hgb.html>.

neers enhancing energy efficiency and reducing greenhouse gases through a fundamental transformation of the energy and transportation sectors. As the IPCC, as a knowledge-based epistemic community, has indirectly become a new *securitizing actor*, the response to this new security danger must be knowledge-based but it must be backed with the policy commitment and the financial resources of the states but also of societal and economic actors.

This emerging *securitization* process has been instrumental for mobilizing political support and public and private funds for the post 2012 climate change regime. Since the release of the fourth IPCC report (AR4) many international organizations have upgraded their climate change activities (e.g. World Bank, UNDP, UNEP, OECD), and their results will further improve our knowledge base and they may further enhance the public concern on the urgency of these new security threats, challenges, vulnerabilities, and risks posed by GEC and GCC.

Desertification has so far primarily been discussed in the framework of food, water, and health security but this discussion did not yet lead to an increasing understanding of the sense of urgency of the security repercussions of eroding and degrading soils, and their impacts on agriculture and rural livelihoods.

On the assumed, claimed, and projected linkages between climate change and conflicts so far the knowledge base has been limited. Bulhaug, Gleditsch, and Theisen (2008) have pointed to a lack of systematic statistical data (on small-scale conflicts between nonstate actors) and of statistical analyses in the social sciences based on a high number of cases on past linkages. Many case studies – referred to above – resulted from commissioned studies for ministries, international organizations, and environmental and development NGOs, and were to satisfy specific policy needs. But in most cases they are not comparable and have not yet contributed to an accumulation of systematic knowledge.

The European Union in its paper on climate change and international security of 14 March 2008 proposed to “intensify EU capacities for research, analysis, monitoring and early warning”. The British MoD has funded a major research project at the Hadley Centre to study these issues. The World Bank has launched a huge effort in preparation of its annual report that is planned to address *Climate Change and Development* by 2010, and in the USA members of both Houses of Congress have requested by the US National Intelligence Council (CIA) and the US Department of Defense to assess the geopolitical im-

pacts of climate change for US national security. It has also been suggested (Brauch 2002; Bulhaug/Gleditsch/Theisen 2008) to add the security dimension of climate change to the mandate of the IPCC and to its agenda for its fifth assessment report.

Whether the *securitization* of GEC and climate change issues – having succeeded to add the security dimension of climate change on the top priority list of governments in OECD and in some developing countries – will galvanize the extraordinary policy measures that are needed to reverse the direction of global warming depends on the outcome of the negotiations on the post 2012 global climate regime, whether substantial and legally binding agreements can be achieved at the COP 15 of the UNFCCC in Copenhagen (2009), and also on the willingness of the countries not only to approve radical goals and measures but to fully implement them nationally. This raises many new issues of global equity but also of compliance.

The conceptual rethinking on security – both on the concept and even more on the substance – in the Anthropocene (Dalby 2008) has been spurred by the *securitization* of GEC and GCC. It remains a challenge both for policy relevant and theory guided conceptual thinking on security and peace but even more so for a new ‘peace policy in the Anthropocene’ that aims at responding proactively to the new security dangers posed by GEC and GCC (Conca/Dabelko 2002; Dabelko 2008; chap. 100 by Brauch/Oswald) to assist *Our Common Journey* (US National Research Council 1999) toward sustainability.

But the needed proactive policy responses that have been suggested by the *Millennium Ecosystem Assessment* (MA; chap. 3 by Leemans) require a new multi-, inter-, and transdisciplinary research agenda (Oswald/Brauch 2008) with qualitative and quantitative, historical and sociological methods, as well as modelling, simulation, and scenario-building motivated by the policy goal to develop early warning indicators and models to address the probable conflict constellations that may under certain societal and political conditions result in conflicts, and to develop strategies for *resolving* them peacefully, and *avoiding* such constellations from occurring and *preventing* an escalation into violent conflicts.

5 Natural Climatic Variations in the Holocene: Past Impacts on Cultural History, Human Welfare and Crisis

Wolf Dieter Blümel

5.1 Introduction: Climate Change – Past and Future¹

Since the late 20th century, research efforts have increasingly focused on past, present, and future climatic changes, and on global environmental change. Their consequences for humankind are still uncertain, but they pose many dangers for human beings, societies and states, including for security. Scientists and non-governmental organizations are concerned as to how humankind could be affected by climatic mutations and could mitigate and adapt to some impacts. This refers to a change of paradigms: The last decades were characterized by a certain ignorance of natural determinations on cultural development (Issar/Zohar 2004).

This chapter reviews how even minor climatic fluctuations might have triggered sensitive environmental changes, and how they affected human activities and civilizations either positively or negatively. Highly industrialized societies are not protected from these natural challenges, but all societies are dependent on solid food and water supplies. Finally it will be discussed whether a retrospective view of (pre-)historic climate events may be helpful for predicting future developments.

During earth history the climate has never been constant – no matter what time scale is used or for whatever reasons. This chapter deals with the young Quaternary period, i.e. the past 20,000 years. It in-

cludes parts of the last glaciations, especially the *Last Glacial Maximum* (LGM), and especially the so-called *Holocene* of the past ten thousand years. This period is most important for the cultural development of humankind.

The Holocene as the post-glacial warm period has been perceived as the most stable climatic period of the past 130,000 years. Based on this unusual climatic stability during the past 10,000 years, many researchers and laymen assumed that the present global warming – indicated e.g. by the retreat of the glaciers since 1850 – has been caused by anthropogenic effects. Thus, global warming was interpreted as a catastrophe for humankind.

A series of natural climatic fluctuations could be reconstructed (see figure 5.1), using archives like pollen, moors, fossil soils, lake sediments, archaeological remnants, artefacts, etc. In prehistoric and historic times, warming was normally accompanied with various advantages for humankind. Warming increased the agricultural effectiveness and extended the arable land to higher latitudes or higher up into the mountains. Simultaneously, air humidity was also enhanced and the tropical monsoons brought more rainfall for larger areas in dry regions. With regard to climate history the following trends may be briefly summarized:

- climatic variations belong to the natural system and have different, partly complex causes;
- in the past periods of warming these mostly led to welfare and cultural progress;
- atmospheric cooling usually coincided with famine, drought, disasters, and cultural decline.

The following chronological references offer selected examples for these linkages and permit some conclusions on future developments. This chapter distinguishes between *climatic optima* and *pessima*. ‘Climatic optima’ are periods with mostly favourable conditions for human societies; while ‘climatic pes-

1 This chapter partly relies on earlier German publications by Blümel (2002, 2006) and it is based on a lecture presented to a workshop. It does not aim at representative and comprehensive insights on the manifold aspects of the topic. It reflects the lead editor’s invitation to offer an overview regarding past climate impacts on human welfare and on crises. It has been revised taking many valuable recommendations of anonymous reviewers from other disciplines into account.

simas are cooler periods with unfavourable, and often precarious living conditions.

Table 5.1: Stratigraphic Table of the Late Glacial and Holocene. **Source:** Blümel (2006: 18) adapted from the National Atlas of the Federal Republic of Germany 2003.

Stratigraphy	Stadial and inter-stadial period	Calendar years before present (cal BP)
Holocene (post glacial period)	Subatlantic	2,800 - 0
	Subboreal	5,100 - 2,800
	Atlantic	8,200 - 5,100
	Boreal	9,800 - 8,200
	Preboreal	11,590 - 9,800
Late Glacial Period	Younger Dryas	12,680 - 11,590
	Alleröd	13,370 - 12,680
	Elder Dryas	13,535 - 13,370
	Bölling	13,670 - 13,535
	Oldest Dryas	13,810 - 13,670
	Meiendorf	14,446 - 13,810
Last Glacial Maximum > 14446		

Reconstructing past climates resembles a difficult jigsaw puzzle: Meteorological measuring started in the 18th century. All climatic information on older periods must be gained from different indicators and archives. Those 'archives' can be e.g. descriptions, paintings, registered dates like grain prices, wine qualities, or crop quantities - they can be interpreted and 'translated' in climatic terms. Going further back into the past fossil soils, pollen and macro-biotic relicts, dendro-ecological or ice-core analysis, lake deposits, eolian sediments, or other geomorphological remnants deliver indirect climatic records. Only several such indicators can contribute to a more precise estimate of past conditions. Absolute datings (radio carbon) or archaeological findings may help to fix the time period concerned.

The author's scientific interest has focused on hot and polar deserts, landscape development and paleoecology. It was attempted to control, if even minor climatic variations or fluctuations have been expressed in peripheral and extreme regions of the globe. One additional method to identify climatic fluctuations is the behaviour of regional populations. Crop failure, starving, migrations, abandoning of settlements, etc. can be compared with references in so-called 'correlated or contemporary sediments' to obtain more reliable information on the attributes, impacts, and geo-

graphical range of climatic variations. Those (minor) fluctuations in the Holocene (table 5.1) have been overlooked for a long time in the previous paleo-climatic discussions.

5.2 Pleistocene Immigration – America’s Early Inhabitants

During the Late Stone Age, periods of migration and distribution of human groups were directly influenced by paleo-climatic conditions. The global average temperature was about 11°C, or 4 to 5°C lower than today. In higher latitudes, huge ice domes covered the continents. In so-called peri-glacial areas in the middle latitudes, like in Central Europe, the annual average temperature was several °C below zero and the land was covered with tundra and cold steppe vegetation.

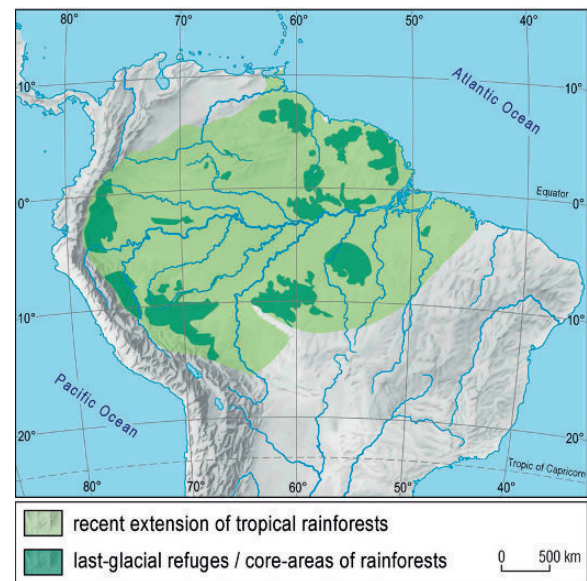

During the *last glacial maximum* (LGM) the sea level was about 130 metres lower. The bottom of shallow ocean floors dried up in some parts of the world. Thus, people could move even by foot between islands of the Asian archipelago and even to Australia. For the population in both Americas the drying of the Bering Strait between Siberia and Alaska had been crucial: about 25,000 years before the present (BP), main stream theories assume that Mongolian groups immigrated to North America – the posterior ‘indigenous’ Indian population²). Anthropologists investigated the population and settlement history of South America. They were surprised that the Monte Verde culture in southern Chile originated already 13,000 years BP (Blümel 2002).³ How could this fast distribution be explained across huge distances, irrespective of immense obstacles like rain forests, mountain barriers, and rivers?

Paleo-geography offers an answer: The global atmospheric conditions in those periods of glacial maximum and late glacial periods were much cooler and had lower humidity. The vegetation cover all over the globe totally differed from today. In Middle and South America, the rainforest in the Amazon Basin had disappeared and remained only in small island-like patches (figure 5.2; Veit 2007; Whitmore 1993, 1990). Areas in between were savannahs, steppes or

even deserts. Thus, the collector and hunter populations could migrate and spread rather quickly. These open landscapes offered abundant prey and vegetable food. Thus, this cool and precarious climate had favoured the early migration processes.

This example illustrates how climatic change really occurred: The margins of ecosystems shifted to a distinct alteration or even to a complete transformation of pre-existing ecosystems (for later developments in the Sahara see Kröpelin/Kuper 2007; Pachur/Altmann 2006; part 5.4.1 below). These integrative and structured natural systems work simultaneously as human habitats. Changes in natural conditions had automatically influenced the land-use pattern and mode, as well as productivity, etc.

Figure 5.2: Refuges of the Amazonian rainforest during the last glaciation, compared with the present situation. **Source:** Adapted from Haffer (1969) and Veit (2007) with permission of both authors.

5.3 North Atlantic Current: The First European Crisis

The transition from the conditions of the Ice Age to the next interglacial period (*Holocene*) was accompanied by periods of warming and cooling. The most effective intersection – the ‘*Younger Dryas Event*’ about 13,000–11,560 yBP (years before present; table 5.1) – was caused by the outburst of huge quantities of melting water from North-America’s collapsing ice shields into the Atlantic Ocean. This light sweet water

2 Other theories of the migration to America by boat (e.g. by Thor Heyerdahl, Norway and by Santiago Genovéz, Mexico) are neglected here. It is shown how climate variations affected and altered the global vegetation cover – the main source of human food.

3 See: G. Forster: “Wandertrieb im Blut”, in: *Der Spiegel*, No. 3 (1997): 152–153.

interfered with the thermohaline convection and interrupted the North Atlantic Current (Gulf Stream) and its heating effect for the north Atlantic surroundings. Thus, large parts of Europe returned to a cold periglacial climate. Living conditions of the stone-age populations deteriorated, because woodlands disappeared again and the food supply with game, fruits and firewood became scarce. People had to move to more pleasant landscapes, i.e. to South-eastern Europe. The last impact of the ending glaciation in North-America occurred 8200 yBP, at the end of the Boreal period (table 5.1). Melting water once more affected the Gulf Current and led to a remarkable cooling in the North Atlantic, and possibly to a disturbance of the thermohaline circulation (Weiss/Bradley 2001). Many researchers are still looking for the geographical range and the ecological effects of the Younger Dryas, and the 8200 BC event. Those ‘natural experiments’ may teach what will happen if the Gulf Current is disturbed: Contemporary global warming with its melting of glaciers and Arctic sea ice has caused fears of a weakening or collapse of the North Atlantic Current. The present discussion on the future of the Gulf Current has been controversial (Bryden/Longworth/Cunningham 2005: 655; Lund/Lynch-Stieglitz/Curry 2006; Rahmstorf 2000; Rahmstorf/Schellnhuber 2006).⁴

5.4 Holocene Climatic Fluctuations During the Past Ten Millennia

According to the reconstruction of the Holocene climatic ‘swing’, some simplified and obvious correlations between climatic milieu and human welfare or crisis will be discussed. The aim is to signal the importance of the climatic environment for human behaviour in general. Favourable climatic conditions may support welfare, cultural rise, and social stability. On the other side: Fixed political or societal organizations may experience chaos, collapse or launch migrations. Looking back may give some picture of what will possibly happen in parts of the world if the global climatic change proceeds.

5.4.1 Postglacial ‘Megathermal’ - Global Welfare and the Neolithic Revolution

Caused by astronomic parameters like the inclination of the earth’s axis and its gyroscoping, barging rotation (precession), the so-called postglacial thermal optimum (‘*megathermal*’ or ‘*altithermal*’) occurred. Between 10,000 and 5000 yBP a global climatic change took place. It was the warmest period since the *late glacial maximum* (LGM) until now, with increased rainfall in dry lands (shrinking of deserts, expansion of savannahs and woodlands). The Saharian desert nearly disappeared (Claussen/Kubatzki/Brovkin/Ganopolski 1999; Claussen/Gayler 1997) and changed into a grassland and bush savannahs with lakes, periodic rivers and lots of game like antelopes, elephants or crocodiles (Kröpelin/Kuper 2007; Pachur/Altmann 2006). Numerous artefacts and fossils documented an abundant environment. The domestication of different animals and pastoral nomadic life emerged. The metamorphosis of the Saharian ecosystem is an impressive and amazing example for the ecological consequences of climatic variations.

This climatic optimum with regard to temperature, rainfall, and seasonal conditions led to the ‘neolithic revolution’ or a settled way of life: Agriculture developed in the Near East (and maybe simultaneously in other regions). Jericho is one of the oldest towns (9000 BP) and counterpart of Çatal Höyük in Anatolia (Issar/Zohar 2004 and chap. 6 below). From the ‘fertile crescent’ (Mesopotamia and adjacent regions) settlements spread to Europe (Müller-Beck 1983; Waterbolk 1968; Issar/Zohar 2004: 557ff). Impressive megalithic cultures settled also in higher latitudes (e.g. in Scotland, Orkney Islands) referring to optimal agricultural conditions and abundant food production to create stone circles like the Ring of Bodgar, Stonehenge, or large megalithic tombs. Astronomic functions and calendars that were integrated into these monuments point to the importance and the perception of the climatic framework within the Neolithic civilization.

It is obvious to recognize the Megathermal period of the Holocene as the mystic ‘paradise’, or the ‘garden of Eden’ or the famous ‘golden era’. It seems to have been a time of easy living and of a surplus of ‘human energy’. All this can be explained by a high and reliable landscape potential, caused by optimal climatic parameters. The impressive megalithic monuments correspond with the social and economic opportunities of those times. This mega-architecture seems to belong to advanced civilizations, and it evi-

4 Susanne Donner: “Viele Modelle - eine Tendenz: Ergebnisse aus Klimasimulationen unterscheiden sich nur im Ausmaß des Klimawandels”; at: <<http://www.wissenschaft.de/wissenschaft/hintergrund/271519.html?Page=2>> (3 November 2006).

dently evolved in favourable warm climates. Similar conclusions may also be allowed for later climatically optimal periods, e.g. concerning the famous Gothic architecture in Europe or the Maya sites in Yucatán, Mexico (see fig. 5.9, 5.10, 5.11).

5.4.2 Cooling Climate - The End of Paradise

The 'end of paradise' occurred immediately. A famous witness of a climatic jump was the well-known 5,300 years old snow-mummy named 'Ötzi'. This member of the Neolithic groups living in the North Italian Alps (South Tirol) was found on a ice free yoke in the Austrian Ötztal Alps. Ötzi probably died in a blizzard, remained permanently buried, and became mummified in the hard snow until 1991 (Blümel 2002). During the altithermal period of the Holocene, the glaciation of the Alps was less expanded than today. The tree line reached 200–300 metres further up. Neolithic summer camps (seasonal grazing) have been found in the high alpine region (e.g. close to the village of Obergurgl in North Tirol). Ötzi's death documents the rapid end of the postglacial Altithermal in Central Europe. The beginning of the following cold Bronze Age was an extreme time of deterioration and of agricultural crisis (crop failure) in Europe, accompanied by frequent famines and loss of population ('Piora-oscillation', Schönwiese 1995). The atmospheric cooling that was accompanied by strongly diminished precipitation ended the 'green Sahara' and the desert expanded again (see 5.5.1). Similar processes could also be reconstructed in eastern Chinese drylands: up to 3400 yBP, these regions have been humid woodlands. Documents prove that in about 2200 yBP the northeast showed a dry climate with steppes and desert conditions (Tarasov/Wagner/Guiyun 2007). Concerning the Mediterranean, Issar/Zohar (2004: 101) stated:

In detail the proxy-data from the Soreq Cave show that a warm and dry period starting around 3500 BCE and lasting a few decades to a century, a cold and extremely humid climate followed, continuing until 3300 BCE. Then came an extreme dry period, peaking around 3200 BCE, followed again around 3000 BCE by a cool and humid period that lasted, with some interruptions, for about seven centuries.

This statement makes clear that contemporary climatic variations express their individual dynamics and features within the different regions and landscapes of the globe. Another example from Mesopotamia also stresses this aspect:

By 3500 BC, urban Late Uruk society flourished in southern Mesopotamia But these colonies and the expansion of Late Uruk society collapsed suddenly at about 3200–3000 BC. ... Now there are hints in the palaeoclimatic record that it may also be related to a short (less than 200 years) but severe drought (Weiss/Bradley 2001).

Have these two examples been an incidental parallel to Ötzi's death?

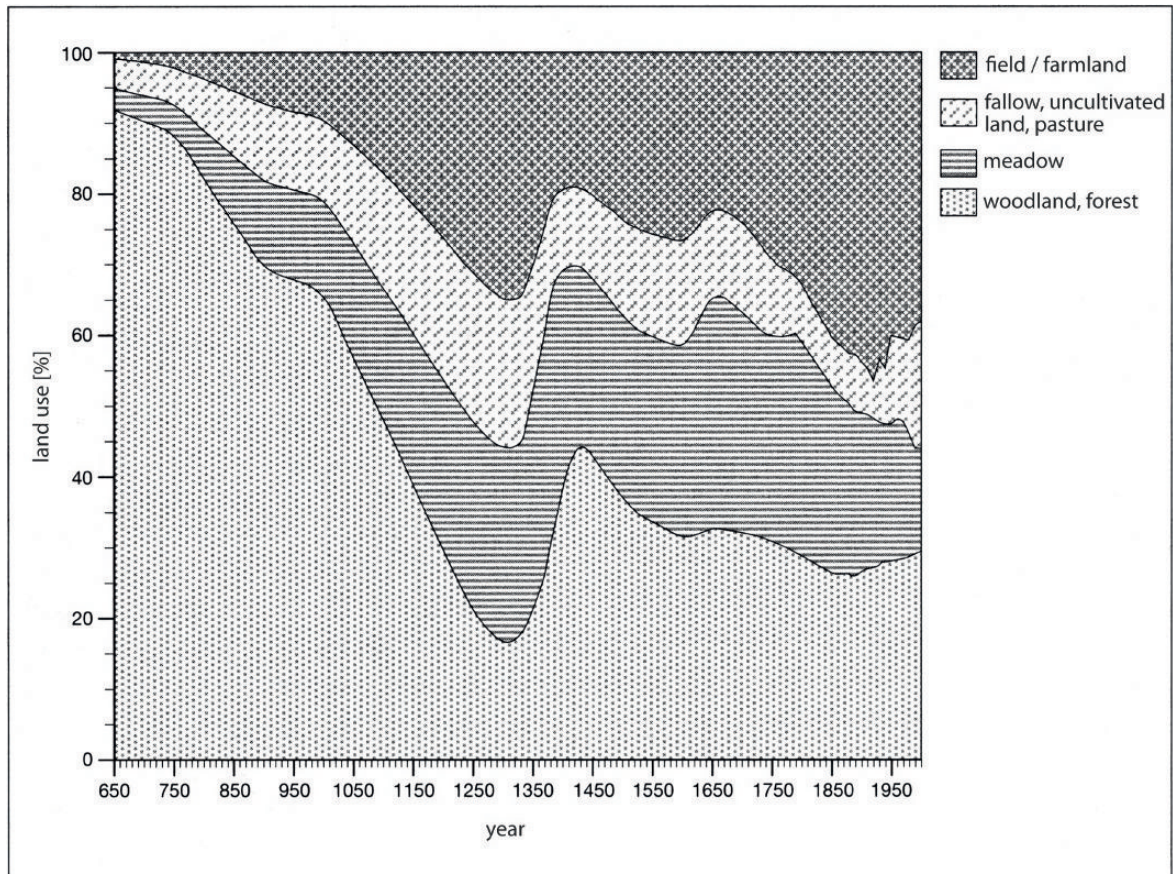

5.4.3 Celtic Culture and Roman Empire: A New Warm Period

The Celtic period (during the Iron Age) started around 700 or 600 BC with the Hallstatt culture and was supported by an appreciable improvement of the climate. Since the 7th century BC the population was growing, the society became complex and hierarchically structured. Centralization occurred steadily and towns emerged. Widespread connections in trade and cultural exchange flourished (e.g. with Greece and other Mediterranean regions). Since the 4th century BC, climatic deterioration stopped this cultural development and Celtic society collapsed. Large migrations started to Southern Europe, the Balkans, and Asia Minor.

A revival of Celtic culture took place in the La Tène era. During the following times the Roman Empire expanded and occupied Celtic and Teutonic territories. Roman cities were founded in *Germania*, supported by an abundant agricultural production. The impressive architectural remnants point to welfare, civilization, and surplus. The administration of these northern territories was facilitated as the Alps could be crossed even in winter. Indicators hint to stable climatic conditions with only low variability – the so-called *Roman climatic optimum*. The warmer climate allowed the growth of grapes even in Britain. Successful trade could be maintained from north to south. More humid conditions supported intensive west-east trading and cultural exchange along the Silk Road to China. Yang, Braeuning, Shi, and Chen (2004) reconstructed a warm and humid period in the arid zones of northwest China between 2200 and 1800 yBP.

The rise and fall of the Roman Empire was evidently accompanied and partly steered by climatic circumstances, which are also reflected in other parts of the world. It can be regarded as a model for expansion and growth, supported by favourable climatic conditions (Lamb 1982, 1989; Schönwiese 1995). To mention only one military aspect: A huge army oper-

Figure 5.3: Development of the land use expansion in Germany since the European peoples' migration. The medieval climatic optimum caused an increase in population and a wave of foundations of towns. Woodlands were cleared and transformed into fields, pasture and fallow. During the 13th century woodlands declined below 20 per cent of the total area. With the beginning of the next climatic crisis after about 1330 (Little Ice Age) the agricultural land shrank and forests spread again. **Source:** Adapted from Bork/Bork/Dalchow/Faust/Piorr/Schatz (1998) with permission of the authors.

ating distant from home must be supported by the occupied lands. Insufficient crops and livestock slow down or prevent military gains. The fall may have been accelerated by disturbances, social crises, and migration movements that were triggered by precarious circumstances. (For a detailed discussion of the Roman fate see: Gibbon 1776–1788, 1983; Huntington 1915, 2001; Lamb 1982, 1989; Brown 2001, Bradley/Jones 1992).

5.4.4 The Climatic Crisis: European Peoples' Migration

Between antiquity and the Middle Ages an evident climatic crisis took place. Climate deteriorations triggered population movements. The most well-known consequence was the European mass migration from the 3rd to the 6th century. The beginning of this 'mys-

terious' process – fraught with consequences – can be explained with crop failure and famines caused by the worsening (or cooling) of the climate. Especially tribes living in Northern or North-western Europe were affected. Malnutrition and social unrest may have been responsible for the mass migrations and conflicts in Europe which contributed to the collapse of the Roman Empire. The famous 'Silk Road' was abandoned due to water shortage and lack of supplies. Increasing aridity in the Asiatic steppes may have been one climatically determined cause for the advances of the Huns (Brown 2001).

The lack of impressive architectural sites was a typical outcome of hardship: There was no surplus or time for demanding cultural activities under those circumstances. On the contrary, destruction and chaos determined life more than development. Social turbulence, collapse of social structures, migrations, and

Figure 5.4: The hyper-arid Skeleton Coast Desert (Namibia): Numerous stone settings of wooden-made wind-shelters, charcoal, bone-remnants of antelopes or lions and ostrich-pearls refer to a former savannah-ecosystem in the present desert. **Source:** photo by Blümel (2006).

conflicts determined the way of life. The scenario of the European migration of people could point to a scenario for regional processes that may be triggered by future climatic changes, especially in less developed countries.

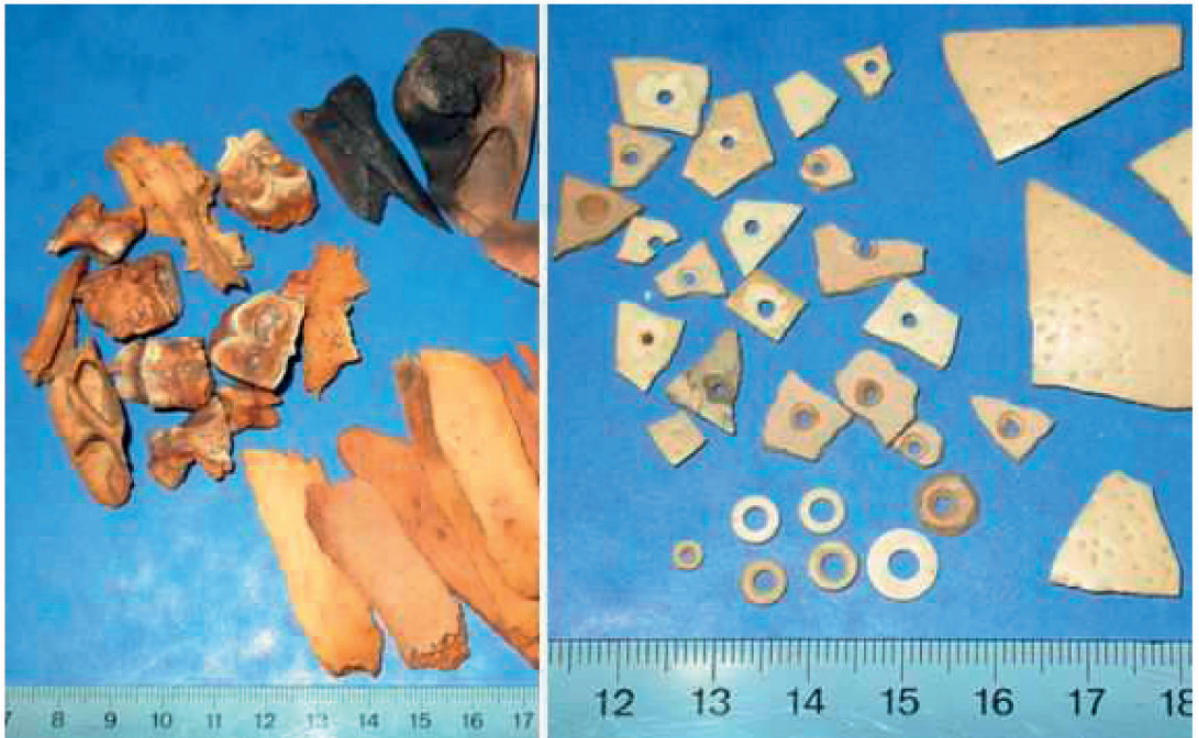

5.4.5 Medieval Warming: Population Growth and Urban Life

Based on the hypothesis that climatic warming contributed to cultural development, a persuasive proof can be found in the European middle and higher latitudes (Bradley/Jones 1992; Brown 2001, Glaser 2001; Hsü 2000; Lamb 1982, 1989). The medieval times (between 1000 and 1330 AD) are marked by a warming and climatic stability, which resulted in high agricultural productivity and a surplus of food, and thus caused an immense population growth. In Central Europe, thousands of cities and villages were founded, establishing the present settlement network. Agricultural production spread out again into the low mountains, more than 200 metres higher than today. La-

bour-sharing, manufacturing, trading, and services developed, supported by the productive rural surrounding. With regard to future effects of climatic change the stable weather and seasonal conditions were important as a guaranty for abundant crops. Thus large wooden areas had to be cleared. The woods dropped to less than 18 per cent of the German surface (Bork/Bork/Dalchow/Faust/Piorr/Schatz 1998; figure 5.3)

The fascinating Gothic architecture symbolizes until today the prosperity and surplus of those times. The medieval period is another example for the dynamic of climatic optima: Reliable and high agricultural productivity was the indispensable prerequisite for creating social and political structures, and it led to a distinct diversity of techniques and cultural development. This climatic framework has been the basis of welfare during all times, irrespective of the systems of rule. The medieval warming also benefited higher latitudes: Grain production was possible in Scandinavia north of the 65° latitude; vineyards grew in Southern Scotland. The polar pack ice retreated considera-

Figure 5.5: ^{14}C -radiocarbon dated by B. Kromer proves the medieval age of these archaeological findings. **Source:** photo by Blümel (2006).

bly. The Normans (or Vikings) settled in Greenland and Iceland, where even grain could be produced (Brown 2001; Lamb 1982). Starting from there, America was discovered prior to the Spanish Conquest.

In *lower latitudes*, the deserts partly shrank in some periods due to increasing humidity (Namib, Atacama). Indigenous southwest African cultures like hunters or pastoral nomads profited from these hydrologic fluctuations. The higher (global) temperatures have been evidently correlated with a greater monsoonal reach and augmented rainfall. These conditions were instrumental for stone-settings belonging to former huts or wind shelters dating back into the medieval period (Blümel/Hüser/Eitel 2000; figures 5.4, 5.5). The present deserts must have been tropical savannah (grassland with bushes or smaller trees).

The shifting margins of the desert depending on the reach of monsoonal precipitation are among the most common problems of people living in semi-arid regions. It is the small and large-scale climate variability. Times of warming strengthened the monsoon reach and triggered human activities, enlarging their territory and welfare. On the other hand, atmospheric cooling caused aridity and increased short-time variability followed by retreat, migrations or collapse of civilizations.

5.4.6 Climatic Pessimism: The Little Ice Age with Famines, Social Crisis and Emigration

The so-called 'Little Ice Age' was the last pessimism in the Holocene see-saw of climatic fluctuations. It lasted from about 1330 up to 1850 AD (see figure 5.1). In the early 14th century, climatic conditions deteriorated again: Seasons proceeded irregularly, the vegetation period suffered, ending up in frequent crop failures (Brown 2001; Glaser 2001; Lamb 1982). The greatest disaster in Central Europe within the last thousand years was caused in 1342 AD by a long and heavy rainfall with cloud bursts and thunderstorms (Bork et al. 1998). It is assumed that half of the total soil loss by erosion since the introduction of agriculture is due to this single event. People starved and abandoned the settlements in the lower mountains due to cooling and various unfavourable conditions. The concentration of rural refugees in urban areas led to increasing hygienic problems. Plague spread and killed a high number of victims. The German territory lost about 50 to 60 per cent of its population.

The climax of this crisis was reached between the 16th and 18th centuries. Glaciers advanced, symbolizing periods of distinct cooling with all consequences such as malnutrition. Storms, floods, and

Figure 5.6: Albrecht Dürer's (1525): *Apocalyptic Riders* symbolizes the horrors of the 'Little Ice Age'.
Source: Internet.

other natural hazards threatened the population. A differentiated documentation of the 'climate downturn' is provided by Brown (2001) and Glaser (2001). Distress and deprivation destabilized the social and political system. The farmers - under severe pressure from their rulers - started rebellions and attacks (1525 AD), but lost their struggle. An additional consequence for the following centuries was that the farmers fell by the wayside, were extremely exploited, and had no rights (especially during the period of absolutism). Overseas emigration took place in waves, triggered by starving, social crises and armed hostilities or wars (especially during the Thirty Years War from 1618 to 1648). Hundreds of thousands of people lost their lives in these decades. Parts of the country were totally devastated. Albrecht Dürer painted his famous 'Apocalyptic Riders' or 'Knights, Death, and Devil' as symbols of the complex horrors of those times (figure 5.6).

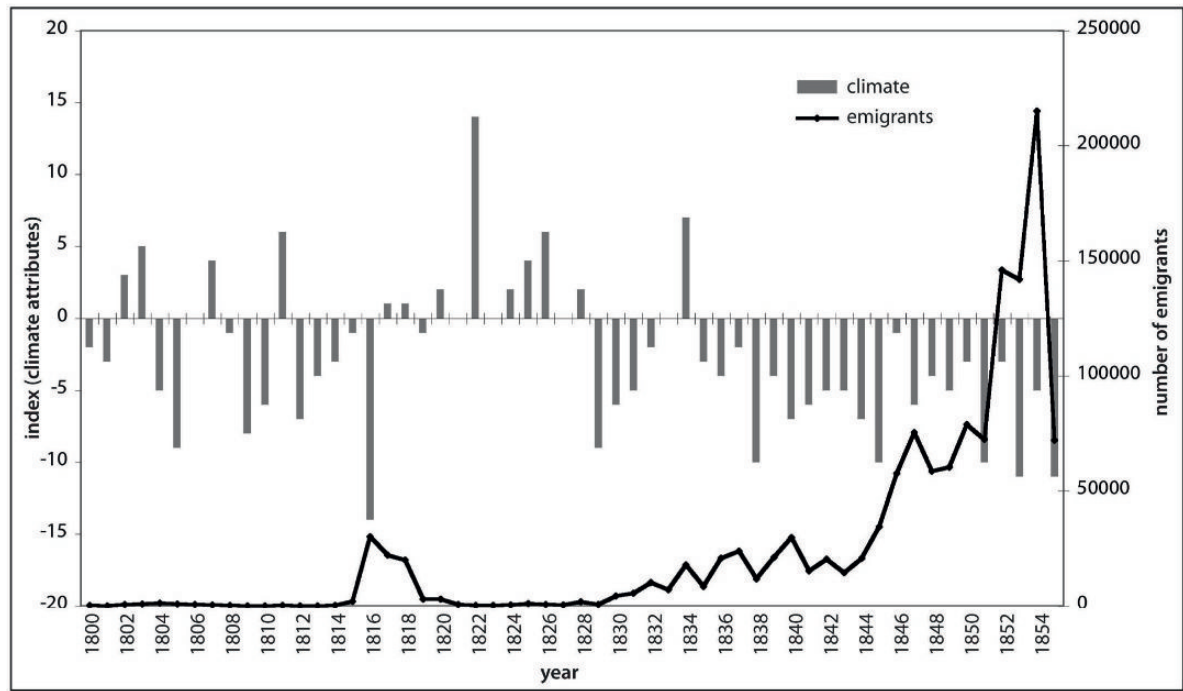

Another famous rebellion and radical social change was presumably also triggered by the results of a pernicious climatic constellation, which prevented sufficient food supply for the majority of the popula-

tion: The French Revolution of 1789 can be regarded as symptomatic: unfavourable climatic conditions (pessimism) have often caused or contributed to the destruction of the political and social systems, sometimes under chaotic and anarchic circumstances (Stock 1996: 38).

Many people tried to find a way out of the troubles by emigrating, especially to the 'New World'. The last huge emigration wave left from Ireland and Scotland immediately prior to the end of the 'Little Ice Age' (1845-1850; Ruess 2005). Several years with dramatic crop failure (esp. rotten potatoes) were the main reason. Emigration was not only pushed by desperate situations, but there were also pull factors. The close causal correlation between negative climatic consequences and emigration overseas is illustrated in figure 5.7.

The title 'Little Ice Age' is not really proper: There have been also warm periods in these five hundred years. Ice was not a real problem for the people. As mentioned above, glaciers advanced temporarily but remained in the inner Alps. On the other side, these 'dark centuries' yielded very warm or respectively hot periods. The natural reasons for these internal changes can be found in less solar radiation (Spörer and Maunder minimum; Rahmstorf/Schellnhuber 2006) and solar variability, partly in volcanism (deMenocal 2001: 668). The latest hypothesis to explain the Little Ice Age period was published by Lund, Lynch-Stieglitz, and Curry (2006: 601): Relating to isotope analyses in marine organisms, the North Atlantic Current (Gulf Stream) should have been ten per cent weaker than today. West and Middle Europe received less warmth during the Little Ice Age. One effect was that connections between Denmark and the Normans on Greenland were interrupted. The Inuit population pushed away the weak Vikings and took over their settlements (Lamb 1982, 1989). In general, the atmospheric cooling was connected with a distinct uncertainty and irregularity concerning the course of seasons - the basis for agricultural production (Hummler 1994). Figure 5.8 shows for the 16th century several years in a row with bad weather conditions for sufficient yields. Agrarian societies are very sensitive and vulnerable to such events. Even short series of small or missing yields can evoke an existential food crisis, especially when trade connections or food imports were undeveloped. This simple scenario still applies to many less developed countries. Highly industrialized countries with food reserves can also be affected. These factors should be taken into account when con-

Figure 5.7: The last phase of the ‘Little Ice Age’: Climate indices above the axis symbolize favourable years for agricultural production etc, indices below (-x) represent precarious years with insufficient crops. The correlation between bad years and the number of emigrants becomes clear. **Source:** Adapted from Ruess (2005) with permission of the author.

temporary global environmental changes are being discussed.

5.5 Climate Change: A Trigger for Growth and Collapse of High Civilizations

After this rapid and cursory excursion through 20,000 years of climatic ‘ups and downs’, three additional examples will be discussed to emphasize the evident correlation or interaction between climatic environmental conditions and cultural as well as social reactions. The simple hypothesis is that to establish and maintain a structured and culturally highly developed society requires an efficient and reliable primary sector.

5.5.1 Egypt

The famous Nilonian culture was a ‘child of the desert’. During the postglacial Alithermal with its luscious rainfalls (see section 5.4.1 above), the Saharian neighbourhood was a green open savannah – full of animals and people. The River Nile and its opulent valley oasis were only scarcely inhabited in those

times. The abundance of water seems to have been less important or even a disadvantage for settlers. Maybe the giant seasonal floods threatened the people. Anyway, the livestock in the ‘green Sahara’ apparently seems to have attracted people (Kröpelin/Kuper 2007; Pachur 2006).

This changed when the postglacial Alithermal ended around 5300 yBP (3200 BC) and the savannah dried out, and became a desert again (Kröpelin/Kuper 2007). People retreated and, as ‘desert refugees’, they discovered the oasis of the river Nile and its potentials. Its floods diminished, could be controlled, and served since then as the base of a new agriculture. Irrigation was the technique and a guaranty for crops during the whole year. Abundant fertility and high productivity led to an immense population growth. A feudal regime arose, supported by the surplus (the Old Empire 2620–2100 BC). The famous pyramids symbolize the welfare of the leadership and of the upper class. On the other side, without an abundant food supply and of slaves and workers, the enormous buildings and tombs could not have been realized. (See Issar/Zohar 2004, 2007 on Egypt, and Bolle 2003 on the Mediterranean in general).

In Egypt, climatic worsening (i.e. expanding desert conditions) led to the depopulation of the former sa-

Figure 5.8: Reconstruction of weather and seasons in the 16th century: Germany often suffered during the Little Ice Age under several year-long phases of bad weather conditions. The seasons strongly varied, were incalculable, and prevent a successful sowing and crops. Famines and social crisis occurred frequently. **Source:** Hummler (1994).

vannahs, but it also contributed to innovative cultures and civilizations outside these regions. This example demonstrates the importance of a reliable access to water. In times with declining rainfall and drought in the width of land, waters from distant humid catchments (Ethiopia, Uganda) formed the basis for a new high culture. Such ‘exotic rivers’ like the Nile occur rather often in dry lands and act as ‘arteries’ of rural and urban life. Facing global environmental change, even these opulent hydrological systems may change, causing scarcities and conflicts (see the chap. 48 by Adly/Ahmed and chap. 49 by Kameri-Mbote/Kindiki in this vol. on water security in the Nile River Basin; and chap. 68 by Ejigu on environmental conflicts in the upper Nile Basin countries).

5.5.2 Nasca Civilization: Shifting Desert Margins

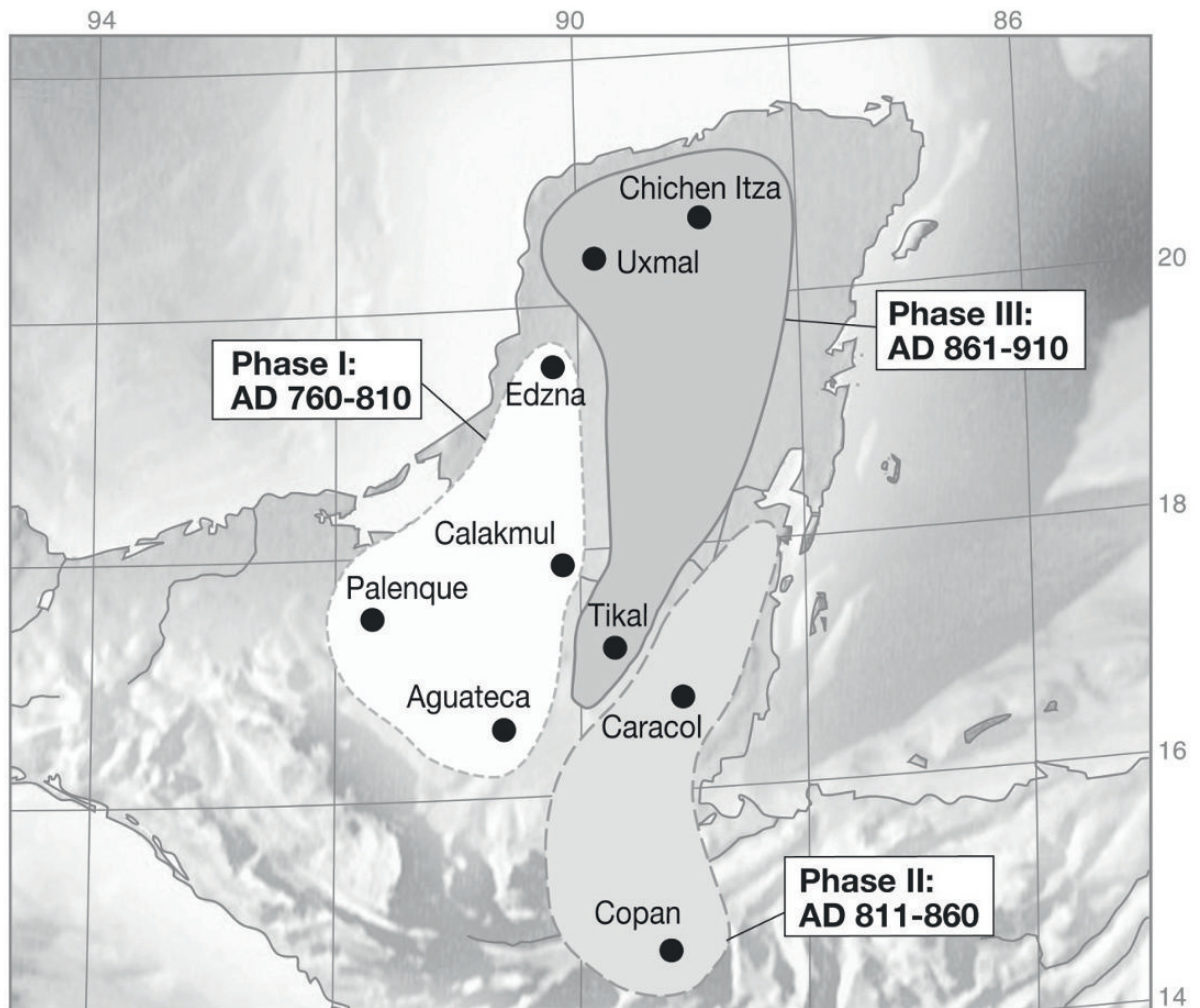

Mysterious engravings – giant ‘geoglyphs’ – are the most well-known characteristics of the Peruvian Nasca civilization. Its fate can serve as an icon to demonstrate the integrative relationship between human beings, climate, and the topographic environment. The previous Paracas culture developed between 800 and 200 BC, followed by the Nasca people. They lived from 200 BC in the fertile river oasis in the Atacama Desert close to the Pacific.

In the Middle of the Nasca Period (after 250 AD) people suffered under increasing aridity. The effec-

tiveness of monsoonal rainfall decreased and the desert margin shifted eastward. Nasca settlements subsequently moved upstream into the mountains. Culminating aridity about 600 AD probably caused the collapse of the Nasca civilization (and of adjacent cultures like the Moche further north). Geomorphological and paleo-ecological investigations support the hypothesis that climatic drought (aridification) and not – as hitherto assumed – El Niño events brought the Nasca culture to collapse (Eitel/Hecht/Mächtle/Schukraft/Kadereit/Wagner/Kromer/Unkel 2005).

Four hundred years later, the eastern Atacama was reoccupied (during the late intermediate period between 1000 and 1400 AD), what coincided with the climatic optimum in Europe and in other parts of the world. The desert then shrank into a small strip of about forty kilometres. *Ciudad Perdida* or the ‘Lost City’ (Unkel/Kadereit/Mächtle/Eitel/Kromer/Wagner/Wacker 2006) is a giant archaeological witness for the medieval comeback of the rainfall into the lower parts of the western Peruvian Andes. Archaeologists could document that this community – situated elevated on a mountain saddle – had great importance in trade and could supply itself from local rainfall and nearby field terraces (Unkel/Kadereit/Mächtle/Eitel/Kromer/Wagner/Wacker 2006).

Figure 5.9: Phases of the Maya collapse during early medieval times: The main reason is to be seen in droughts and in a great variability in rainfall. **Source:** Adapted from Arz/ Haug/Tiedemann (2007) with permission of the authors.

5.5.3 The Mayan Collapse: Natural Causes for Cultural Decline

The discussions and hypothesis about the collapse of the Maya civilization (Yucatán Peninsula) are rather old and contradictory.⁵ New investigations on sedi-

⁵ There are different positions to be found in the literature: e.g. Webster (2002) argues with the disproportion between population and resources. In Culbert (1973) different opinions are presented. Demerest/Rice/Rice (2004) hint at the complicated findings in different archaeological sites and neglect uniform ecological interpretations. Huntington (1915), as famous representative of deterministic explanations presumed, that an increasing precipitation was responsible for the Mayan collapse

mentary cores taken on the shelf north of Venezuela prove that climatic changes - increasing drought and great variability in rainfall - diminished the agrarian productivity and water resources between 810 and 910 AD. Haug/ Günther/ Peterson/ Sigman/ Hughen/ Aeschlimann (2005) succeeded in reconstructing the exact time schedule of the proceeding decline. Increasing aridity caused the collapse (figure 5.9). At first, the region around Palenque (figure 5.10) and Calakmul was abandoned (AD 760-810), followed by Copan and Caracol (AD 811-860), and finally in the north with Uxmal (figure 5.11) and Chichén Itzá (AD 861-910; figure 5.12; Arz/Haug/Tiedemann 2007; deMenocal 2001; Peterson/Haug 2005; Curtis/Hodell 1996).

Figure 5.10: The Mayan Archaeological Site of Palenque, in Chiapas (Mexico) experienced its climax between the 7th and 10th centuries AD and was deserted by 950 AD. **Source:** photo by H. G. Brauch (January 2007).

Figure 5.11: The Mayan Archaeological Site of Uxmal, Yucatán (Mexico) that was suddenly deserted without any signs of destruction from wars. **Source:** photo by H. G. Brauch (January 2007).

Before the decline of the highly civilized Mayas started, an impressive growth in population and cultural development took place. Living conditions were supported by favourable agricultural conditions,

including reliable seasons, access to abundant water resources and fertile soils. This climate triggered a cultural development: A distinct subdivided social structure originated, comparable with other civilizations. It

Figure 5.12: The Mayan Archaeological Site of Chichén Itzá, Yucatán (Mexico). **Source:** photo by H. G. Brauch (January 2007).

is significant that high civilizations have often constructed impressive buildings with integrated astronomical observatories: Priests and political leaders tried to keep control over their people – by ‘observing’ the climate as a basis of subsistence.

The dramaturgy of the cultural decline of the Mayas, caused by worse climatic conditions, seems to be similar in different times and regions, and may also be a model for future developments: The basis of the food supply deteriorated. The environment was stressed, soils were overused and eroded, and water became scarce. The starving and suffering people were forced to abandon old values like solidarity and common sense, and they became rebellious. Social disturbances overthrew the hierarchic system and this civilization lost its basic structure. Campaigns against neighbours or emigration have often been a loophole in critical situations.

5.6 Outlook on Present Global Warming – Learning Lessons from Climatic History?

Natural climatic fluctuations and variations were quite common during the past millennia. Humankind has

definitely been influenced in its cultural development, regardless of the type of political regime. Can one draw lessons from 20,000 years of climate history for the 21st century? How dramatic might the projected change be (Rahmstorf/Schellnhuber 2006; IPCC 2007)? It may be assumed that natural warming – the next climatic optimum after the precarious Little Ice Age pessimism – is further enhanced by human activities.

The natural system was clearly influenced and damaged by human activities since the beginning of human settlements, but especially during the past 150 years (IPCC 1990, 1990a, 1992, 2007). The present situation has never existed before in world history: More than 6 billion people (causing an enormous change of land cover) and huge emissions of carbon dioxide from the burning of fossil fuels.

The effect of CO₂ emissions cannot be directly determined, but to release fossil energy – i.e. of stored solar radiation – within a short period and in enormous quantities, undoubtedly will have an effect on the atmospheric dynamic. In addition, there is an increasing, accelerated consumption of the global land surface and biosphere. The altered earth surface (parameters of albedo/= proportion of reflected solar radiation, of vegetation cover, transpiration, surface

water run-off, etc.) has also influenced the climate. In total, the recent quality and quantity of the anthropogenic impact on the climate does not have any ancient parallels. In Europe, the Near East and North Africa, Antiquity and the Medieval period already caused enormous landscape damages with climatic effects. In both Americas and in Asia, the anthropogenic impact on the earth's surface was enforced in and since the Renaissance by the immigration of Europeans.) Probably all these impacts have an additional lasting and altering effect. As a result, from the perspective of this author, the (pre)historic experiences and comparisons seem to be rather worthless – facing ‘totally’ new atmospheric parameters (see Claussen/Brovkin/Ganopolski/Kubatzki/Petoukhov 2003 who argued that “the past is not the future”).

But many physical rules will remain effective. Warming will lead to more precipitation in some regions. All global ecosystem margins will be on the move. Especially some of the dry-land areas will profit from the shifting desert margins, others will be the losers. Kröpelin and Kuper (2007) remarked on their expeditions that parts of the eastern Sahara have received more rainfall during the last few years. Nomads graze their camels now, where a hyper-arid desert existed during living memory. It is to be expected that the border of arable land and the timber line will shift towards the Polar Regions and higher into the mountains, similar to the post-glacial Megathermal (chapter 5.4.1).

Looking backward and reconstructing ancient climatic conditions can teach us general aspects of complex interactions between environmental conditions and human activities. This is indispensable for understanding the natural system, for prognostic, modelling purposes, and even for the comprehension of social behaviour or reactions. But what really will happen in the macro- and meso-scale dimension depends on the variable borders of air and water masses, chaotic reactions, or very complex feedbacks and synergetic processes. Micro-scale changes and developments depend on the specific geographical situation of the regional features (on topography, drainage systems, settlements and infrastructure, etc.).

Most likely there will be more disadvantages than gains: The synergetic processes caused by the greenhouse effect and the projected progressive warming may have other consequences than the natural fluctuations in the past. Frequency and magnitude of gales, thunderstorms, or flooding are expected to increase (IPCC 2007). The gradient between the cold arctic air masses and warmer mid-latitude or tropical air may es-

calate. Permafrost will disappear in high mountains and cause more mass movements (rock falls, landslides). Torrential rain will lead to a flooding of lowlands or alluvial plains and landslides. A rising sea level will threaten the areas along the coastline as well as flat islands. Energy and water supply will be affected by diminishing glaciers – there are many additional aspects to be considered.

Undoubtedly humankind with its more than six billion people has changed the global ecosystem in different ways, not only the atmosphere. Together with all synergies and feed-backs, humankind has become much more vulnerable than in the past. We must face these challenges: Stop the emissions and take actions to guard against the hazards and risks mentioned above. Growing damages must be faced because an overcrowded earth is much more put at risk. There is no doubt about increasing social and economic damages because even precarious sites have been settled by the poor and vulnerable people.

Already now there are conflicts on the distribution and use of scarce water resources. The expected shifts in the ecosystem margins due to altering rainfall conditions, new types of conflicts may arise or intensify. The productivity of the arable land and pastures underlies altering conditions, too. The social conflict potential in large cities or in overcrowded areas and the youth bulge especially in less developed regions is another fact to be taken into account: Migrations with all their consequences will be triggered and possibly lead to violent conflicts. The spectre of human reactions on changed natural conditions is widespread and multiple.

The review of (pre-)historic interactions between climatic fluctuations, evolving environmental changes and human societies can be helpful for general assessments and prognoses. But very simple deductions, models, or parallels will be false – the world has become too complex, as roughly described above. The Nobel laureate in chemistry, Paul Crutzen, coined a proper term by changing the name of the most recent period in earth history – the late Holocene – into the ‘Anthropocene’. This term expresses very well the creative and pernicious human influences on the natural global system (see below chap. 98 by Oswald/Brauch/Dalby).

The quality and quantity of inputs have reached new dimensions. Modern man is able to damage fundamentally or even destroy his basic living conditions. Ancient cultures were adapted to natural milieus. They profited or perished when climatic changes occurred. Nature often constrained the society and de-

terminated the opportunities of human beings. Now, humankind is able both to control the natural system and to lose control. According to a report by the British economist Nicholas Stern (2006), the costs of not acting will be much higher than early adaptation and mitigation methods in coping with global and climate change (Brauch/Oswald/Mesjasz/Grin/Kameri-Mbote/Chourou/Dunay/Birkmann 2009).

6 Climate Change Impacts on the Environment and Civilization in the Near East

Arie S. Issar and Mattanyah Zohar

6.1 Shifting Paradigms: From a Determinist to an Anthropogenic Model¹

During the late 19th and early 20th century, political geography or 'geopolitics' was dominated by a deterministic paradigm that was launched by a group of geographers in *Germany* (Friedrich Ratzel; Karl Haushofer), in *Sweden* (Rudolf Kjellén) and the *United Kingdom* (Halford J. Mackinder) as well as a navy strategist in the *United States* (Alfred Mahan).² This approach experienced a revival during the 1980's and 1990's as 'new geopolitics'³, and since the 1990's also as 'critical geopolitics'⁴ that challenged many of assumptions of their predecessors or as ecological geopolitics or 'political geo-ecology' (Brauch 2003, 2005, 2005a).

1 This text is based on a summary of the book by Issar and Zohar (2004/2007) published by Springer. This original text was used with the permission of the publisher and modified and extended reflecting the detailed comments and suggestions of two anonymous reviewers.

2 See i.a. Ratzel (¹1897, ²1903, ³1923, 1882, ³1909, 1898, 1969); Haushofer (1928, 1932); Kjellén (1915, 1916, 1917, 1924); Mackinder (1890, 1895, 1904, 1905, 1907, 1918); Mahan (1897, 1900, 1900a, 1907, 1957). These references were added by the lead-editor with the consent of the authors.

3 See in *France* (Claval 1996; Chauprade 1999; Defarges 1994; Dussouy 1998, 2000; Gallois 1990; Lacoste 1976, 1980, 1984, 1987, 1993, 1996, 1997; Laid 1998); *Germany* (Brill 1993, 1994, 1998), *Italy* (Ferro 1993; Jean 1995), *Spain* (Vincens 1955, ³1981), *Israel* (Bernstein 2000; Biger 1990; Kimmerling 1983; Kliot/Newman 2000; Newman 1999), in the *UK* (Dodds/ Atkinson 2000; Gray 1977, 1985, 1986, 1988, 1999; Parker 1985, 1988, 1988a) and in the *U.S.* (Agnew (1993, 1993a, 1995, 1998, 2000); Agnew/Corbridge 1989; Cohen 1963, 1982, 1991, 1991a, 1993). These references were added by the lead-editor with the consent of the authors.

With regard to climate issues its main proponent was the American geographer Elsworth Huntington (1876-1947). The essence of this paradigm was that the geographical-physical conditions, which are determined mainly by the climate and climate changes, decide the character of the people, as well as their history (Huntington 1915).

Since the 1930's this paradigm was replaced by the anthropogenic model, which placed all blame for the emergence and collapse of civilizations (including the improvement and degradation of the natural systems supporting them, such as water, soil, and vegetation) on human mal-practice.⁵

The impact of the Sahelian droughts (1968-1984) on the people of this region, the paleo-environmental research as a function of the research concerned with the greenhouse-effect, and the development of objective research tools, especially environmental isotopes, bring an increasing number of geographers, archaeologists and historians to start shifting a significant part of the blame back from man to climate changes and other natural causes.⁶

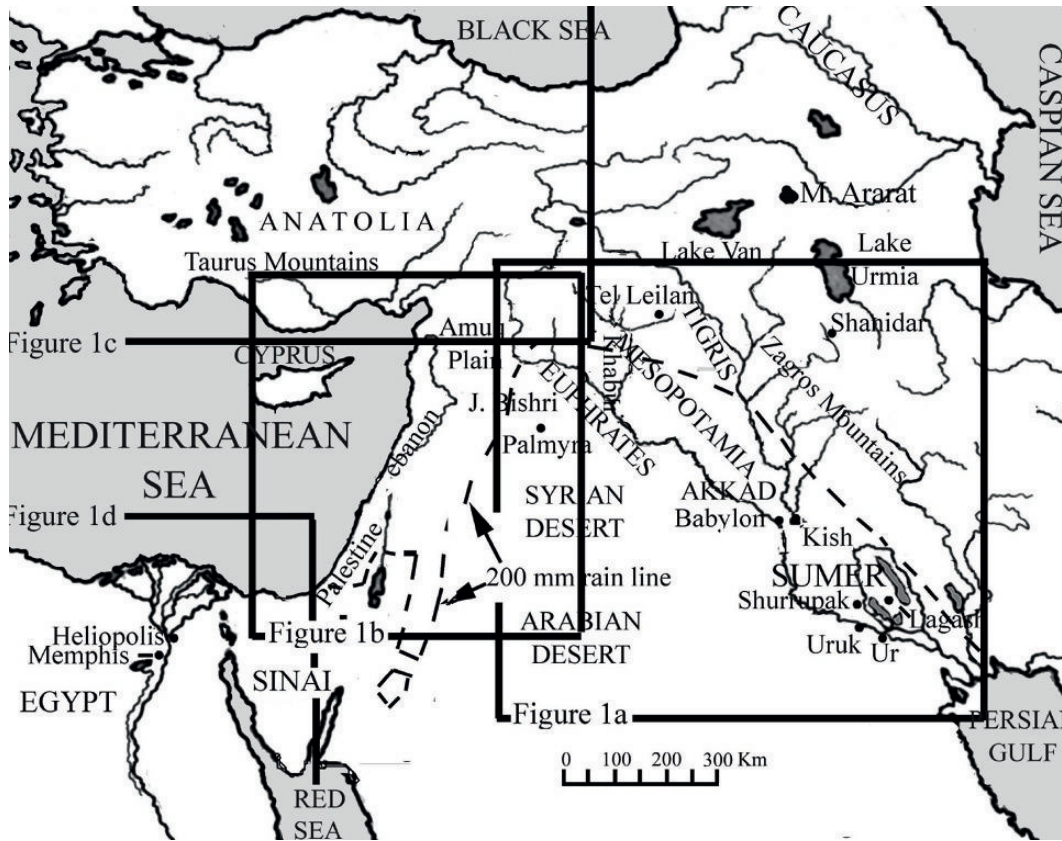

In some aspects it is a revival of the deterministic paradigm, but it can better be described as the emergence of a new neo-deterministic paradigm. This emphasizes the dynamic interaction between the natural

4 See e.g. Dalby (1991, 1999); Ó Tuathail (1989, 1996, 2000); Ó Tuathail/Agnew (1992); Ó Tuathail/Dalby/Routledge (1998). These references were added by the lead-editor.

5 Representatives of the anthropogenic school are: Woolley/Lawrence 1936; Albright 1949, Glueck 1968; Lowdermilk 1946; Worster 1982; Evenari/Shannon/Tadmor 1971.

6 The major representatives of this school are: Carpenter 1966; Braudel 1972; Le Roy Laudrie 1971; Lamb 1977, 1982, 1985; Issar 1990; Angelakis/Issar 1996; Issar/Brown 1998; Brown 2001; Yoshino/Domrös/Annick/Douguédroit/Paszyski/Nkemdirin 2006 (1997); Issar 2003; Issar/Zohar 2004, 2007.

Figure 6.1: Overall Map of the Near East and Maps of Sub regions. **Source:** Issar/Zohar 2004/2007 reprinted with permission of Springer Verlag.

environment as decided by the geographical position, climate, water, soil, vegetation, etc. and the human society supported by that environment. This interaction oscillates within the endurance capacity of both systems dictated by their sustainability, as well as by the flexibility of the natural system and the agility of the human mind.⁷

Issar and Zohar (2004, 2007) have shown that human society responds to change in the environment by inventing new ways to cope with shortage. Yet, once the changes were extreme, continuous and beyond the resilience capacity, catastrophe is imminent. Moreover, each human society tends to overexploit the natural resources and thus accelerate the collapse of both systems. The recuperation may come when an amelioration of the natural conditions occurs, or by adopting new subsistence technologies or strategies or the influx of new societies better adapted or more innovative, enabling the development of a new level

of tolerance and interaction between the systems. Recently computerized models were introduced in order to simulate the interaction between the various components of the natural and human systems (Daily/Ehrlich 1990; Roson 2003; Mendelsohn 2005).

This chapter concentrates on the major climate changes, which have affected the Near East (figures 6.1, 6.2, 6.3, 6.4 and 6.5) during the last ten thousand years, and will show that indeed these were concurrent with major transformations in the history of the people of this region. In other words, the impact of climate changes on the history and culture of the region along equi-chrono-zones (iso-time slices) will be discussed.

The specific research question concerns the shift of the pendulum of paradigms, from the extreme deterministic in the beginning of the 20th Century to the extreme anthropogenic since the mid of that century, to the neo-deterministic paradigm. This paradigm acknowledges the primary importance of climate changes in shaping the history of human communities, especially in regions along the margins of the deserts (warm and cold), but takes into consideration

⁷ The neo-deterministic paradigm is obvious in the work of: Dalfes/Kukla/Weiss 1997; Issar 2003; Issar/Zohar 2004, 2007.

the role of human intelligence and innovation to ameliorate the impact of climate changes.

In order to answer this question the proto-history and history of the Near East, from the establishment of the first agricultural communities to the present will be surveyed and the impact of climate change will be discussed, for each change and for each region.

6.2 Constructing the Jig-Saw Puzzle of Paleo-Climates of the Last Ten Millennia

In their detailed analysis Issar and Zohar (2004, 2007) have used the following methods, which enable scientists to reconstruct the climates of prehistoric and historical times. These include geomorphologic observations such as ancient sea, lake, and river levels, environmental isotopes ratios (like oxygen 18/16, deuterium/hydrogen, carbon 12/13) in deposits of stalagmites and shells, tree rings, and pollen assemblages. Some case-studies like that of the sea levels of the Dead Sea, the stalagmites of the Soreq cave near Jerusalem (figure 6.6.), and the trees from the Roman siege ramp of Masada have been discussed in the book in detail (Issar/Zohar 2004: 30–33; 2007: 27–30). In the attempt of portraying the causes and effects of climate changes on Near Eastern societies, the results of recent archaeological, historical, and socio-economical field work have been interwoven with the picture obtained by the geo-physical methods.

They distinguished among the following major theories, which try to explain the reasons for these changes. In the first place the *deterministic paradigm* focusing only on climate changes and as already mentioned this was the leading paradigm since the end of the 19th century up to the 1930's. The opposing opinion was that suggesting the *anthropogenic paradigm*, according to which all blame was put on the human society for its failures. One of the major blames was the humans' interference with the natural processes and thus causing environmental, economic and political crises.

The region is located along the northern margins of the desert belt of the Sahara and Arabia (figure 6.1). Because the borderline moved considerably a few times during the last ten thousand years, this region is an optimal area for studying the reverberating counteraction between the natural and the cultural human systems. The fact that in this region writing and thus documentation was first invented enables to explore its history to greater depth (Neumann/Sigrist 1978;

Neuman/Parpola 1987; Hallo/Simpson 1998; Kramer 1963; Weiss 1986).

Figure 6.2: Map of Mesopotamia. **Source:** Issar/Zohar 2004/2007 reprinted with permission of Springer Verlag.

As the availability of water in a semi-arid region is seasonal and random the storage of water, on a seasonal and multi-annual basis is essential. Natural storage of water is provided either by sub surface water bearing rocks, or by rains falling on neighbouring areas where the climate is more humid. From this point of view the Middle East has a five-fold pattern. The most easterly fold, the Iranian plateau, depends on the storage of ground water in its alluvial fans. The valley of Mesopotamia (figure 6.2) depends on the subsurface storage of the Tauride and Zagroide mountain chains, from which the big springs feeding its big rivers emerge. The most south-western river valley of the Nile (figure 6.3) depends on the humid and semi humid climate system of the tropics and subtropics. The central mountainous terrain, in which the Judean-Syrian arch (figure 6.4) interconnects with the Taurides and Zagroides arches (figure 6.5), the storage is provided by ground water aquifers, built mostly of karstified limestone rocks (Shuval/Dweik 2007).

Artificial storage is either by irrigation, when water available during the rainy season is stored in the soil, or by cisterns and dams. The history of the spread and survival of human societies in this region was interrelated with his capacity to invent new methods of storage (Issar 2007a).

Figure 6.3: Map of Egypt. **Source:** Issar/Zohar 2004/2007 reprinted with permission of Springer Verlag.

Through the long history of this region, the two great rivers flood plains of the Euphrates and Tigris (figure 6.2) as well as of the Nile (figure 6.3) have been the locales of big water projects, contrived by states and empires while the mountainous regions have typically been subdivided into small ethnic and often political entities, each drawing an independent water supply from springs and wells, plus rainwater collected in cisterns.

Historically, the low-land empires repeatedly endeavoured to exploit the diversity of resources available in the adjoining hills and the mountains to widen their own imperial domains (table 6.1, figure 6.6). Thus, warfare with neighbouring native tribes or nations and collisions with similar aspirations of another power were unavoidable: examples were the Akkadian empire of the third millennium BCE, the Egyptians and Hittites of the second, or the Assyrian and Persian Empires the latter emerging from the irrigated plains of their dissected plateau joined the contest. Later on, Hellenistic dynasties and Rome extended

Figure 6.4: Map of the Levant. **Source:** Issar/Zohar 2004/2007 reprinted with permission of Springer Verlag.

their rule over the whole region. Roman dominance cannot be understood without appreciating the efforts invested in civil engineering, such as aqueducts and roads. The conquest of the entire area by the Arabs under the banner of Islam, with the exception of the northern highlands, concurred with one of the warmest and driest periods in recorded history (Issar 1990, 2003; Issar/Zohar 2004, 2007).

Special sections dedicated to various important topics are appended. The first deals with the technological evolution of means of harvesting, storage, transportation, and lifting of water. Irrigation methods, from simple ditches and canals bringing water from the outlets of springs to diversion dams on small rivers and the large-scale irrigation systems of Mesopotamia and Egypt, to the Roman aqueducts are described and their history discussed. Water wells as a system to draw water from subsurface storage since the Neolithic period to modern times include the Iranian Qanats (i.e. chain of wells), the deep rock-cut wells and galleries of the Canaanite and Israelite walled cities, the storage systems of reservoirs and cisterns, as well as the evolution of devices for lifting water (Issar 1976, 2007a, 2007b).

6.3 From the Palaeolithic to the Pre-Pottery Neolithic Period (from 2 Million to 8000 Years Ago)

During the last glacial period, the Fertile Crescent went through a series of cold and mainly humid phases during which many lakes spread out over wide areas. For example, the Dead Sea was about 200 meters above its present level and its precursor, the Lisan Lake, extended to the Sea of Galilee. Flint tools found in deposits of dried up lakes and springs in what is now the desert bear evidence to the fact that the presently arid lands were once hospitable to vegetation and life. When the glaciers in the higher latitudes melted due to the warming climate and reduced precipitation, the lakes and springs in the middle latitudes dried up. As a consequence, the vegetation and animal or human life retreated to refuge areas along perennial rivers and spring outlets emerging from water bearing rocks fed by rains falling on more humid terrain. The apparently earliest known sedentary settlements, such as Natufian Jericho and Mureybet in northern Mesopotamia as well as many other sites along the inner flank of the Fertile Crescent, bear witness to the initiatory steps of its peoples to become

settled. It was during this period of steady desiccation that in some refuge areas the first attempts of sowing of grain outside its natural habitat took place (preceded or concurrent with the domestication of animals) and ushered in the agricultural revolution of the Neolithic Period (Flannery 1973; Ovadia 1992; Zohary/Hopf 1994, Zohary 1999).

It is thus argued that the inhabitants of the Near East were among the first to respond to the post-glacial warm and dry climate conditions by developing agriculture and herding as a way of life. However, the warming and increasingly arid climate brought more randomness in the availability of water and thus fluctuations in the supply of food growing naturally and without human help. In order to overcome this new state of affairs, agricultural settlements were established near perennial sources of water allowing irrigation of the crops. For instance, a well from the Neolithic period was discovered in the coastal plain of Israel. The domestication of the goat enabled the dispersal of human societies into the desert fringe. The herders overcame the randomness of the natural system by thinning out their herds over large territories and moving from one grazing ground and water resource to another: Throughout human evolution mo-

bility was a primary tool of survival which by now had acquired a new dimension (Muzzolini 1983; Zohar 1992).

In conclusion, the peoples of the ancient Near East overcame the constraints caused by the warmer climate by modifying the natural environment and fitting it to its own rhythm and requirements. By around 6000 BCE the shift from a summer and winter rain regime to the present Mediterranean system of wet rainy winters and warm dry summers caused a severe crisis which coincided with the end of the Natufian-PrePottery Neolithic cultural traditions of the Near East. At that time, the first agrarian villages appeared throughout the Mediterranean islands and countries and southern Europe, whether by diffusion or by acculturation, but probably both, is still an open question. Meanwhile, foraging, fishing, hunting, and incipient cattle herding continued in the subtropical parts of the Sahara and the Arabian peninsula, an area influenced by the subtropical rain systems which had moved northward. Many lakes covered vast areas of the Sahara as well as central Arabia and were surrounded by subtropical vegetation (Petit-Maire 1980, 1987; Kuper/Kroepelin 2006).

6.4 The Great Transition - From Farming Villages to Urban Centres

Oxygen and carbon isotope ratios in cave and lake deposits show that around 4500 BCE the climate became colder and thus more humid all over the Fertile Crescent. Agricultural settlements re-appeared in areas which were not settled during past millennia.

In the eastern part of the Fertile Crescent, people had descended from the highlands to settle in the lower part of the valley along the rivers of the Euphrates and Tigris and began to build the first agricultural urban centres in the lower Mesopotamia. In order to ensure the success of their crops, irrigation methods based on diversion dams and canals from the big rivers had to be developed which needed an ever growing complex of engineering, organization and control (Lloyd 1978).

The interaction between human society and a basically hostile local nature in need of harnessing promoted organization of labour, hierarchy of society, complex administration, and conceptualization of authority by installing cult institutions. In the western end of the Fertile Crescent, terraces for controlling flash floods were built in the desert of the Negev, and

copper metallurgy was introduced, probably by people originating in the northern highlands of Anatolia and Caucasia (Ilani/Rosenfeld 1994).

In northern Africa the subtropical rain belt eventually retreated southward and caused the Sahara to dry out; some of its former inhabitants moved into the Nile Valley and adopted an agricultural way of life laying the foundations of the Egyptian civilization (Caton-Thompson/Gardner 1934).

The magnificent Chalcolithic cultures of the Levant with their artistic tradition and technical knowledge lasting for about thirteen centuries disappeared towards the end of the 4th millennium BCE. Its disappearance was explained in various ways, either by way of invasion of other peoples and/or by the devastations at the hand of the Egyptian armies who had invaded the southern parts of the Levant. Yet, archaeological remains do not reveal any indications of warfare or destruction. The examination of the isotope and paleo-environmental data, on the other hand, shows that the whole region underwent another severe dry climate phase, which lasted for about 200 to 300 years (Helms 1981). It is probable that during this period specialized pastoral nomadism (Khazanov 1984; Zohar 1992) began to spread in the wake of the Secondary Product Revolution (dairy products,

sheep wool, and using animals for traction, transport, and riding.

6.5 The Early Bronze Age - The Urban Revolution and the Dawn of History

After a relatively short warm and dry period and a retreat of the front line of agriculture, a colder and wetter climate affected again the Fertile Crescent. For the Mesopotamian plain it brought in its wake not only surplus of food and unprecedented population growth but also great floods which destroyed many cities, a commonplace experience which was apparently memorialized in the ancient Babylonian myths and the Biblical story of the Flood (Khazanov 1984, Speiser 1969).

The myths of creation and elaborate cults were canonized, and codes of laws were established in order to explain randomness of nature as well as to safeguard laws guaranteeing the structure of organized society: Civilization was born.

Going west, people, whose only remains consist of stone built tombs and tumuli, settled the grasslands bordering the Fertile Crescent. In the Levant, fortified

towns and later cities were built, the largest centres of population this area has seen until the modern period.

The early pre-Pharaonic kingdoms of the Nile valley were united during the Old Kingdom to form the land of Egypt, its most famous legacy being the pyramids erected as royal tombs. In the coastal lands and on the islands of the Mediterranean Sea megalithic tombs and temples mushroomed. For instance, on Malta colossal temples were built, allegedly to worship the Great Goddess of Fertility (Zohar 1996).

In the Indus valley the first signs of what was to become the later Harrapan civilization were seen, its cities founded towards the end of this period. In China's Yangzi River flourished the Liangzhu culture, famous for its jade and sumptuous royal tombs containing dozens, sometimes hundreds, of slaughtered human victims. The organization of human societies into river agglomerates of kingdoms on one hand and towns or city-states in the intermountain valleys on the other hand seems now to have been well established (Adams 1981; Maisels 1993, chaps. 5-8; Kenoyer 1998).

6.6 Dark Age, Renaissance and Decay – The Intermediate to the End of the Late Bronze Age

A variety of evidence from all over the globe shows that towards the end of the 3rd millennium BCE the climate became warmer on a global scale. Again, it caused the glaciers to melt and the oceans' level to rise flooding coastal areas. In the Near East, by contrast, the levels of the lakes dropped and the deserts expanded. Mesopotamia dried up and its soils became increasingly salinized (Jacobsen/Adams 1958; Jacobsen 1957-1958).

The drying up of the semi-arid regions triggered the movement of its inhabitants towards the remaining greener areas. According to Mesopotamian historical sources, the semi-nomadic Amorites invaded the plains of the Euphrates and the Tigris. A related aggregate of warring folks of the northern part of the Fertile Crescent moved southward, dominated Canaan by building fortified cities, and subsequently even penetrated and ruled parts of Egypt, to the Greek historians known as Hyksos (Redford 1993; Josephus Flavius 1960).

As the plains of central Asia and the Iranian plateau became drier, its inhabitants migrated west and south. It could well be that among them we could have found the first groups of speakers of Proto-Indo-Europeans infiltrating into Europe, Anatolia, Iran, and India (Mallory 1989). The coastal territories of many Mediterranean islands were lost. Malta's temples' culture and its sophisticated art vanished. Immigrants from Anatolia (fleeing the Luwians and Hittites?) settled in Crete and founded the Minoan 'palace' civilization (Zohar 1996; Trump 1990).

Once the climax of climate change was over, the societies in those areas which were most affected developed new methods to cope with scarcity of water and food. The inhabitants of the new Middle Bronze Age cities of Canaan developed their sub-surface water systems to irrigate land and withstand siege in their fortified cities. In Mesopotamia and Egypt new and impressive water projects on a wide regional basis were built. Eventually, the climate ameliorated and a more humid climate followed (figure 6.6). Egypt benefited most and was able to expel the 'Asiatics'. By pursuing them into their homeland, the Egyptian New Kingdom established its hegemony over most parts of the Fertile Crescent and eventually collided with the powers of northern Mesopotamia and Anatolia.

6.7 Migrations and Settling (The Early Iron Age)

After a short period of a mild climate, another short but marked warm phase around 1300 BCE hit central Eurasia and triggered a complicated domino-like movement of various peoples, among them the so-called Sea Peoples. Some of these populations may have originated in the Balkan peninsula or Anatolia, and from around the Aegean Sea; others probably from different Mediterranean lands and islands. They appeared to have moved by land and by sea into the Fertile Crescent in reaction to the disintegration of the Mycenaean civilization, the destruction of the Hittite empire, and the Canaanite cities along the Levantine coast. Egypt appears to have fought back, first against the Libyans, then against the 'Sea Peoples' and settled some of along the coast of Canaan to form the alliance of Philistine cities. The Hebrews (probably derived from *habiru*, i.e. pastoral nomads) roaming along the desert fringe belt had to enter the green lands and settle down, either peacefully or by force. The camel has finally become fully domesticated and

enabled a small population of oasis dwellers to live in the desert.

It was also the time of the disintegration of the Harappan or Indus civilization in north-western India as well as the end of the Shang Dynasty in China.

6.8 The Age of Iron and of Empires: The Persian, Hellenistic And Roman-Byzantine Empires

After a short moderate climate interlude, a cold global spell characterized the turn of the first millennium BCE. The level of the lakes in the Mediterranean countries and in the Near and Middle East rose: for instance, the Dead Sea by about 50 meters (its total rise during the Last Glacial period was 200 m). The levels of the crater lakes in Italy rose, too, and an intricate gallery in order to drain Lake Fucino was started by Claudius and finished by Hadrian (Giraudi 1989).

The grasslands and semi-deserts of the Levant flourished, allowing the build-up of an extended trade network. The Israelites, the Aramaeans, and the Nabateans all have built their cities and developed terracing and magnificent irrigation systems (Ron 1985; Ron 1986).

In contrast, in more northern latitudes a series of invasions of nomadic tribes encroached, again and again on the frontiers of the Roman, Persian and Chinese empires due to the shortening of the warm and dry season from the cold steppes of central and north-eastern Asia. To protect their empire the Romans built a line of fortifications, the *limes*, while the Chinese completed the Great Wall. In the same time, hunger and strife due to the failure of rice crops characterized the Kofun (royal mound graves) Period in Japan (Sakaguchi 1983).

6.9 Crusaders, Mamluks and Ottomans on the Eve of the Industrial Era: Islamic Period to Present

At ca. 600 AD the global climate turned warm and dry again. The sea level began to rise and gradually covered Roman port installation and other buildings all along the former shorelines, all the way from Caesarea in Palestine to Cadiz in Spain. On the other hand, the level of the Dead Sea fell below that of the present and its southern shallow part dried up (Bookman/Bartov/Enzel/Stein 2006).

As the tropical monsoon rain regime became stronger, the level of the Nile inundations rose. Silts and sands carried from the Nubian Desert and blown in from the coast of northern Africa covered most of the coastal plain of Palestine. The once flourishing Roman-Byzantine cities along the border of the desert were abandoned, becoming stony ghost towns. Northern and central Arabia also became drier due to its dependence on a weakened system of the west-lies, its oasis population on the brink of starvation. The desertion of the *limes* settlements of the Byzantine Empire and the collapse of Sassanid Persia, facilitated the momentum of the invasion of the Arab tribes under the banner of Islam, enabling them to conquer not only the entire Fertile Crescent, but also northern Africa until the Iberian Peninsula and Iran (Donner 1981). A wave of Turkish tribes mixed with Indo-Iranians, Avars and Bulgars, caused the Slavs to penetrate eastern Europe and the Balkan peninsula.

Ca. 900 AD the warm climate reached its climax in parallel with the optimal conditions in Europe where an increase in population created a deficiency of cultivatable land. Around 1000 AD started a cooler phase. Are we correct in connecting these abrupt climatic transitions with the push south of new Turkish tribes and the Hungarians in the east and the Nor-

mans in the west? The second wave from Europe, known as the crusades, started half a century later on the initiative of the Catholic Church, joining forces with the Normans. Whereas the effect of the colder and, therefore, worsening conditions in Europe are on the rise, the Near East became increasingly more hospitable. Here, Turkish Moslems' states and Christian kingdoms rise and fall during two centuries. Slowly the climate becomes still colder and the Little Ice Age prevailed in Europe. With it the Mamluk State flourished, to be replaced by the Ottomans in the early 16th century who remained the rulers of the region for about four centuries (Inalcik 1970; Lord Kinross 1977).

6.10 An Epilogue

The proxy-data time series and tree ring data available from various parts of the Near East show a phase of warming, and thus drying, of the Levant beginning in the first half of the 17th century. This turn of fate led to a general trend of desertion of the villages and decline of agriculture in the central and southern parts of the coastal plain of Palestine. This may have been also the period when the sand dunes completed their conquest of Palestine's coastal plain. It was also the

period at which the Ottoman Empire began its decline (McCarthy 2001).

On the other hand, the scientific and industrial revolutions in Europe enabled its countries to procure colonies and spheres of influence all over the world, including the Near East. Dams were built on the large rivers of the region and irrigated land was extended. Modern methods of excavation of wells and pumping of water improved the state of agriculture (Issar 2007a).

Pogroms in Europe brought many Jews to immigrate to this region and establish agricultural settlements, and later acquire independence. The settler's applied modern methods of irrigation and land management and regions hitherto covered by sands and marshes become arable land (Issar 2007a).

A natural trend of warm climate started about a century ago. Simultaneously, recent observations show that the quantity of the carbon dioxide in the global atmosphere is on the increase claimed to be due to global industrialization. Whatever the reason, the knowledge of the past tells us that the Near East will again become drier and tensions will increase unless a solution to the water problems of the region on an international scale will take place (Issar 2007b).

7 Human Security, Climate Change and Small Islands

Yannis N. Kinnas

7.1 Introduction¹

This chapter examines the impact of climate change on *Small Island Developing States* (SIDS) and its consequences on the human security of their populations. This theme is elaborated by focusing on the linkages among climate change, poverty alleviation, the social cobweb, political stability, and peace through a more holistic definition of security. Pre-existing economic, social, and physical conditions influence how an island is affected by a hazard or climate change (Tompkins/Nicholson-Cole/Hurlston/Boyd/Brooks Hodge/Clarke/Grey/Torz/Varlack 2005: 11). At the International Meeting to Review the Implementation of the Programme of Action for the Sustainable Development of Small Island Developing States in Port Louis, Mauritius on 10–14 January 2005, UNEP presented an *Environmental Vulnerability Index* (EVI) for SIDS.²

Vulnerability differs according to space and time, the priorities existing in a society, the perceived and real threats in various scholarly and policy communities. Some threats or events, which are perceived by one community, may be of minimal importance for another. One unifying aspect of security and risk is the survival imperative, which changes the priorities, according to space, time, and severity of events or phenomena.

“In all considerations on security (and vulnerability), be it international or internal, two elements are crucial: *prediction* of threats (risks, dangers, disturbances), and designing of actions necessary to *respond* to those threats” (Mesjasz 2008). According to

John Coomber (2005) of Swiss Re: “You identify risk. You manage it. You set in place a programme. You measure it. You identify ways to mitigate it.” In the case of climate change, “mitigation will take the form of building, construction standards, location of buildings, flood defences”.³

“There is no consensus on definition, criteria and indicators for the measurement of vulnerability” (Brauch 2005a: 41). According to the Intergovernmental Panel on Climate Change (IPCC), vulnerability is a function of the change to which a system is exposed, its sensitivity, and its adaptive capacity (IPCC 2001b). In a rapidly changing, complex, and interdependent world, vulnerability can only be attacked by increased resilience. In particular, “the vulnerabilities of small islands have increased over the last decade whilst resilience has not kept pace” (Howorth 2005: 225). “The concepts are related in non trivial ways. For example, vulnerability is not the opposite of resilience” (Jansen/Ostrom: 2006: 11). And further: “There are implications of globalization on the resilience, vulnerability and adaptability of social-ecological systems at scales ranging from the local to the global.”

This chapter discusses linkages between human security and the impact of climate change on SIDS. First the concept of human security (7.2) is introduced and applied to climate change (7.3), its relevance for human security (7.4), and its specific impact on the sea and on SIDS (7.5) are discussed. A key assumption is that risk - understood as the probability of expected losses - can be quantitatively determined as a function of hazard, exposure of the element at risk and vulnerability.

1 The author wishes to thank Hans Guenter Brauch and two anonymous referees for their valuable comments to an earlier draft of the text.

3 The *Clinton Global Initiative* (CGI), a non-partisan project of the *William J. Clinton Foundation*, is a catalyst for action, bringing together a community of global leaders to devise and implement innovative solutions to some of the world’s most pressing challenges; at: <<http://www.clintonglobalinitiative.org>>.

7.2 Security Concepts

Globalization and climate change require a new approach to security in the coming decades. Security is both global and human, and it transcends the traditional approach of 'national security'. Human security has become a cornerstone for survival, because human beings are increasingly vulnerable. According to the *United Nations Millennium Declaration* (2000, section I, §6), for every person there must be 'freedom from fear' and 'freedom from want', which requires human security and poverty alleviation respectively. This approach was further developed in the report *Human Security Now* (CHS 2003). Bogardi and Brauch (2005: 85–109; Brauch 2005, 2005a) suggested a third pillar for human security as 'freedom from hazard impact', which may also be classified as a subcategory of 'freedom from fear'.

The impacts of a natural hazard may differ in several societies. The reasons that a risk may result in conflict can be traced to culture (Kinnas 2001), a lack of infrastructure and/or different priorities. Climate change has contributed to an increase of vulnerability and uncertainty.

According to the report on *Human Security Now* (CHS 2003), human security requires 'protection' and 'empowerment'. It means protecting people from critical and pervasive threats and situations, and building on their strengths and aspirations. It also means creating systems that give people the building blocks of survival, dignity, and livelihood. Thus, human security connects different types of freedoms – 'freedom from want', 'freedom from fear' and 'freedom to take action on one's own behalf'. Kazuo Ogura (2004) suggests that for coping with threats to human security one should distinguish at least three approaches: a) protection from genocide or violation of human rights by civil war combatants of dictatorial military regimes; b) protection from hunger and poverty; and c) a wider approach for human security which includes protection from environmental degradation, terrorism, infectious diseases, international crime and similar risks. According to Ogura the latter constitutes a new type of threat to humanity in general. It is obvious that (b) and (c) are closely linked. A series of international agreements covering security and sustainable development was adopted (Mirovitskaya/ Ascher 2001).

In the perspective of the United Nations University, Environment and Human Security Institute (UNU-EHS), safeguarding and improving human security requires a new approach that would enable a

better understanding of many interrelated variables – social, political, institutional, economic, cultural, technological, and environmental. Deterioration of these factors amplifies the impacts of environmental change and their superposition with the consequences of extreme events when they occur. When the availability of resources and services is undermined, the resulting insecurity can range from hunger and susceptibility to disease, to loss of income and livelihood, to social tensions and open conflict, and to an acute vulnerability to natural hazards. Such vulnerability is apparent in SIDS.

According to Mary Kaldor "conventional military forces organized to defend borders or fight wars are not able to cope with the new sources of insecurity."⁴ Human security refers to the protection of individuals, as opposed to 'state security', which refers to the defence of borders. The European Union can now promote human security in its *European Union Security Strategy* (European Council 2003), which entails a military – civilian planning and integration of environmental issues into external relations. In October 2001, the European Commission and the European Space Agency launched a plan of action for a *global monitoring for environment and security* (GMES), which is supposed to provide Europe by 2008 with an independent, operational capacity.

The growing recognition worldwide that concepts of security must include people as well as states has marked an important shift in international thinking during the past decade. The report on *The Responsibility to Protect* (ICISS 2001) focuses attention on basic human needs (Kinnas 1992). According to the official Canadian perspective, human security refers to the security of people – their physical safety, their economic and social well-being, respect for their dignity and the worth as human beings, and the protection of human rights and fundamental freedoms (ICISS 2001: 15).

For the *Human Security Network* (Dedring 2008; chap. 75 by Fuentes/Brauch) to enhance 'freedom from fear', to be productive, there is a need to find an appropriate balance between the international and national dimension. Such initiatives work best when they are tied to clear multilateral processes and need to complement rather than duplicate existing international initiatives (Hutton 2002). There is no contradiction between the promotion of human security and

4 Mary Kaldor: "A human security doctrine for Europe, and beyond", in: *International Herald Tribune*, 30 September 2004.

the maintenance of national security. The definition provided in the Science Plan of the *Global Environmental Change and Human Security* (GECHS) project (Lonergan 1999a: 29) is relevant for this chapter. It postulated:

human security is achieved when and where individuals and communities have the options necessary to end, mitigate, or adapt to threats to their human, environmental, and social rights, have the capacity and freedom to exercise these options, and actively participate in attaining these options.

However, the degree of security or insecurity depends to a large extent on actions or inactions of people. After the earthquake in Pakistan in 2005, soldiers did not act decisively because as they said, they had no orders. New initiatives may improve resilience to cope with emergency situations. Thus, it is useful to examine the linkages between vulnerability and human security. According to Vogel and O'Brien (2004), vulnerability approaches may be used to assess the seven categories of threats under the wide human security (UNDP 1994), each of them answering to the question 'vulnerable to what' (table 7.1).

Table 7.1: Seven dimensions of human security of UNDP and vulnerability concepts. **Source:** Adapted from Vogel and O'Brien (2004: 6); permission was granted.

Seven dimensions of human security	Types of vulnerability (vulnerable to what?)
<i>Economic security</i> (assured basic income)	Global economic changes
<i>Food security</i> (physical, economic, and social access to food)	Extreme events, agricultural changes, etc.
<i>Health security</i> (relative freedom from disease and infection)	Disease
<i>Environmental security</i> (access to sanitary water supply, clean air, and a non-degraded land system)	Pollution and land degradation
<i>Personal security</i> (security from physical violence and threats)	Conflicts, natural hazards, 'creeping disasters' (e.g. HIV/AIDS)
<i>Community security</i> (security of cultural integrity)	Cultural globalization
<i>Political security</i> (protection of basic human rights and freedoms)	Conflicts and warfare

These seven vulnerability types apply to SIDS. From a social view Cardonna (2004: 49) argues that "vulnerability signifies a lack or a deficiency of development" that often contributes to 'disaster vulnerability'. In his view, population growth, rapid urbanization, environmental degradation, global warming, international financial pressures, and war have all increased vulnerability.

In January 2005, the UN Conference on the Review of the Implementation of the *Barbados Plan of Action* (BPOA of 1994) focused on vulnerability and coping measures for SIDS. At this Conference the *Mauritius Declaration* was adopted that established a set of principles and measures, including the establishment of a regional natural disaster early warning system for the Indian Ocean and the ASEAN region.

While the tsunami in South East Asia in December 2004 illustrated the high vulnerability of small islands and low coasts, a larger scale problem will emerge from sea level rise, which threatens low lying lands with complete destruction. Another tsunami occurred during April 2007, at the Solomon Islands which devastated the region due to an earthquake of grade 8 magnitude in the Pacific.⁵ Sea level rise will be a threat associated with climate change, which is caused, inter alia, by anthropogenic interventions on nature. Other threats from climate change for SIDS include the rise of overall temperature and sea surface temperature, changes in rainfall patterns, in ocean acidity, and the intensity of tropical cyclones.

7.3 Climate Change

The UN Framework Convention on Climate Change (UNFCCC 1992) and the Kyoto Protocol (UNFCCC 1997) were adopted to mitigate the impact of the consequences of climate change and, indirectly, to improve human security by education and public awareness, so that people will be able to face a complex and vulnerable world and build preventive resilience, particularly in the SIDS.

Climate change has contributed to an expansion of the traditional narrow definition of 'international security', focusing more on environmental security (Brauch 2002, 2003, 2005). Poverty leads to insecurity and environmental degradation, e.g. of forests:

While forest degradation contributes to human insecurity, the reverse is also true. Insecurity in the form of

5 AFP: "Tsunami aux Salomon: treize villages rayés de la carte, au moins 20 morts", in: *Le Temps*, 3 April 2007.

chronic poverty, civil war or the mass movements of internally displaced people can destroy ecosystems and as resource rich, multifunctional systems, forests in particular often bear the brunt of insecurity (Hamill/Brown/Crawford 2005: 10).

As Strong (2001: 43) put it: “Climate change is shaping up as the mother of all environmental battles and it will not be resolved quickly or easily.” Climate Change is defined in art. 1,2 of the UNFCCC as follows: “Climate change means change of climate which is attributed, directly or indirectly, to human activity that alters the composition of the global atmosphere.” The Kyoto Protocol of 1997 entered into force in February 2005 after ratification by Russia (Korpoov/Karas/Grubb 2005). By 2012 industrialized countries are required to reduce their collective GHG emissions by 5 per cent, compared with the GHG emission levels of 1990.⁶

A basic weakness exists at the interface between technology and decision-makers; it remains almost impossible to eliminate human error. “The speed of technological change, whether reflected in new developments or new uses of existing technology, is faster than the ability of regulators and others involved in risk governance to fully assess and control the risks of these new developments” (Bunting 2005: 359). It is difficult to solve problems in climate change, and even if some are resolved the solutions may bear new problems. Environmental risks occur when an environmental hazard has the potential to inflict harm (Tompkins/Nicholson-Cole/Hurlston/Boyd/Brooks/Hodge/Clarke/Grey/Torz/Varlack 2005: 10). Therefore environmental risks are cardinal to the insurance sector (Raissouni 2001).

The IPCC⁷ has defined vulnerability from climate change in terms of three interrelated elements: *exposure*, *sensitivity*, and *adaptive capacity*. Sensitivity is the degree to which a system will respond to a given change in climate including beneficial and harmful effects, while exposure is the degree to which a human group of ecosystem comes into contact with particular stresses. Adaptive capacity is broadly defined as the ability or capacity of a system to modify or change its characteristics or behaviour so as to cope better with existing or anticipated external stresses (IPCC 2001b: 22). However, problem resolution often pro-

duces more complex issues. Environmental organizations have long argued that poverty and environmental degradation are interrelated, and have indirect impacts on environmental issues. Discussions on response strategies must be considered against the background of the poverty and environment relationship (Lonergan 1991: 41). The notion that there is both a pollution of affluence and a pollution of poverty has gained much broader acceptance (Conca/Dabelko 2004: 4).

The importance of the sea level rise, due to climate change, was emphasized by the former IPCC Chairman, Bolin.

Undoubtedly, the rise of the sea level that would be associated with a change of climate and its impact on the coastal zone is one of the most important issues needing our careful attention. The fact that a large part of the world’s population lives in the vicinity of the coast adds further justification to address this problem with some urgency (IPCC 1994: 3).

The term “in the vicinity of the coast” includes islands, and particularly the SIDS. If these islands are submerged or vanish completely, further deterioration of global social problems will occur. On 26 December 2004 the tsunami in the Indian Ocean resulted in approximately two million people without shelter. If there is no understanding of the urgency of the situation in the SIDS especially, and in African countries, global problems will become more acute. Thus, greater attention must be given to how the land is used or abused (Watson/Dixon/Hamburg/Janetos/Moss 2000). The use or abuse of land depends also on climate change, which may increase the probability and intensity of extreme weather events and may thus increase internal displacements, transboundary and even intercontinental migration, and in some extreme cases even crises and conflicts (Brauch 2005a).

The SIDS complain that many industrialized countries did not respond to their commitments regarding reduction of GHG emissions. While the EU tends to drive technology through its emissions trading scheme (ETS) policy, the US seems to rely on a policy based on technology. Jonathan Pershing (2006) of the World Resources Institute (WRI) stressed this linkage in a testimony before a US Senate Committee:

There is no single technology - no silver bullet - that can drive the scale of emissions reductions that are required; we must be prepared to rely on a portfolio of options. But there are many important and promising technologies - some ready today, and others on the verge or economic and technological breakthroughs - that have the capacity to reduce emissions cost-effectively.

6 The Protocol includes three flexible mechanisms in order to eliminate emissions: *Joint Implementation (JI)*, *the Clean Development Mechanism (CDM)*, and *the Emissions Trading Scheme (ETS)*.

7 IPCC was granted the Nobel Peace Prize for 2007.

In the European Union (EU),

the most recent official figures, for 2003, show that greenhouse gas emissions in the EU-25 are down by 5.5 per cent from their level in 1990. With current measures taken to reduce emissions, the EU-15 is estimated to achieve an overall reduction of 4.1 per cent below the base year by 2008–2012, and the EU-25 an overall reduction of 7 per cent. This is a good result, but it is not enough. More work is necessary if we are to reach our Kyoto target. (Dimas 2005).

Furthermore, Commissioner Stavros Dimas, speaking at the IPCC WGII in Brussels in April 2007 emphasized *inter alia* that:

The European Council has set out key targets that need to be included in a global and comprehensive new agreement that would take effect after the Kyoto Protocol targets expire in 2012. The group of developed countries must reduce its emissions to 30% below 1990 levels 2020. The EU has committed itself to take on this target in the context of an international agreement that comprises other industrialized countries. [...]

Naturally, no mandatory reductions would be asked for the least developed countries by 2020, should also participate although in a differentiated manner. Those among them that reach that level of economic prosperity similar to developed countries should take on obligatory emissions reduction commitments. These should reflect each country's per capita emissions, its potential to reduce them and its financial capacity.

According to the European Environment Agency (EEA 2006), action to combat climate change will deliver considerable ancillary benefits in air pollution abatement by 2030 so that overall costs of controlling

air pollutant emissions of the order of €10 billion per year will be reduced. In addition, such reduced emissions will lead to a fall in damage of public health and ecosystems. Further action to reduce air pollution is needed, including emissions from non land-based sources to move closer to the EU long-term objectives for improving air quality.

The 11th *Conference of the Parties* (COP-11) in Montreal in 2005 dealt also with the post-2012 period. There the *Meeting of the Parties* (MOP 1) for implementing the Kyoto Protocol was for the first time convened, and in March 2006 in Bonn the Committee on Compliance met for the first time. A three track approach (Tracks I, II, III) was finally adopted in Montreal under a compromise solution proposed by the Canadian Environmental Minister, Stephane Dion (Stostedt/Huber 2006). An impressive development in 2007 although without a follow-up was the discussion, after British initiative, for the first time during the 16 April 2007 session of the UN Security Council on climate change.⁸

7.4 Small Island Developing States (SIDS)

After the 1992 Rio Conference, the United Nations decided during the 48th General Assembly in 1993 (Res 48/193) that a Global Conference on the Sustainable Development of SIDS be convened in 1994 that

⁸ *New York Times*, 18 April 2007.

resulted in the adoption of the *Barbados Plan of Action* (BPOA). During the first mid-term review (1999) no spectacular achievements were noted. During the second review meeting in Mauritius (2005) the official list of SIDS comprised 37 United Nations members (table 7.2) and 14 Non-UN members (table 7.3) associated with the Regional Commissions of the UN.

In addition to the SIDS there are the members of the *Association of Small Island States* (AOSIS), a larger group of countries, which emerged during the negotiations of the UN Framework Convention on Climate Change (UNFCCC). There are also bigger island states, such as Sri Lanka or Ireland, and tiny islands which belong to various states in the world (e.g. Hong Kong alone has over 260 islands). This latter category is the most vulnerable and they might vanish in the long run, depending on the specifics of sea level rise. The *Regional Seas Programme* of UNEP has been requested to play a central role, because all SIDS cooperate in at least one Regional Seas Programme. There is also provision for the SIDS in Agenda 21, Chapter 17, Section G.

The European Union also has introduced its *Islenet*, which is the *European Islands Network on Energy and Environment*, a network of the European island authorities to promote sustainable and efficient energy and environmental management (Howorth 2005).

According to the European Commission (COM 2006 248 final: 2) the Pacific ACP countries “are today experiencing a number of important challenges in terms of vulnerability, poverty and weak governance”. Six out of the fifteen Pacific island states are least developed. The Pacific Ocean covers one third of the Earth’s surface and somehow these islands are the guardians of the region, and the Pacific Ocean may be considered a global public good.

Consequently, “when communities make unsustainable demands and wrong priorities on ecosystems, this may result in an ecological breakdown, which in turn leads to worsening poverty, tensions

and even conflict” (COM 2006 248 final: 3). In general, the human security situation in the Pacific SIDS can be considered as fragile. Therefore, sustainable management and education is an imperative policy for them, as well as research cooperation to be promoted under the EU Research Framework Programme.

Capacity building, including financing, and access to environmentally sound technology are elements of cardinal importance in improving the resilience capacity of SIDS, which decreases due to external or internal factors. Such needs as those just mentioned were also emphasized during the 3rd Global Conference on Oceans Coasts and Islands in Paris (IISD 2006), and during the 14th session of the *Commission on Sustainable Development* (CSD) in New York in May 2006, where 8 May was devoted to SIDS.

The small island states constitute a priority issue on the global agenda. Saving their coral reefs is also a major activity in wildlife related treaties, such as the *Convention on Biological Diversity* (CBD) that includes a coral reef programme, and the *Convention on International Trade of Endangered Species* (CITES) that protects many coral as well as other species inhabiting reefs. The *World Summit on Sustainable Development* (WSSD) in 2002 adopted targets on sustainable reefs management and a plan of implementation (Hepworth 2003).

It is necessary that the carrying capacity of a coastal area or island must be constantly monitored. The specific development of a region can make islands and cities in coastal areas more attractive than others. Such cities present a special interest due to the particular role they may acquire as growth poles and gates to their hinterland in a broader process of spatial integration, but also as centres of growing economic activities such as tourism, transport, and fishing. Balancing tourism with an appropriate use of heritage constitutes a difficult task. Visitor numbers in SIDS should not exceed the islands’ ability to provide facilities without suffering damage, including their special character (Abrahams/Kelman 2005).

According to the *World Meteorological Organization* (WMO), many human settlements are already facing increased risk of coastal flooding and erosion, which could be exacerbated by sea level rise and storm surges. Tens of millions of people living in deltas, low lying coastal areas, and on small islands, will face the risk of displacement and loss of infrastructure, despite substantial efforts and costs to protect vulnerable coastal areas. The predicted future climate will place these populations, especially those on small islands, at particular risk of severe social and economic effects (WMO 2003). This challenge will become even more acute due to the projected population change (table 7.4).

The *Mauritius Declaration* of January 2005 includes, *inter alia*: a reaffirmation that SIDS continue to be a special case for sustainable development (§5); a welcome to the proposed establishment of a regional natural disaster warning system for the Indian Ocean and the ASEAN region (§7); the recognition that good governance is essential for sustainable development (§11); the impact of health issues (§7); the adoption of the Mauritius Strategy for the further implementation of BPOA (§18); and the recognition that international trade including services is important for building resilience and sustainable development (§13). It is evident that sea level rise has become a manifold security challenge for SIDS, bearing on their very existence in the long run with national, economic, societal, environmental, and human repercussions.

7.5 Climate Change as a Human Security Challenge for SIDS

SIDS are ecologically highly fragile and global warming could be devastating for local populations. According to the GECHS Report (Loneragan 1999a) issues of inequality and impoverishment must be incorporated into the analysis of environment and security links. The populations of SIDS must have the option to end, mitigate, or adapt to threats to their human, environmental, and social rights. In this connection, policies and measures that will help towards this end will be introduced as a priority issue by the international community. Participation in the formation of such policies and measures is necessary because local populations possess the necessary experience on relevant issues, and this should avoid imposition or irrelevant and unneeded measures.

For SIDS human security has become a current issue in policy-making and in research. They are more

vulnerable to hazards but also in adapting to situations for which they bear hardly any responsibility. Their populations have contributed little to global warming while they are mostly affected by it. Thus, their 'human' and 'national' security is at risk and the uncertainties they feel in facing the future are no good basis for creative solutions. An initiative on infrastructure was set up with the *Global Sustainable Energy Islands Initiative*⁹ (GSEII) by a consortium of NGOs and multilateral institutions to support AOSIS. Joint efforts by NGOs and enterprises are undertaken, e.g. by WWF and Toyota Company in Galapagos. Desalination has become affordable not only for the SIDS group but also for small islands of other states.

It is not only in the interest of the SIDS that human security can be safeguarded. There is a need for greater solidarity and enhanced cooperation among members of the international governmental and non-governmental community to undertake appropriate initiatives in enhancing resilience in these sensitive areas of the world.

7.6 Conclusions

It is evident that climate change affects human security with a particular impact on the SIDS. To enable the SIDS to respond with high capacity there is a need to strengthen "regional and international cooperation and education, training and awareness raising. Countries also need to be encouraged to perform integrated impact assessments in addition to sectoral ones" (SPREP 1997: 2). Furthermore, the provisions of chap. 36 of Agenda 21 should be globally implemented to reorient education towards sustainable development awareness and public understanding, but also training. Such an effort should also include the goals of UNESCO's *Decade of Education for Sustainable Development (2005-2014)*. The efficient coordination of UN agencies should be a primary task. The WMO, ITU, UNEP, FAO, UNESCO, UNDP and others, together with regional organizations like the European Union, should demonstrate their contribution to counter the challenges of climate change. A much more radical shift in the pattern of consumption and production is needed, otherwise humankind is heading for an environmental catastrophe (Tandon 2005).

9 The GSEII supports AOSIS members by bringing renewable energy and energy efficiency projects, models, and concepts together in sustainable energy plans for SIDS. See at: <<http://www.gseii.org>>.

Furthermore, “Risk evaluation and assessment need to become two of the focal points of environmental and sustainability research. These are essential for decisions being made with incomplete knowledge” (ProClim 1997). In substance, incomplete knowledge means increase of uncertainty (Prigogine 1996; Kinnas 1992: 43). Cross-cutting issues, such as monitoring, financing, and governing require broader attention. Monitoring needs criteria and reporting, what is often done by the secretariats of intergovernmental organizations but needs more refinement and coordination. Financing is a sensitive issue and the recent debt relief for several countries is part of its solution. Among these issues of a general nature is the implementation of the targets of the *Millennium Development Goals* (MDGs). Both Africa and the SIDS lag behind other regions in achieving the MDGs.

There are also issues of more specific nature for the SIDS, such as infrastructure, education, and cooperation between the public and private sector. Regarding infrastructure there is a need for technology transfer and for organizing the public sector by adapting constructions to avoid repercussions from climate change and thus decrease vulnerability of the SIDS. Synergies must be developed in coordinating policies among IGOs, e.g. by the *United Nations Environmental Management Group* [UNEMG] (Ivanova 2005: 29). Education projects for protecting biodiversity, combating desertification, and addressing climate changes are also necessary. “Lack of knowledge is the underlying ... cause of behaviour leading to climate change, the thinning of the ozone layer, the loss of biodiversity, land degradation and many other problems” (Briceno 1998: 71) that must be addressed through reliable information and public awareness, which is fundamental for improving the protection of the environment. This includes improved local geographical information through *Geographic Information Systems* (GIS). The *Sustainable Development Networking Programme* (SDNP) or UNEP’s *International Network of Information Referral System* (INFOTERRA) can also be helpful. The UNESCO initiative to establish two academic chairs on sustainable development in the Pacific Islands should be expanded to other SIDS. Training in interdisciplinary and integrated approaches would thus be reinforced. In addition to the information provided to the public at large through the media and NGOs, there is also a need for training of specific professional sectors, particularly lawyers and judges, but also educators themselves.

There is a lack of adequate awareness of existing problems and there is a knowledge gap, but there is also a digital divide. An easy access to internet facilities and the necessary local infrastructure in SIDS is absolutely necessary. Finally, a better framework of cooperation between the public and private sector (Nelson 2002) can face the complex needs of the SIDS. Solidarity and cooperation have become imperative on our planet, which is in need of an equilibrium among ethics, environment, and spirituality so that human security, including human dignity, will prevail (Agha Khan 2005: 70; Kinnas 1997: 42). As Yolanda Kakabadse (1997) noted, during a conference in Thessalonika: “cooperation and synergy among those prompting education for a sustainable future is an opportunity”. Therefore a strategic alliance among UNESCO, UNEP, The World Bank, UNDP, UNICEF, WHO, international NGOs, such as WWF, IUCN, ICSU, and regional organizations should be developed. In this connection, the Bali December 2007 COP-13 of UNFCCC was considered as the springboard for the post Kyoto Protocol era, which is closing in 2012.

It is not only how knowledge is used, but from where knowledge is provided, and the reliability of its sources. Information and communication technologies (ICTs) and infrastructure are spread thinly and unevenly in SIDS, which leads to a greater need for transparency in environmental and sustainable development policies. “Greater information availability could also promote a more effective issue linkage and bargaining strategy and more efficient and equitable technology transfer” (Figueres/Ivanova 2004).

In public policy there is a need for a shift from the politics of fear (Furedi 2005) to the politics of hope. “The future of global governance is likely to rest not on a single system like the UN, but on a new mixture of bottom-up and top-down authority; public, private and civic institutions; and informal norms as well as formal laws and standards. The result will be ‘light but firm’: less bureaucratic, but with more chances of being implemented” (Edwards 2004). “If environmental regulation is to work, the North must pay more, the South must demand less, and all of us who care about the future have to make our views known in the political process” (Humphreys 1996).

8 Redefining Sustainability: A Policy Tool for Environmental Security and Desertification

Rajeb Boulharouf and Douglas Pattie

8.1 Introduction: Evolving Landscape of Sustainability

Major environmental threats such as desertification carry the seeds of disruptive factors that can cast a long lasting shadow on the socio-economic security of nations and interstate relations. The magnitude of these disruptions is exposing the weakness of sustainable development, in its *stritu sensu* conception, as a policy paradigm for environmental security.

The central, distinguishing policy feature of desertification is that it shifts the terms of debate from a traditional sustainable development doctrine holding that the goals of economic development and environmental stewardship are interdependent, to the notion of environmental security, which requires a much more complex process of trading off social, economic and environmental priorities. This formulation suggests that poverty, underdevelopment, and political disenfranchisement are both the cause and effect of environmental degradation.

Given its universal nature, global impact and the close relationship it holds with key socio-economic issues such as food security, agricultural productivity, water resources and water management, population and demographic flows, the desertification process embodies a strong disruptive potential in terms of global stability. By directly contributing to food insecurity, famine, poverty and migrations it should retain public attention in so far as it carries the constitutive elements of few but rather specific dynamics able to give rise to social, economic and political tensions and act as catalytic dynamic for conflict generation.

The environmental dimension of conflicts and migration point at the comparative advantage of the *United Nations Convention to Combat Desertification* (UNCCD), as a process and unique conceptual intervention platform to address the challenges of environmental stress, conflict prevention and the security-environment interlinkages.

One of the major conceptual revolutions in the fields of international public law and international law of development was marked by the materialization of the concept of “sustainable development”. For the first time since the industrial revolutions our self-defined convictions of munificent development and the dogma of continuous growth had to be overcome through an ambitious effort of socio-cultural regeneration. The premise was simple and the conclusion disenchanting: our development, the system of production, that constituted the very basis of our wealth, was no longer viable in its conception and nature.

A new generation of international legally binding instruments was soon to be adopted, effectively redefining the international legal frameworks of reference in the field and proposing strategies for ‘sustainable development’ - ways to improve human well being in the short term without threatening the local and global environment in the long term. The general definition of sustainable development is found in *Our Common Future*, a report from the UN *World Commission on Environment and Development* (WCED). Its targets were multilateralism and interdependence of nations in the search for a sustainable development path. The report sought to recapture the spirit of the 1972 Stockholm Conference, which had introduced environmentalist concerns to the formal political development sphere.

The established dynamics of multilateral negotiations were deeply shaken by the concept of sustainability, genuinely reshaping classical solidarity schemes traditionally established on regional and/or political group basis.¹ The issue of the environment acquired its *lettres de noblesse*, at the very top of the international global agenda when political momentum gathered at Rio de Janeiro in 1992. The *United Nations Conference on Environment and Development* (UNCED) was strong enough to generate real changes in the different spheres of international relations, be it at the bilateral or multilateral levels. The

continuity of such changes, their perennial capacity to overcome the challenges of implementation could, however, only be assessed in the long run.

Critics had already pointed at that early stage that, to a large measure, the wide acceptability of the environmental agenda of the Brundtland Report by world leaders was due to its unequivocal embracing of economic growth. The WCED (Brundtland 1987) report positioned sustainable development not a fixed state of harmony, but rather a process of change in which the exploitation of resources, the direction of investments, the orientation of technological development, and institutional change are made consistent with future as well as present needs. Indeed, the Commission's "overall assessment is that the international economy must speed up world growth while respecting environmental constraints" (UNGA 1987: 96). However, it does not say how this balancing act is to be achieved. Expansion of the global economy through rapid growth in both the North and South, more free trade, increased aid, greater transfer of efficient technology were all part of the Brundtland scenario for sustainable development. However, many policy analysts have critiqued the Brundtland report

as dreamy idealism, blind to the structured inequalities and inequities of existing third world societies. In that context, William Adams (1990) argued that the strategy was basically contradictory.

This criticism translated the difficulties then faced by many scholars and policy analysts with the endorsement of a single definition of sustainable development, that would not, in their views, embody the conceptual capacity to address and/or integrate critical economic and social challenges. This conceptual antagonism would prove to be enduring throughout the evolution of this definition.

Since the UNCED conference, the world has indeed witnessed an exponential proliferation of definitions of sustainable development. Such spread of definitions has become evidence of its limitative conceptual frame rather than its contestability. Pearce, Markandya and Barbier (1989) provide a 'gallery' of over 40 definitions. The proliferation of meanings is not just an exercise in academic or practical clarification but a highly political process of "different interests with different substantive concerns trying to stake their claims in the sustainable development territory" (Dryzek 1997). As it has become more important, key interests have tried to define sustainable development to suit their own purposes. As Lele (1990) has put it, "sustainable development, like beauty, is in the eye of the beholder; it therefore promises something for everyone". Ironically stated in her critical review, sustainable development is a 'metafix' that will unite everybody from the profit-minded industrialist and risk-minimizing subsistence farmer to the equity-seeking social worker, the pollution-concerned or wildlife-loving First Worlder, the growth-maximizing policy maker, the goal-oriented bureaucrat and, therefore, the vote-counting politician. This universal appeal is enhanced by the apparent ideological neutrality of sustainable development. It offers no clear vision of an ideal end state, whether green utopia or otherwise, and no set of political or economic arrangements is specifically excluded. Instead, sustainable development involves a *process of change* in which core components of society - resource use, investment, technologies, institutions, consumption patterns - come to operate in greater harmony with ecosystems.

Recognition and attempted amelioration of environmental damage is part of the growing effort among academics, journalists, and government officials to come to grips with post-modern social ills - maladies that have less to do with a lack of wealth than with the unintended consequences of the misallocation of wealth. Maarten Hajer (1995: 14) suggests

1 Most accounts of the history of 'sustainable development' as a global idea begin with the United Nations Conference of the Human Environment held in Stockholm in June 1972. It was attended by 113 nations, many of them, developing nations; the organizers made a deliberate effort to put Third World concerns on the 'environmental agenda'. The conference promoted the idea that environmental protection and economic development were compatible; indeed, development was presented as essential for undertaking improvement of the environment. The Stockholm effort to bring together the issues of environmental protection and development was continued in The World Conservation Strategy (WCS) which appeared in 1980, a study commissioned by UNEP and executed by the International Union for the Conservation of Nature and Natural Resources (IUCN). Three major priority objectives were defined: (1) maintain essential ecological processes; (2) preserve genetic diversity of plants and animals; and (3) ensure the sustainable utilization of species and resources. The document established a framework for national and subnational conservation, and priorities for international action. It laid stress on the complete compatibility of conservation and development; its objective was to integrate conservation and development in order for the latter to be sustainable. Development was deemed necessary but should be based on the principles of conservation. The key concept in the WCS was sustainability. For a complete history see Adams (1990).

that the “coalition for sustainable development can only be kept together by virtue of its rather vague story-lines at the same time as it asks for radical social change”, whereas insistence on a precise formulation of the term is more likely to deter potential supporters. Thus the ‘motherhood’ idea of sustainable development can win broader acceptance for radical ideas such as equity and democratization.

Multilateral negotiations represent the quintessence of global democracy and, as such, they are duty-bound to fully encompass in their approach the diversity of positions and ideas that characterize the international community. The capacity of such a process to deliver measurable results over a given period of time is further challenged by the level of complexity and sensitivity surrounding them. Lundqvist (2001: 470) has attempted to determine how far ecological states can pursue sustainable development without intruding on principles of democracy and argues that “the state is the best political unit for achieving legitimate binding decisions in a multifaceted goal of sustainable development because it has the best resources, the ability to enforce rules and support scientific research.” However, the more an issue entails strong national, or corporate interests, the less would be its ability to self-generate a consensual decision making processes. The classic ‘command and control’ strategies used to regulate environmental practices have had decreasing marginal returns, and so some have questioned whether democratic governmental controls can achieve movement toward sustainable development. But for those who believe that the ‘Rio Spirit’ hasn’t outlived the favourable conjuncture that its own momentum had once generated, such negative assessments are unjustified and derive from a Manichean perception of international relations, where the credibility of multilateral processes are conditioned to unrealistic quality-like benchmark of imperativeness and immediateness.

This chapter is structured around the premise that factors leading to desertification often carry the seeds of potential conflicts. The challenges to global stability and sustainability are discussed in the context of conflict and threats to security. Two early warning signs of a faltering environmental security are to be found in the pressure points of water resources and migration. The conclusion points to the advantages of the UNCCD as a necessary mechanism for the emerging security paradigm.

8.2 Dawn of the Security Age: The Anatomy of the Desertification Crisis

Nicolas Hildyard argued that underpinning Agenda 21 and the attendant environmental crises was the view that environmental and social problems are primarily the result of insufficient capital, outdated technologies, a lack of expertise and faltering economic growth (Sachs 1993). Increasingly man-made environmental catastrophes were seen as causing extreme human poverty. The Earth Summit in Rio had articulated what may be called the official mainstream view of the ‘environmental crisis’, showing much continuity with the earlier Brundtland Report. One of the most important environmental agreements to address this crisis was the negotiation, adoption and entry into force of the *United Nations Convention to Combat Desertification (UNCCD)*² on 26 December 1996. Unlike its sister conventions of climate change (UNFCCC) and the protection of biological diversity (CBD) which were opened for signature at the 1992 Rio Summit, the UNCCD was a pure product of Rio and showed, in some respects, a new approach to the problem. The UNCCD treaty is the only legally binding instrument whose origin and direct justification can be found in Chapter 21 (UNCED, 1993). As such, the treaty counts today more parties (191 members) than any other similar environmental convention, and

2 The United Nations Convention to Combat Desertification (UNCCD) in countries experiencing drought and/or desertification, particularly in Africa. The negotiated convention text states that “desertification is land degradation in arid, semi-arid and dry sub-humid areas resulting from various factors including climatic variations and human activities.” Desertification is not the natural expansion of existing deserts, but the land degradation in arid, semi-arid and dry sub-humid areas. Desertification is recognized as a process of land degradation in arid, semi-arid, and dry sub-humid areas of the world that is the result of natural phenomena (e.g. climate variation) and anthropogenic factors. The outcome of this type of degradation has typically been considered to be either a reduction or a loss of both biological and economic productivity. Drought, desertification, devastating floods and hurricanes are all in the same range of variant climatic phenomena that ravage ecosystems and impoverish vulnerable local populations. The existence of land degradation, particularly soil erosion and salinization, is testimony to the inappropriateness of certain types of land use. Desertification undermines the fertility of the world’s land, with productivity losses reaching 50 per cent in some ar-eas (Glantz/Orlovsky 1983).

represents one of the most concrete achievements of the Rio legacy in the field of codified global sustainability.

By contrast to other global issues, desertification and land degradation can be defined as non-controversial. The process doesn't generate major political divergences and powerful business interests have been replaced by an emphasis on local community empowerment and traditional soil and water conservation – well being instead of well having. Yet, the UNCCD implementation has been hampered by lack of global attention and adequate financial resources. For example, the UNCCD has only been granted access to GEF resources, after nearly ten years of existence³, while consensus had already emerged to grant those resources to instrument/conventions that had not even entered into force.

The atypical nature of the UNCCD process, this 'desertification exception', derives from a series of factors, the most important of which is to be found in the erroneously perceived spatial and temporal nature of the desertification threat.⁴ Desertification, indeed, is still perceived in the developed world as a far away problem, limited in scope to a regional manifestation and lacking the magnitude of a global scale cataclysm. A second, equally important limiting factor relates to the discernment of desertification as a full-fledged environmental issue. Desertification still carries in the public perception the hallmarks of a purely developmental process. This singular view is further backed by established bilateral schemes that persistently address desertification through the restrictive optic of traditional cooperation for development. Desertification for example, is hardly ever entrusted to Ministries of Environment but rather delegated to Ministries of Cooperation, which often results in a chronic misunderstanding of the emerging environmental se-

3 The UNCED conference produced two treaties on climate change and biodiversity signed by more than 150 nations; the Rio Declaration on Environment and Development, an Earth Charter of principles to govern the relationship of people to the earth; and Agenda 21, a 800-page document containing a programme of action for implementing the principles enunciated in the Earth Charter. The Conference did not contain any proposals to strengthen the United Nations Environment Programme (UNEP); instead a new environmental body called the Global Environmental Facility (GEF) was created and placed under the control of the World Bank. A large part of controversy at the Summit concerned money for the actions provided in Agenda 21: sources of funds, which was to receive how much and so on (The Ecologist, 22,4, 1992).

curity issue at stake. By slowly eroding the environmental dimension of desertification, this flawed perception may result in further removing the issue from the global environmental agenda and seriously limit an enhanced and coordinated response from the international community. Desertification for instance, is often neglected as compared to food or humanitarian crises, as an important factor for migration.

Worldwide media focus seems to exclusively concentrate on selected environmental issues, deemed more suitable for public attention. Under such a selective approach, over-mediatization has often produced counterproductive effects, constraints and exaggerations that privilege sensational aspects over true information (Blumler/Gurevitch 2001). As a consequence, Hans Kepplinger (2003) stated that global threats to a common environment and their complex inter-linkages have been reduced to the distorted image based on a handful of semiotic media icons. The tensions of difference and similarity erupting from the processes of globalization, the emergence of stereotypes, the multiplication of science fiction-like scenarios and the slow erosion of a serious scientific basis, all militate against the issue of sustainable development and ultimately, in favour of a weakened environmental agenda. In *The Song of the Dodo* David Quammen (1996: 635) asserts that even the costly strategy of setting aside nature preserves will ultimately fail to save endangered species. In humankind's 'war' on other species, "the current cataclysm of extinctions is in-

4 The term 'desertification' was originally used by Aubreville (1949) to mean the creation of deserts in tropical regions: the removal of indigenous trees and excessive cultivation by marauding natives of nutrient-weak soil was leading to soil erosion, and eventually to the creation of deserts via edaphic (soil) desiccation. Aubreville viewed desertification primarily as a process but also referred to it as an event (the end state of a process of degradation). He described how forested regions were transformed into savanna and savanna into desert-like regions. One of Aubreville's central concerns was the rate of destruction, resulting from human activities, of Africa's tropical forests. He noted that cultivation, deforestation, and erosion were so entwined as to lead to the destruction of the vegetative cover and soils in the forested regions of tropical Africa where "the desert always threatens, more or less obviously, but is always present in the embryonic state during the dry and hot season" (le désert menace toujours, plus ou moins évidemment, mais il est toujours présent, à l'état embryonnaire, dans la saison sèche et chaude). Savanna would result. Continued disregard for the fragility of the savanna would result in the creation of desert-like conditions.

deed likely to stand among the worst half-dozen such events in the history of the Earth.” Heaping scorn on efforts like the Endangered Species Act of 1973 (in the USA) he states that the market-oriented ideas of free-market environmentalists, such as debt-for-nature swaps and eco-tourism, will not keep earth’s other creatures alive. Only a drastic change in human ways can stop the downward spiral toward doom.

Desertification and environmental security are forcing a shaky ground under sustainable development, now characterized by the challenge of survival as a new *raison d’etat*. Major environmental threats and disruptive factors such as desertification can cast a shadow on the socio-economic security of nations and interstate relations. The magnitude of these disruptions is exposing sustainable development’s Achilles heel, as a policy tool for environmental security.

The central, distinguishing policy feature of desertification is that it shifts the terms of debate from the traditional sustainable development doctrine holding that the goals of economic development and environmental stewardship are interdependent, to the notion of environmental security, which requires a much more complex process of trading off social, economic and environmental priorities. This formulation suggests that poverty, underdevelopment, and political disenfranchisement are both the cause and effect of environmental degradation.

Environmental scarcity functions in a society within a complex matrix of historically derived economic and political situations. Mohamed Suliman (2004) has indicated that traditional analyses of conflict which rely primarily on ethnic, religious and cultural explanations do not take account of the increasingly obvious link between the growing scarcity of renewable resources and violent conflict in developing countries. The environmental dimension of conflicts and migration points at the comparative advantage of the UNCCD as a process, and as a unique conceptual intervention platform in which to address the challenges of both environmental stress and conflict prevention. Major disruptive factors are understood as challenges to the concept of sustainable development in so far as they are capable of substantially modifying the conceptual nature of the issue and the notional shift towards the environmental security challenge in ‘sustainable development’ which can inculcate a new dynamic to the established multilateral processes.

8.3 An Emerging Challenge to Global Stability

The risks of desertification are substantial and clear. Under present scenarios of population growth (chap. 12 by Lutz), climate change (foreword essay by Pachauri, chap. 5 by Bluemel, 6 by Issar/Zohar and 7 by Kinnas) and loss of ecosystem services (chap. 3 by Leemans), even within a *stricto sensu* classic sustainable development approach, the challenges posed by desertification are enormous and should therefore be easily comprehended. Desertification critically undermines the fertility of the world’s land (foreword by Di-allo). In Africa alone, an estimated US\$ 9 billion are lost from desertification every year. The problem, however, is not confined to the African drylands. Desertification affects over 110 countries worldwide. Some 70 per cent of the 5.2 billion hectares of dryland used for agriculture worldwide – 30 per cent of the Earth’s total land area – is already degraded and threatened by desertification. If this is left unchecked, arable land is expected to shrink by one third in Asia, two thirds in Africa and one fifth in South America, putting livelihoods at risk and propelling people to migrate. Desertification is a global problem that directly affects 250 million people worldwide and a third of the earth’s land surface.

Beyond the cold technicalities of such wording lies a chilling reality. Desertification has a firm grip on China. With an estimated 28 per cent of its land affected by desertification, the livelihoods of 400 million people are at direct risk. In China alone, some 24,000 villages, 1,400 kilometres of railway lines, 30,000 kilometres of highways and 50,000 kilometres of canals and waterways are constantly threatened by desertification. Dust storms from deserts in northern China and Mongolia blow as far as Korea and Japan – and across the Pacific Ocean (Youlin 200).

Desertification and drought force people to leave their home in search for a better life (chap. 9 by Rechkemmer; Brauch 2006, 2006b, 2006c, 2007e). Current estimates are that the livelihoods of more than one billion people are at risk from desertification and that, as a consequence, 135 million people, the combined populations of France and Germany – are at risk of being displaced by desertification. Half of the 50 million people expected to be environmental refugees by 2010 are from sub-Saharan Africa. By 2020, it is estimated that 60 million refugees will have moved from desertified areas in the Sahelian region to North Africa and the shores of Europe. Meanwhile, by the same year, the mass exodus from desertified drylands

is projected to multiply the urban population in coastal cities of the Sahel, 3.5 times over from its 1996 level, to reach 271 million (ECOSOC 2007).

In December 2003, at a NATO funded seminar on *'Desertification in the Mediterranean Region: A Security Issue'* 200 leading experts and policy-makers of its Mediterranean Dialogue countries focussed on related security issues and desertification was seen as a common threat to the Mediterranean region that required international trans-boundary solutions. Participants argued that while droughts aggravated the situation by inducing instability and generating competition between farmers and herders for limited land and water resources, desertification increased conflicts between grazing rights and ownership rights resulting in very high economic damage from the ensuing land degradation. Greater pressure on productive land caused an increase in the migration of people within their own countries as well as foreign countries, eventually producing an imbalance between more populated urban areas and desertified areas (Kepner/Rubio/Mouat/Pedrazzini 2006).

Given its universal nature, global impact and the close relationship it holds with key socio-economic issues such as food security, agricultural productivity, water resources and water management, population and demographic flows, the desertification process embodies a disruptive potential in terms of global stability. By strongly contributing to food insecurity, famine, poverty and migrations it should retain our attention in so far as it carries the constitutive elements of few but rather specific dynamics able to give rise to social, economic and political tensions and act as catalytic dynamic for conflict generation.

8.4 Environments in Conflict

The factors that lead to desertification often carry the seeds of potential conflicts. In fragile ecosystems, already characterized by a high level of natural resources vulnerability, lack of and competition for resources can constitute a major disruptive factor. As participants in the UNCCD sponsored workshop on *'Desertification and Migration'* held in Almeria, Spain in 1995, pointed out that the trend in the over-use of renewable resources may accelerate at a speed unprecedented in human history. Evidence is emerging for a correlation between poverty, desertification and conflicts of various kinds in arid and semiarid areas.

In Africa, for example, analysts have reported a steady increase in conflicts fuelled by disputes over

scarce grazing land, as the result of severe desertification. The UN Office for the Coordination of Humanitarian Affairs (UNOCHA) points at alarming figures in terms of the loss of human lives and forced migrations. In their analysis of the 21 reported cases of conflict with desertification as a present source or potential source of conflicts, Bächler (1995) identified 13 such cases in Africa, 4 in South and Central America, 2 in the Middle East and in Central Asia and 2 in South/South East Asia. In particular, evidence showed that environmental stress – especially the depletion and degradation of renewable resources such as water, fish, cropland, and forests – can engender and interact with social and economic conditions to produce violent conflict within nations. It is developing nations that are most vulnerable to these interlinkages because these nations often lack the means required to mitigate the impact of environmental stress.

While there is an evident lack of systematic analysis of desertification induced risks, numerous documented case studies have been presented on environmental conflicts, including specific instances of desertification-induced conflicts in drylands. The common denominator in these studies, beyond subjective consideration of the nature of the threat, clearly resides in the multiplier effect of desertification as a proactive parameter in the conflict dynamic.

However Jon Barnett (2003) has argued that the meaning of environmental security is ambiguous and open to appropriation. The examination of its various interpretations and applications reveal much about the state of global environmental politics and that environmental security may be driven more by the power of security-makers than by the need to address environmental problems. Addressing security in the context of desertification requires rethinking the specific challenges posed by the evolving dynamics of sustainable development. Advocates of a wider security concept (Buzan/Wæver/de Wilde 1998) promote a more inclusive notion of security, capable of internalizing less classical, but fundamental environmental parameters for an enhanced and more reliable conceptualization of security in which the economy and the environment constitute key parameters.

The security component often driven by the challenge of desertification is increasingly perceived as pertinent by countries outside of the drylands. Indeed, while addressing the threats posed by desertification in the Mediterranean, experts at the first Almeria workshop (1995) concluded that given Europe's close proximity to Northern Africa, desertification could negatively impact on food resources, people's

health and the region's economy (Puigdefábregas/Mendizabal 1995). A second workshop in Valencia (2003) analysed in greater detail the future effects of population growth, climate change, urbanization and pollution, water scarcity and management, soil erosion and desertification, and food scarcity in the Mediterranean (Kepner/Rubio/Mouat/ Pedrazzini 2006). Expected migration into cities or onto marginal lands will accelerate the impoverishment of land, resources and people and may lead to persistent upheaval or further migration, potentially stimulating ethnic conflicts or social unrest elsewhere.⁵

8.5 Water and Migrations: Two Reliable Indicators

Joseph Romm (1993: 15-16) pointed to a threat as anything that could "narrow the range of policy choices available to government," a definition so sweeping that one wonders what important foreign policy problem would not constitute a threat. Since then many studies have argued that current migration flows may further exacerbate existing local or supranational conflict dynamics, by substantially altering their pressure absorbing limits. The superposition of substantially modified elements of pressure on existing but formerly 'contained' conflict dynamics may generate new effects both in terms of the nature, quality and spatial situation of the conflict.

Equally, issues relating to freshwater quantity and quality are increasingly becoming the source of strategic considerations in many regions of the world. Insufficient fresh water may prove to be the most vexing problem in the developing world over the next decade, as agricultural, commercial, and residential uses increase. Water tables being drawn down at an alarming rate especially in the most heavily populated nations, are common to all regions and ecosystems. While arid and semi-arid regions are caught in a penury type of dynamic with increasing stress from water scarcity, much of the rest of the world faces growing pollution problems as a result of environmental change and inefficient management of natural resources.

Samson and Charrier (1997) in a report issued by Green Cross International indicated that the potential

for conflict over freshwater is enormous, given its importance for basic survival, industry, energy production and other fundamental components of society. Many freshwater basins, estimated to be more than 300, lie on or across international borders. A number of conflicts linked to freshwater are already apparent at various local and international levels, and the risk for more grows as population and degradation pressures accelerate. In many cases, little preventive action is being taken. So far, only limited fact-finding and even less concrete planning has been systematically carried out to analyse this dangerous potential and to propose integrated management solutions.

The same report indicated that in the Middle East, 9 out of 14 countries currently experience water scarcity and the others are rapidly approaching this state. Although water represents, as David Wishart (1990) explains, one facet of the multidimensional nature of the environmental conflict in Jordan, its importance cannot be ignored in a region where conflict dynamics have produced on average a major military confrontation every ten years. Based on current population and consumption projections, regions such as the Maghreb, the Sahel, East Africa, northern China, and South Africa as well as southern Europe and part of the US will experience water scarcity in the near future. Global environmental change, especially climate change and desertification, will greatly increase these risks both as the result of natural climatic cycles and anthropogenic drivers.

In his comments on the desertification synthesis of the "Millennium Ecosystem Assessment" (2005a) Walter Reid, director of the assessment, observed that drylands systems in developing countries are the regions where people are experiencing the greatest problems from the breakdown in the supply of ecosystem services and that "the ecological, social, and economic impacts of desertification can affect not just the people living in drylands, but also countries far removed from those regions" (see chap. 3 by Lee-mans). Large-scale migrations started to be systematically documented at the beginning of the twentieth century. Lester Brown (2004) from the Earth Policy Institute has indicated that environmental migration in the United States began when nearly three million "refugees (*okies*)" from the southern Great Plains left during the dust bowl of the 1930's, many of them migrating to California. He also points out the scenario of water refugees becoming 'commonplace' in the near future, particularly in arid and semi arid regions. Most of an estimated three billion people to be added to the world population by mid-century will originate

5 A second symposium on Desertification and Migration took place in Almeria, Spain, 25-27 October 2006 that is documented at: <http://www.sidym2006.org/eng/eng_ponencias_conclusiones.asp>.

from countries characterized by falling water tables and demographic pressure, thereby creating an escalation in 'hydrological poverty'.

As posed by Brauch (2003a) desertification requires an analysis of its environmental security dimension. Approximately sixty million people are expected to eventually move from the desertified areas of sub-Saharan Africa towards Northern Africa and Europe in the next 20 years (Brauch/Liotta/Marquina/Rogers/Selim 2003). In Mexico, drought and over-exploitation of land and water have lowered the aquifers in the most heavily populated central region of the country to 40 per cent of their former levels. As a result, between 700,000 and 900,000 Mexicans leave their homes in the rural drylands every year and go to seek their livings as migrant workers in the urban centres and in the United States. Many of the 12 million people affected by drought in Brazil's North Eastern Sertao region have migrated to São Paulo, swelling the population of the city by 300,000 in 1999. Over the last two decades 1.3 million people have fled Haiti as a result of environmental degradation compounded by political unrest resulting in a drop in the island's per capita grain production by half between 1926 and 1996. Mohamed Suliman (1999b) noted the scientific corroboration of an ever-increasing environmental dimension as a triggering element of national and trans-boundary migration flows may radically change the elements of the conflict equation.

Homer-Dixon (1999) provided a composite concept of the environment/scarcity/violence nexus which includes the conflict groups within states are subjected to as a result of three large forces for change: population increase, environmental impacts, and increased inequality. A number of large international research projects with this focus were carried out during the 1990's. As the pressure from increasing environmental scarcities has begun to impact on governments in developing countries, the perception of the problem in focus has shifted to how societies could adapt to unavoidable scarcities of strategic renewable resources. The research thus has shifted to scarcities of those social resources necessary for societies to be able to adapt to natural resource scarcities. Leif Ohlsson (2003) has observed that the pattern of conflict appears between groups within states, rather than between states; and the resource scarcities in focus are renewable resources, such as arable land and water, as opposed to non-renewable resources, such as oil and strategic minerals, which earlier were studied as causes of conflicts between states.

Depending on how environmental transformation translates into the social, economic, and political realms, environmental decline could grow into an increasingly significant factor in violent disputes in the coming decades. Michael Renner (1996) argued that countries whose economies are heavily geared toward agriculture, or other sectors that directly depend on the health of the natural resource base, are most immediately confronted by environmental problems. What matters most in this regard are not necessarily the hardships of environmental degradation per se but the fact that the harmful impacts will be felt unevenly by different social strata, communities, and countries.

8.6 Conclusion

The relationship between environmental degradation and migration is important, complex, and yet little understood. Due to the accelerating dynamics of desertification as a land degradation process, its steady globalization and intimate relationship with extreme and worsening poverty, environmental security is a major new challenge for sustainable development. Survival is casting a shadow on the shaky round of sustainability impeding its ability to react to sharply diversifying global challenges with adequate policy.

The real challenge to the paradigm of sustainability will not come from the capacity to deliver concrete development results in increasingly short periods of time, but from its efficiency and sufficiency in responding to changing dynamics and its ability to foresee long term challenges amid the ambivalences and ironies, the controversies and conflicts that pervade the terrain of global environmental politics.

Further research and investigation of the linkage of security and environment, driven by desertification, acting as both a cause and a consequence of displacement and cross-border migrations should be pursued through programmes facilitating the exchange of technical and scientific data and the constant monitoring of the desertification process. The UNCCD, as the only legally binding instrument at the disposal of the international community in the field of land degradation, desertification and environmental stress can offer the enabling framework for a programme on environmental conflict prevention, by encouraging comparative studies between affected regions with different cultural and economic constraints, establishing an historical perspective and fostering environmental

education and training initiatives in affected areas, with a view towards developing successful models.

The Convention is based on the principles of participation, partnership and decentralization – the backbone of good governance and suggests ways to go beyond conventional modernity models by promoting sophisticated yet moderate-impact technologies based on traditional technologies and local knowledge, redirecting relentless accumulation, and advocating ways of living that are simpler in means, but richer in ends. The bottom-up approach it adopted for the implementation process has raised the profile and strengthened the capacities of those directly affected by desertification, and assists key local actors in identifying and addressing challenges linked to the vision of sustainable development.

Attaining sustainability has proven to be difficult – technically, economically and politically. And without a framework to give direction to new efforts and approaches to counter land degradation, the impact of policy coherence will dissipate. Within this particular context, partnerships should be sought with the academic world, the research community and fellow UN bodies to promote research on desertification-induced population movements and perceptions of security challenges with the view to accurately disaggregate and defining the primary factors motivating migration from the drylands. Future assessments of dryland ecosystems should investigate the correlation between desertification, poverty and migration and become part of a global early-warning system for humanitarian crises in the making.

Recent United Nations estimates (Adeel/Bogardi/Braeuel/Chasek/Niamir-Fuller/Gabriels/King/Knabe/Kowsar/Salem/Schaaf/Shepherd/Thomas 2007) are that upwards of 50 million people may be on the move in five years due to environmental disasters and degradation. The threat posed by desertification has been effectively ascertained when sectorially conceptualized through a variety of reliable indicators, such as food, water and health security. However, analysts still lack dependable tools for a more in-depth and horizontal coherence of policies at the international level, at the national level and the local level. This requires actors at the international level to work together and make an effort to ensure that their policies compliment each other and address the suspicion that the Western development model is at odds with both the quest for justice among the world's people and the aspiration to reconcile humanity and nature.

Most and foremost however, it requires them to challenge the prevailing conceptual dogma of devel-

opment, whereby single development models are presented as unique viable alternatives.

If sustainability in the social and economic soils of desertification is to be effectively addressed along with its global impacts on human security and extreme human poverty, the current work on environmental security must acknowledge and internalize the unique comparative advantage of the UNCCD.

9 Societal Impacts of Desertification: Migration and Environmental Refugees?

Andreas Rechkemmer

9.1 Introduction¹

In its preamble the *United Nations Convention to Combat Desertification* (UNCCD) points to the significant impact of desertification-induced displacement and migration on sustainable development. Indeed, growing evidence on the linkage between land degradation, the reduction of drylands ecosystem services, poverty, and migratory movements has raised the awareness of scholars and policy makers. These linkages were traditionally understood as the interplay between physical patterns of change and human activities. Recent research efforts, however, have shown that desertification must be understood as a social phenomenon largely driven by human activities. Hence migration triggered by land degradation can be perceived as of a socially constructed phenomenon in the age of global change (see chap. 8 by Boulharouf/Pattie; chap. 10 by Ghazi).

This chapter introduces the concept of environmental migration and refugees, describes the various aspects of the interaction between desertification and people and the difficulties to assess them scientifically in a straight-forward manner, and finally takes a look at recent efforts at the multi-lateral level with a view to identify effective mitigation measures. Its thrust is based on a review of recent literature and assessments undertaken at the global level and within the United Nations system.

9.2 Environmentally Triggered Migration and Environmental Refugees

When the “Convention Relating to the Status of Refugees” was adopted in Geneva in 1951, environmental

degradation and natural hazards were not in the focus of the negotiators when they defined refugees as people suffering the “well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion” (Art. 1)². In 1972, with the Stockholm Conference on the Environment, world opinion turned to global environmental issues and led to the establishment of the *United Nations Environment Programme* (UNEP) in 1973. However, the case of worsening environmental degradation leading to environmentally triggered migration remained unnoted until the 1980’s when El-Hinnawi (1985) coined the concept of environmental refugees (Myers 1993, 1995, 2002; Brauch 1997, 1997a, 1997b, 2000–2001).

Environmental refugees are a dramatically growing group of refugees, mostly migrating from rural areas to cities. They are not yet officially mentioned in UNHCR’s statistics as they do not fulfil the criteria of the Geneva Convention. They are neither mentioned in the statistics of the UN Populations Division (2001a, 2001b; UN 2001a) nor in the annual U.S. World Refugee Survey (USCR 2001, 2003, 2004, 2005). As they are not officially counted, only approximate estimates exist. But they may have surpassed all other types of refugees and may become the largest group of migrants in this century.

There have always been people migrating due to natural and environmental changes, hazards or disasters, and several civilizations – such as the Maya (chap. 5 by Bluemel) – collapsed due to environmental change. Since then, the degradation of natural resources has dramatically increased. In the late 1980’s the ecological footprint of humankind finally exceeded Earth’s capacity, marking the first time in history when humankind managed its ecosphere not

Box 9.1: Number of Refugees and Migrants Globally. **Source:** Dow/Carr (2005). Permission was granted.

Refugees are a specific category of people within the broader context of the global population movement. First, to put environmentally induced movement in the context of all global population movement, we note that the International Migration Organization estimates that there were 175 million migrants in the world in 2003 (IOM 2003). Of this number in 2003, the UN High Commissioner for Refugees estimated that there were approximately 10.4 million refugees in the world (UNHCR 2004). An additional 10.2 million people, including asylum-seekers, recently returned refugees, internally displaced persons, and people without nations were identified as populations of concern.

Estimates of Environmental Refugees Today

There are a variety of estimates of environmental refugees. These differ by data source, environmental stressor, and length of forecasts, as well as by the definition of 'refugee'. Estimates of the number of environmental refugees today start at 10 million, more than half of whom are believed to be in Sub-Saharan Africa (Lonergan 2000). According to Westing's (1994, 1994a), three per cent of the African population has been permanently displaced largely as a result of environmental degradation. Other estimates put the number of environmental refugees in 1995 as high as 25 million (Myers 1995).

only locally or regionally, but globally in an unsustainable way (WWF 2004: 1).

During these past decades, increasing scarcity and overexploitation of natural resources, such as soil and freshwater, has become a severe problem due to an unprecedented rate of expansion. These circumstances have evoked a new type of migratory movements of people, i.e. the environmentally induced migration. The causes for this migration are mostly anthropogenic: transformations like degradation of soil or vegetation, fresh water and fresh air, and global climate change.

9.3 Land Degradation, Desertification and its Assessment

As far as land degradation and desertification are concerned, there are about four groups of countries with different causes but comparable results: the very heterogeneous group of the developing countries with their fast overexploitation of land because of growing populations, worsening ecosystem services and international trade patterns without real chances for coping mechanisms; the group of industrializing countries in Asia and South America with their strong extension of food production and population growth, foremost in urban areas; the group of fuel exporting countries like OPEC with their own kind of overexploitation and desertification phenomena; and Eastern European countries with their chemically and agriculturally induced land degradation. They all have to face similar results as loss of ground, desertification and its impacts. The tropics suffer most from these events. As the figure 9.1 indicates, the *Living Planet Index* (LPI) of tropical grasslands, savannahs, and

deserts dropped by 80 per cent since 1970, while temperate areas remained quite stable – which is to some extent the case because these areas have already been altered before. The sharp drop in tropical areas, however, does not mean a loss of 80 per cent of existing species, but a loss of 80 per cent of the former existing individual animals which is the highest number of all observed ecosystems (Prokosch/Heinrich 2006).

In the early 21st century, “[d]rylands occupy 41 % of the Earth’s land areas and are home to more than 2 billion people [...]. Some 10–20 % of drylands are already degraded [...]. About 1–6 % of the dryland people live in desertified areas, while a much larger number is under threat from further desertification.” (MA 2005a: 1). Another synthesis of the state of Earth’s deserts was published by UNEP (2006).

Traditional approaches to assess and combat land degradation distinguished between

the meteorological and ecological dimensions of desertification (the *biophysical factors*) and the human dimensions of desertification (the *socioeconomic factors*). Previous failures to recognize and include the interdependencies of these dimensions in decision-making have slowed progress toward the synthetic approaches needed to tackle the enormous problem of dryland degradation (Reynolds/Stafford Smith 2002: 1).

In the past this has hindered the scientific community in its approach to present a comprehensive understanding of the “causes and progression of desertification” (Geist 2005, 2006).

Therefore, “[s]ynthesis of dryland degradation studies continues to be plagued by definitional and conceptual disagreements, and by major gaps in global coverage.” (Ramankutty/Achard/Alves/Turner II/DeFries/Klein/Kees/Graumlich/Reid 2005: 5) Even the *Millennium Ecosystem Assessment* (MA) with its broad research agenda had to acknowledge wide gaps

Figure 9.1: Living Planet Index. **Source:** Living Planet Report 2004 – published in October 2004 by WWF. © Text and graphics: 2004 WWF. All rights reserved. Reprinted with permission of WWF.

in the scientific understanding of desertification processes as well as their underlying causal factors (MA 2005a: 2).

Nevertheless, with the concept of ‘ecosystem services’,³ the MA used an important and widely underestimated link between environmental degradation and human well-being, partially putting together ecological and human dimensions of desertification, and offering an important answer to the question on how desertification leads to migration: through poverty. Already, dryland populations are being shaken off by the rest of the world, given the fact that they rank very low in terms of human well-being and relevant development indicators (MA 2005b: 625). The UN Millennium Project in its 2005 report also puts some empha-

sis on a healthy environment in order to effectively combat poverty:

Environmental sustainability is also essential to any effort to improve the well-being and health of the world’s poorest people. A degraded environment has dramatic and harmful effects on health, education, gender equality, and economic development. People cannot work and study if they are frequently ill from drinking and bathing in polluted water or if they are malnourished because of soil erosion and desertification (UN Millennium Project 2005: 64).

These effects of poverty also appear in Reuveny (2005) who developed a new theory, arguing that people are able to adapt to environmental changes in only two ways: they can defend the changes, or they can leave the affected area. Which option they choose, he continues, depends on the severity of environmental degradation and on the society’s technical capabilities. In extreme situations, land degradation can remove the economic foundation of a community or society. Experience from recent decades can be interpreted as showing that land degradation and desertification have been a major driving force behind the displacement of people.

In the 20th century, Africa witnessed a whole set of drought-driven migrations to neighbouring countries. In a long-term perspective, the intercontinental

3 „Ecosystem services are the benefits people obtain from ecosystems. These include provisioning services such as food, water, timber, and fiber; regulating services that affect climate, floods, disease, wastes, and water quality; cultural services that provide recreational, aesthetic, and spiritual benefits; and supporting services such as soil formation, photosynthesis, and nutrient cycling. [...] The human species, while buffered against environmental changes by culture and technology, is fundamentally dependent on the flow of ecosystem services.” (MA 2005: V)

migration that has already started from North Africa to Europe can be expected to escalate dramatically as a result of rapidly growing water scarcity (Brauch 2006d).

Myers (2005) mentioned the number of at least 10 million people who had become environmental refugees in semi-arid lands and expects a by far greater number for the time ahead as regarding the one billion people at risk and their population growth rate of often three percent per year. Desertification reduces the land's resilience to natural climatic variations and thus undermines food production, contributes to famine and affects obviously the local socio-economic conditions. It thereby triggers a vicious circle of poverty, ecological degradation, migration and conflict. Desertification-induced migration and urbanization may worsen foreign living conditions by overcrowding, unemployment, environmental pollution and oversteering of natural and infrastructural resources, and by social tension, conflicts and vices such as crime and prostitution in the destination centres. These adverse effects are increasingly contributing to environmental degradation.

Africa has always been in the centre of debates about desertification: the Sub-Saharan Africa, the Sahel and the Horn of Africa, where by far the largest number of environmental refugees exist. It has already triggered some of the most broad scale migrations in recent decades. Even given the fact that now Asia is being called the "main area with degraded drylands, and no evidence was found supporting claims of the Africa Sahel as being a desertification hotspot" (Ramanakuty/Achard/Alves/Turner II/DeFries/Klein/Kees/Graumlich/Reid 2005: 5), desertification happening in Africa, and "Sub-Saharan Africa remains the prime locus of environmental refugees" (Myers 2005).

Thinking of the income situation and human well-being first, the "worst situations can be found in the drylands of Asia and Africa; these regions lag well behind drylands in the rest of the world" (MA 2005a: 8). The situation regarding the present and prospective availability of key ecosystem services appears to be similar: "The greatest vulnerability is ascribed to sub-Saharan and Central Asian drylands. For example, in three key regions of Africa - the Sahel, Horn of Africa, and Southeast Africa - severe droughts occur on average once every 30 years. These triple the number of people exposed to severe water scarcity at least once in every generation, leading to major food and health crises" (MA 2005a: 13). And they, in combination, already triggered an increasing need for refuge, combined with a regional shift: "Initially concentrated

in the East African region, where environmental disasters, such as drought and desertification, and ethnic, border and guerrilla wars in the Horn of Africa (Somalia, Eritrea, Ethiopia and southern Sudan) gave rise to large movements of refugees and IDPs in the 1980's and 1990's, in recent years there has been a shift to Central and West Africa" (IOM 2005: 37).

The synchronous appearance of conflict, migration, and desertification doesn't happen by chance. Their links are clearly visible. "Conflicts and environmental degradation further aggravated the pressure for migration from poorer to relatively prosperous regions, within and outside the [West African] sub-region. In the Sahel, in particular, desertification and cyclical famines have triggered waves of environmentally-displaced persons across national frontiers within the sub-region" (Adepoju 2005: 3). The described environmental events are expected to appear even more often and more severe with ongoing and exacerbating global warming (NEF/IIED 2005, IPCC 2001a), especially when sustainable agriculture practices are not being implemented soon and resolutely.

9.4 Drylands Ecosystem Services, the Causes of Migration and Conceptual Problems

Since people in drylands are very dependent on functioning ecosystem services, their reduction hits them extremely hard. Normally, drylands people are used to hardship and they have evolved traditional coping mechanisms. But when overcultivation and overgrazing lead to permanent and increasing losses in yield, the traditional means of dealing with crisis fail. Then, the typical chain starts: crop yields fall rapidly and animals die from lack of fodder. Industries based on crop and animal products fail, unemployment rises and people get poorer or even reach the state of severe famine. When a land's productivity is being reduced, this automatically leads to a reduction in income, to malnutrition, and to health risks. Together these effects result in serious threats like famine and increasing mortality rates. In order to protect themselves against such impacts, people frequently abandon degraded areas (MA 2005b: 645). This chain of events, combined with structural social and economic disparities, are a powerful driver in migratory movements towards wealthier or at least more promising regions, with large cities as the most attracting destination. "Rapid urbanization is largely a function of rural poverty. Environmental shocks, such as drought

and flooding, have accelerated this process, as has the failure of the rural development industry and state agricultural policies to stabilize populations in the countryside" (Cush/Williams/Peberdy 2005: 16).

According to Biermann (2001), there is little doubt about what drives people to abandon their lands. He categorizes the four main drivers as follows: *deposition* (by regional environmental pollution), *degradation* (e.g. by soil erosion or water scarcity), *disaster* (and sometimes its countermeasures like dam build-ings to control floods), and *destabilization* (as a consequence of stressed and finally failing social nets).

There are numerous well-known empirical exam-ples for large scale migration due to environmental deterioration of a different, natural as well as human-induced, kind. Just to mention two, take the Dust Bowl which forced hundreds of thousands of US citi-zens to leave their homelands in the 1930's (Reuveny 2005: 7), or the Chernobyl reactor catastrophe in 1986 which made large areas uninhabitable for at least sev-eral decades.

However, a fundamental question arises with the notion of 'environmental refugees' as a recent phe-nomenon: Is it conceivable to use this term for a large group of people escaping a degraded environment, while anthropogenic drivers are often mainly respon-sible for both degradation as well as the bad manage-ment of degraded ecosystems? Since in nearly every natural disaster a human fingerprint can be found - due to lacking early warning systems as was the case with the Indian Ocean Tsunami disaster of 2004, or because of social disparities between the rich and poor only allowing wealthier people to escape as was the case with Hurricane Katrina in New Orleans in 2005 - the concept of a changing environment alone leading to large scale migration fluxes has been ques-tioned (Vine 2005). In addition, the scientific concep-tualization of migration through environmental degra-dation can be seen arbitrary. "There are abundant typologies of 'environmental refugees' and 'environ-mental migrants', but little agreement on, or under-standing of what these categories might really mean" (Black 2001: 13). Even authors principally supporting the thesis of environmental refugees do note that there is indeed an urgent lack of theoretical clarifica-tion (Finton 2001).

On the one hand, this lack of scientific consensus may be the reason why the case of people (involuntarily) escaping their habitats due to environmental stress is very slowly, if at all, being put upon the agenda of the relevant governing bodies. The Office of the United Nations High Commissioner for Refugees

(UNHCR) does not recognize environmental degra-dation as a reason for the displacement of people in its "Refugees by Numbers 2005 Edition" (UNHCR 2005), and the same applies to the annual "World Re-fugee Survey" conducted by the United States Com-mittee for Refugees and Immigrants (USCR 2003, 2004, 2005). Only in some very recent publications, environmental disasters can be found as a reason for the forced displacement of people (UNHCR 2006: 27ff.), while in others especially concerning desertifi-cation it remains unnoticed (UNEP 2006). Official unawareness of the environment as a major factor in people's displacement can be seen as one of the causes for the high uncertainties in their exact num-bers.

On the other hand, there is a growing attention to-ward global environmental change as a driver for mi-gratory movements worldwide. For example, the Swedish and Finnish governments have already adapted their asylum policy now including people es-caping natural disasters, as did the United States (USCR 2003). While this - with some caution - can be seen as the beginning of a more integrated concep-tualization of migratory movements in the 21st century, UNHCR and USCR still seem to be sticking to what looks more like an end-of-pipe approach: USCR ac-knowledged a connection between environmental degradation and people's displacement in the way that around refugee camps ecosystems often suffer from exacerbating stress by thousands of people living in barely inhabitable areas (Chen 2005). The newly developed environmental programme of UNHCR therefore aims at these effects and wants to "prevent, mitigate and rehabilitate the negative impact of refu-gees on the environment" (UNHCR 2005a). Refugees fleeing from degrading environments are not yet a concern of UNHCR, but environmental degradation caused by refugees has become an issue of concern.

These statements, as important as they are for the well-being of fugitives in their camps, lack the recogni-tion of recent scientific data about both the causes and consequences of desertification worldwide and in developing countries in particular. One should not only look at what comes out of the pipe (refugees and resulting environmental degradation), but how and why it is being put into it. Or, as Frank Biermann put it, the question is not whether one estimates the number of environmental refugees to half a billion or rather decides not to perceive them as such - the question is merely how we can prevent people from having to give up their homes due to an uninhabitable environment (Biermann 2001: 28). "In this instance,

Box 9.2: Eighth Proposal by the German Advisory Council on Global Change for Managing migration through cooperation and further developing international law. **Source:** WBGU summary; at: <http://www.wbgu.de/wbgu_jg2007_kurz_engl.html>. Permission was granted

Developing comprehensive international strategies for migration. In order to manage environmentally-induced migration, a comprehensive migration policy strategy is required which takes account of the interests of all stakeholders. Its long-term objectives must be geared towards the interests of the destination, transit and home countries alike. In WBGU's view, an approach which focuses primarily on the industrialized countries' internal security - current EU policy being a case in point - is too one-sided, reactive and, at best, only effective in the short term. Prevention strategies do not feature in the numerous bilateral readmission agreements between the industrialized nations and countries of origin. WBGU recommends that at future international migration forums, environmentally-induced migration feature on the agenda and that appropriate plans be developed to deal with this issue. Focusing solely on economically motivated migration is not enough. Germany and the EU must step up their engagement in this area.

Integrating migration policy into development cooperation. In the Least Developed Countries, unabated climate change would increase the risk of people being forced to abandon their home regions due to the collapse of their natural life-support systems. Development cooperation can help to strengthen the adaptive capacities of people living in absolute poverty and thus make it easier for them to remain in their homes. However, development strategies must take greater account of foreseeable climate impacts at the local level. It can be assumed that climate-

induced migration within and between affected states will increase in future, opening up a new field of action in development cooperation. The importance of a comprehensive, pro-active and development-oriented migration policy is increasingly being recognized at the political level as well.

Enshrining the protection of environmental migrants in international law. Environmental migrants currently do not fit into the agreed categories of international refugee and migration law, even though a strong increase in environmentally-induced migratory movements is anticipated. Under current international refugee law, states have no specific obligations in relation to the treatment of environmental migrants, nor are any other legal mechanisms in place for the protection of the affected individuals. In the interests of improving the legal status and protection of environmental migrants, it is important to consider ways of closing this gap in international law. WBGU recommends that rather than adopting an additional protocol to the existing United Nations Convention Relating to the Status of Refugees, vigorous efforts be made at this stage to establish a cross-sectoral multilateral Convention aiming at the issue of environmental migrants. UNHCR should be involved as fully as possible in negotiations on the adoption of the requisite international agreement. This agreement should institutionalize the cooperation between UNHCR and the bodies established within the framework of the participating conventions. Furthermore, the United Nations' efforts to protect internally displaced persons, which have already begun, should be intensified.

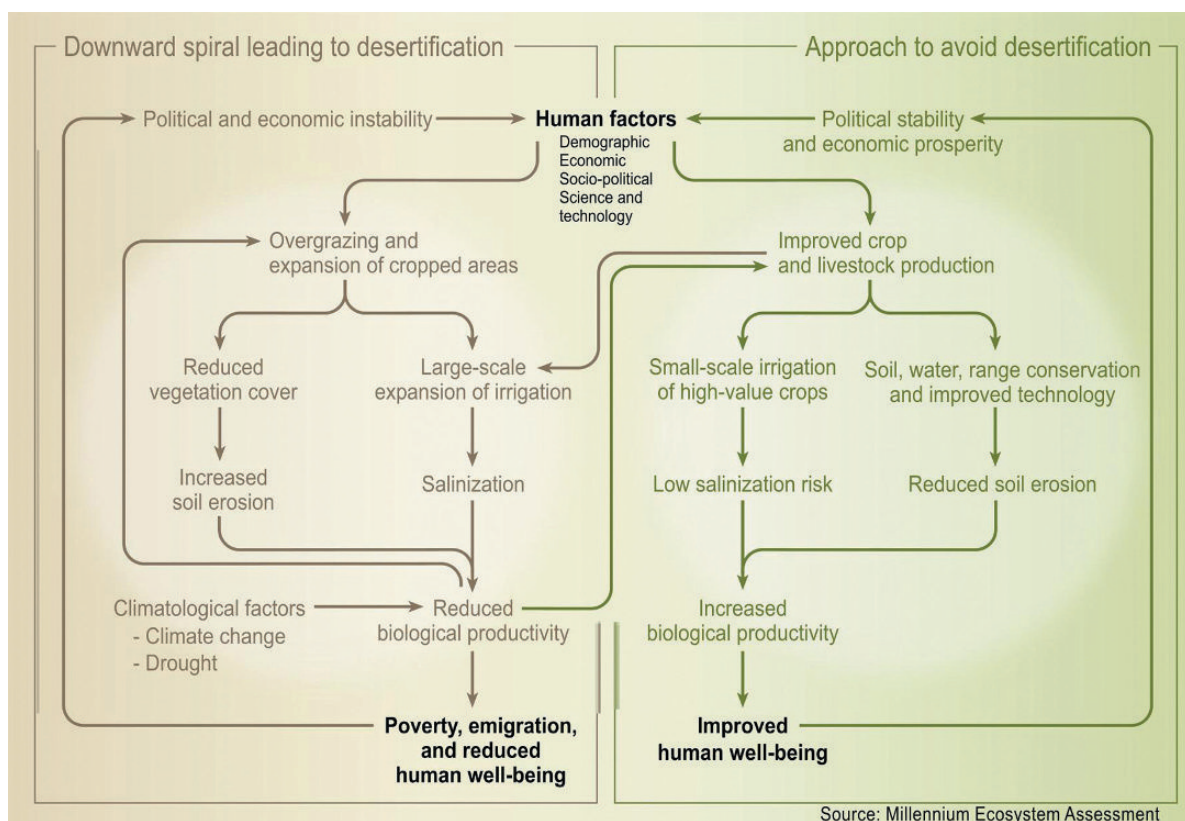

with poverty and 'life on the environmental limits' as the main motivating force, it matters little to the migrants whether they view themselves primarily as environmental or economic refugees" (Myers 2005). While there is surely some truth in this, nevertheless the recognition of desertification as a reason why people are forced to take refuge is an important step towards actually helping them (Conisbee/Simms 2003), because it may open doors to additional funds e.g. for increased activities of UNHCR, and it raises awareness of political decision makers for this yet widely unnoticed or at least unmanaged outcome of environmental degradation. Estimates by the *United Nations University* (UNU) expect that until 2010 there will be up to 50 million environmental refugees. Therefore, former UN Under-Secretary-General and Rector of UNU Hans van Ginkel's call goes for the recognition of environmental refugees within international frameworks, realizing that limited resources already restrain

the relevant global organizations' capabilities to deal with conventional refugees (UNU-EHS 2005a). This is also reflected in a proposal by the German Advisory Council on Global Change (WBGU 2007, 2008) for managing migration through cooperation and further developing international law (box 9.2)

9.5 Growing awareness at the multilateral level, and mitigation efforts

In affected countries awareness is rising about the connection between ongoing drylands degradation and migration. At the 7th *Conference of the Parties of the United Nations Convention to Combat Desertification* in Nairobi 2005 (UNCCD COP-7), Morocco for example "urged parties to be proactive in their response to the impact of desertification on migration"

Figure 9.2: Schematic Description of Development Pathways in Drylands. **Source:** Millennium Ecosystem Assessment (2005). This is in the public domain.

(IISD 2005: 1). On the other side of the Mediterranean Sea, Spain held a second International Symposium on Desertification and Migration⁴ in autumn 2006, relating to the agenda of the *International Year of Deserts and Desertification* (IYDD).

The IYDD was agreed upon by the 58th United Nations General Assembly (2004) in 2004, stating its concern over the exacerbation of desertification especially in Africa and its implications for reaching the Millennium Development Goals in general and on half of Goal No. 1 in particular: The eradication of extreme poverty (UNGA 2005: 1). Among the expected achievements of IYDD is the awareness of desertification implications. This ought to be reached by pointing to the threat desertification poses to vulnerable ecosystems, underlining the most serious consequences

under climate change, and the meaning of further loss of biological diversity. In addition, the perception of relationships between food insecurity, poverty, migration and conflicts should be strengthened (UNGA 2005: 3). So the agenda is supposed to be interdisciplinary, aimed at a more detailed understanding of human dimensions, and it comprises a linkage between desertification and migration.

To complete the overview of 2005 conferences, the *Third session of the Committee for the Review of the Implementation of the [UN] Convention [to Combat Desertification]* in Bonn (CRIC-3) put some attention to this issue. During CRIC-3, two global interactive dialogues were conducted by the plenary, one being about *Land Degradation/Desertification and their impact on Migration and Conflict*. There, by different participants it was noted “that many migrants come from rural areas, and live on agriculture. They are often forced to migrate due to pressures from such land-related issues as industrialization and low productivity of land”, “that land degradation is the greatest threat to the South Sahel and West Africa, which contributes to poverty”, and that *National Ac-*

4 At the first “International Symposium on environmentally induced population displacements and environmental impacts resulting from mass migration”, organized by IOM, RPG and UNHCR from April 22–24 1996 in Switzerland, it was estimated that more than 135 million people are at risk of being displaced mostly as a consequence of severe desertification (IOM 1996).

tion Programmes (NAP) “should include strategies to reduce the causes of environmental migration and resettlement” (IISD 2005a: 15).⁵

The good news is: The downward spiral of overpopulation, overgrazing, and other influences leading to desertification including all its side effects like exacerbated poverty and increased emigration is not inevitable. As presented in figure 9.2 (MA 2005a: 4), effective approaches exist to prevent desertification, increase of biological productivity and thus leading to improved human well-being.

The two sides in figure 9.2 represent two partially competing scientific approaches: The ‘desertification paradigm’ and the ‘counter-paradigm’ (MA 2005b: 645). The left side represents the older, indeed fatal desertification paradigm. It states that drylands are basically stable ecosystems which turn to collapse when human influence exceeds certain levels, and, most important, that few, if any, measures exist to prevent this downward spiral. In the more recent developed and scientifically backed up counter-paradigm, this is only one of two possible outcomes. It first states that deserts are by themselves unstable and therefore highly vulnerable areas. This does not neglect human influence in land degradation and its sometimes disastrous outcomes, but puts it into the broader picture of natural droughts and anomalies which are still far from being fully understood. Following this counter-paradigm, it is also possible, but dependent on social developments and political decisions, to avoid land degradation by using e.g. sustainable farming practices or integrated water system management. Indeed, some research has been undertaken for example during a series of international workshops since 2001 on the role of freshwater resources and on otherwise possible rehabilitation of drylands, on sustainable management of marginal drylands, and on prevention of land degradation

through traditional knowledge and modern technology (UNESCO 2003, 2004).

A recent large scale study by Pretty, Noble, Bossio, Dixon, Hine, Penning de Vries and Morison showed that using sustainable agriculture practices on 12.6 million hectares (roughly 1 per cent of the cultivated area in developing countries) helped increasing the average crop yield by 79 per cent, and it improved water-use efficiency. Also the use of pesticides, where checked, declined by 71 per cent, while crop yields grew by 42 per cent (Pretty/Noble/Bossio/Dixon/Hine/Penning de Vries/Morison 2006: 1114). Such successes are best reached by bottom-up-policies, as top-down policies often exacerbate land degradation (MA 2005b: 648). These policies need to be addressed at sub global levels by regional strategies and their integration in national action plans. This strategy seems to be the most promising and can lead to sustainable management of transboundary watersheds and biodiversity as well as to prevention of further desertification (UN Millennium Project 2005: 223).

Desertification, with all its underlying factors and its manifold consequences, will not be defeated easily. Though, there are ways to combat it effectively, and there are ways to live with the natural instability of drylands. In addition, we do not lack any longer the ability to end poverty (Sachs 2005), one of the main human drivers as well as impacts of desertification. But we do lack the political will to combat it effectively (and surely we still do lack scientific understanding of soils, their degradation, and the human dimensions of desertification). Therefore, we should prepare for growing numbers of environmental refugees, both nationally in our own countries and globally to prevent further political destabilization in developing countries.

5 During the UNCCD Third Session of the Committee for the Review of the Implementation of the Convention (CRIC 3): a Global Interactive Dialogue (GID) was held on 10 May 2005 in Bonn, Bundestag Conference Centre that was chaired by Amb. Mohamed M. El Ghaouth, Representative of Mauritania at the United Nations, New York, and moderated by Hans Günter Brauch, Free University of Berlin and AFES-PRESS; See the speeches by Brauch, at: http://www.afes-press.de/pdf/Brauch_Almeria_Valencia.pdf; and by Oswald Spring/Brauch, at: http://www.afes-press.de/pdf/Oswald_Brauch_lang.pdf; and the official summary in the UNCCD Journal No. 8 of 11 May 2005; at: http://www.afes-press.de/pdf/UNCCD_journal_050511.pdf.

10 Desertification in Algeria: Policies and Measures for the Protection of Natural Resources

Ghazi Ali

10.1 Introduction

With a total surface area of 2.4 million km², Algeria stretches 1,200 km from the east coast of the Mediterranean to the west, and 2,000 km north to south in the heart of the Sahara Desert. This vast area is home for 32 million people, the majority of whom (90 per cent) live in the north of the country. In Algeria three ecosystems prevail:

- The *mountainous ecosystem*, situated in the Tellian zone, with mountain chains and secondary mountain ranges characterized by land which is developed (calgimagnesian, fersialitic, brown), having a fragile structure subject to major degradation due to erosion.
- The *steppe ecosystem*, defined as part of the national territory demarcated in the North by the 400 mm isohyets and in the South by the 100 mm isohyets. It is characterized by soil of poor quality, exhibiting a predominantly hard layer of limestone.
- The *Saharan ecosystem* which covers almost 80 per cent of the total surface area, and which extends to the south of the Saharan Atlas divided by large morphological structures, the sandy ergs, the Hamadas (stony plateaux) and the Hoggar mountain region characterized by absolute dryness and a pronounced salinity.

This varied phytogeography generated a multitude of landscapes and biotopes that are extremely rich in biological diversity. Indeed, biological resources are a strategic element of sustainable development, and include animal and vegetable resources, and biodiversity in general. Sustainable development can only be achieved if these resources are protected and developed.

10.2 Status of the Environment

More than 12 million hectares are subject to water erosion which causes considerable soil loss, resulting in the silting of barriers, particularly those related to the degradation of the natural environment (flora, soil). About 20 million hectares that constitute the steppe region are threatened by desertification. This is linked to systems of exploitation of the environment by human beings who, in most cases, have been ignoring the traditional systems which, although not highly productive, nevertheless ensured a balance and protection of resources.

Thus, this degradation presents a huge problem for the authorities as more than 12 million hectares are subject to water erosion which causes major soil losses and the silting of barriers. This seriously impacts on the drinking water supply for industry, and especially agriculture.

The whole infrastructure of southern Algeria, which covers 200 million hectares, is subject to intense silting as a result of rapid development on the one hand, which often failed to take into account the fragile nature of the oasis ecosystems, and a certain 'laxness' on the part of the 'Touiza' population on the other hand; community work carried out by volunteers which involved the maintenance of foggaras¹, the restoration of AFREGS, sand grids, and the permanent maintenance of the drains. Taking all this into account, the authorities have launched major efforts to combat environmental degradation.

10.2.1 Desertification in Algeria

The degradation of natural resources in Algeria has reached a serious level. There are fears that it cannot be reversed in the medium term. This situation due, to overexploitation of the natural environment as a result of unsuitable agro-silvopastoral activity, makes the process of biological recovery difficult. From the

country's total surface area of 238 million hectares, 3,900,000 hectares are covered by forest. In the north 11 per cent of the land is covered by forests; while for the whole country barely 1.5 per cent is forested (figure 10.1).

Figure 10.1: NOAA Satellite Image of Algeria. Source: FAO Country Profiles and Mapping Information System, Algeria; at: <<http://www.fao.org/countryprofiles/Maps/DZA/19/im/index.html>>.

This shows the difficulty for a rational land protection. The problems of degradation are discussed for the ecological regions. Of a total of 238 million hectares, 200 million are taken up by the Saharan region where all oases suffer from silting caused by intense wind erosion. Demographic growth and urbanization have completely disturbed the precarious balance in the oases, and resulted in a spectacular removal of palm groves that may completely disappear in the medium term if no countermeasures are undertaken (figure 10.2).

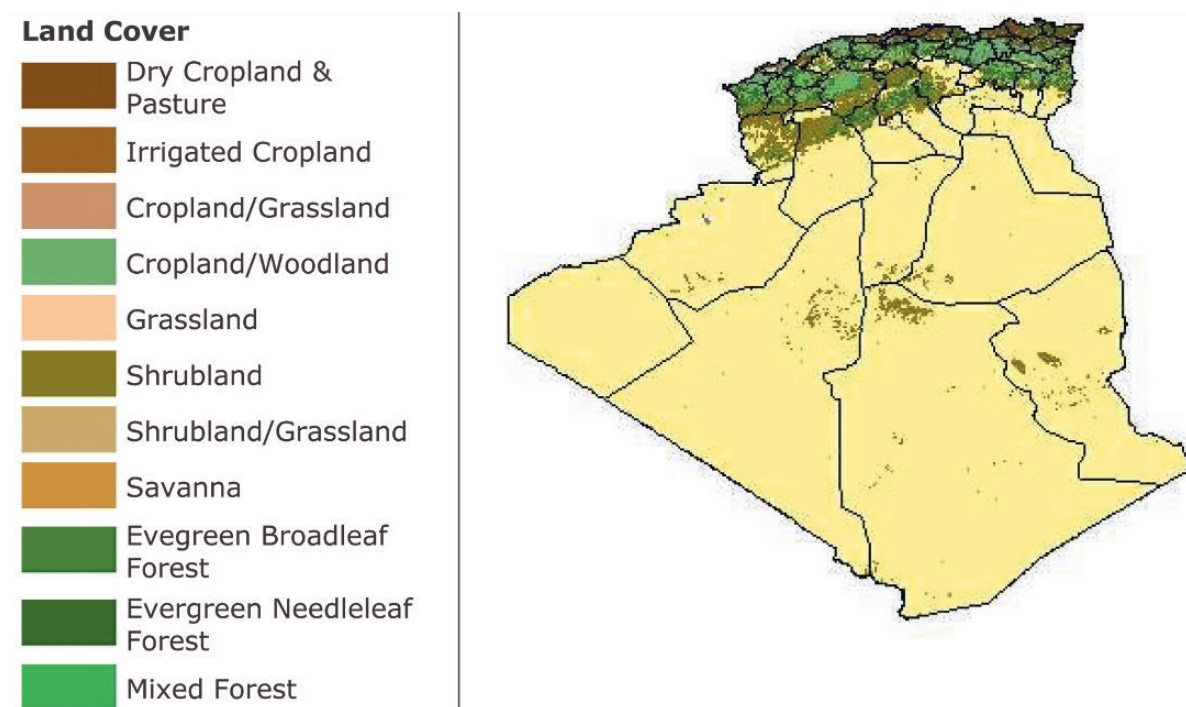

In the arid and semi-arid steppe region in the Northern Sahara nearly 20 million ha are subject to degradation. The population which lives mainly from extensive pastoralism did hardly anything to preserve this steppe, and its livestock of over 15 million animals far exceeds existing capacities. A satellite-based evaluation led to a national map that illustrates the regions that are sensitive to desertification. It shows that the very sensitive surfaces amount to over 7 million ha.

Exacerbated by cyclic drought, today more than 50 per cent of the land is degraded, and natural species are progressively disappearing. This has become worse because traditional land management practices are on the decline. Socio-economic changes occurred before the traditional methods could be replaced with new land management systems that assure the protection and sustainable development of pastoral land. Despite major efforts the situation remains alarming, since this damage caused multiple constraints for the traditional organization system and a migration of those people who until then had ensured the protection of these resources. For this region the demand for resources has been far greater than the supply, which has complicated the introduction of conservation methods. The increasing demand for resources has caused unprecedented environmental degradation with often spectacular effects, such as silting or even the total disappearance of vegetative cover.

Even if the intervention in the steppe has in most cases been mastered, the major problems causing this degradation have not yet been placed in a framework of land management planning. Further, the existing land system does not impose any legal restrictions, which has resulted in the exploitation of vegetative cover. More than 2 million hectares of land have been farmed. This increase in farmland and the introduction of mechanization into agriculture are major causes for degradation due to wind erosion and sterilization of the soil.

1 According to Wikipedia; at: <<http://en.wikipedia.org/wiki/Qanat#Algeria>> (12 November 2007): iQanats (designated foggaras in Ageria) are the source of water for irrigation at large oases like that at Gourara. The foggaras are also found at Touat (an area of Adrar 200 km from Gourara). The length of the foggaras in this region is estimated to be thousands of kilometres. Although sources suggest that the foggaras may have been in use as early as AD 200, they were clearly in use by the 11th century after the Arabs took possession of the oases in the 10th century. "The water is metered to the various users through the use of distribution weirs which meter flow to the various canals, each for a separate user. The humidity of the oases is also used to supplement the water supply to the foggara. The temperature gradient in the vertical shafts causes air to rise by natural convection, causing a draft to enter the foggara. The moist air of the agricultural area is drawn into the foggara in the opposite direction to the water run-off. In the foggara it condenses on the tunnel walls and the air passed out of the vertical shafts. This condensed moisture is available for reuse."

Figure 10.2: Map of Land Cover in Algeria. **Source:** FAO, at: <<http://www.fao.org/country-profiles/maps.asp?iso3=DZA&lang=en>>

10.2.2 The Affected Steppe Land

Pastoral land covers 36 million ha, and accounts for 14 per cent of the country's landmass that is distributed administratively into eight steppe wilayas and 11 agropastoral wilayas. The climate of these pastoral areas is characterized by:

- Weak precipitations with an irregular and complex space-time variation.
- Temperature patterns marked by stark contrasts, with a wide temperature range (cold and rainy winter, hot and dry summer).

With regard to precipitation four large areas with specific ecosystems may be distinguished:

- The area south of Piedmont of the Tellian Atlas with 400 mm/per annum where the more or less degraded forests and scrub are to be found.
- Areas prized by pastoralists, with *artemisia herba alba* (scientific name) situated on the high southern Algiers and Oranian plains, the Aures and Ouled Nail with precipitation of 300 mm/per annum.

- The foothills south of the Saharan Atlas where the terrain is poor, with sparse vegetative cover and precipitation of only 200 mm/per annum.
- The pre-Saharan steppe with precipitation of 100 mm/per annum on scrawny soil of poor quality that is sometimes covered with a thin layer of sand.

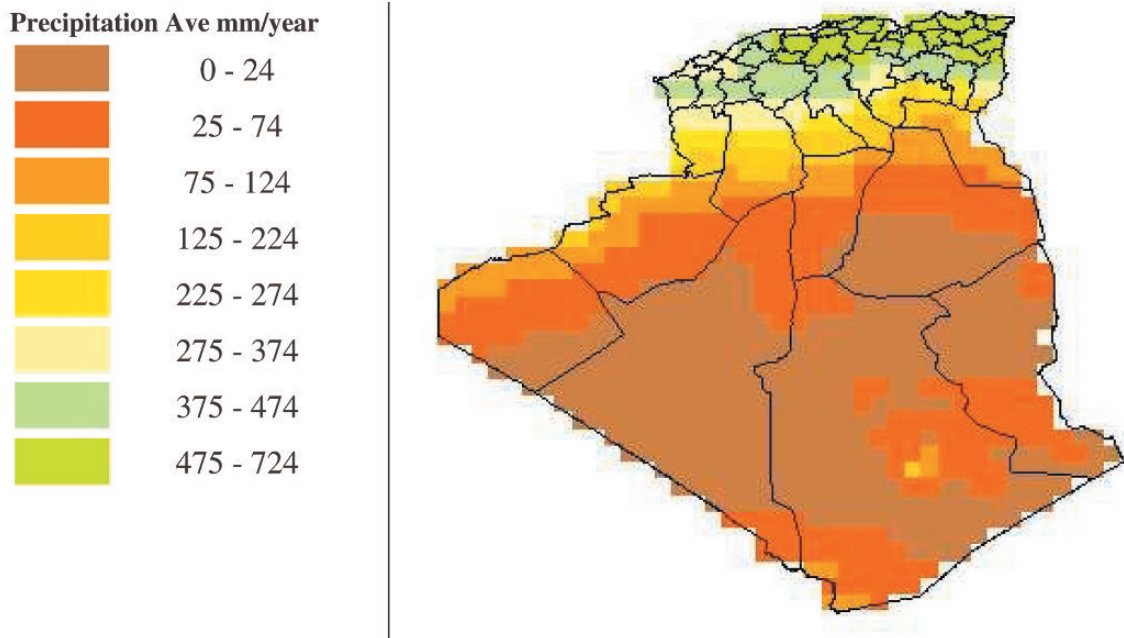

A wide temperature range shows the continental nature of the steppe climate (mm) in Djelfa which can reach a peak of 38° C in the summer and very low temperatures in December.

There is much wind in the steppe and this is a major factor causing soil degradation as they transport fine particles of sand which causes dunes to form. Winds with a speed above 5 metres/second can transport fine particles of soil from land unprotected by vegetative cover.

These winds coming from the north-east to the south are particularly dangerous during spring when they cause severe sandstorms. They also blow from the south-west to the north-east, particularly in the summer when their drying effect inflicts major damage on the vegetation.

There has been an increase in the sand volume in the oases in recent years causing significant damage to living areas as well as to their structures. Books and

Figure 10.3: Precipitation in Algeria. **Source:** FAO Country Profiles and Mapping Information System, Algeria; at: <<http://www.fao.org/countryprofiles/Maps/DZA/06/pp/index.html>>.

cartographic documents on the sandy structures of the south show that this is not a new phenomenon. Due to the vigilance of local populations over many decades, this could be contained. Sand covers more than a quarter of the surface area of the Sahara and constitutes structures of diverse shape and size.

Today siltation has become a major challenge. From aerial records and from observations plausible information on its predominant factors exist, among them are:

- The relaxation of the traditional ancestral battle by the people (Touiza) against the sands. Since many now have jobs in administration, tourism, and industry they no longer defend their small plot of land.
- The absence or disregard of town planning that takes into account the fact that wind directions are primarily responsible for transporting sand. Due to the unplanned and anarchical expansion of settlements, buildings were often established at right angles to old lanes, thus becoming sand traps.

The combination of these two factors has created areas that are susceptible to silting. These oases, situated principally at the edge of the humid ergs, contain major sand dunes and cover more than a quarter of the Sahara's surface.

10.2.3 The Arid and Semi-arid Region

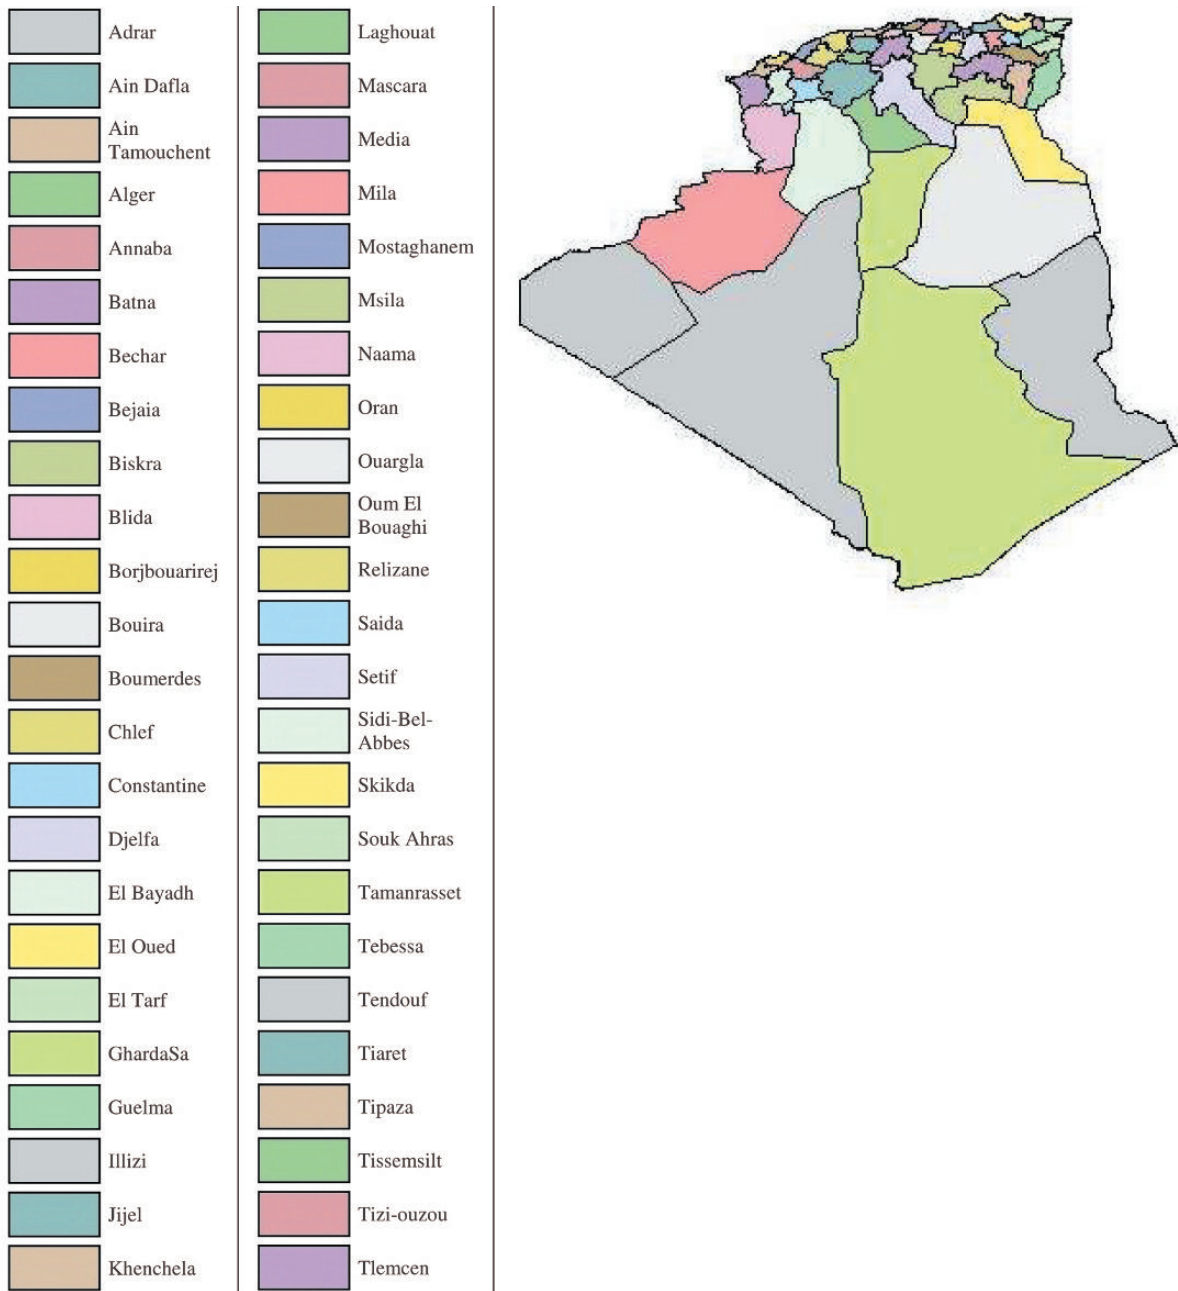

This region comprises nearly 20 million ha and has a population of nearly three million. Income is derived mainly from extensive pastoralism, the requirements of which cannot be met. Thus, overgrazing, together with the mechanization of agricultural practices and cyclic drought, have led to an increasingly dangerous degradation of the vegetation cover, thereby triggering the general process of wind erosion (table 10.1).

Table 10.1: Overview of the areas affected by Silting.

Wilaya (districts)	U	Living Dunes Organized	Silted areas (Sand-covered)
Naâma	Ha	90,000	400,000
El Bayadh	Ha	7,000	10,000
Laghouat	Ha	35,000	500,000
Tiaret			
Saïda	Ha	30,000	570,000
M'Sila	Ha	200,000	800,000
Djelfa			
Batna	Ha	2,000	40,000
Tebessa	Ha		50,000
		364,000	2,370,000

These estimated figures do not take the Saharan sands into account. The ergs alone cover more than a quarter of the surface area, at least 50 million/ha.

Figure 10.4: Districts in Algeria. **Source:** FAO Country Profiles and Mapping Information System, Algeria; at: <<http://www.fao.org/countryprofiles/Maps/DZA/16/ad/index.html>>.

The mountain region with nearly 12 million/ha has a traditional agriculture based predominantly on cultivation of cereals. Torrential rain in the form of very heavy showers on sloping ground with a substratum of tender rocks causes intense erosion resulting in the silting of water reserves estimated at more than 20 million m³/an of sediments. The general degradation of the land is reflected by the poor quality of the land

and the economy of the mountain region, whose agricultural earnings are progressively diminishing.

It should also be noted that soil erosion is inversely proportional to the vegetative cover protecting the land against the mechanical energy of water. Thus (according to Hadjiet), the Tellian massifs are completely stripped of cover, exposing them to intense erosion. The Atlas massifs, on the other hand, are better protected, thanks to the presence of forest cover

Table 10.2: Sensitivity of Administrative Districts in Steppe Land to Desertification.

Wilaya (district) in steppes	Little or not sensitive		Medium sensitive		Sensitive		Very sensitive

which limits water erosion. Thus, nearly 58 per cent of the Tellian surface area is affected by erosion, compared to only 10 per cent of the Atlas massifs. This shows that a durable vegetation cover remains the best protection against water erosion.

10.2.4 Evaluation of Desertification

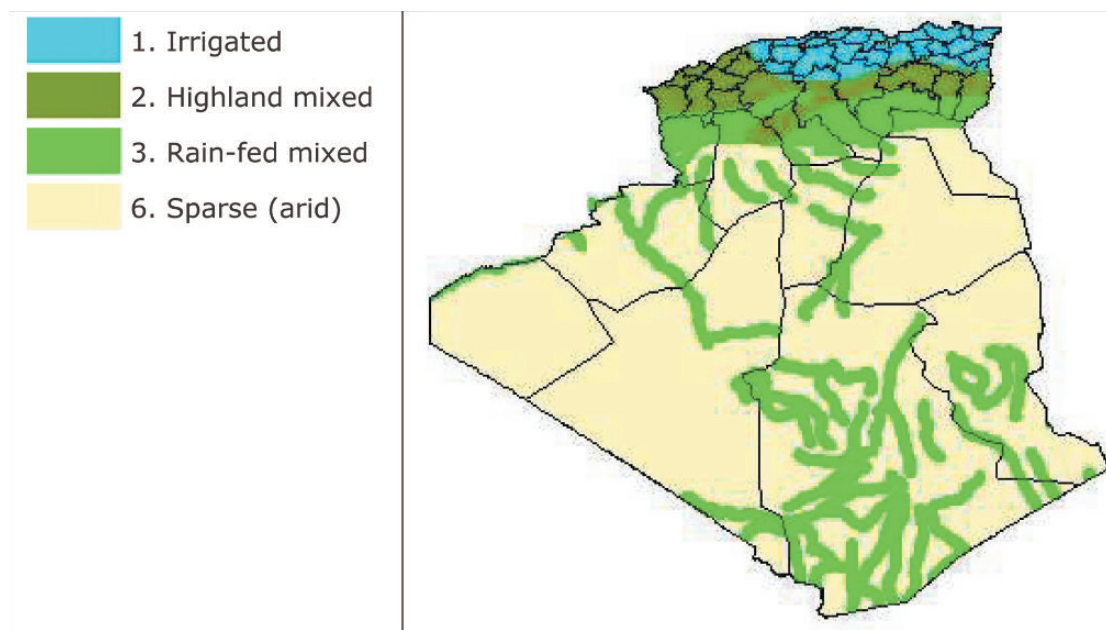

The study initiated by the Ministry of Agriculture (Head Office of Forests), and carried out by the National Centre for Spatial Techniques (CNTS) covered almost 70 per cent of the steppe regions and related to the chart of sensitivity to desertification. This cartography of sensitivity of the steppe regions was drawn up on the basis of: a) satellite data, b) maps of land use, and c) morphologic and paedologic (soils) maps (table 10.2). Each entry was assessed with regard to its potential sensitivity to desertification. Thus five types of sensitivity were defined. The regions classified as moderately to very sensitive were found to amount to 9,226,694 ha, or 67 per cent of the total surface area assessed in this study. The regions classified as suffering from desertification represent 487,902 ha, or a little more than 3 per cent of the total area assessed.

In order to better define the level of sensitivity to desertification at the local level, the study produced these results for the different administrative districts (*wilayas*) in the steppe land. The areas classified as little sensitive cover only 17 per cent of the surface area studied, whereas those areas classified as sensitive to very sensitive cover more than 52 per cent, which amounts to more than half of the territory, underlining the gravity of the situation.

10.2.5 Factors Exacerbating Desertification

Before independence, in the event of a severe drought, there was a significant death rate among the animal population, which eased the burden on the steppe, thereby reducing the pressure on the land. This period also saw cultivation, but only in the (Dhayas) and terraces of the Wadis where the soil is deep and moist. Only cereals were cultivated and they rarely exceeded 4 quintals/ha (1 quintal: 100 kg) in volume that were harvested in spring. This form of management worked for centuries with well-established social rules followed by each community from generation to generation. But this system of balanced management no longer exists due to social, economic, and political changes as a result of:

Figure 10.5: Farming Systems in Algeria. **Source:** FAO Country Profiles and Mapping Information System, Algeria; at: <http://www.fao.org/countryprofiles/Maps/DZA/01/fs/index.html>.

- dramatic population growth, from less than one million in the 1960's to more than three millions in the early years of the 21st century, thus increasing demand and putting more pressure on the environment. Since independence (1962) accelerated urbanization has also created a very speculative market due to the strong demand for meat, which has led to a disproportionate increase in cultivated land to satisfy an increasingly large livestock, which has also been very profitable.
- the inadequate techniques used to exploit the land which proved to be destructive, for example the disk plough which churns up the land, thereby exposing these wide open spaces to harmful winds. This contrasts with past methods, where the swing-plough made it possible to cultivate the land while safeguarding the vegetation (post-farming) thus protecting the soil (for example the pastoral artemisia).
- the impossibility of easing the burden on the steppe, if only temporarily, and even in the event of a severe food shortage, because of the availability of cattle feed. This form of assistance, praiseworthy in the sense of avoiding the ruin of the pastoralists, unfortunately has negative consequences for the land which does not have time to recover from the pressure of an increasingly large herd. Thus herds are maintained and nourished with external factory-produced foodstuffs (concentrates, barley).

Furthermore, the technical progress in the steppe due to state-provided veterinary medicine in combating diseases has significantly decreased the death rate among livestock. Vigorous campaigns against diseases such as Blue Tongue, Clavele, Rabies, Brucellosis, Anthrax, and Hydatid Cyst are regularly carried out.

Free access to the land has also given rise to a multitude of investors in livestock breeding, taking into account its profitability and the exemption from payment of a fodder tax. There has been an influx of large stockbreeders, generally city dwellers with significant means at their disposal, and who are therefore not put off by the existing constraints with regard to water, poor land quality, or the movements of the herds.

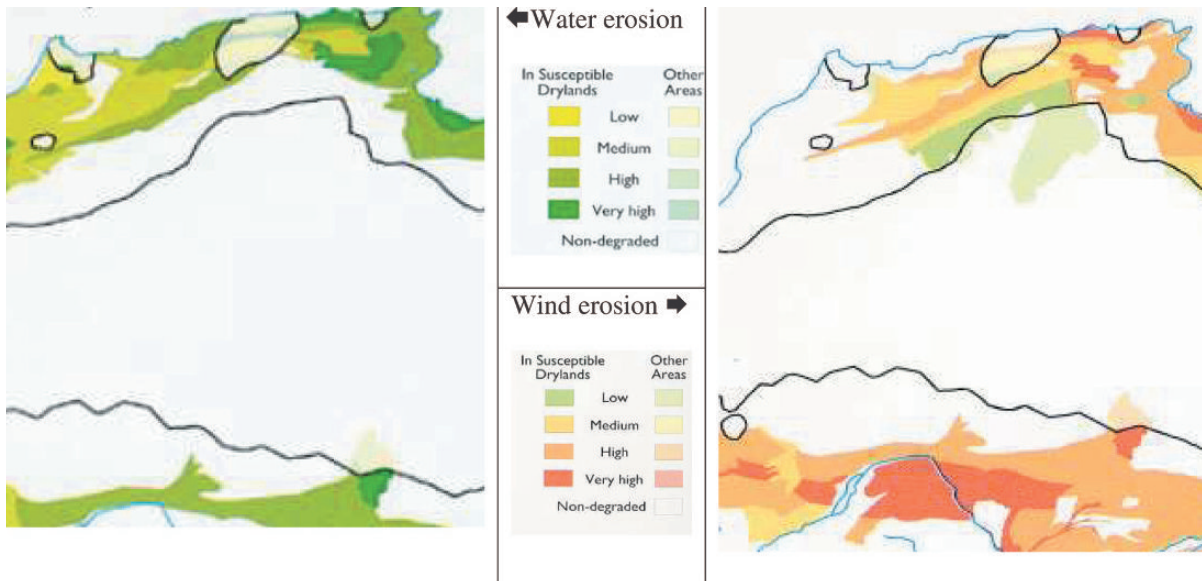

Such breeding backed by considerable financial means has been carried out to the detriment of the small stockbreeders who are not in a position to bring food from outside for their livestock. This situation has been primarily responsible for the progressive disappearance of the small stockbreeders who had no choice but to settle in the outskirts of towns, hoping to find work there.

10.2.6 Degradation Phenomena

10.2.6.1 Water Erosion

The land in high altitudes and slopes is particularly vulnerable to water erosion. As 68 per cent of Alge-

Figure 10.6: Water and Wind Erosion in Algeria. **Source:** UNEP/ISRIC, CRU/UEA; at: <<http://lada.vrtualcentre.org>>.

ria's territory has an average altitude above 800 m, and as 30 per cent of the land consists of slopes with a gradient of more than 12 per cent, this land is especially vulnerable to water erosion. This is further intensified by torrential rains and flash floods. The weather statistics show an average rainfall of 45 mm in a 24-hour period several times a year.

Other factors exposing the land to water erosion include: a) forest fires which undermine the fragile soil; b) excess soil leading to run-off, thus preventing the vegetation from regenerating; and c) traditional farming techniques practised by farmers on slopes, thereby increasing run-off and soil erosion. All these factors cause not only the loss of fine soil particles, but also landslides. The total surface threatened by water erosion is estimated at almost 10 million ha. Soil losses amount to 120 million tons per annum, which equals 40,000 ha of arable land.

Calculations on the basin inclines refer to an annual erosion of 16.6 m³ of land per hectare, which equals 1.6 mm. Water erosion also has other consequences, including the loss of water resources caused by non-alimentation of the groundwater as a result of reduced infiltration and silting of the barriers, some of which reached a rate of sedimentation bordering 100 per cent (especially the Fergoug, Ksob, and Foun-El-Gueiss dams).

10.2.6.2 Wind Erosion

This very important phenomenon particularly affects the arid and semi-arid regions in general, and the steppe in particular. Although it has reached alarming

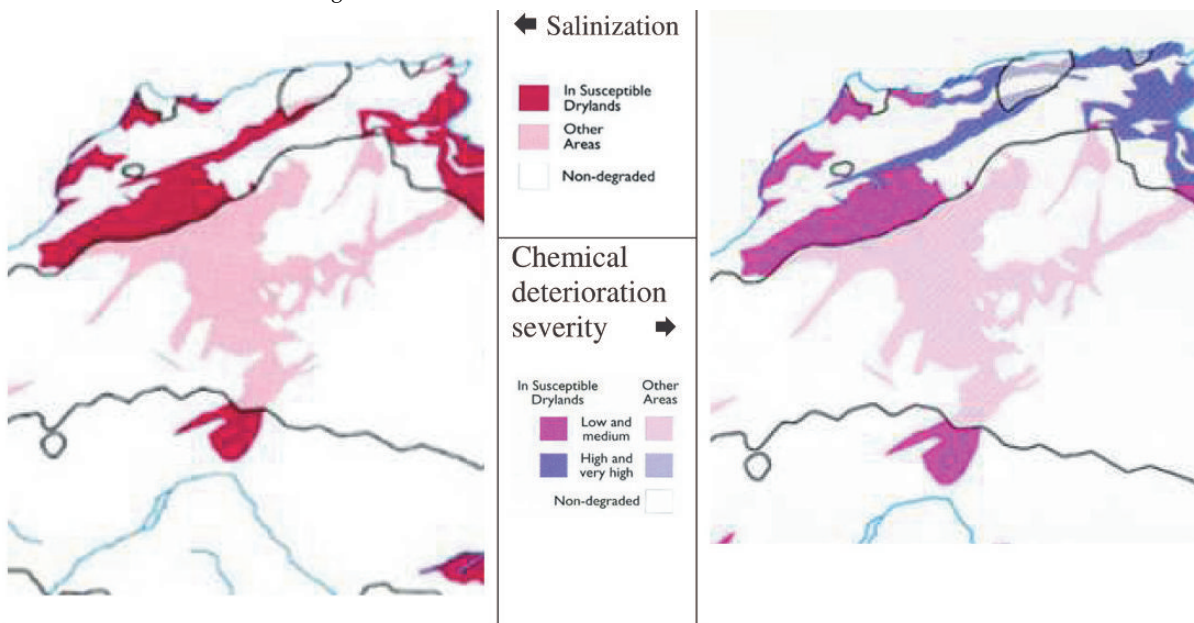

proportions over the years, no scientific quantification has been made in Algeria to assess the soil losses caused by wind erosion. However, a report initiated by the forest administration and developed with teledetection shows worrying results. It claimed that almost 600,000 ha of land in the steppe region suffer from desertification without the possibility of a biological recovery, and that nearly 6 million ha are seriously threatened due to wind erosion.

This erosion is caused by an imbalance in the interaction between climate, soil, vegetation, and human beings. It comes from the combined effects of climatic change (persistent drought) and human activity that is adapted to the fragile soil. These actions are 'imposed' by the increasing needs of a constantly growing population which leads to an expansion of cultivation on land that is unsuitable for agriculture, and the spread of the settlements into areas that were traditionally reserved for farming.

10.2.6.3 Salinization

In addition, the land of *chotts* and *sebkhas*, the irrigated agricultural land, is also prone to salinization due to the poor water quality, evapotranspiration, and bad drainage conditions. This phenomenon is particularly visible in oases and certain agricultural areas situated in the arid and semi-arid regions (Abadla, Relizane et al.). In 2007, about 300,000 ha of land was fit for irrigation out of 1.4 million ha that were classified as prone for irrigation. Thus the risk of salinization exists if adequate drainage conditions are not met.

Figure 10.7: Salinization and chemical deterioration severity in Algeria. **Source:** UNEP/ ISRIC, CRU/UEA; at: <<http://lada.vrtualcentre.org>>.

10.2.6.4 Chemical Pollution

The uncontrolled use of manure and plant health products often causes the disappearance of the earth's microfauna and microflora, and consequently decreases the fertility of the arable layer. It is currently difficult to assess the surface areas affected by such pollution since no follow-up statistics are available, but it should be emphasized that these surfaces are important, particularly in the case of land with high agricultural potential, considering the large quantities of manure used by agriculture (more than 600,000 quintals per annum). Other forms of pollution undermine soil fertility, such as waste water disposed of in the natural environment, as well as waste dumped close to arable land.

10.2.6.5 Cultivation Methods

Inappropriate cultivation methods often cause soil erosion, particularly the cultivation of slopes. The traced furrows create channels where the fast water run-off generates intense erosion. Other farming practices are also responsible for soil erosion, such as the cultivated fallow and the introduction of the disk plough in a steppe environment. The surface areas cultivated annually and subject to wind erosion are estimated at almost 1.2 million ha.

10.2.6.6 Urbanization

Urbanization and industrialization often occur on the most fertile arable land, since those responsible choose the easy options which do not require substantial investment in civil engineering. This negative development generally continues despite the protests from environmental protection associations. The authorities have failed to control this haemorrhage of fertile land. The potential agricultural surface area lost is estimated at 250,000 ha, including 10,000 ha of irrigated land. Thus, the situation with regard to land heritage is most alarming. This multiple degradation, combined with population growth, has meant that the available agricultural surface area per capita is in progressive decline.

Thus, the statistics show that in 1962, the SAU (used agricultural surface) per capita was 0.82 ha; in 1982, it declined to 0.36 ha then to 0.32 ha in 1989, and is currently approaching 0.20 ha/hab. These figures clearly indicate an extremely grave situation for Algerian agriculture, and especially for the country's food security. This implies not only the need for substantial protection efforts, but also for the possible cultivation of new areas in order to increase the agricultural surface area, which of course would require major investment.

Attention should be drawn to the fact that approximately 60 per cent of the total population currently lives on a coastal strip accounting for approximately

1.7 per cent of the total surface area of the country, and where the majority of the water resources, arable land, and industrial infrastructure are concentrated. The density of the population in this region is estimated at 233 inhabitants per km² in 2003, compared to 169 persons/km² in 1977. The pressure exerted on the most productive land by this increasing density is alarming, and only serves to exacerbate degradation and the permanent loss of soil.

10.3 Assessment of Soil Protection Activities

Action taken to combat soil erosion in Algeria began with experiments in anti-erosion techniques, some of which did not produce the expected results. The principal operations carried out concerned the defence and restoration of land (DRS), torrential correction, afforestation, and land improvement.

10.3.1 Defence and Restoration of Land

The defence and restoration of land combines a series of actions to combat soil erosion that have been initiated in 1942 with the creation of the 'DRS technique'. This bench technique consists of cutting the slopes at regular intervals by terraces on which forest trees or rustic fruit trees are planted. In 1964, the total surface area thus treated over a period of 20 years amounted to 375,000 ha that was concentrated primarily on the protection of the plains and barriers in order to ensure the expansion of colonial agriculture.

In 1984, an assessment was made of the physical and economic effects of this technique. It emerged that the benches led to an increase in water erosion, particularly in areas where the structure is unstable, and owing to the fact that this method was strongly opposed by the local population who systematically destroyed the work of the DRS, thereby exacerbating land degradation. This technique has since been abandoned. Probably one of the reasons for its abandonment is the extremely high cost of implementation and the lack of maintenance of its infrastructure.

10.3.2 Control of Flash Floods

This is one of the DRS techniques still in use that allows the regulation of intensive rain and flash floods through the construction of small successive barriers and thresholds along the torrent. These thresholds are generally created using dry stones, and are some-

times maintained with baskets. These barriers amount to more than 1 million m³ across the country. But this is insufficient, given the surface area requiring treatment and the lack of dry stones in many places. The effort to control the torrents is generally accompanied by biological protection through the fixing of banks. The amount has increased during the last few years due to a major work programme that envisages the creation of 330,000 m³ within three years.

10.3.3 Land Improvement

Land improvement indirectly affects the protection of the land against erosion and encourages farmers to work their land, thus mitigating against the effects of erosion. It consists of a major cultivation requiring the use of bulldozers with rooters which dig the ground up to 1.20 m. This technique permits good water infiltration, while increasing the productive potential of the land, and therefore the revenue. Almost 50,000 ha have been treated so far.

10.4 Action Undertaken

Despite the disappointing results from various development programmes, the steppe has nevertheless benefited from major investment in its development. Moreover, this area is promoted by the authorities. Many programmes have been implemented since the 1970's which have resulted in a number of concrete projects:

10.4.1 The Green Barrier

The Green Barrier, situated on a fringe located between the isoyetes 200 and 300 mm of rain, was launched in 1970 by the National Defence Ministry (Office of the High Commission for National Service) and seeks to protect the land from degradation. This national effort initially aimed at a massive afforestation of over three million hectares, and it was soon to become a project of integrated development primarily with regard to the following:

- The reconstitution of degraded forests of the Saharan Atlas covering an area of 300,000 ha.
- The protection of living areas and socio-economic infrastructures from silting through the establishment of dunes and green belts extending to almost 16,000 ha.
- The cultivation of pastoral plantations to increase the amount of fodder over 25,000 ha.

- Integration of the population through new road networks of more than 5,000 km.
- The mobilization of water resources for the local people through the creation of 90 water points.

The first plantations met with hostility by local people who opposed plans which limited the freedom of movement of their herds. These plantations were quickly redirected towards sloping ground that did not interfere with pastoral activity. To avoid damage to young plantations several activities were launched for the benefit of local people. Roads were built to make them less remote, access to water resources was improved, and pastoral plantations were encouraged. However, independent management implied that their durability could not be guaranteed.

Parallel studies were undertaken in each *wilaya* affected by the green barrier where the socio-economic aspect that was previously missing was taken into account. But these studies did not meet the requirements for technical, scientific, and socio-economic knowledge of the steppe, and suffered from an obvious lack of intersectoral coordination.

It is difficult to mention all activities undertaken in the steppe region since independence due to their number, but also due to the lack of intersectoral coordination. The concern of the state has been to ensure a regional balance, which often did not pay sufficient attention to the specific conditions of the area.

10.4.2 Land Utilization

The purpose of this programme has been to increase the agricultural potential, thus creating permanent jobs, particularly in the steppe region. The programme resulted in durable investment in the development of 280,000 ha, what represented almost 55 per cent of the national total. However, land utilization, while permitting the creation of large and economically viable agricultural areas, also created barriers, sometimes preventing the circulation of the herds.

10.4.3 The Afforestation Programme

Special projects (CPR) were launched between 1962 and 1967. The objective was to reduce unemployment in rural areas and to mobilize the citizens for community action in the national interest. During this period a surface area of 38,500 ha was afforested. Other programmes followed in the framework of the triennial plan (1967-1969), the 1st four-year plan (1970-1973),

the 2nd four-year plan (1974-1977), the special programmes (1967-1978), the communal plans (1967-1978), the 1st five-year plan (1980-1984), the 2nd five-year plan (1985-1989), the programme of development of the steppe, the 'Green Barrier' programme, the annual programmes of 1990 to 1993, and the major work programme of 1994. Between 1962 and 1994 more than 1 million hectares were afforested. But given the damage suffered by the plantations and the deterioration due to drought, fire, or lack of maintenance, the actual surface areas which has undergone reforestation is estimated at nearly 700,000 ha.

The qualitative assessment carried out in 1986 showed that only 50 per cent of the plantations had a success rate of 80 per cent, 35 per cent had a success rate ranging between 20 and 50 per cent, and 15 per cent of the plantations had a success rate below 20 per cent. Based on this assessment the actual surface area that was successfully reforested and whose vegetative cover can be classified as forest amounted to nearly 700,000 hectares.

10.5 Assessment of Environmental Protection Legislation

Environmental legislation started in the 1980's dealing in particular with:

- *Ordinance 75-43* on farming transferred all pastoral or agricultural land to the state. This law covered all areas between the isohyets of 200-400 mm as well as the pre-Saharan region below the isohyet 200 mm, but excluded the land subject for permanent development.
- *Law 90-25* on land classification which defines pastoral land as "any land covered by a natural, dense or sparse vegetation including species with an annual or multi-annual vegetative cycle".
- *Law 83-18* on ownership of agricultural land (APFA), which does not refer to pastoral land, seeks to encourage agricultural investment in the steppe. The local authorities have the right to grant land, in particular to young people, to make it productive within five years. If they succeed, the recipients are granted the right to own the developed area. This development is restricted to potential land that requires mobilizing water resources and excludes pastoral land.
- *Law 84-12* on the 'General Regime for the Forests' also applies to the land that declares the protection and rational use of land subject to erosion and desertification as a national interest. The land

of the steppe region is thereby obviously most affected.

- *Law 01-20* of 12 December 2001 on sustainable development of the land in an integrated, coherent and prospective manner integrates economic and social development as well as protection and development of the natural resource potential into public policy.
- *Law 83-03* of 5 February 1983 on environmental protection, modified and updated by the new law 03-10 of 19 July 2003, is entitled as the “law relating to environmental conservation within the framework of sustainable development”. This new law takes international agreements into account to which Algeria has subscribed and it is based on modern sustainable development principles. The provisions contained in this law made nature conservation a task that is in the national interest, and consequently “it is the responsibility of each and every person to protect our natural inheritance”. The protection of the land from erosion and desertification is in the public interest. Thus, environmental protection associations can be created in accordance with the pertinent regulations.

The law of 2003 concerning environmental protection constitutes major legislative support for protective action, in particular the participation of those people affected by desertification. It envisaged the role of associations for the protection of the natural environment, which indicates a willingness to involve all people concerned. With regard to law 84-12 on the general forest regime, the state plays a major role in the process of development, realization, and financing of projects to combat desertification. Thus, in many cases the participation of the population has contributed to the success of multiple previous projects. But these laws are often difficult to implement because the texts are missing which explain and describe the areas of application.

10.6 Natural Resources Requiring Protection

These laws refer to both plant (10.6.1.) and animal resources (10.6.2.) that require protection.

10.6.1 Plant Resources

Natural plant resources are characterized by three principal ecosystems: a) forest ecosystems, b) pastoral ecosystems, and c) Saharan ecosystems.

With a surface area of 238 million ha, Algeria has very limited forest cover. With 4,150,000 ha of forest, the level of forestation is only 1.5 per cent. If we take into account sylvan grounds, i.e. those in the north, the level is only 10 per cent, compared to the level necessary for ecological balance, which stands at 20 to 25 per cent. However, the Mediterranean forest is subject to continuous degradation due to human-induced pressure and fires.

With regard to the steppe, pastoral ecosystems undergo persistent degradation, in particular desertification. In addition to persistent and cyclic drought, pastoral vegetation in spite of its variety and richness is subject to exploitation of the ‘mining type’ which, if this situation persists, would see it disappear completely in the medium term. The *esparto*, with 3 million ha, remains the dominant homogeneous vegetation with the *artemisia* (4 million ha), the *lygeum spartum*, as well as the *pistachio* tree and the *jujube* tree in the days.

The flora of the Sahara is in most cases of the relic type, such as the *cypress* of the *tassili*. Occasionally there are the *acacias radiana*, but the herbaceous flora remains the most important, with 500 species of *vascular plants* and 700 species of *cryptogams*.

10.6.2 Animal Resources

The genetic inheritance of domestic and wild fauna is rich and diversified. Its location is dependent on agricultural practices and plant resources for domestic fauna (10.6.2.1) on the one hand, and on the other hand on the situation of natural biotopes for wild fauna (10.6.2.2).

10.6.2.1 Domestic Fauna

Domestic fauna is characterized above all by its genetic inheritance, being well adapted to the climatic conditions of the country, particularly the ovine livestock. The latter is estimated at 17 million, with 50 per cent made up of the local breed *Ouled Djellal*, 30 per cent of the *Hamra* breed, and 15 to 20 per cent of the *Rembi* breed. The highly prolific breed of *D'mina* is found primarily in the south-west. The bovine race is estimated at 1.2 million, more than 80 per cent of which can be found in the Tellian regions. This livestock principally consists of the *Brune* breed of the Atlas and the *Guelma*.

During the last decade, imports of highly productive bovine breeds took place, such as the black and white and the red. This imported livestock is estimated at between 200,000 and 300,000. The alpine

breed, 70 per cent of which can be found in the steppe regions, is estimated at more than 2 million. The *equidae*s consist of *barbes*, Arab thoroughbreds and *Arab-bores*. A 150,000 of equidae livestock exist particularly on the high plains. The donkey breed which suffered major decline is estimated at 450,000, similarly the mule is estimated at 200,000. The dromedary accounts for a herd of 100,000, and is located exclusively in the Saharan regions. Finally, there are farm animals where there has been spectacular development during recent years due to industrial breeding (poultry, turkey, guinea fowl, goose, and duck).

10.6.2.2 Wild Fauna

The privileged situation of Algeria explains the diversity of the biotopes which extend from the Mediterranean to the Saharan regions. The protected areas contain important animal species, including 90 species of mammals, 350 species of birds, 70 species of reptiles, 12 species of amphibians, and 70 species of freshwater fish. In addition to the importance of endemic species, the wetlands contain significant populations of migratory species.

Among the species which have disappeared or are in the process of disappearing from the steppe ecosystems are the lion of the Atlas, the ostrich of North Africa, and those which are in the process of extinction or even in some places extinct, include the *addax*, the *oryx*, the gazelle, the stag, the lynx, the bustard. This has been a result of overzealous hunting and competition between humans and beasts.

10.7 Perspectives

Three perspectives are distinguished focusing on the land (10.7.1), on vegetable (10.7.2.), and animal resources (10.7.3).

10.7.1 Perspectives on the Land

The current situation of land resources will probably get worse for the following reasons:

- Intensive winter rain which occurs regularly will continue to be the principal cause of severe erosion, particularly when the soil loses its vegetative cover. Drought is also a periodic natural risk creating conditions for soil erosion. The soil will be characterized by an elevated salt and limestone content leading to salinity. This situation applies particularly to newly developed land which re-

quires irrigation. It is essential to create a network of drainage for any new act of development in all areas.

- Demographic growth, although it has slowed down during the last decade (from 3.2 per cent in 1966-1977 to 2.3 per cent at present). Urbanization will continue, in particular with regard to small- and medium-sized towns in the country's interior due to the fact that large urban centres have reached a saturation point.

If this situation persists the loss of arable land may be expected to increase in the years ahead, considering the country's housing deficit and the intensive development of the cities. While an annual loss of more than 7,000 ha has been registered so far, this loss could be 2 or 3 times greater in the medium term, considering the requirements referred to above. This situation can only be controlled with the implementation of:

- a rigorous and sustainable regional planning policy through the development of various land use plans: PDOS (Plan of the Occupation of Land), PDAU (Urban Planning)).
- increased activities to combat soil erosion, particularly in the sloping basins of the belt and the steppe region.

With regard to the slopes of the basins, development must be multi-sectoral in nature, with each sector having the duty to ensure a comprehensive and harmonious development. The active involvement of the population must be achieved through an introduction of appropriate agricultural rotation, the practice of adapted techniques, and the availability of specialized equipment.

These objectives can only be achieved by a permanent and intensive popularization, where the ways and methods must be adapted to the sociological conditions of each specific terrain to meet the traditional practices which are already well anchored in rural areas. The control of medium-term planning with regard to the creation of large water reserves is necessary to allow for the treatment of the catchment area at least five to ten years before a dam is built. These activities must be integrated within the framework of a long-term national strategy to combat erosion and desertification (e.g. through national plans).

10.7.2 Plant Resources

Forest fires, the uncontrolled cultivation in the steppe, misguided agricultural practices, as well as

overgrazing and the anarchical introduction of exotic species provide a very pessimistic picture with regard to the future of plant resources, unless active measures of management, conservation, and development are undertaken. Accordingly, it is necessary to:

- continue the national inventory of flora to be aware of and control the existing potential;
- identify areas which are fragile and under threat to enable priority measures to be taken;
- continue with studies on the development of forests as well as their application in order to ensure their protection and to exploit their products in a rational way;
- intensify afforestation activities in particular within the framework of the National Afforestation Plan currently under development;
- continue the diversification of species by selecting and producing quality seedlings based on local vegetation, what includes modernizing the seed-bed network;
- consolidate the adequate protection of the forests;
- set up a seed bank, botanical gardens and stations for the conservation and multiplication of plants with a view to reintroducing them into their original ecosystems;
- organize the agro-pastoralists, particularly in the steppe, in order to limit degradation of the vegetation. The legal status of these lands appears to be an essential issue to be resolved in order to ensure appropriate organization in the future;
- intensify research and experimentation, especially on local species to increase their productive potential;
- engage specialists (particularly in education) to assume scientific and technical responsibility for the development and protection of vegetable resources (systematization of the genetic potential).

10.7.3 Animal Resources

Of utmost importance for domestic fauna is the conservation and selection of local breeds adapted to our ecosystem. For this purpose, it is necessary to create a record of national breeds in order to first recognize our potential, and subsequently to improve it. To do this it is necessary to establish priorities so that they may be dealt with by the existing specialized institutions which must be strengthened in terms of staff (specialists) and material.

- To take charge of matters of current concern, it is necessary to reinforce specialized structures, in

particular those dealing with artificial insemination, identification of the livestock, as well as the permanent control of performance and production. This approach must be supplemented by enhanced and comprehensive medical cover at all levels.

- For wild fauna, it is necessary to:
- intensify the reintroduction of rare or extinct animal species;
- update the list of species requiring protection following completion of the inventory in progress.
- create a reference of existing national fauna;
- reinforce protection legislation and to ensure its application on the ground;
- organize hunting associations and to engage them in the protection of wild fauna;
- implement training schemes directed towards specialization in the field of wild fauna.

10.8 Conclusion

In conclusion, we can say that considerable effort has been made by the authorities, but which unfortunately has not succeeded in reversing the trend towards degradation. Moreover, all the programmes initiated were very technocratic and did not take into account the situation on the ground which should logically integrate the populations set to benefit from these programmes. The voluntary objective to do good, not taking into account the various players in a specific area, combined with the exclusion of the populations living in the areas to be developed, resulted in projects which were certainly ambitious, but very scattered, producing results which failed to match the effort made.

Moreover, the programmes carried out were mostly of a curative nature, and were applied without thorough knowledge of the real situation, i.e. without a comprehensive assessment, quantified so that these projects could produce the desired results. These projects are also potentially hampered by an annual planning system which blocks programming due to the fact that important files are treated in the long term, for example those dealing with the fight against erosion or the protection of biological resources in general.

Given this situation, if the methods of approach remain the same, the trend will be towards continued degradation at a rate difficult to estimate, but certainly considerable. Therefore, the best means of combating desertification is to ensure the harmonious

development of the regions concerned, which is closely linked to the question of security. A situation of continued degradation of the country's natural resources will only cause famine, which in turn will generate social conflicts, and consequently insecurity.

11 Securitized Water

Úrsula Oswald Spring and Hans Günter Brauch

11.1 Introduction¹

There can be no life on earth without water. Water for life can be either ‘blue water’ for drinking or ‘green water’ for the production of food. Water shortages may be offset through trade with ‘virtual water’ (chap. 41 by Allan) while the lack of ‘blue water’ may be compensated by desalination of brackish and seawater or by water imports via pipelines (Gruen 2007; Rende 2007; Güreler/Ülger 2007).

‘Water scarcity’ of blue and green water, ‘water degradation’ due to the intrusion of waste water and industrial pollution and ‘water stress’ as a result of an increasing gap between water supply (decline in precipitation) and ‘water demand’ (caused by population change, industrialization, and increased personal consumption) are the result of complex interactions between natural and climatic factors (precipitation patterns) and human influences that can result in manifold hydro-meteorological hazards (storms, floods or drought). In human history water scarcity, degradation, and stress were major factors for the decay and disappearance of many high civilizations (e.g. in Egypt and of the Maya). They were key push factors for people movements as well as for forced migration away from drought and famine stricken areas. Access to and control of water have been persistent causes or triggers of communal, tribal, regional, national, and in very few cases international conflicts. But in many cases international water management has been an area of cooperation in international river basins. Water has been an object (poisoning of wells, water cut-off) as well as a tool of warfare (bombing of water reservoir dams).

Throughout human history water issues have been highly political (*politicized*) and in a few cases they have even been ‘*securitized*’, where they have become political issues of utmost importance that require ex-

traordinary policy responses to avoid warfare and further environmental destruction. In the Nile River Basin (chap. 48 by Adly/Ahmed; chap. 49 by Kameri-Mbote/Kindiki) any unilateral modification of the water flow among the ten riparians may seriously affect the livelihood of people in downstream countries, and thus could become a cause of political and even military conflict. To prevent this from happening, the *Nile Basin Initiative* (NBI) was set up, as one of many *International River Basin Management* (IRBM) regimes.

The goal of this chapter is a systematic conceptual review of the securitization of water in the context of the triple reconceptualization of security (Brauch 2008). In the following sections the evolution of the water security concept will be mapped (11.2), water will be discussed in the context of the *widening* (11.3), *deepening* (11.4), and *sectorialization* (11.5) of security. The concluding part suggests a dual scientific and policy-oriented complex analysis of water security (11.6) that combines bottom-up initiatives of water conservation with top-down strategies of water management, water laws, hydro-diplomacy, and conflict resolution.

11.2 Evolution of the Water Security Concept

The links between ‘water’ and ‘security’ issues are complex and directly linked with many other security concepts:

- Water is a major object of analysis in *environmental security* to maintain ecosystem services, and to protect the biological and hydrological cycles and the ecosphere.
- Water as a key problem of *social* and *societal security* permits livelihood, recreation, and joy of life. It requires policy initiatives to avoid hydrological disasters and illnesses through protection, preven-

1 The authors are grateful to three reviewers for their detailed, very helpful and critical comments.

Box 11.1: Ministerial Declaration of The Hague on Water Security in the 21st Century, 22 March 2000. **Source:** <http://www.worldwatercouncil.org/fileadmin/www/Library/Official_Declarations/The_Hague_Declaration.pdf>. This text is in the public domain.

1. Water is vital for the life and health of people and ecosystems and a basic requirement for the development of countries, but around the world women, men and children lack access to adequate and safe water to meet their most basic needs. Water resources and the related ecosystems that provide and sustain them, are under threat from pollution, unsustainable use, land-use changes, climate change and many other forces. The link between these threats and poverty is clear, for it is the poor who are hit first and hardest. This leads to one simple conclusion: business as usual is not

an option. There is, of course, a huge diversity of needs and situations around the globe, but together we have one common goal: *to provide water security in the 21st Century*. This means ensuring that freshwater, coastal and related ecosystems are protected and improved; that sustainable development and political stability are promoted, that every person has access to enough safe water at an affordable cost to lead a healthy and productive life and that the vulnerable are protected from the risks of water-related hazards...

tion, resilience-building, early warning, and evacuation to safe places in case of extreme weather events.

- Water as an issue of *economic security* creates development opportunities.
- Water is a precondition for *food security* that requires permanent, sufficient, accessible, safe, and nutritional food that is also culturally accepted.
- Water is essential for *health and livelihood security* to protect people from thirst, waterborne illnesses, vector diseases, but also from floods, drought, and plagues.

This chapter will address the following research questions:

- When and how has water been securitized by government representatives, and how has the concept of water security been used in the scientific literature?
- Which role has been given to water in the different 'dimensions' of security (political, military, economic, societal, environmental), for different levels of analysis, actors or reference objects (national, international, and human security) and in other sectoral security concepts (food, health, gender)?

The water security concept will be introduced first as a political concept (11.2.1), and its major use in scientific analyses (11.2.2) and by international organizations (11.2.3) will be reviewed.

11.2.1 Notion of Water Security as a Political Concept

The concept of 'water security' was introduced in the Ministerial Declarations of the *Second World Water*

Forum (WWF) in The Hague (2000, see box 11.1) and developed further at the third WWF in Kyoto (2003) and fourth WWF in Mexico City (2006).² The scientific application of the water security concept is offered in part VII below.

The Ministerial Declaration of The Hague (2000) pointed to these main challenges for achieving water security that refer to several other security concepts: a) *meeting basic needs* (societal security); b) *securing food supply* (food security); c) *protecting ecosystems* (environmental security); d) *sharing water resources* (political security); e) *managing risks* (environmental, human and gender security); f) *valuing water* (economic security); g) *governing water security* (political security).

In an analysis of this Ministerial Declaration, John Soussan and Rachel Harrison (2000) offered an issue-oriented definition of water security that

relates the management of water resources to the vulnerabilities and overall livelihoods of poor people and to the integrity of ecosystems. Included in it are both resource issues (scarcity of water, problems of water quality, the effects of storms, floods or droughts, etc) and human issues (conflicts over water allocation, limited knowledge or capital assets for efficient water management, etc). ... This includes the need to consider issues of enhancing sustainability and environmental integrity and reducing the vulnerabilities that so many people face. Equity is also a core concept, so that the needs of *all* users and value and potentials of *all* uses of water resources are recognized in decisions over their future.³

2 See "Water Security in the 21st Century", Ministerial Declaration, Second World Water Forum, The Hague, 22 March 2000, para.3, available at: <http://www.thewaterpage.com/hague_declaration.htm>; Ministerial Declaration, Third World Water Forum, Kyoto 23 March 2003, para.11, available at: <<http://www.mofa.go.jp/policy/environment/wwf/declaration.html>>.

This ‘water vision’ suggested many changes in water management, with three key objectives for 2025:

- Empowering women, men, and communities to decide on levels of access to safe water and hygienic living conditions, and on the types of water-using economic activities that they desire – and to organize to obtain them.
- Producing more food and creating more sustainable livelihoods per unit of water applied and ensuring access for all to the food required for healthy and productive lives.
- Managing water use to conserve the quantity and quality of freshwater and terrestrial ecosystems that provide services to humans and all living things.

From the pledges and commitments made by governments in The Hague six main themes emerged:

- Integrated water resources management and river basins.
- Water policies and laws.
- Institutional capacities and development.
- Participation, empowerment, and gender.
- International collaboration and assistance.
- Education, awareness, and training.

The 2nd WWF in 2000 also launched *The African Water Vision* that is “concerned with the equitable and sustainable use of Africa’s water resources for poverty alleviation, socio-economic development, and regional integration. It seeks to address the water paradox of the continent (floods and droughts, water scarcity and under-exploited water resources). The Vision also seeks to address the sustainable supply of water to meet the requirements of food and energy security and improved access to safe drinking water and adequate sanitation.”⁴

The ‘Mexico Ministerial Declaration on Water’ of 17 March 2006 emphasized the goal of achieving water security by stating that “to improve water security, African countries need to invest in water infrastructure up to the level where they can, in order to achieve a self-sustaining auto-induced growth to eradicate pov-

erty and achieve sustainable development.” The “Concept Note for the First African Water Week” (AWW) from 26 to 28 March 2008 outlined a strategy for “Accelerating Water Security for Socio-economic Development of Africa.” This note defined water security as:

the capacity to provide sufficient and sustainable quantity and quality of water for all types of water services (drinking, sanitation and health, food production, energy, industry, ecosystem protection) and protect society and the environment from water-related disasters.

The first *African Water Week* discussed the global and regional experience with water security and socio-economic development, reflecting on Africa’s positive and negative experience, and on the impact of climate change and variability on Africa’s water resources. Among the water security challenges it addressed the sanitation gap and the strategies for closing it, as well as on infrastructure for water security. Similar strategies have been developed in many Latin American and Asian countries.

Water security has also been defined by the *Global Water Partnership* (GWP 2000) as an overarching goal where: “... every person has access to enough safe water at affordable cost to lead a clean, healthy and productive life, while ensuring that the environment is protected and enhanced.” Since 2000, the water security concept has been used by water specialists in the natural and social sciences, by policy-makers and international organizations.

11.2.2 Water Security in International Scientific Analyses

The application of the security concept for water-related issues has gradually evolved in the literature where different definitions and approaches coexist. Naff (1993: 257–259, 273–274) used a state-centred security concept with regard to these water-related issues: agriculture (food security), demographic pressures (migration), resource scarcities (environmental degradation), health and economic issues, ideological and cultural differences that have potential security implications. He argued that in the Middle East “water exhibits all ... elements of conflict” due to its vital nature and complexity as a terrain security issue. Water is perceived as a zero-sum security issue that carries “a constant potential for conflict.”

From a bottom-up perspective, the Sri Lanka Rainwater Harvesting Forum (1999: 8ff.) defined *household water security* (HWS) based on research con-

3 “Commitments on Water Security in the 21st Century. An Analysis of Pledges and Statements made at the Ministerial Conference and World Water Forum, The Hague, March 2000”, at: <<http://www.unesco.org/water/wwap/targets/watersecurity.pdf>>

4 See the African Development Bank; at: <http://www.afdb.org/pls/portal/docs/PAGE/ADB_ADMIN_PG/DOCUMENTS/NEWS/CONCEPT%20NOTEENG.PDF>.

ducted in rural communities where water is a scarce resource and “not only a commodity but also a natural resource and a perceived human entitlement.” Ariyabandu (1999) and others have defined household water security as “accessibility, reliability and timely availability of adequate safe water to satisfy, basic human needs” for drinking, sanitation, bathing, and cooking.

In an analysis of water discourses, Allan (2001: 184, 2003) has used the water security concept in the context of both “economically and environmentally logical policy priorities” and “politically feasible policy priorities” for “achieving strategic water security” by securing the supplies of ‘virtual water’. He argued that “the idea of food insecurity is not part of the ‘sanctioned discourse’ in most Mid-East countries and therefore the relationship between water and food deficits cannot be debated.” He discussed the securitization approach and security complex theory for the MENA water, and for the security sub-complexes for the Levant and the Gulf sub-complex and especially for Israel for the 1950’s to the 1990’s (Allan 2001: 243–250). He stressed that in this region “water security and water adequacy however defined are political issues. Peoples and their leaders need to assure each other that they are secure. Water is an important dimension of communal and national security in arid and semi-arid countries” (Allan 2001: 332).

Falkenmark (2000: 11) defined water security:

as freedom from fear related to water supply and society’s dependence on water for a whole set of different functions... The topic *water and security* has arisen as a by-product of the growing interest in environment and security (Priscoli). This reflects arguing for a more ‘holistic’ conception of security that goes beyond protecting the state from external aggression to addressing environmental problems that threaten the health and well-being of individuals or economic security of countries. It could be that the developed countries are more likely to think of environment and security in terms of global environmental changes, and developing countries more with the human security implications of local and regional problems. Water is in fact forcing us to rethink the notions of security, dependency and interdependence. While increased interdependence is often viewed as increasing vulnerability and reducing security, there is an alternative way to look at interdependence. These notions can be seen as networks that increase our flexibility and capacity to respond to exigencies of nature and reduce our vulnerability to events such as droughts and floods and thereby increase security.

Falkenmark (2001) summarized the results on “how hydrosolidarity between upstreamers and down-

streamers may be approached in a realistic way.” Turton argued that

water scarcity has basically been addressed as a national security issue in view of the interest raised in CIA and similar national security-oriented circles for the case of water-scarce multinational river basins (‘securitization’ of the issue). He therefore stressed the need to ‘insecure’ the water management issue by replacing the international conflict focus by a cooperation focus and a focus on societal capability to cope within the constraints given by the natural resource situation (summarized by Falkenmark 2001: 9).

In contrast, the seminar discussed water rather from a human security perspective “in terms of safe household water” for human health (health security), food security linked to local production, and environmental security that “depends on [the] ability to minimize environmental threats in terms of i.a. ecosystem degradation”. This discussion was later taken up in the new approach to ecohydrology, where Falkenmark and Rockström (2005: 21–22) argued that three policy perspectives have to be included in their integrated approach: a) human security; b) environmental damage security; and c) human and environmental security (table 11.1). From these three security perspectives they asked: What has to be *secured*? What has to be *avoided*? What has to be *foreseen* or *anticipated* and met by risk reduction?

For balancing water for humankind and nature through a socio-ecohydrological approach Falkenmark and Rockström (2005: 217–218) distinguished three lines of action:

- *Securing* water security, food security, and ecological security, acknowledging water’s life-giving characteristics.
- *Avoiding* difficulties in terms of pollution and silting linked to water’s lift-up/carry away functions and its mobility, to be achieved by water pollution abatement and soil protection.
- *Foreseeing* unavoidable conflicts and difficulties linked to climatic variability (droughts, floods), and to water’s multiple functions and mobility reflected in non-negotiable natural processes in the landscape.

This approach refers to many different ways to achieve social acceptability and to avoid water conflicts within a wider notion of water governance. In a similar direction, David Grey and Claudia W. Sadoff (2007: 2) argue that achieving water security implies: “both harnessing the productive potential of water and limiting its destructive impacts.” They defined “‘water security’ to be the reliable availability of an ac-

Table 11.1: Fundamental policy directions and water security perspectives. **Source:** Falkenmark and Rockström (2005: 22). Permission was granted.

Human and environmental security	Foresee	Biosphere linkages	<ul style="list-style-type: none"> • Climate variability • Transport function • Rainwater partitioning 	<ul style="list-style-type: none"> • Recurrent floods/droughts • Upstream/downstream linkages • Green/blue flow linkages

ceptable quantity and quality of water for health, livelihoods, and production, coupled with an acceptable level of water-related risks.” In their analysis three factors influenced the “societal challenge of achieving and sustaining water security”: a) the hydrologic environment (the absolute level of water resource availability, its inter- and intra-annual variability and its spatial distribution); b) the socio-economic environment (the structure of the economy and the behaviour of its actors); and c) the impact of climate change on the future environment that “will play important roles in determining the institutions and the types and scales of infrastructure needed to achieve water security” (Grey/Sadoff 2007: 5). To achieve water security in the 21st century both authors argued that

this challenge must be met by building on the environmental and social lessons of the past. The once unforeseen consequences of environmental change and social displacement have been clearly identified and documented... Setting environmental and social standards so high that they greatly constrain, or even prevent, achieving water security is equally unacceptable. There are always some trade-offs which need to be identified and debated by governments and their citizens, and, to the extent possible, mitigated (Grey/Sadoff 2007: 20).

They concluded that

most poor, water-insecure countries face a far greater challenge than that faced by those who had achieved water security in the last century and are wealthy coun-

tries today. Today’s water-insecure countries face more difficult hydrologies, much larger populations with more varied water demands, and a greater understanding of, and therefore greater responsibility for, the social and environment trade-offs inherent in water management. In this increasingly inter-connected world, there is a growing realization of the imperative of protecting vulnerable people and livelihoods, and providing for basic human needs and broader human opportunities. In order to do this, achieving water security at the global, regional, national, and local levels is a challenge that must be recognized and can be met (Grey/Sadoff 2007: 25).

Ashton and Turton (chap. 50) use the related concept of a ‘hydro-political security complex’ that emerged from an extension of ‘national security’ concerns to include transboundary environmental issues. Schulz (1995) defined a ‘hydro-political security complex’ as a set of states that are geographically part owners and technical users of a water body, and that consider that water body to be a major national security issue (Mathis/Aguilar-Barajas 2003). In both definitions a wider understanding of security is included (Buzan/Wæver/de Wilde 1998).

Jansky, Nakayama, and Pachova (2008: 1) argued that ensuring water security – which they defined as: “adequate protection from water-related disasters and diseases and access to sufficient quantity and quality of water, at affordable cost, to meet the basic food, energy and other needs essential to leading a healthy

and productive life without compromising the sustainability of virtual ecosystems” – has become a key global goal during the past decade. From a narrow state-centred security perspective issues of sovereignty are crucial, while from a wider conceptualization many non-state actors have achieved more prominent roles in national and international water governance.

In her synthesis of the 2001 SIWI seminar, Falkenmark (2001: 13–14) noted many conceptual obstacles due to the “compartmentalized approach taken by most water professionals, representing typical differences in their *sectoral focus*. Second, there are a set of scientifically based *paradigm locks*, which originate from a deep-going sectarianism within science incompatible with water’s large complexity in both roles and functions” between the different approaches of the geosciences and the biosciences. She concluded that the effort to reach a

water-related human security, that encompasses both water security, food security and environmental security, will depend on a new generation of responsible and knowledgeable hydrocitizens, carried by ethical principles of sharing rather than by conventional principles of capturing the water resources in a catchment (Falkenmark 2001: 15).

11.2.3 Use of the Concept in International Organizations as an Issue of International Security

Many international organizations have extensively used the water security concept but often with different meanings. For the UNESCO Institute for Water Education (IHE) in Delft, “water security involves protection of vulnerable water systems, protection against water-related hazards such as floods and droughts, sustainable development of water resources and safeguarding access to water functions and services.” This research theme “is primarily concerned with human interventions in water systems. These are aimed at the enhancement of the beneficial and sustainable use of water for various purposes such as water supply, irrigation, drainage, navigation, hydro-power, environmental purposes and the protection against water-related risks such as floods and droughts.” These interventions are “to meet the needs of society in the widest sense and in order to be able to face the challenges of all kinds of global changes (e.g. climate change, land use change, etc.).”

Within the framework of the joint UNESCO-Green Cross International project entitled “From Potential Conflict to Cooperation Potential (PCCP):

Water for Peace,” Cosgrove (2003) offered a synthesis of the UNESCO’s work on water security and peace that focused on

practical projects in six international river basins: the Danube, the Jordan, the Okavango, the Plate, the Volga, and the Volta. These locally managed projects have worked to raise awareness and identify solutions to disputes and conflicts by facilitating dialogue between citizens, governments, local authorities, the private sector, and water experts from the different basin states. One major objective of the Water for Peace project has been to ensure that civil society is actively engaged in the process of developing agreements and solutions as to how to share water, and the benefits of water, in the basins in which they live.

Many other international organizations (UN, FAO, WHO, UNEP, UNDP, UNU, etc.) have extensively used the water security concept – in most cases without a definition. In many cases the goal of achieving water security for the water insecure countries has been linked to the UN *Millennium Development Goals* (MDGs) that were adopted at the Millennium Summit in September 2000, thus committing their countries to a new global partnership to reduce extreme poverty with a series of time-bound targets. Its Goal 7: *Ensure Environmental Sustainability* includes target 10 that requests to “halve, by 2015, the proportion of people without sustainable access to safe drinking water and basic sanitation” that should be measured with two indicators: a) Proportion of population with sustainable access to an improved water source, urban and rural (UNICEF-WHO); b) Proportion of population with access to improved sanitation, urban and rural (UNICEF-WHO).

But in the *Report of the World Summit on Sustainable Development* (2002) and in the Secretary-General’s *Report On Larger Freedom* and in the *World Summit Outcome Document* (2005) there has been no single reference to the ‘water security’ concept. The above review of the water security concept in scientific discourses and policy declarations has shown that the different notions of security require a discussion of the widening, deepening, and sectorialization of the security concept since the global turn (1989).

11.3 Widening: Dimensions of Water Security

In the aftermath of the Cold War the security concept has been widened by many governments – at least in Europe – in their defence white papers and policy dec-

larations, from the narrow political dimensions to include economic, societal, and environmental issues that directly impact on security dangers and concerns. This ongoing transformation has been conceptually mapped by Buzan, Wæver, and de Wilde (1998).

Above (chap. 1 by Brauch; Brauch 2008, 2008a) five dimensions of a widened security concept were distinguished: environmental (11.3.1), societal (11.3.2), economic (11.3.3), political (11.3.4), and military security (11.3.5) that offer a context or different conceptualizations of water security. These dimensions will be reviewed by focusing more on the related substantial than solely on conceptual and definitional issues.

11.3.1 Water as an Issue of Environmental Security

Three basic factors affect the environmental security of water: first, the reduction of water supply due to climate change and the modification of soils and productive activities that diminish the green water flow and affect biodiversity. Second, the process of water degradation and pollution due to human and productive activities, and the missing infrastructure for waste water treatment, sanitation, and recycling. Third, the effects of more numerous and intense hydro-meteorological hazards (storms, floods, landslides, drought, and forest fires) that affect biodiversity, human beings, their infrastructure and thus create pollution.

United Nations sources estimated that 'blue water' run-off through the ecosystem and recharge of groundwater account for about 35 million km³. The annually available water in form of environmental service amounts to about 40,000 km³, of which roughly 10 per cent were diverted for human uses in 1995, thereof 70 per cent were used in agriculture, 20 per cent in industry, and 10 per cent for domestic proposals (Cosgrove/Rijsberman 2000). Their data do not include the green water flow, used in the small farmer rain-fed agriculture and the return flow from irrigation.

'Green water', coming from precipitation (25 millions km³) is stored in soils and evaporates from it. It is the main source for ecosystems and is essential for 60 per cent of food production worldwide, especially for poor peasants who depend on it for their rain-fed fields. The remaining 40 per cent are used for fish production and aquaculture in fresh waters. Shiklomanov (1993, 2005) and Shiklomanov and Rodda (2003) also analysed the distribution of green water in aquifers, glaciers and permafrost, in everglades, lakes, rivers as well as for biological and atmospheric water.

Shiklomanov (2005; table 11.2) estimated that of the global freshwater resources less than one third are located in aquifers, two thirds in glaciers, atmospheric humidity, everglades, rivers, and in biological water. With climate change more water will get into the system through melting glaciers that produce first floods and later droughts, above all in the Himalayan and Andean regions. Thus any change will directly affect environmental and human security.

11.3.1.1 Water Security: Use and Distribution

Water security is directly linked to human activities and well-being. Of the total world population of 6.6 billion, 1.2 billion people have no access to water; 2.2 billion experience water scarcity, and 3 billion lack improved drainage and treatment which pollutes fresh water and groundwater due to faecal material and industrial waste dumped without treatment.

Water scarcity and pollution are related to the global water distribution, which is unequal in space and time (see figure 11.1). More than half of the world population lives in regions experiencing water stress that is often aggravated by economic stress. Water scarcity may induce either to save water or to waste this precious liquid. Thus, the *Global Water Partnership* (GWP) argued:

On the one hand, the fundamental fear of food shortages encourages ever greater use of water resources for agriculture. On the other, there is a need to divert water from irrigated food production to other users and to protect the resource and the ecosystem. Many believe this conflict is one of the most critical problems to be tackled in the early 21st century (GWP 2000: 58).

In geographical terms water access differs regionally. North and Central America receive about 15 per cent of global water resources for 8 per cent of the world population. South America obtains 26 per cent of global water for 6 per cent of the world population. Europe receives 8 per cent for 13 per cent of the world population, while Australia and Oceania account for 5 per cent of global water for a population share of less than 1 per cent. Africa receives 11 per cent of water for 13 per cent of the global population; but the greatest scarcity exists in Asia where 36 per cent of global water is available for 60 per cent of the world population (UNESCO/IHP 2005). Middle Eastern countries, especially Palestine, Jordan, Saudi Arabia, and Israel are far below this average.

Regarding global demographic growth, the per capita availability of water will decline from 6,600 m³ to 4,800 m³ in 2025, affecting especially those countries with high population growth rates in Africa,

Total	35,029.2	100	–	–

Asia, and Latin America. During the past century population increased three times and water demand six times, due to changes in human behaviour and production. During the past two decades global water consumption alone has doubled. The future demand for direct consumption will increase by 2025, reaching between 4,300 to 5,200 km³. This average does not reflect the unequal distribution among social classes, or the differences of access within families and local communities.

11.3.1.2 Water Security in Consumption Patterns

Water use can be divided into consumptive (urban, domestic, agriculture, livestock, services, industry, and environment) and non-consumptive use (hydro-energy, aquaculture, recreation, navigation, transportation; Oswald 2005: 26). The per capita water consumption depends not only on the physical availability, but also on the existing infrastructure and cultural habits. Figure 11.2 shows that major differences of daily water consumption exist between industrialized and developing countries, but also between different regions. Undoubtedly Africa is the continent with the lowest domestic consumption, followed by Asia and Latin America. These countries suffer from a weak water infrastructure and sanitation problems, mostly due to economic stress. The projection shows that these differences will continue at least until 2025. This

refers not only to difficulties to obtain the daily required amount of water, but also to threats for health and livelihood security.

During the next two decades global water consumption will undergo significant changes (figure 11.3), above all due to an increase in water demand in developing countries as a result of population growth and additional demand for agriculture and domestic purposes. In the industrialized countries water consumption is estimated to remain stable.

The seasons also affect water access. Most people in southern countries with low socio-economic capacities depend on rain-fed agriculture for their subsistence, and in these regions climate change will threaten their livelihood and survival. Climate change is closely related to desertification, which is affecting large semi-arid and arid regions, mostly in poor countries. More than 250 million people are directly threatened by desertification, and 24 million tons of arable land disappears each year.

Regions hit by desertification lose also their biodiversity and therefore menace food supply of wider regions. “The current extinction rate is up to one thousand times higher than the fossil one. The projected extinction rate is more than ten times higher than the current rate” (MA 2005). Different scenarios exposed by projected impacts of climate change depend on the capability of humanity as a whole to reduce green-

house gases” (Oswald 2007: 4). Vörösmarty, Green, Salisbury and Lammers (2000) projected that precipitation will decline in Pakistan, in Northern China, in Mexico, the Middle East, and in Sub-Saharan Africa where severe droughts are highly likely, while rainfall is projected to rise in the North and South (IPCC

2007, 2007a). Different scenarios, referring to climate change, desertification, and population growth have projected that water scarcity is most likely to increase significantly in arid and semi-arid regions, and this will affect developing and poor countries and megacities most severely.

Water as an issue of environmental security has been conceptualized for different referent objects, e.g. with regard to human beings and humankind (human security), the state (as ‘national water security’) and the international realm (as ‘international water security’, e.g. Pachova/Nakayama/Jansky 2008; see 11.4).

11.3.2 Water as an Issue of Societal Security

Water as an issue of societal or communal security focuses on all three policy directions (Falkenmark/Rockström 2005: 22) to *secure* (household and industrial water supply and crop production), to *avoid* (water pollution, degradation, and silting) and to *foresee* (climate variability and change, hydro-meteorological hazards, upstream/downstream linkages, and green/blue flow linkages).

Water scarcity, degradation, and stress directly affect the society and its representatives, from the family to the local community, the village, town or city, regional, national and international non-governmental organizations and social movements. Water as a ‘basic human need’ has also been discussed as a ‘basic human right’. Water is a prerequisite for human life that is essential for the production of food and for human health and well-being. As hydropower, water has been an essential renewable energy source, displacing millions of people, primarily indigenous and peasants from their land. But too little and too much water often results in hydro-meteorological hazards that kill and affect people and damage and destroy their belongings and public and private goods.

Given the projected water scarcity and the decline in per capita water supply, soil and groundwater represents a potential source to satisfy the water needs of a growing population and of their productive needs for fresh water and agriculture. In some regions (figure 11.1) water stress will rise with declining supply and growing demand. In the past, due to rainfall and returns from irrigation, water was considered a renewable resource, but the higher demand has resulted in many regions in water stress and depletion of aquifers. The relationship between society and water has been further aggravated by climatic and bio-chemical factors that have limited water supply. The quality of this scarce resource has deteriorated especially due to inadequate management. Finally, there is an invisible relationship between society and the economy with nature, where the excess of productive capacity, the concentration of people in mega-cities, and the unsustainable use of aquifers is rapidly depleting water.

The overuse of water is often increased by an unsustainable hydrological demand, and the lack of investment in treatment and recycling infrastructure has been threatening water security, thereby creating irreversible environmental damages. Water as an issue of societal security is also closely linked with the economic dimension of human, national, and international security.

11.3.3 Water as an Issue of Economic Security

Water as an issue of economic security refers to both an essential public good and to a commodity of the free market. Economic stress (poverty, lacking finan-

cial resources) reinforces the physical and environmental stress due to water scarcity, pollution, and hazards. This dual water stress is being further aggravated by social stratification, lacking access to money and political incapacity to deal with inequity. It also relates to cultural factors and social representations where women are normally responsible for caring for families and thus suffer most from water scarcity, pollution, and diseases. In most cases, they have no opportunity to participate in water policy decisions and to propose investments to improve the access to water and its quality, and to avoid potential threats due to disasters and environmental destruction. The physical and economic stress undercuts human and civil rights and therefore the management of economic security has to take into account the distinction between the value of water for survival in form of the *logic of value* and for the market in form of the *logic of change*.

11.3.3.1 Values of Water

The theory of value in general and of the value of water relies on three philosophical assumptions: 1. The Platonic theory argues that the value is absolutely independent of things, and therefore it can only be situated in the spheres of metaphysics and mythology. 2. The nominal approach relates value to subjectivity, to the aggregated or disaggregated processes, and can thus not constitute an ultimate value. In extreme cases this position denies the link between value and the deposit of value by a person who understands it as a medium and not as a final goal. 3. Finally, there is an appreciation, related to the previous understanding of nominalism, where a moral value is only given through its appreciation (Terricabras 1994: 3637). Scheler in his pure axiology disagreed with these three theories and established six criteria for his own theory of values.

1. The *process of validation* implies a difference between the validating being and the entity that is being validated.
2. *Objectivity*: The values do not depend on individual preferences and are fundamental for all acts.
3. *Lack of independence*: While values are not independent, they are not subjugated to external

instances, but represent an ontological independence expressed as an attribute of being.

4. *Polarity*: The present values are always opposites and the negative value is considered as being without value.
5. *Quality* is independent of quantity and its quality is pure.
6. *Hierarchy*: the values are not indifferent, not only with regard to their polarity, but the total value establishes a hierarchical order from agreeable to disagreeable (Oswald 2005: 131).

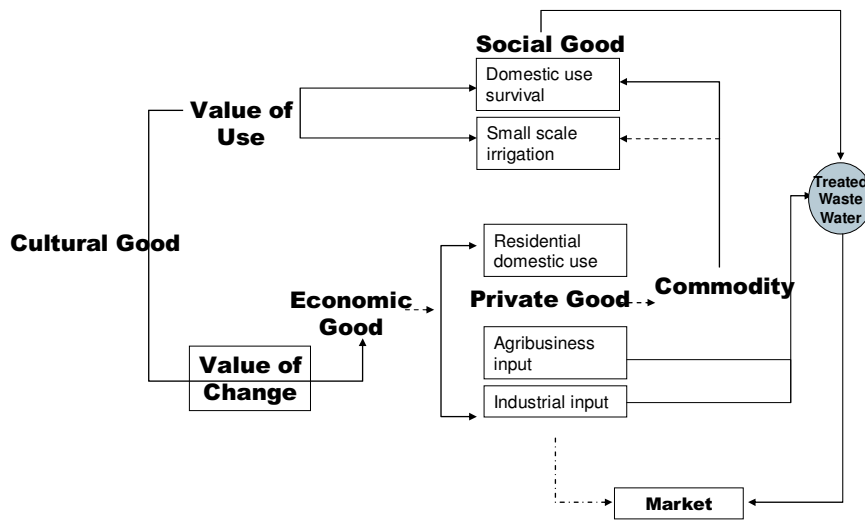

These philosophical approaches to the theory of values indicate that any consideration of value is a social construction related to the occidental philosophical tradition of opposites, centred in human beings and not in abstract economic entities. Thus, a socially responsible approach should distinguish between 'value of use' and 'value of change' of water (figure 11.4). With this distinction water is treated as a cultural good with collective property rights and the state as the administrator and arbiter.

The 'value of use' grants a basic human right for everybody to get clean and sufficient water for survival and well-being (ontological independence). This *human right to water* (HRTW) includes a domestic minimal water requirement, depending on each country that differs between 50 and 250 litres/day. This includes in rural areas the water needed for small-scale irrigation to produce the subsistence for a family (hierarchy). Nevertheless, the free market system is threatening this basic human right for livelihood for poor people, imposing on governments their logic of 'value of change'.

Within the logic of 'value of change', economic goods are produced within the market economy with profits and the costs of the use, administration, and treatment of water must be paid. Supply and demand are basically regulated by market forces, and water is used for the production of commodities and luxury lifestyle. Both logics are apparently opposed and generate a contradiction. Nevertheless, the linkage between both values could permit a stable water administration, consisting of cross-social subsidies to protect the highest vulnerable regions and social groups (figure 11.5).

The 'value of change' should also cover the costs for sewage water treatment and the market of treated water for agriculture and industrial processes. Within this system the process of privatization of water services, in ethical terms and based on the theory of social and ontological values, should only be permitted in the sphere of 'value of change', while the 'value of

Figure 11.4: Logic of the Values of Water. **Source:** Ramos (2004), modified by Oswald Spring (2005: 147).

use' must be granted by any government to vulnerable citizens as the fulfilment of their basic human and civil rights. However, in poor countries an important number of people lack the money for the service of safe water and sanitation, and therefore depend on unsafe water access. To overcome this injustice and to offer any person clean water and safe environment, transparent systems of administration and socially agreed tariffs are required (OECD 1999a).

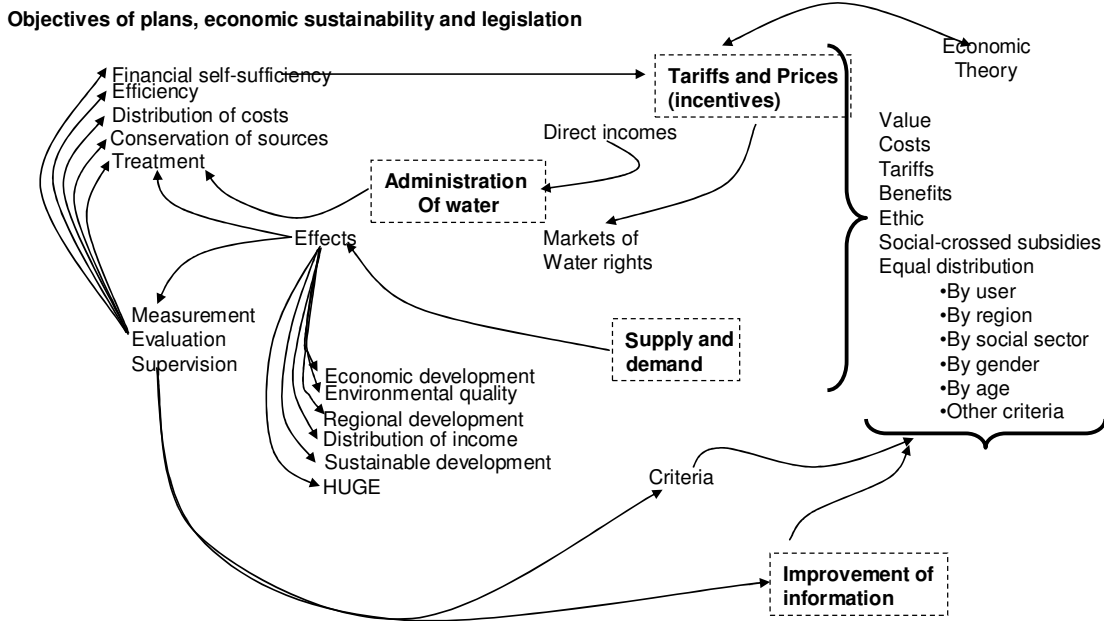

11.3.3.2 Administration of Water Security and Tariffs

An efficient administration of water includes a complex societal arrangement far beyond the traditional market mechanisms of supply and demand. Undoubtedly, tariffs and prices of water should enhance the conservation of the resource and the economic sustainability of the water system. Whenever the subsidies are greater than the income, then budget transfers must be introduced to maintain the stability of the administration. The complexity of the variables requires an efficient system of information, a transparent policy on subsidies depending on water stress, the social conditions of consumers, and regional development policies to avoid economic stress. To prevent corruption within the system, citizen audits and agreed social policies should establish an equilibrium between the income from tariffs and basic water rights. This should prevent that the private use of water for profit will destroy the fragile equilibrium of the hydro-balance within a region, including e.g. aquifer overexploitation and insufficient recharge. The inter-

vening variables explain why the theory of value is not an exclusive economic issue, but much more a social and moral one, especially in countries where water stress is physical and economic, and where scarce resources must be optimized to fulfil the basic human rights including the most vulnerable.

Oswald (1999) discussed a law of tariff in the state of Morelos in Mexico based on three key criteria: social, environmental, and regional. The *regional* variable refers to the real cost of the service, including the extraction from the aquifer, the purification of drinking water, wastewater treatment and recycling, water administration, and infrastructure maintenance. The investment for new infrastructure came from the state budget. The *environmental* criteria encouraged saving techniques within households, in agriculture, industry, and services. For a minimal consumption quota a minimal price applied, while with increasing consumption the price increased progressively. The economic opportunities persuaded people to introduce water-saving procedures in consumption patterns and the recycling of grey water. With regard to domestic use, 85 per cent of the consumption applied to treatment costs. When the consumers installed dry toilets (Vietnamese Latrines) or recycled waste water they did not have to pay for its treatment. Finally, the *social* criteria permitted that poor neighbourhoods and villages benefited from cross-subsidies from residential areas, industries and services, but only for a minimal consumption. Industries that obtained profits from water use (bubble water) were obliged to pay an additional tax. This law was socially accepted and

Figure 11.5: Sustainable Economy of Water. **Source:** Sandoval 2000, modified by Oswald Spring (2005: 153).

audited by citizens, because local people know the economic situation of neighbours much better, and corruption was thus limited.

In terms of Scheler’s theory of value, water is an object that cannot be validated by market forces and that has an intrinsic value as a survival good. Therefore, the value does not depend on individual preferences or market forces, but is fundamental for everybody. Scarcity and other external instances should be mitigated to not affect this ontological value. Any pressure put on the ‘logic of use’ is able to destroy the survival of vulnerable people. Thus, market pressure is understood in precarious life conditions as a negative value, and for this reason it is without value. In ethical terms, the market should never be allowed to destroy the life of a person or a community; human beings come before profits. Further, the quality of water for consumption must be pure and only one drop of polluted water or a limited number of pathogens are able to destroy health and life quality. Finally, the sum of the announced criteria, hierarchically ordered, permits vulnerable social groups a quality of life. On the contrary, if these values are not respected they result in illness and misery. For the nation state and international organizations (e.g. WTO and GATS) this signifies the respect for and the enforcement of basic civil and human rights, based on national constitutions that are supposed to grant everybody a livelihood and human security.

The combination of this case study with the philosophical reflections offers an instrument for overcoming the economic stress and generating ideas to fulfil for everybody its basic human right to safe water and improved health. To achieve this goal, investments in the range of 35 and 100 billions US\$/year are required globally, in addition to the 75 billion US\$ that were spent in 2005. Robert Lenton (2005) estimated that investing about 100 US\$/year/person for the next 25 years would guarantee every person in the world water security with safe water and sanitation.

Thus, poor countries could achieve the MDG for water by 2015. The costs for infrastructure in poor countries decline due to the rural-urban migration into megacities and technological advances. The costs for services in densely populated areas are cheaper, compared with the investments in remote and dispersed rural regions, and treatment facilities are getting cheaper with the use of micro-organisms.

11.3.4 Water as an Issue of Political and Military Security

Water as an issue of political and military security refers to the level of national and international politics both within and between nation states, but increasingly also with non-state actors on competing goals for ensuring access to water for their own survival. In very few cases water was used as a tool of war in efforts to kill people by poisoning water or attacking

water reservoir dams to cause artificial flooding. Water scarcity and degradation has triggered domestic and international conflict, but hardly resulted in all-out ‘water wars’ where armed forces were involved. (II.3.4.1). In many cases water scarcity or pollution has resulted in cooperation among the affected states (II.3.4.2).

On the political and technical level a new paradigm of an *Integrated Water and Resources Management* (IWRM) was launched (II.3.4.3) that has not yet been fully implemented in many regions and countries due to a lacking horizontal cooperation between ministries and stakeholders, and among different ministries and stakeholders. An integral IWRM approach requires a multidisciplinary, multi-stakeholder, multi-institutional, and multilevel decision-making processes that includes payment for environmental services and financial support at the basin level. The establishment of water regimes in transboundary river basins (II.3.4.3) has been used to foster cooperation among states that has resulted in very few cases even in an ‘environmental peacemaking’ with a spillover to other issue areas (Conca/Dabelko 2002).

11.3.4.1 Water as an Object of Conflicts and as a Cause of Disputes

Throughout history, water has been used as a tool of conflict, e.g. by poisoning of the wells or water supplies of the opponent, by diverting rivers (e.g. in 539 BC by Cyrus II who diverted the Euphrates during the siege of Babylon) or by attacking dams (during WW II and during the Korean War) to cause artificial flooding or by attacking water infrastructure and bridges (during wars in Yugoslavia, 1999 and Iraq, 2003). The protection of water in conflict (chap. 58 by Tignino), but also the prevention of water as a tool of conflict, has become an object of humanitarian law, of human rights conventions, and also of international environmental agreements.

Within the first policy dimension (to *secure* the water supply), the control over scarce water resources has been an issue of political security and of diplomatic negotiations among neighbouring states in international river basins that resulted in many international water treaties (Wolf 1998, 1999; Bogardi/Castelein 2002) and water regimes (chap. 51 by Kipping; chap. 52 by Borghese; chap. 53 by Lindemann). Many conflicts in international river basins had a hydro-political component, but water considerations were seldom the sole cause of conflict. Especially in water-scarce countries, domestic water disputes between rural zones and urban centres, between and

within communities, towns and villages, and between neighbours have been on the domestic political agenda for millennia. In periods of severe water scarcity and drought, e.g. in the Sahel zone, many violent clashes have occurred between herders and resident farmers that have so far not been recorded in the existing war and conflict databases.

In the scientific debate there has been a dispute between those who claimed that there have been no ‘water wars’ (Wolf 1998) and others who have documented many violent ‘water conflicts’ between (Gleick 1993, 1998, 1998a, 2008) and within countries (Shiva 2003; Oswald 2005). These debates are based on different definitions of wars and conflicts that have guided the data collection. Aaron Wolf and his team’s argumentation is based on the *Transboundary Freshwater Dispute Database* that provides

a framework for quantitative, global-scale explorations of the relationship between freshwater resources and international cooperation and conflict. Projects were designed to test common theories linking freshwater resources to cooperation and conflict, in particular within the context of geography and environmental security. The projects, which follow in sequence, consider three main hypotheses on the likelihood and intensity of water resource disputes. To test these hypotheses, a unique set of tools was created that links water-specific event data with a geographic information system (GIS) that meshes biophysical, political, and socio-economic data sets at the river basin and other scales. There are three linked data sets: (1) an event data set documenting historical water relations, including a methodology for identifying and classifying events by their intensity of cooperation/conflict; (2) a GIS data set of countries and international basins, both current and historical; and (3) a spatial data set of biophysical, socio-economic, and political variables, linked to the GIS.

Peter H. Gleick (1993, 1998, 2008) in his *Water Conflict Chronology* listed close to 200 water conflicts between 3000 BC and the end of 2007. He argued that “water resources have rarely, if ever, been the sole source of violent conflict or war.” He documented “a long and highly informative history of conflicts and tensions over water resources, the use of water systems as weapons during war, and the targeting of water systems during conflicts caused by other factors.” In his view:

Conflicts may stem from the drive to possess or control another nation’s water resources, thus making water systems and resources a *political or military goal*. Inequitable distribution and use of water resources, sometimes arising from a water development, may lead to *development disputes*, heighten the importance of water as a

strategic goal, or may lead to a degradation of another's source of water. Conflicts may also arise when water systems are used as instruments of war, either as *targets* or *tools*.

In his update of February 2008, Gleick distinguished among six categories or types of conflict: a) *Control of Water Resources* (state and non-state actors), where water supplies or access to water is at the root of tensions; b) *Military Tool* (state actors; 56 cases), where water resources, or water systems themselves, are used by a nation or state as a weapon during a military action; c) *Political Tool* (state and non-state actors; 16 cases), where water resources, or water systems themselves, are used by a nation, state, or non-state actor for a political goal; d) *Terrorism* (non-state actors: 68 cases), where water resources, or water systems, are either targets or tools of violence or coercion by non-state actors; e) *Military Target* (state actors; 43 cases), where water resource systems are targets of military actions by nations or states; and f) *Development Disputes* (state and non-state actors; 3 cases), where water resources or water systems are a major source of contention and dispute in the context of economic and social development.

Following Libiszewski (1999) and focusing primarily on the first policy direction (table 11.1), Lindemann and Kipping (2005: 13-14) distinguished among four types of international water conflicts: *absolute* (in the Nile and Jordan river basins) or *relative allocation conflicts* (between upstream and downstream countries, e.g. in Central Asia), *disputes over water pollution* (Rhine or Rio Bravo/ Grande) and *development conflicts* (e.g. on cooperation to prevent and reduce flooding). Wolf, Stahl, and Macomber (2005) have argued that the conflicts over the allocation of water quantities and on water infrastructure projects are most prone for escalation. But there is a lack of systematic and statistical evidence, as environmental factors including water scarcity, degradation, and stress were not coded as causes of wars.

The *Uppsala Conflict Data Program* (UCDP) has collected information on armed violence since 1946, including ongoing violent conflicts. More recently the scope of data collection was broadened to include other cases of organized violence. However, this database neither lists environmental causes of conflict nor does it even refer to water as a source of conflict. The database of the *Heidelberg Institute for International Conflict Research* (HIIK) in its annual Conflict Barometer on: "Crises - Wars - Coups d'État - Negotiations - Mediations - Peace Settlements" did not list 'water' among its nine causes of conflict (territory, se-

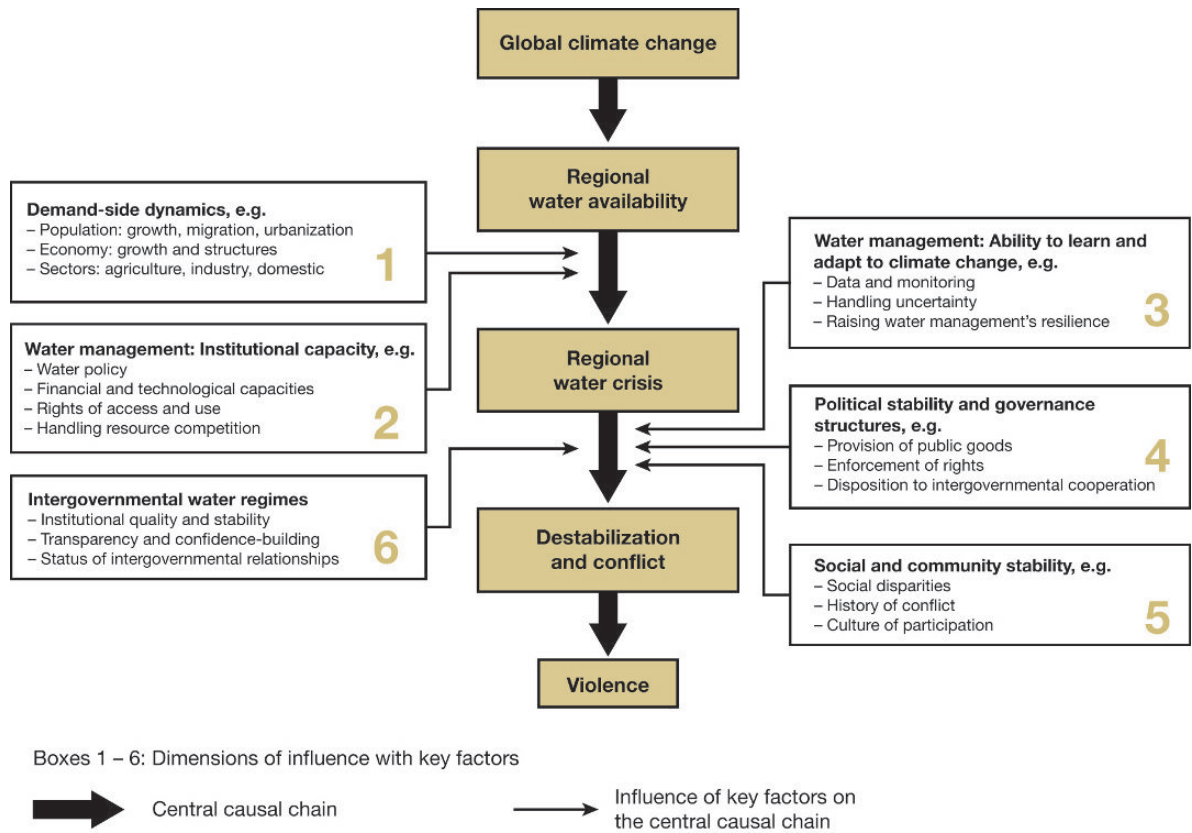

cession, decolonization, autonomy, system/ideology, national power, regional predominance, international power, resources, others). But in two cases for the Middle East it listed water as a cause of a latent conflict between Israel and Jordan (1945), and for Israel and Lebanon (2001). HIIK stated that "a positional difference over definable values of national meaning is considered to be a latent conflict if demands are articulated by one of the parties and perceived by the other as such."

While the two conflict databases (UCDP, HIIK) ignored water as a cause or trigger of violent conflict since 1945 (or 1989), the databases of the *Transboundary Freshwater Dispute Database* by Wolf and the *Water Conflict Chronology* by Gleick point to the two contrary outcomes of the many water disputes in human history, of water cooperation as a means of conflict resolution or of the application of force by using water as a military tool or target. However, based on the available literature and statistical data no conclusive answer on the claims (Gleick) or denials (Wolf) of the existence of water wars, conflicts or disputes between states or non-state actors is possible.

Comparative studies on water scarce regions show structural similarities and differences on water cooperation through agreements (e.g. between Israel, Jordan and Palestine, or between the USA and Mexico). In most Third World countries demographic pressure, global environmental and climate change, competition between different water uses (agriculture and domestic vs. industrial and services), pollution and often a militarily, socially, and technically powerful upstream partner or unstable border conditions, could create increasing water stress and therefore potential disputes and violent conflicts between non-state and even state actors (Salman/Upreddy 2002; Pachova/Nakayama/Jansky 2008).

Whether the water-related conflict potentials result in domestic violence or even in international armed confrontation depends on the policy decisions of the governments in the water stressed regions, and on the success or failures or basin-wide water management schemes, cooperative regimes, and institutions. Among the four conflict constellations of the WBGU (2008) two are directly water-related, focusing on a) climate-induced degradation of freshwater resources due to the differentiated impacts on precipitation patterns (figure 11.6); and b) climate-induced increase in hydro-meteorological hazards (figure 11.7). But the other two are closely related with too little or too much water resulting, c) in a decline in food produc-

Figure 11.6: Conflict constellation 'climate-induced degradation of freshwater resources: key factors and interactions.
Source: WBGU (2008: 83)

tion, and d) forcing or inducing the affected people to migrate (GTZ/BMZ 2008: 64–67).

Figure 11.6 illustrates for 'the climate-induced degradation of freshwater resources' the influence of six factors: 1) demand-side dynamics, 2) water management; institutional capacity, 3) water management ability to learn and adapt to climate change, 4) the political stability and governance structures, 5) the social and community stability, and 6) the contribution of intergovernmental water regimes on the outcome of the central causal chain whether it leads to destabilization and violent conflict or to cooperation.

Figure 11.7 shows for the conflict constellation of a 'climate-induced increase in storm and flood disasters' the influence of four factors: 1) the hazard impact, 2) social vulnerability, 3) the social stability, and 4) the political stability and governance structure that determine whether the central causal chain escalates into violence or whether emergency relief contributes to a de-escalation.

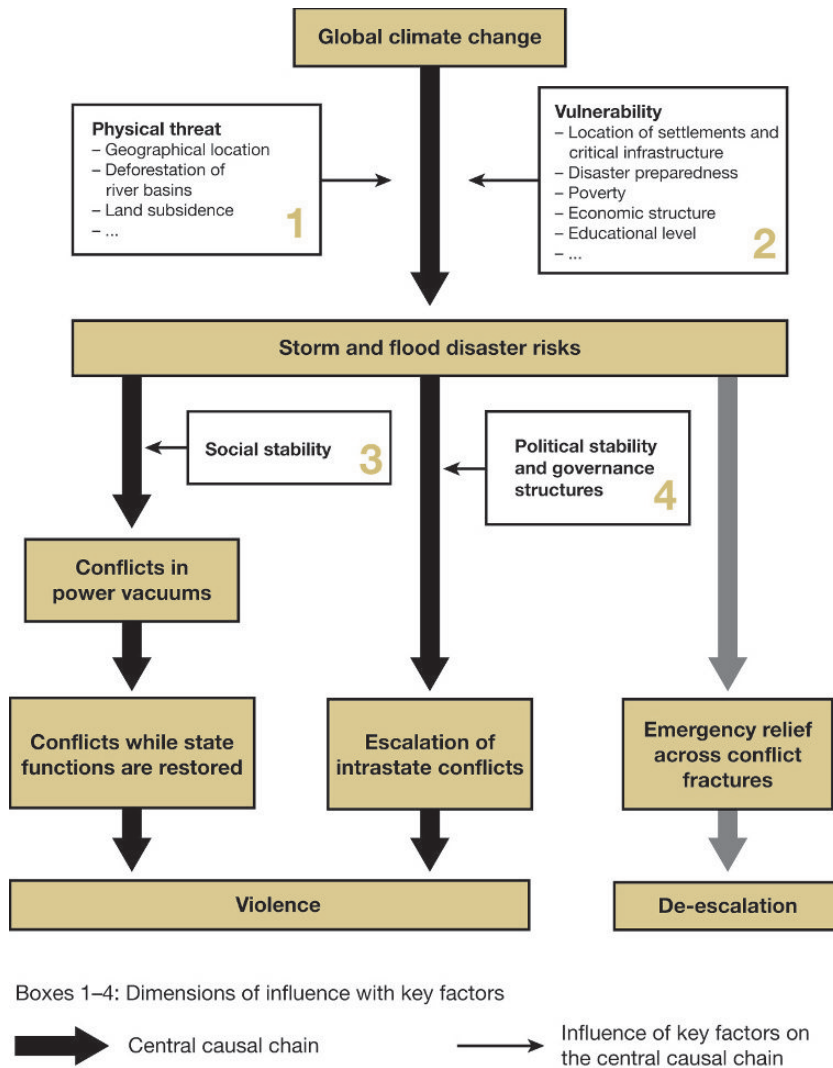

Conflicts are not always negative; they have been motors of changing the world. They are present in each human and social relationship. But a negative

outcome in form of violence should be avoided through negotiation, conflict management, and peaceful conflict resolution. There are several ways to resolve conflicts: socially, politically, and technically. Frequently, conflicts are postponed, transformed, manipulated, and their resolution is administered in little doses; but it is also possible to resolve them by aiming at the roots through an effort towards hydro-diplomacy (Oswald 2007).

Gleick (1993; 2001) has linked violent outcomes of water disputes to a shortage of resources often due to *absolute* or *relative* allocation problems. The *Cornucopians* (Lomborg 2002) have proposed technical solutions, political agreements, and cheap methods for desalination of sea water to resolve problems of water shortage. A third group, the *Neo-Malthusians*, have linked the increasing resource scarcity and violence to population growth (Meadows/Meadow/Randers/Behrens 1972; World Bank 2004; FAO 2005).

These approaches were criticized by some political scientists (Selby 2003; Kipping/Lindemann 2005). They were less optimistic and emphasized that the dis-

Figure 11.7: Conflict constellation ‘climate-induced increase in storm and flood disasters: key factors and interactions.
Source: WBGU (2008: 109).

tribution of water must include the specific interests of stakeholders and the environmental deterioration of international basins due to growing contamination. These problems cannot be resolved in the traditional framework of sovereign states, and therefore specific policies and negotiations are required, where neighbouring nations can find collective advantages to achieve an amicable agreement based on consensus (Oswald 2007).

In an overview of environment and conflict linkages, Schwartz (2002) combined socio-economic factors with environmental stress and violent outcomes. Bohle (2002) linked human security with globalization, while the Swiss group (Bächler/Böge/Klötzli/Libiszewski/Spillmann 1996, Bächler/Spillmann 1996a, 1996b; Bächler/Spillmann/Suliman 2002) re-

lated human activities to natural factors, economic agents, and suggested to increase resilience through networks of proactive empowerment that try to reduce risks and hazard impacts. Furthermore, anthropological studies and gender specific research have shown a higher social vulnerability of women, children, and elders in terms of persons who died or were seriously affected during extreme events, but also higher personal and economic costs to obtain this vital liquid (Oswald 2008).

11.3.4.2 Water Stress as a Cause for International Cooperation

Water scarcity, degradation, and stress require that neighbouring social groups and governments must ne-

gotiate economically sustainable water management agreements on this scarce resource. Both the technical water management efforts and political concerns about human, gender and environmental security in a framework of sustainable development could be reinforced by scientific and technological training to optimize existing financial and physical resources (Dombrowsky 2003). In addition, a participative bottom-up approach involving all stakeholders could promote a new water culture (Oswald 1999). A resolution of water conflicts through negotiations of water disputes may lead to a consensus among antagonistic groups, economic concerns, and could thus constrain wider geopolitical and military interests.

Conca's (2002: 1–22) concept of 'environmental peacemaking' was empirically discussed for several water-related case studies, and in *Governing Water* Conca (2006: back cover) examined political struggles to set up a global framework for water governance. He argued that "threats to the world's rivers, watersheds, and critical freshwater ecosystems have resisted the establishment of effective global agreements through intergovernmental bargaining ... because the conditions for successful interstate cooperation ... cannot be imposed upon water controversies." He further stated that "while interstate water diplomacy has faltered, less formalized institutions - socially and politically embedded rules, roles, and practices - have emerged to help shape water governance locally and globally." Thus, inter- and transnational epistemic communities of water experts and professionals and water regimes have developed.

These activities create an opportunity for technical solutions (desalinization of brackish and sea water), for the construction of infrastructure, such as sewage plants and recycling facilities of treated water, and could thus also increase the availability and quality of water for complex and fragile ecosystems and offer fast growing populations future development opportunities. A hydro-diplomatic approach combines geopolitical factors with social organization, technological alternatives, and training at the local, regional, national, and international basin level, where goodwill improves the possibility to reach a win-win situation for all people involved.

11.3.4.3 Integrated Water and Resources Management (IWRM)

Water management integrates human activities on the use and conservation of water. The concept of *Integrated Water and Resources Management* (IWRM) has been introduced as a new paradigm that has been

defined by the *Global Water Partnership* (GWP) as "a process which promotes the coordinated development and management of water, land and related resources in order to maximize the resultant economic and social welfare in an equitable manner without compromising the sustainability of vital ecosystems" (Technical Advisory Committee 2000). The IWRM "encourages the development of integrated basin-wide water use and management strategies, action plans and institutions" (Jansky/Nakayama/Pachova 2008: 1).

The IWRM concept explicitly challenges conventional water development and management systems. It starts with the recognition that traditional top-down, supply-led, technically based and sectoral approaches to water management are imposing unsustainably high economic, social and ecological costs on human societies and on the natural environment. Business as usual is neither environmentally sustainable, nor is it sustainable in financial and social terms. As a process of change which seeks to shift water development and management systems from their currently unsustainable forms, IWRM has no fixed beginnings and will probably never end. The global economy and society are dynamic and the natural environment is also subject to change, IWRM systems will, therefore, need to be responsive to change and be capable of adapting to new economic, social and environmental conditions and to changing human values.

IWRM pursues three key strategic goals: a) to enhance efficiency of water resources; b) to achieve equity in the allocation of water across different social and economic groups; and c) to aim at environmental sustainability, to protect the water resources base and associated ecosystems. In the IWRM toolbox this new paradigm was introduced as going beyond the business as usual approaches what implies "a process of change; a process which can start from small beginnings", that aims at a gradual and incremental change that is inspired by the 'Dublin Principles' (1992, see box 11.2).

The IWRM concept refers to multiple causations. With regard to the problem of *increased threats from flooding* it points to at least 9 key causes: a) climate change, more extreme events; b) increased occupancy of flood plains; c) inadequate maintenance of existing flood defences; d) dam siltation; e) deforestation and upstream rural land use change; f) urbanization of catchments; g) improved land drainage or flood defences upstream; h) ineffective land zoning or building regulations; and i) lack of incentives for local/community vulnerability reduction measures. The IWRM concept also refers to three types of governance failure, which are inherent in most countries:

Box 11.2: Principles for Effective Water Governance. **Source:** GWP IWRM Toolbox; at: <http://www.gwpforum.org/gwp/Media/Toolbox/main_features.pdf>. Text is in the public domain.

- *Open and Transparent:* Institutions should work in an open and transparent manner.
- *Inclusive and Communicative:* Improved participation - depending on all levels of government - is likely to create more confidence in the end result and in the institutions that deliver policies.
- Policies and action must be

Coherent and Integrative:

- *Equitable and Ethical:* All men and women should have opportunities to improve or maintain their well-being. Equity between and among the various interest groups, stakeholders, and consumer-voters needs to be carefully monitored throughout the process of policy development and implementation.

In terms of *Performance and Operation*, good governance requires that processes and operations are:

- *Accountable:* Roles in the legislative and executive processes need to be clear. Each institution must explain and take responsibility for what it does.
- *Efficient:* providing economic efficiency, and also concepts of political, social, and environmental efficiency.
- *Responsive and Sustainable:* Policies must deliver what is needed on the basis of demand, clear objectives, an evaluation of future impact and, where available, past experience.

- *Market failure* (e.g. incomplete/non-existent property rights, uncorrected environmental and social externalities, incomplete information, information asymmetries, monopoly);
- *Institutional system failure* (e.g. lack of worker commitment, no public respect/compliance culture, incomplete regulatory systems, failure to regulate monopolies, no legitimacy for regulators or service providers);
- *Government failure* (e.g. water agencies acting to further internal, not public interests, capture vested interests, capacity constraints, bureaucracy, lack of accountability).

The toolbox offers specific instruments for dealing with each of these three failures. The toolbox stated that for the suitability of particular tools, four factors must be taken into account: political, professional, implementation, and compliance capacity. The tools must also take the enabling environment into account.

The Plan of Implementation adopted at the WSSD in Johannesburg in 2002 called on all countries to develop IWRM and water efficiency plans by 2005. The *Global Water Partnership* (GWP) stressed in a Paper on “Guidance in preparing a national IWRM plan: advancing the WSSD plan of implementation” (GWP 2004) that the IWRM approach implies recognition that truly sustainable water resources management involves managing demand, not just supply.

The IWRM concept integrates water, environmental, and food security issues with poverty alleviation. Focusing on irrigation efficiency, IWMI (1998) concluded that an additional 17 per cent of investment would be needed in the period 1995–2025. More nor-

mative scenarios for the World Water Vision (Gallop/Rijsberman 2000; Cosgrove/Rijsberman 2000) stated that additional changes in lifestyle and diet are required, including improved rain-fed management, what will increase crop yield by 6 per cent.

The technological vision of these measures for achieving water security, represented by the *World Water Vision* (WWV), the IWRM concept and FAO activities, were criticized by social movements. They argued that this focus continues the policy that led to the exhaustion of aquifers, to the pollution of surface water and of coastal areas and sea water. Several social movements claimed that these approaches never questioned the root causes of poverty, often related to the deprivation of water rights in traditional societies, and that they often hinder small-scale bottom-up projects and technologies and support the interests of agribusiness. Land and water rights were traditionally owned by local people while modern water laws have promoted privatization processes and water concessions abolishing these rights. Finally, they argue that these analyses lack methodological criteria for evaluating the policy outcomes. In theoretical terms they abolish the ‘value of use’ and impose a ‘value of change’. This logic may deprive poor people of their human right to water (Young 2005).

11.3.4.4 Management Schemes and International River Basin Regimes

On the international level, much attention of the international donor community has focused on integrated political, economic, social, and technical management schemes at the level of international river basins that would not only increase economic and so-

cietal security and sovereignty of poor countries and of vulnerable social groups, but also contribute to improving health. To achieve these goals, two different concepts were developed referring to the *Integrated River Basin Management* (IRBM) or, as in Agenda 21, to the *Integrated Water Basin Management* (IWBM) that attempt:

to treat the river and its tributaries together with the land and underground water as a unit. It recognizes the need to manage the river basin as an entity, and implies the importance of land use, as well as the value of ponds, lakes and wetlands within the basin. The National River Authority's *Catchment Management Plans* (CMPs), the subsequent EA *Local Environment Agency Plans* (LEAPs) and the plans generated under *Local Agenda 21* (LA21) are examples of a way of thinking sometimes referred to as 'catchment consciousness'. This idea links society and economics to the more familiar technical aspects of water management. However, CMPs were river focused, LEAPs are of variable quality and LA21 plans are also of variable quality and incomplete.

Since the 1990's, many studies were published, from different scientific disciplines (from the perspective of geography, economics, law, political science and international relations) as well as by NGOs (ENDS/Gomukh 2005), national ministries (Sweden, Ministry of Foreign Affairs 2000) and international organizations (UNEP 2002; OECD 2003; UNESCO 2003, 2006) that have been guided by the policy goal to resolve water allocation conflicts on the basin level by setting up joint institutions for the transnational information exchange, cooperation, and management of water resources in multinational river basins (Clarke/King 2004).

A key issue is the interrelationship between water and human and gender security issues, as water directly affects human security. Further, most water-related issues from hygiene, cooking, and caring for ill people is traditionally in the hands of women, and thus affects gender security what represents a key element in the conceptualization of security.

11.4 Deepening: Referents of Water Security

The referent object of the water security concept and for achieving water security is no longer solely the state, but with the deepening of the security concept, the conceptual and analytical focus has widened to the individual human being and to humankind (*human security*) including a specific gender focus (*gen-*

der security), to the society (*societal or communal security*) and beyond the nation state to regional and global international organizations and non-state societal and business actors.

11.4.1 Human Security Approach on Water Issues

According to Gutiérrez (1999), water security goes beyond the availability of water and includes the individual right of access to water as well as the national sovereignty over water. Nicol (2005: 4) claimed that water security, from the household to the global level, implies "that every person has *access* to enough safe water at affordable cost to lead a clean, healthy and productive life, while ensuring that the natural environment is protected and enhanced" (GWP Framework of Action document). Wouters (2005: 168) defined water security as "the state of having secure access to water; the assured freedom from poverty of, or want for, water for life." From a human security perspective, Falkenmark and Rockström (table 11.1) argued that water is a necessity and life support that directly affects the preparedness dimensions of human health, employment, income generation, and food supply. The discourse on water security has been influenced by Annan's (2005) three pillars of human security:

- Water security is based on three core freedoms: freedom from want, freedom from fear, and freedom to live in human dignity.
- Ensuring water security may lead to a conflict of interests, which must be capable of being identified and effectively dealt with at the international, national, and local levels.
- Water security, like water, is a dynamic concept, and one that needs clear local champions and sustained stewardship (Wouters 2005: 169).

11.4.2 Gender Security Approach on Water Issues

In developing countries, small-scale food production is owned by women, indigenous and poor peasants, and normally depends on traditional technology, what often results in low crop yield averages. Traditional agriculture with its integral management of natural resources, water conservation, polycultivation, and mixed agriculture has maintained for centuries the fertility and humidity of soils, and therefore represents a typical case of sustainable management, including

environmental services. In most developing countries, poor women have been key food producers and about half of the world food production is cultivated in orchards mostly by women (FAO/SDWW 1999; FAO/IFAD/WFP 2005; FAO 2006). Women are also crucial actors in water management for drinking water and food preparation, and they are also the main persons responsible for food production and market activities. Food storage and food security depends primarily on the ability of women to conserve their surplus production.

But at the international, national and local level, planning, development, and management of water is controlled mostly by men. Therefore, the gender perspective must be globally integrated, and women must be involved in water policy decisions. UNIFEM has supported the enhancement of the economic security of women by engendering their access to water, the recollection of data, enhancing market access for selling subsistence production, and empowering women especially in vulnerable situations such as extreme weather events and in armed conflicts (Bennett/Davila-Poblete/Nieves Rico 2005).

11.4.3 Water Security as an Issue of National Security

While the concept of 'water security' often refers to the impact of too little (scarcity, degradation, stress) and too much water (hazards), in the context of the US led War on Terror, 'water security' has become an important issue of US national security to ensure water protection and safety against deliberate and large-scale poisoning by terrorists.

The US *Environmental Protection Agency* (EPA) established a "Water Security" Division that pursues a somewhat different policy agenda:

Improving the security of our nation's drinking water and wastewater infrastructures has become a top priority since the events of 9/11. Significant actions are underway to assess and reduce vulnerabilities to potential terrorist attacks; to plan for and practice response to emergencies and incidents; and to develop new security technologies to detect and monitor contaminants and prevent security breaches.

Water security has also become a key concern of the US Departments for Homeland Security and Defence as well as for the US intelligence community. But the Report of the National Intelligence Council's 2020 Project, *Mapping the Global Future*, did not specifically address water security threats for US national

security, as they have plenty of water resources in the northern part of the country.

Besides the specific case of the narrow conceptualization of water security and its link with US national defence and homeland or internal security, in many other countries achieving and maintaining water security has become a major national prerogative that requires the utmost efforts, especially in democratic societies, to satisfy the basic human needs of citizens for drinking water and food ('value of use'). For some countries, especially in the Middle East, the goal of achieving water and food security has been solved with imports of 'virtual water' in terms of cereals and meat products. Satisfying food needs at affordable prizes for all societal groups has become a political object to avoid bread or food riots, and thus to maintain domestic stability and internal security.

11.4.4 International Security

As was discussed above (11.2.3) the concept of water security has been extensively used by international organizations in the framework of international development and security concerns and strategies. A major goal in many studies and policy declarations has been to avoid a militarization of disputes over water scarcity, degradation, and stress. Major tools for achieving international water security have been discussed in the context of geopolitical approaches to 'hydropolitics' (Ohlsson 1995) or in the framework of bi- and multi-lateral hydro-diplomacy (Oswald 2006). There is also a concern among upstream and downstream users, above all when the downstream countries are politically weaker (Río Bravo dispute between USA and Mexico), but also when the livelihood of a powerful downstream user depends on a river basin (Egypt). International strategies and measures, such as IRBM or IWBM, diplomatic agreements and treaties as well as conflict resolution initiatives (hydro-diplomacy), are among the most efficient international activities to avoid water wars and to mitigate tensions among involved nations.

11.5 Sectoral Applications of Water Security

Water security has been introduced as one of several sectoral security concepts, such as food (11.5.1) and health (11.5.2) security. Below selected linkages between water security and these other two sectoral concepts will be discussed.

11.5.1 Water as a Food Security Issue: Virtual Water

While developing countries often use more than 90 per cent of their water resources for primary activities (agriculture, mining), many industrialized nations have reduced their water consumption for agriculture and industrial production. The high input of water into food production processes is called 'virtual water' (Allan 1998, see chap 41) and it allows water rich countries to produce water-intensive crops for export, and those with scarce water resources can import these products (table 11.3).

Table 11.3: 'Virtual Water': Average requirement of water in productive activities. **Source:** FAO (2000a).

Product	Unit	Equivalence of water in m ³
Cow	head	4,000
Sheep, goats	head	500
Fresh meat	kg	15
Meat from labour	kg	10
Fresh chickens	kg	6
Cereals	kg	1.5
Rice	kg	1,900
Citric fruits	kg	1
Palm oil	kg	2
Roots and tubercles	kg	1
Steel	ton	190,000

Virtual water permits regions experiencing water stress to import food products from areas with better water conditions, and therefore use their scarce resources for domestic and industrial purposes instead for agriculture. Wheat and other cereals, as basic food crops, are traded globally. Many water scarce countries in Asia, Latin America, and in the Middle East have been importing cereals for several decades, and thus substantially reduced their water demand.

This is a logical answer for rapidly growing populations with a rising water demand for domestic purposes and industry. But due to climate change the water demand for irrigated agriculture will increase (figures 11.8 and 11.9) in arid and semi-arid regions. With present irrigation patterns, water demand may increase less than with potential irrigation schemes that are responding to a better quality of life and industrial countries, due to their present high level of irri-

changes in the diet e.g. in China and India, what will raise water and food needs in both countries.

Favourable climate conditions allow developed countries to concentrate their production in rain-fed areas while poor countries are highly dependent on irrigation (figure 11.10). This dependency will increase with a decline in precipitation and will require technological improvements in water management to obtain higher yield averages by drop. But it will create also an increasing dependency on basic food imports for the highly populated nations in the tropical areas.

Water resources are not unlimited and the projections for future precipitation levels indicate a reduction in the reliability of rainfalls and of the amount of water available for irrigated areas worldwide. Due to higher temperature evapotranspiration will rise and crop yields in many countries have been projected to decline, both factors leading to an increase in water needs (table 11.4). Many regions in Africa suffer already from a low reliability of their water supply for irrigation. Similarly, in Asia and Latin America the reliability of precipitation levels will decline drastically during the next two decades, and only some developed countries in moderate climate zones will most likely improve their situation. This implies that water security is globally threatened due to high population growth and greater food and water demand in regions where the supply of water and the reliability of irrigation will drop. Thus, climate change will also create, through the increasing water stress, problems for food security of many developing countries. These new environmental challenges posed by climate change will oblige planners and producers to seek a better understanding of the links between production methods, crops, yield averages, and the local food culture.

Table 11.4 documents the results of three scenarios with regard to crop yields in rain-fed and irrigated agriculture. The *business as usual* (BAU) scenario shows for rain-fed cultivations the worst results, while *higher rainfall area* (LINV-HRF) will offer for poor and industrialized countries the best results. These scenarios do not reflect governmental recommendations, which are related to higher investments and water saving technologies. For the irrigated areas the BAU scenario shows the best results while the other two methods are almost the same and therefore new irrigation techniques are required to feed the growing population. Nevertheless, the reliability index for irrigation water supply is declining in all developing countries (table 11.5) and rises only in industrialized countries. Severely affected are Asian and Latin American countries and often overexploitation of aquifers.

Figure 11.8: Total water consumption for irrigation with projections to 2025. **Source:** Rosegrant/Cai/Cline (2002: 5, figure 4). Reproduced with permission from the International Food Policy Research Institute <www.ifpri.org> and the International Water Management Institute <www.iwmi.cgiar.org>. The report from which this figure comes can be found online at: <http://www.ifpri.org/pubs/fpr/fprwater2025.pdf>.

When comparing the amount of virtual water for different production schemes, there is no doubt that, with population growth, climate change, and desertification, the global food supply cannot shift to occidental meat patterns. On the contrary, also in industrialized countries a shift will be needed to a diet that is based more on cereals. This diet not only requires less water (except for rice where seeds with a lower water demand are developed), but this will also lead to a healthier diet for people, create less obesity,

and reduce diabetes, and cardiovascular and degenerative diseases.

In synthesis, the global trend to achieve food and water security refers to a complex linkage among several factors, including the ‘virtual water’ trade (Hoekstra/Hung 2002; Allan 2003 and chap. 41). To consolidate a sustainable water policy that can achieve both food sovereignty (chap. 33 by Oswald) and a healthy nutrition, several processes must simultaneously be developed together with different consumption patterns:

REGION	Rainfed yield (metric tons/hectare)			Irrigated yield (metric tons/hectare)		
	BAU	LINV-HRF	LINV-HIER	BAU	LINV-HRF	LINV-HIER
Asia	2.46	2.96	2.49	4.50	4.05	4.13
Latin America	2.92	3.13	3.08	5.46	4.85	4.92
Sub-Saharan Africa	1.19	1.22	1.30	3.08	2.95	2.99
West Asia/North Africa	1.75	1.93	1.89	4.86	4.55	4.61
Developed countries	3.89	4.24	3.95	5.97	5.54	5.59
Developing countries	2.08	2.36	2.18	4.53	4.09	4.16
World	2.77	3.07	2.86	4.80	4.37	4.43

SOURCE: Authors' estimates and IMPACT-WATER projections, June 2002.

NOTE: BAU stands for business as usual, LINV-HRF stands for lower irrigation investment and higher rainfall area and yield, and LINV-HIER stands for lower irrigation investment and higher effective rainfall use.

- Assess all crops with their different water needs and establish a regional balance of water requirements (Oki 2002).
- Prioritize basic food crops for all social groups, protecting the most vulnerable, and analysing soil, seed, and production methods to increase the productivity per drop of water through a democratic and participative process, taking the needs of vulnerable groups into account.
- Develop regional water balances between the supply of green and blue water, including evapotranspiration and run-off with regard to short, medium, and longer-term time horizons, including climate change scenarios.

Table 11.5: Irrigation water supply reliability index by regions, 1995 and 2025. **Source:** Rosegrant/Cai/Cline (2002: 5, figure 4). IRRIGATION WATER SUPPLY RELIABILITY INDEX		
REGION	1995	2025
Asia	0.81	0.76
Latin America	0.83	0.75
Sub-Saharan Africa	0.73	0.72
West Asia/North Africa	0.78	0.74
Developed countries	0.87	0.90
Developing countries	0.81	0.75
World	0.82	0.78

- Transform productive systems for strategic crops in any water-scarce country through modernization of irrigation systems (micro-tunnel, drop irrigation system, micro-aspersion, greenhouse techniques, capture of dew, recycling of treated waste water, desalinization of sea and brackish water, etc.), and substitution of water-intensive crops with those that need less water.
- Return to a diet based on cereals and reduce meat consumption and water-intensive crops in dry and semi-arid areas with high population growth.
- Monitor the atmospheric conditions, including the impact of climate change, aquifer behaviour, water table decline, physical-chemical conditions of water for irrigation, water demands in agriculture, society and industry, including water-saving processes, recycling of treated waste water.
- Establish water laws for each country and for regions with clear priorities for domestic, industrial, and agricultural water uses, and without omitting ecosystem requirements.
- Develop water tariffs that take social, regional, environmental, productive, and saving techniques and costs for maintenance of hydrological infrastructure into account.
- Compute the virtual water content and flows, eventual substitution of export crops, and regional consolidation of food crops that can also reduce the emission of greenhouse gases caused by trade.
- Invest in water infrastructure to reduce evapotranspiration, loss of flow, infiltration techniques, and increase the recharge of aquifers (blue water flow), and of lakes and rivers (green water flow). Renewable energy desalinization of sea and brackish water can increase the supply of domestic, industrial, and irrigation uses.
- Use different water qualities for different purposes and productive processes, thus caring about safe water for human consumption.
- Aquaculture or inland small-scale fish production permits the horizontal integration of productive cycles, where the waste of the primary production (pig, chicken, and cow sheet is used for feeding fish) and the bones of fish contribute to fertilization of crops. The horizontal integration of productive processes improves food intake in poor rural areas and boosts through adequate nutrition the health of marginal people.
- The vertical integration of small-scale businesses (dried fish; transformed crops; agro-industrial transformation of cereals, vegetables and fruits; orchards; backyard livestock production) at the regional level stimulate regional markets, increase local incomes, and improve the nutrition of marginal people.
- A new ‘culture of water’ must be developed, where consumption patterns are changed and saving practices introduced in all phases of water management – extraction, production, service, re-use and recycling.

11.5.2 Water as an Issue of Health Security

Every year more than three million people die from waterborne diseases and vector-related illnesses. Of these about 2 million are children less than five years old. The links between water and health security are related to three factors: First, an insufficient amount of water destroys a sustainable and healthy livelihood. Second, the water supply in any community should be free from waterborne micro-organisms by offering people safe drinking water and an environment with-

out vector-related diseases (malaria, dengue, and schistosomiasis). Third, waste water must be treated and recycled in the production process, while sludge could be composted and used for soil improvement.

Many health problems are directly linked to the lack of access to safe water, especially in developing countries. Water scarcity and lacking treatment facilities increase the pollution of clean water. Waste water and contaminated food products combined with chronic undernourishment due to water shortage in agriculture creates serious health problems and reduces life expectancy. Furthermore, desertification processes and the destruction of ecosystems due to modernization projects such as hydroelectric dams, tourist development, urbanization, and the dry-out of marshes and everglades contribute to a perverse cycle of illness, illiteracy, undernourishment, poverty and greater disaster impacts. Water scarcity is therefore a complex process which has a cultural impact. Poverty is not only related to scarce resources, but also to economic stress due to a lack of investments for the creation of infrastructure.

11.6 Conclusions: Towards a Comprehensive Analysis of Water Security

With the adoption of the “Ministerial Declaration of The Hague on Water Security in the 21st Century” at the second World Water Forum in 2000 ‘water security’ has been introduced as a new political concept that has since been developed further by the Global Water Partnership, the following World Water Fora, and widely used in political declarations by governments and international organizations, and in scientific analyses and discourses on environmental, water, and security issues, but in most cases without a specific definition.

After the *politicization* of water at the Dublin Conference (1992) and at the Rio Earth Summit (1992), since the year 2000 the *securitization* of water has upgraded water issues to a policy problem of utmost importance that requires extraordinary measures in facing and coping with the manifold related development and security-related problems posed by global environmental change, especially by climate change and desertification.

Water security can only be achieved by multilevel and horizontal societal, national, and international coordination and cooperation, with an enhancement of the life-creating and sustaining role of water and

simultaneously through a better control and management of its destructive impacts through hydro-meteorological hazards.

This requires that water as a basic human need and as a human right for everybody must be available to all human beings in sufficient quantity, in safe quality, and at an affordable price. Thus, water should not be privatized, commodified, and controlled by a few multinational corporations whose primary interest is to achieve the highest possible profits to satisfy their shareholders. Rather, water as a global commons should be treated as a major public good (‘value of use’), where knowledge creators (scientific community) and distributors (education, media) as well as societal, economic, and state actors should be guided by an ‘ethic of responsibility’ (Jonas 1984).

11.6.1 Scientific Tasks for Achieving Water Security

Water security issues require a complex analysis that combines in the scientific realm the knowledge of several scientific disciplines of the natural (hydrology, chemistry, biology, medicine, agriculture, etc.), engineering (water engineering, construction), and social sciences (economics, political, legal and, administrative science) as well as the humanities (philosophy, religion, literature, ethics) in order to search for multidisciplinary solutions that go beyond the narrow engineering approach that has focused only on the construction of technical tools, while often ignoring the political and cultural processes as well as values and human behaviour.

This multidisciplinary approach that involves a pluralism of methods (from empirical data collection to modelling and scenario development) must be complemented in the policy realm with a ‘horizontal coordination’ (Scharpf 1994; Oswald 2005) of different ministries responsible for aspects of water-related policy problems (environment, economics, agriculture, fishing and aquaculture, food, health, hazards, justice, city planning, rural development and foreign relations, etc.).

While the results of both supplementary multidisciplinary scientific approaches that aim at the ‘concilience’ (E.O. Wilson 1998) of different disciplines, and of the horizontal coordination among different ministries and agencies on the national level and among international organizations, agencies, and programmes on the regional and global level, may always be suboptimal, this holistic approach to water security issues

Figure 11.11: Sustainable consumption of water in rural and urban areas. **Source:** Rosegrant/Cai/Cline (2002: 5, figure 4). Reproduced with permission from the International Food Policy Research Institute <www.ifpri.org> and the International Water Management Institute <www.iwmi.cgiar.org>. The report from which this figure comes can be found online at: <http://www.ifpri.org/pubs/fpr/fprwater2025.pdf>.

may nevertheless create synergies and cost savings, compared with business as usual approaches.

Achieving water security through “the reliable availability of an acceptable quantity and quality of water for health, livelihoods and production, coupled with an acceptable level of water-related risks” (Grey/Sadoff 2007) requires

the need to consider issues of enhancing sustainability and environmental integrity and reducing the vulnerabilities that so many people face. Equity is also a core concept, so that the needs of *all* users and value and potentials of *all* uses of water resources are recognized in decisions over their future” (Soussan/Harrison 2000).

Scientists from their respective disciplines should create basic and applied scientific knowledge, concepts, and technologies for demand management through water-saving, conservation, recycling as well as supply side management, including political strategies for dealing with water scarcity (drought) and abundance (during storms and floods) in international river basins. The key policy goal should be to enhance environmental and water cooperation through ‘environmental peacemaking’ (Conca/Dabelko 2002) and ‘hydro-diplomacy’ (Oswald 2007) to peacefully resolve unavoidable water disputes, thus preventing an escalation of these water conflicts into water wars.

11.6.2 Policy Tasks for Achieving Water Security

Achieving ‘water security’ at home and maintaining a ‘water peace’ with neighbouring states in shared river basins can be achieved by combining *top-down* policies related to water management, water laws, resolution of the many domestic water conflicts at home, use of hydro-diplomacy for resolving intra-state water conflicts, with *bottom-up* societal initiatives aiming at water conservation, water harvesting, and improved sanitation at the household, community, and village or city level.

By taking urban and rural water security into account in a framework of sustainable water management and consumption, developing countries can better cope with the coming scarcity. Therefore, a complex water culture should be developed that involves affected people. As part of a long-term perspective top-down governmental policies and locally adapted bottom-up practices should be combined. Different scenarios necessitate that developing countries promote a sustainable water management to deal with both population growth and declining water availability due to climate change (figure 11.11) without ignoring water needs for ecosystem management and future generations.

In technological terms a key formula of a hydrological balance assumes that the amount of water entering the soil equals the amount of water leaving the

soil plus the water used for plants and stored in the ground. This water balance considers four key components: infiltration of precipitation into the soil and used by plants; evapotranspiration, deeper infiltration for recharge of aquifers and run-off from surface water into rivers, lakes, and seas.

To improve regional water security for all social groups and above all for vulnerable people, international and national plans must be developed in cooperation with local authorities and organized citizens. First, a precise diagnosis of existing water resources and of regional and temporary changes is needed, while scientists develop long-term scenarios of probable impacts of climate change. Second, scientists analyse the use and the loss of water and propose technologies for improving water efficiency. Third, governments must develop a long-term plan for investments to overcome the economic stress, to build the lacking infrastructure, and to maintain the existing water supply system in good conditions. Fourth, particular care must be used for irrigation technologies, for recovering watersheds, and for the protection of aquifers. This could imply changes in crop patterns and a substitution of water-intensive products with those requiring less water. Fifth, water is a public good and there should be a clear distinction between the logic of 'value of use' and the 'value of change'. All people, including the most vulnerable and poor, have a right to get sufficient access to clean water for their personal needs and enough food for a healthy life. Sixth, preventive efforts must avoid and reduce human losses during hydro-meteorological events. This includes the restoration and protection of mangroves, coral reefs, forests, and river basins in a framework of IWRM activities. Seventh, education and training from the kindergarten to the university should create a culture of water with the goals of saving water, avoiding pollution, and promoting the reuse of treated water in different processes.

In synthesis, the reflections on value, on ethics, and on scenarios have shown that water cannot be promoted as a commodity, and that it cannot be left to the whims of the free market. Water should not be commodified, privatized, traded or exported for profits. Water must be exempted from financial speculation as a good or as a service (GATS) or as an investment, in all bilateral and multilateral agreements. It is a basic human right that belongs to all human beings. To understand water security, *Vía Campesina*, a social peasant movement that is active in many developing countries, insisted:

Water belongs to the earth and to all species for all time. It is an inalienable human right and a public common good to be protected by all peoples, communities and nations, and the bodies that represent the local, state and international political authorities.

12 Changing Population Size and Distribution as a Security Concern

Wolfgang Lutz

12.1 Introduction

Population concerns are at the very heart of most security concerns ranging from more traditional military and political to economic, environmental, social, and human security considerations. The changing size and structure of the population matters for almost any conceivable definition of security because security always has to do with people, the wellbeing of individuals, of states, and the rivalry among sub-populations of the human species on this planet. On top of the ubiquitous importance of changes in population size and structure for security, all three forces of demographic change – fertility, mortality, and migration – are in their own right critical factors in various concepts of security: in the context of human security, survival (i.e. avoiding mortality) can be viewed as the ultimate criterion for the presence or absence of security; in the context of societal security, international migration constitutes a major challenge for social cohesion and national/cultural identity; finally, in a national security context, the possible disappearance of a state through the ‘dying out’ of its national population as a long term consequence of very low fertility rates may be viewed as a more serious threat to the integrity of the state than any possible outside aggressor.

Given the complex importance of population and demographic change for very different aspects of security, this chapter will not attempt to discuss the importance of population dynamics and its specific driving forces for any specific definition of security. Instead, it will present a synthesis of what we do and do not know about likely future trends in the determinants of population change, and the impact this has on our view about future trends in population size, structure, and human capital in general. We then leave it to the reader to draw conclusions about the implications of these trends on whatever aspect of security he or she has in mind. A non-exhaustive list of possible impacts that demographic trends may have on dif-

ferent concepts of security will be briefly mentioned only in the following paragraphs and in the conclusions.

We begin with a more traditional national and military security concept. First and foremost, it is the size of one population as compared to that of other states that throughout history has influenced the balances of power and the conceptualization of ‘hard’ security. This is particularly the case when populations grow and shrink at different speeds (through migration or natural growth). This exerts pressure on an established regime to change and produce a new balance of power. While traditionally larger populations have been equated with more military power, in a modern economic and military setting, the skills of the population (human capital) and the technologies used may be more important for its geopolitical standing. For this reason, this chapter also reviews new methods for projecting human capital, in addition to the more traditional focus on population size and age structure. But the traditional way of focusing primarily on population size is still pervasive. Russian President Putin, in May 2006 in a speech to the Duma, called Russia’s declining population the biggest problem of the nation, while Bulgaria’s Prime Minister recently noted that demographic trends in his country pose the most important security threat. While there has been a long-standing fear of population decline (Teitelbaum/Winter 1985) that has, for instance, inspired the elaborate pro-natalist policies in France, actual population declines that are not the consequence of wars or famines are a new phenomenon. Currently, several Eastern European countries are shrinking rapidly due to a combination of out-migration, very low fertility, and rather high mortality. The population of Bulgaria, for instance, declined by 15 per cent over the past 15 years and is expected to continue to shrink.

A change of population size in the other direction, namely rapid population growth in developing countries, has given rise to an equally long-standing security concern, but with an emphasis on environmental

and human security. In the extreme, the concerns about rapid population growth, the so-called ‘population explosion’ (Ehrlich/Ehrlich 1990), has often been described as the single, most important threat to humanity. Over the past decade there has been a rapidly increasing body of scientific literature studying in a more differentiated way the complex interactions between population and the environment. Progress has been made in the field of new methods of analysis (Lutz/Prskawetz/Sanderson 2002) as well as in terms of sectoral assessments with respect to climate change (O’Neill/MacKellar/Lutz 2001), food security (Fischer/Shah/van Velthuisen 2002), coastal ecosystems (Curran/Agardy/Cruz/Dasgupta/Kumar/Lutz/Williams/Kessler/Adams 2002), and other key dimensions of environmental security. This literature will be briefly discussed in section 12.6.

But aside from changes in the sheer number of people, demographic variables have much to offer in terms of implications for security concerns under a societal security perspective. When we look at a population not primarily as a national population, but rather in terms of its composition by different ethnic, linguistic or religious groups, changes in the relative sizes of these groups often raise important questions of social cohesion and, in many instances, security. International migration, one of the three forces (along with birth and death rates) that shape population size and structure, is a key element with respect to such changes and associated concerns. Another change in the structure of population, namely, the significant ageing of populations in many countries in the world, has been giving rise to serious concerns about the sustainability of existing social security systems, and may even have implications for future economic growth and the geopolitical balance of power which brings us back to the more traditional national security concerns. Hence, in this respect population ageing may be viewed as a national and a societal security issue.

In the following sections, this chapter will first present some data on the current demographic divide between rapidly ageing and still rapidly growing populations, then discuss what we do and do not know about the range of likely demographic trends over the 21st century, and finally add the ‘quality dimension’ in presenting projections by level of education in addition to age and gender. Toward the end of the chapter we will briefly discuss issues in population and environmental security, and conclude with policy considerations.

12.2 A Demographically Confusing World

Current global demographic trends and the associated challenges are somewhat confusing to many observers. This may also be the reason why in the context of security concerns population is often left out or is being viewed in contradictory ways. On the one hand, in many developing countries population growth rates are still very high due to birth rates well above replacement level (of two surviving children per woman) and a very young age structure.¹ For this reason, in a number of countries the population is likely to double over the coming decades. On the global level, the world population will increase from its current 6.4 billion to somewhat below 9 billion by the middle of the century (Lutz/Sanderson/Scherbov 2001). On the other hand, there are an increasing number of countries in which the birth rates have fallen well below replacement level and the population is ageing rapidly. For these countries we expect a future of even more rapid population ageing and in many cases, a shrinking of total population size. Because of these significantly different demographic trends for some parts of the world, there is still concern about the negative consequences of rapid population growth, while simultaneously, in other parts of the world, there is concern about the negative implications of rapid population ageing.

The picture is further complicated by the fact that this demographic divide does not always go along the traditional divide between industrialized and developing countries. Some developing countries have recently seen very rapid fertility declines, and the number of ‘poor’ countries with sub-replacement fertility is increasing. China is the most prominent example, where fertility has recently fallen to an uncertain level between 1.3 and 1.7 (Lutz/Scherbov/Cao/Ren/Zheng 2005). For this reason, over the coming two decades, China will have both significant further growth and significant population ageing. It is expected to grow by around 200 million people due to a momentum caused by the very young age structure, with the consequence that more women enter reproductive age. At the same time, the one-child family policy is causing serious problems in terms of the support of the rapidly increasing number of elderly. Surprisingly to some, the USA will also belong to this same group, which will simultaneously experience growth and ageing, because – unlike Europe – it is ex-

1 This section partly draws on Lutz (2004).

pected to grow significantly due to high immigration and higher birth rates than in Europe.

Figure 12.1 illustrates the trends in population growth rates for different world regions from 1950 to 2050, based on UN estimates for the past and the medium variant projections (United Nations 2003). These projections give the paths considered as most likely from today's perspective. But the future demographic trends have significant uncertainties which will be discussed in the following section, and which are not adequately reflected in the UN population projections. In their high and low variants the UN presents only alternative assumptions with respect to fertility trends, and combines them with identical mortality and migration assumptions. Since these trends are equally as uncertain as fertility, the high-low range significantly underestimates uncertainty, particularly with respect to ageing (Lutz/Vaupel/Ahlburg 1999; Lutz/Goldstein 2004).

Figure 12.1 shows that Europe consistently has the lowest population growth rate of all continents, falling from one per cent per year in 1950 to zero growth at the moment, and an expected 0.5 per cent shrinking by 2050. The figure also shows that all world regions have passed their peak in growth rates, and have entered a declining trend that is expected to continue over the next half century. The only continent depart-

ing from this general pattern is North America, which saw rather stable population growth of around one per cent from 1965 to present. That growth is expected to decline only moderately in the future. Actually, by 2050 the UN expects North America to have a higher population growth than Latin America, and higher than the world average (United Nations 2003).

Table 12.1 gives the trends in the two main drivers of population growth, namely, mortality and fertility. It shows that over the past half century, life expectancy increased considerably in all parts of the world. Only in Africa has HIV/AIDS caused a moderate decline at the continental scale over the past decade, with life expectancy having considerably declined in some of the hardest hit countries. For the future, a recovery in Africa is assumed, along with a continued increase in life expectancy in all parts of the world.

Fertility rates have also declined considerably around the world over the past decades. With below 1.4 children per woman, Europe has the lowest level with the other extreme in Africa, where the average is still around 4.9 children per woman. For the coming decades, the UN assumes continued declines in fertility around the world with the exception of Europe, where a recovery is assumed. While the assumed continuation of the fertility transition in developing countries is uncontroversial, the assumption of substantial

Table 12.1: Life expectancy at birth and total fertility rates by selected regions (1950-2050). **Source:** United Nations 2003 (medium variant).

Region	Life Expectancy at Birth (both sexes)					Total Fertility Rate				
	1950-1955	1975-1980	2000-2005	2025-2030	2045-2050	1950-1955	1975-1980	2000-2005	2025-2030	2045-2050
Africa	37.8	48.2	48.9	57.1	64.9	6.74	6.59	4.91	3.23	2.40
Eastern Asia	42.9	66.4	72.1	75.0	77.7	5.68	3.13	1.78	1.83	1.85
South-central Asia	39.4	52.6	63.2	69.1	74.0	6.08	5.09	3.25	2.18	1.91
Western Asia	45.2	60.6	69.1	75.2	78.0	6.46	5.30	3.45	2.57	2.19
Europe	65.6	71.5	74.2	78.1	80.5	2.66	1.97	1.38	1.63	1.84
Latin America & Caribbean	51.4	63.0	70.4	75.5	78.5	5.89	4.48	2.53	1.98	1.86
Northern America	68.8	73.3	77.4	79.7	81.8	3.47	1.78	2.05	1.96	1.85
WORLD	46.5	59.8	65.4	70.2	74.3	5.02	3.90	2.69	2.25	2.02

fertility increases in Europe is more disputed. There are indeed good reasons to assume that fertility may even continue to decline as a consequence of further declining family size ideals and possibly worsening expected income for the young generations relative to their consumption aspirations. This reasoning has recently been pulled together to a consistent 'low fertility trap hypothesis' (Lutz/Skirbekk/Testa 2006). Whether this hypothesis is true, or whether other forces that exert an upward pressure on fertility are stronger, is a completely open question at this point.

12.3 Demographic Transition as the Main Driver

Explanations and projections of fertility trends in different parts of the world have been generally guided by the paradigm of demographic transition, which assumes that after an initial decline in death rates, birth rates also start to fall after a certain lag. In this general form, the model has received overwhelming empirical support in capturing the remarkable fertility changes that happened over the 20th century.

The demographic transition began in today's more developed countries (MDCs) in the late 18th and 19th centuries, and spread to today's less developed countries (LDCs) in the last half of the 20th century (Notestein 1945; Davis 1954; Davis 1991; Coale 1973). The conventional theory of demographic transition predicts that, as living standards rise and health conditions improve, mortality rates first decline and then, somewhat later, fertility rates decline. The demographic transition theory has evolved as a generaliza-

tion of the typical sequence of events in what are now MDCs, where mortality rates declined comparatively gradually, beginning in the late 1700's and then more rapidly in the late 1800's and where, after a varying lag of up to 100 years, fertility rates declined as well. Different societies experienced transition in different ways, and today various regions of the world are following distinctive paths (Tabah 1989). Nonetheless, the broad result was, and is, a gradual transition from a small, slowly growing population with high mortality and high fertility to a large, slowly growing or even slowly shrinking population with low mortality and low fertility rates. During the transition itself, population growth accelerates because the decline in death rates precedes the decline in birth rates.

The demographic transition paradigm that has been useful for explaining global demographic trends during the 20th century and that has strong predictive power when it comes to projecting future trends in countries that still have high fertility, has nothing to say about the future of fertility in Europe. The recently popular notion of a 'second demographic transition' is a useful way to describe a bundle of behavioural and normative changes that happened recently in Europe, but it has no predictive power. The social sciences have not yet come up with a useful theory to predict the future fertility level of post-demographic transition societies. All that forecasters can do is to try to define a likely range of uncertainty.

12.4 Mapping the Uncertainty Range of Demographic Trends in the 21st Century

All three components of demographic change – fertility, mortality, and migration – are uncertain in their future trends. The UN medium variant presented above is based on an attempt to make the assumptions that are most likely from today’s perspective. But we already know today that there is a high probability that the actual future trends will either be above or below the medium assumption. How should we deal with this significant uncertainty in population forecasting? This question is the title of a recent special issue of the *International Statistical Review* (Lutz/Goldstein 2004). This state of the art report shows that in the field of population forecasting, we are currently seeing a paradigm change from scenarios to probabilistic forecasting. Scenarios, as used in many fields of forecasting, are descriptions of possible future paths without any statement of the likelihood of these paths. Particularly in the case of deep uncertainty, i.e. when there is not only parameter uncertainty but the entire model is uncertain, they have become a standard tool for thinking about the future. Since we know the model, as described by the cohort component model of population projections, only the parameters are uncertain. For this reason, some decades ago forecasting agencies around the world, following the example of the United Nations Population Division, produced high and low variants in addition to the medium variant. This high-low range is supposed to indicate a ‘plausible range’ of future population trends. But such a high-low range can only be defined in terms of one of the three components of change and is mostly based on alternative fertility assumptions, while uncertainty in mortality and migration is disregarded.

To remedy such shortcomings, IIASA (Lutz/Sanderson/Scherbov 1997) produced the first fully probabilistic projections of the world population. These were essentially based on subjective probability distributions for future fertility, mortality, and migration, as defined by a group of experts. In 2001 new probabilistic projections were performed that are based on a synthesis of three alternative approaches (time series analysis, ex-post error analysis, and argument-based expert views) (Lutz/Sanderson/Scherbov 2001). The examples below are taken from this most recent forecast. Such probabilistic projections go in several important dimensions beyond the traditional scenario analysis: They are able to simultaneously consider the uncertainty in all three components of change; they

can define in more precise quantitative terms what uncertainty intervals the given ranges cover; and based on the assumption of certain correlations, they can aggregate from the regional to the global level in a probabilistically consistent way. These important advantages of a probabilistic approach over a scenario approach make it worthwhile to consider whether in other fields, such as environmental change or future health, one should go beyond scenarios.

The key findings of Lutz/Sanderson/Scherbov (2001) are that with a high probability of above 80 per cent, world population will peak over the course of this century and then start to decline. They also show that the 21st century will bring significant population ageing in all parts of the world. In short, it is concluded that while the 20th century was the century of population growth, with the world growing from 1.6 to 6.1 billion people, the 21st century will be the century of population ageing, with the global proportion above age 60 increasing from currently 10 per cent to between 24 and 44 per cent (80 per cent uncertainty interval). Even more significantly, the proportion of the world population that is above age 80 will increase from currently one per cent to between 4 and 20 per cent, depending largely on the future course of life expectancy.

Figure 12.2 shows that for Western Europe the proportion above age 80 might even increase much more dramatically than on the global level. The figure shows that currently around 3 per cent of the population is above age 80, and that this proportion will not change much over the coming decade. After the year 2030, however, the uncertainty range opens up very quickly. In 2050, the 95 per cent interval already goes from around 4 per cent at the low end to more than 20 per cent at the high end, with the median at around 10 per cent. In other words, in 2050 the proportion above age 80 is likely to be three times as high as today, but it could even be six times as high. Its actual level will depend mostly on future old-age mortality – whether life expectancy will level off toward a maximum or whether it will continue to increase unabated. This difference becomes even much more significant during the second half of the century. By the end of the century, the 95 per cent interval is extremely wide, ranging from essentially the current level of 3 per cent to an incredible 43 per cent of the population above age 80. Even the median shows a proportion of about 20 per cent. Societies with such significant proportions of the population above age 80 will clearly be very different from today’s societies. Most likely, however, an average 80-year-old person

Figure 12.2: Proportion of population above age 80 in Western Europe. **Source:** Designed by the author.

during the second half of the century will be in much better physical health than an average 80-year-old person today.

What will this significant expected population ageing in Western Europe mean in terms of future security challenges? This is clearly a new situation that has never been experienced in human history, with Europe and Japan spearheading the trend. For this reason there is no empirical evidence to refer to when trying to anticipate the consequences of ageing. Depending on the model used, the results tend to differ significantly. Some researchers conclude that the additional burden on the pension system can easily be compensated by productivity growth and higher capital intensity. Others claim the opposite, that ageing may actually lead to lower productivity in the future with the elderly less eager to engage in new technologies and investments going to other parts of the world, where the population is younger and the expected returns to investments greater. Depending on which view is correct, the implications for geopolitical power and economic growth and hence the national security as well as the social security of the ageing countries will differ significantly.

12.5 The Changing Global Distribution of Population and Human Capital

The demographic trends of the past decade, together with those expected for the future, result in major changes in regional population distribution on our planet. Asia, which holds the giant share of the world population, has the most stable proportion (about 55–60 per cent) over the period 1950–2050. The shares of North America, Latin America, and Oceania are also surprisingly stable over time. Big changes affect only Europe and Africa, where over the course of 100 years they fully exchange their positions. In 1950, Europe (including Russia) was home to some 550 million people, constituting 22 per cent of the world population. At present, Europe has increased to 725 million, but since the world population has increased much more rapidly, Europe's share has declined to only 12 per cent. This is similar to that of Africa, which started at 8 per cent in 1950. By 2050 Europe is expected to shrink to some 630 million, which at that point will only be 7 per cent of the world population. Africa, on the other hand, is likely to continue to grow to around 1.8 billion by 2050, almost three times the expected population of Europe.

As significant as these changes in relative population size are, it is not clear exactly what they will imply for a region's geopolitical standing. The strength and

Table 12.2: Population (in millions) aged 20-65 by education and gender in 2000 and in 2030 according to the 'constant' and the 'ICPD' scenarios. **Source:** Author's calculations (together with Anne Goujon).

b) FSU Europe = European part of the former Soviet Union.

influence of a nation or a continent is not directly a function of its population size. If this were the case, then Africa today should have a similar standing in international politics, economics or military strength to that of Europe, and this is not remotely the case. What seems to count more than the sheer number of people is the human capital, which can be defined in a simplified way by looking at the people of working age stratified by their level of education. The global distribution of human capital is changing as well, but the pattern looks rather different from that of mere population numbers.

The first global projections of human capital have been recently produced by IIASA (Goujon/Lutz 2004). Table 12.2 lists the persons of working age that have at least some secondary or tertiary education in 2000, as well as for two alternative scenarios to 2030. The scenario 'constant' assumes that current school enrolment rates remain unchanged over time, which will result in significant improvements of human capital in many countries because of past improvements in education and the process by which the less-educated, older cohorts will be replaced by better-educated, younger cohorts.

The other scenario, called 'ICPD', assumes that the ambitious education goals defined at the International Conference on Population and Development (ICPD) 1994 in Cairo will be achieved. These include a closing of the gender gap in education and universal primary education.

Table 12.2 shows that in terms of human capital, Europe (including Russia) is still a world power, with well over 350 million working age people with a higher education - many more than in Africa, and even more than the huge South Asian subcontinent. This helps to put the pure population numbers into perspective. But the table also shows that significant changes in the global distribution of human capital are to be expected, even under the constant enrolment scenario. Under this scenario, every world region will see some improvement of its overall human capital. On a relative scale, gains in today's least developed regions will be strongest partly because the recent improvements in educating the younger generation have already been a significant gain in comparison to the virtual absence of education for the older cohorts. In absolute terms, even under this constant enrolment scenario, huge gains in the

Figure 12.3: Population (in millions) aged 20-65 by level of education, according to the 'ICPD' scenario in four mega-regions, 2000-2030. **Source:** Goujon/Lutz 2004: 138.

number of working age people with secondary or tertiary education are to be expected in Latin America, South Asia, and the China region. In today's industrialized countries, only moderate gains are to be expected. Comparing these results to the most optimistic scenario assuming the education goals of the ICPD, there is surprisingly little difference to the constant enrolment scenario. This is due to the great momentum of educational improvement. Increases in school enrolment today and over the coming decade will only very slowly affect the average educational attainment of the whole working age population. The difference is worth noting in Sub-Saharan Africa, because the current school enrolment rates there are still far below the Cairo targets. Because the ICPD also implies lower fertility in some regions, the absolute numbers are even smaller under the ICPD than under the constant rate scenario.

Figure 12.3 summarizes the information of table 12.2 in graphical form. It compares four 'mega regions'. It shows that currently Europe and North America together still dominate the world in terms of

human capital, although South Asia and the China region are already bigger in terms of working age population. The figure also shows the different pathways of China and South Asia (India), which reflects the fact that unlike South Asia, China has invested heavily over the past decades in primary and secondary education, and will see a peaking of its population size over the coming decades. South Asia will soon surpass the China region in terms of population size, but will fall back in terms of human capital.

Even under the most optimistic scenario, Africa will see only very moderate increases in human capital. An interesting point worth noting is that China's human capital is increasing so rapidly, that by around 2015, the China region will have more people of working age with secondary or tertiary education than Europe and North America together.

These global shifts in human capital are likely to result in changing geopolitical and economic weights, and also have significant implications for global security in several respects. The changing weights may destabilize current institutional arrangements on the

international level when a country's economic and military power is out of proportion with its traditional influence in international politics. This problem of instability of the traditional role may equally apply to the rising superpowers in Asia and the European countries which are losing in their relative standing.

12.6 Population and Resources, Climate Change and Environmental Security

Ever since the writings of Thomas Malthus (1798), the assumed negative impact of population growth on food security and environmental conditions has been a topic of much discussion. From an ecological perspective, there has been little doubt that the increase in human numbers has been and will be a major reason for environmental degradation, including climate change that will significantly affect the living conditions on this planet. While the most vocal of these voices on the ecological side have coined the notions of 'population bomb' (Ehrlich 1968) and 'population explosion' (Ehrlich/Ehrlich 1990), there have been equally vocal economists claiming that there is essentially no limit to the number of people that the earth can potentially support (Simon 1981, 1990). A comprehensive summary of this discussion is given in Cohen (1995).

Recently there has been much serious scientific analysis that goes far beyond the simplistic dichotomy described above and accounts for the highly complex nature of population-environment interactions which go in both directions and are subject to many intervening factors. Progress has been on both the methods of population and environment analysis (Lutz/Prskawetz/Sanderson 2002) as well as on specific sectoral studies. In particular, the areas of population and land use change (National Research Council 2005) as well as population and climate change (O'Neill/MacKellar/Lutz 2001) have seen major progress. With respect to climate change, the number of people has usually been considered a key factor in the total emission of greenhouse gases, together with wealth and technology, which is reflected in the famous $I=PAT$ equation (where I stands for impact, P for population, A for affluence, and T for technology). But since emissions cannot be expected to grow directly proportional to population, more recent work has also considered the impact of changing household patterns and age structures on emissions. Since a certain proportion of energy consumption is dependent

on the number of households (such as heating, cooling, construction, etc.), rather than on the number of individuals, and in the context of population ageing, the number of households tends to increase significantly while population size stagnates, this factor may lead to continued emissions growth, even in the absence of population growth.

In quantitative terms, O'Neill/MacKellar/Lutz (2001) show that the projected reduction in greenhouse gas emissions in 2100, which result from slowed population growth, remains at a substantial 30 per cent (12.4 GtC) under the rapid demographic transition scenario versus 17.6 GtC under a reference population scenario. Based on various sensitivity analyses, the authors conclude that alternative population paths can have a substantial impact on future greenhouse gas emissions. This is a highly relevant finding for the different kinds of environmental and human security that are assumed to be affected by global climate change.

Another important question for which population matters in terms of the security threats associated with climate change is the adaptive capacity of a population. It is highly likely that demographic factors and in particular the educational composition of the population affect the ability of societies to cope with the consequences of inevitable climate change. In countries in which major resources are being absorbed for coping with the consequences of rapid population growth, and in which (partly for this reason) large segments of the population have little to no formal education, it might be significantly more difficult to successfully fight off some of the assumed consequences of climate change, such as extended droughts, extreme weather events including more frequent and more severe tropical storms, and a rise in the sea level. The importance of population and human capital for the adaptive capacity of societies needs more explicit attention in the scientific literature because this line of influence might be an even more important effect of population change on environmental and human security than the traditional view of population growth as a driver of climate change.

There are many relevant sector-specific (water, air, land, etc.) aspects to this, but there is no space here to discuss the rapidly growing field of population and environment analysis. Most of these studies are site-specific and deal with different aspects of the environment, such as land-use change, deforestation, fresh water availability, water pollution, air pollution, biodiversity, protected areas, and coastal marine systems.²

In general, the outlook of an end to world population growth and likely global population shrinking in the longer term future is good news from an environmental security point of view, because it will tend to make efforts towards sustainable development easier. In addition, the fact that the most highly polluting countries (except for the USA) are already on a declining trajectory, and the most rapidly growing countries in Africa have the lowest per capital emissions, is in principle a force in a more optimistic direction. However, as economic growth in these countries picks up, per capita emissions are likely to increase in parallel with population size. This realistic view that some harmful climate change may be inevitable makes it even more important to increase environmental security through the enhancement of adaptive capacity.

12.7 Population Policies and Security

The history of international population policy is inextricably linked with the history of the international family planning movement, which emerged in the 1920's as a complex amalgam of eugenicists, public health advocates, and social reformers (Adams 1990; Hodgson 1991).³ Scientific advances in genetics and large-scale human rights abuses in Germany under National Socialism thoroughly discredited both eugenics and the policies derived from it. As a result, the international population movement was in disarray after World War II (Kühl 1997).

In reconstructing itself, the early post-war movement relied heavily on two justifications for public support of voluntary family planning. One justification was the health and well-being of women, children, and young families. The second justification, not stated openly but never far in the background, was geopolitical in nature. During the 1950's, new census data revealed staggering rates of demographic increase in India and other LDCs. With the Cold War as a background, policymakers in the West feared that exploding Third World populations would be fertile breeding grounds for political instability. Early US government international assistance for family planning was explicitly justified in these political terms (Donaldson 1990).

Concerns over national economic and political standing have also sometimes served as the basis for pro-natalist policies, such as generous parental leave, child allowances, public provision of day care, etc. (Teitelbaum/Winter 1985). In the 1960's and early 1970's, for example, a number of East European countries, alarmed by the prospect of population decline, restricted abortions and put in place financial incentives for childbearing. With many countries in Europe and East Asia facing labour force shrinkage and even possible overall population decline, pro-natalism seems to be on the rise again.

At the Bucharest population conference in 1974, MDCs argued that higher fertility in LDCs was an impediment to macroeconomic growth. By the time of the next international population conference, held in 1984 in Mexico City, virtually all countries, with the exception of the United States, had adopted this view.

Over the past two decades – and centred around the 1994 Cairo population conference – the view that policies affecting population should, above all, stress the welfare of individuals, as opposed to demographic trends and their macro-consequences, has gained primacy. In this view, ensuring access to health care and education, fostering women's empowerment, and guaranteeing reproductive rights are ends in themselves, not means to achieving particular demographic goals (Bok 1994). Overemphasis on 'number', according to this school of thought, has led to coercive practices and insufficient attention to contraceptive safety, with consequences falling largely on women. Voluntary family planning programmes are now seen as a means of guaranteeing the rights of individuals and couples to have the number of children they desire, not as a means of reducing fertility. They are viewed as just one part of what should be a broad provision of reproductive health services that also includes pre- and postnatal health care, treatment of infertility, and other reproductive health problems, including sexually-transmitted diseases, and education and counselling on all aspects of pregnancy, childbirth, infant and women's health, and parenting.

But in terms of their implications for aggregate security concerns, over the most recent years the discussion of demographic trends has again started to add aggregate level concerns such as population ageing and its consequences for human security, as well as the consequences of population on environmental degradation and hence environmental security to the pervasive individual welfare rationale. In the end, we need to move to a balanced approach because both levels of consideration matter: It is hard to think of in-

2 A comprehensive summary of many of these studies can be found at: <www.populationandenvironment.org> which also organizes regular global cyber-seminars on related topics.

3 This section partly draws on Lutz/Sanderson/O'Neill (2004).

dividual well-being without the aggregate level conditions of security – be it military, human or environmental security – at the national and even global level.

12.8 Conclusions

In this contribution we tried to summarize the state of the art in demographic analysis and forecasting of the population by age, gender, and level of education in different parts of the world. Probably the most important message is that we now see the end of world population growth on the horizon. The world population is likely to level off at around 9 billion during the second half of this century and then possibly start a declining tendency, with an increasing number of populations experiencing fertility rates below the replacement level of two surviving children per woman. This is very good news for all kinds of human and environmental security concerns that focus on the negative consequences of ‘exploding’ human numbers. While the end of world population growth by itself will not solve any of the world’s problems, it clearly makes solutions easier by taking off some of the pressure, e.g. in the expected level of future environmental pollution or in achieving global food security. In many parts of the world, particularly in Africa and South Asia, rapid population growth will remain a major concern for the coming decades. But on the global level it seems fair to say that many difficult solutions are likely to become a bit easier to achieve than they would be under continued population growth.

With the end of global population growth in sight and population ageing and shrinking already being experienced in an increasing number of countries, the focus of the security attention is moving from total size to the distribution of the population. In this context the rapidly changing age distribution is largely a human security concern challenging the viability of established social security systems and creating fears about who will care for the rapidly increasing number of elderly in the societies concerned. There are also concerns that population ageing will result in lower economic growth. On the other side of the spectrum in developing countries that only recently experienced their fertility declines, there are concerns about the political and public safety consequences of a ‘youth bulge’, i.e. unusually large cohorts of young people entering adulthood and not finding jobs or other means of getting integrated into society. Here it is hoped that the ‘demographic window of opportunity’ that temporarily results from low total age dependency ra-

tios (few children and not yet many elderly) and often leads to accelerating economic growth will help to provide jobs for these large numbers of restless young adults.

Another changing distribution that is considered to be highly relevant for more traditional national and military security concerns is the changing spatial distribution of people and their human capital over the planet. When Russian president Putin raises prominent concerns about the low fertility in Russia and the shrinking population size, particularly in the eastern part of the country, while simultaneously Chinese businesses spread rapidly across Siberia, there is a clear fear that changing population distributions may make it difficult in the future for Russia to maintain control over its vast territory. Another relevant change in distribution that affects many European countries and the USA is the changing ethnic, linguistic, and religious composition of national populations caused by past, current, and likely future international migration. Whether or not this is viewed as a national security threat is a matter of the conceptualization of national security: whether it is viewed as the security of a specific ethnic group which traditionally occupied the state territory and which now finds itself in a position of shrinking relative size, or whether it is applied to all residents of a country, regardless of their ethnic background.

Finally, as with many other security threats it is important to distinguish between objective dangers and subjective perceptions of them. In this contribution we focus on the objective trends and their likely future evolutions according to the best available science. But it is important to understand that the topic of population is also highly emotional and ideologically controversial at all levels, ranging from discussions in individual families to international negotiations among states. A good example of the latter is the treatment of population at the World Summit for Sustainable Development in Johannesburg in 2002. A very balanced and carefully worded statement produced by the Global Science Panel on Population and Environment (Lutz/Shah 2002) was dismissed from the agenda of the meeting because diplomats were afraid of reopening the European-American conflict over abortion and reproductive rights. Hence population, a key element in environmental change and sustainable development, was completely absent from this important conference on sustainable development in the 21st century.

13 Life on the Edge: Urban Social Vulnerability and Decentralized, Citizen-Based Disaster Risk Reduction in Four Large Cities of the Pacific Rim

Ben Wisner and Juha Uitto¹

13.1 Background and Objectives

Rapid urbanization and the growth of megacities have for the first time in history resulted in a predominantly urban world. Such an urban explosion, most of which has been in the less developed countries, has increased human exposure to natural and anthropogenic hazards. In particular, the 1990's the world witnessed an exponential growth in disasters. There were 700 large-scale disasters in 1999 alone, which resulted in the death of approximately 100,000 people and caused economic losses in excess of US \$ 100 billion. This figure reflects an annual 10 percent increase in losses throughout the decade. In 2003 weather related disasters alone cost insurers \$ 60 billion (UNEP 2003).

In 1996 the United Nations University (UNU) launched an international comparative study of the social geography of urban disaster vulnerability. Research on factors contributing to urban social vulnerability was carried out with the aim of incorporating social vulnerability in urban disaster risk management. Collaborative case studies were undertaken in six megacities, four of which are located in the Pacific Basin: Tokyo, Los Angeles, Manila and Mexico City.²

During the initial phase, citizens' participation and strong links between municipal authorities and non-governmental organizations (NGOs) working with vulnerable groups were identified as critical factors for reducing vulnerability. The extent of these partnerships and whether vulnerability had been included as a planning variable varied considerably amongst the municipalities studied. This chapter attempts to provide an explanation for that variability and also tries to draw out implications for policy and practice.

13.2 Theoretical Grounding

13.2.1 Social Vulnerability

Disasters affecting human beings are the result of complex interactions between human and natural systems. While such an interpretation of disasters is not new (Burton/Kates/White 1978), the depth, diversity, and complexity of the human side of these transactions have only been more fully appreciated in recent work.³ 'Social vulnerability' to disasters is one of the most important factors at work on the human side of the society - environment relationship.

'Social vulnerability' is defined (after Wisner/Blaikie/Cannon/Davis 2004: 11) as the characteristics of a person or a group that affect their capacity to anticipate, cope with, resist and recover from the impacts of a disaster. Vulnerability is, thus, defined by a number of factors that include social and economic status, as well as the political conditions prevailing that influence a person's or a group's position and

1 Wisner was coordinator for the UNU study of urban social vulnerability in six large urban regions (1998-2002), and study site manager for greater Los Angeles while Professor of Geography and Director of International Studies, California State University at Long Beach (1996-2000). Uitto was academic officer at the UNU (1990-1999) at the beginning and throughout most of the UNU study. The authors are grateful to the UNU project city coordinators: Dr. Sergio Puente, Mexico City; Dr. Jean Tayag, Manila; and Dr. Shigeo Takahashi, Tokyo.

2 The other two megacities were Mumbai in India and greater Johannesburg (Gauteng Province) in South Africa.

3 See: Maskrey 1989; Blaikie/Cannon/Davis/Wisner 1994; Cutter 1996; Hewitt 1997; Twigg/Bhatt, 1998; Morrow 1999; Alexander 2000; Buckle/Marsh/Smale 2000; Wisner/Blaikie/Cannon/Davis 2004; Pelling 2003a, 2003b; Wisner 2004; Bankoff/Frerks/Hilhorst 2004.

power in a society. There is also a time dimension, as people's degree of vulnerability may vary depending on his or her life situation, age, and also seasonality (Uitto 1998). The spatial dimension of vulnerability is dependent on the fact that people and groups with similar characteristics tend to occupy the same or similar areas. The United Nations Habitat Agenda (see at: <www.unhabitat.org.agenda>) recognized that:

Vulnerability and disadvantage are often caused by marginalization in and exclusion from the socio-economic mainstream and decision-making processes and the lack of access on an equal basis to resources and opportunity...Vulnerability and disadvantage are mainly caused by circumstances, rather than inherent characteristics.

Alexander (2000: 12-22) distinguishes between several types and levels of vulnerability, especially between 'deprived vulnerability' and 'wilful vulnerability.' In the first case, the knowledge generated concerning hazards and their impacts is not diffused nor utilized for disaster mitigation. In the latter case, this knowledge is deliberately ignored. This implies that the state of wilful vulnerability is maintained because powerful groups in a society have an incentive not to invest in hazard mitigation or to enforce laws and regulations (Wisner 2001; Oezerdem 2003). A typical case might be when there is no incentive to enforce building codes, thus rendering residents vulnerable to hazards, e.g. earthquakes. A further point made by Alexander is that the level of vulnerability is related to the level of economic development in a society. Poorest societies have the least resources to reduce vulnerability. At the stage of rapid development, the assets at risk grow faster than the possibilities of mitigation, thus increasing vulnerability.

Disaster risk is thus a function of the vulnerability of people, including their settlement and livelihood, and the degree to which society has engaged in disaster mitigation activities (Wisner 1999). This can be expressed in a formula, where R = risk; H = hazard (extreme event or process); V = vulnerability; M = mitigation:

$$R = (H \times V) - M.$$

Distinguishing between social protection and self protection (Cannon 2000: 47; Wisner/Blaikie/Cannon/Davis 2004: 88-95), one also recognizes that vulnerability is also to some extent a function of the degree to which people's own capacities for self protection are blocked by social, political, and economic constraints and obstacles. Thus, taking, such local capacity (C) into account, in addition to the social protec-

tion afforded by governments (M), the expression for disaster risk becomes:

$$\frac{R = (H \times V) - M}{C}$$

'Capacity' has become a major focus of organizations on the front line of disaster management such as the International Federation of Red Cross and Red Crescent Societies (IFRC), UNDP, and many non-governmental organizations (NGOs). The concepts of capacity and vulnerability are keys to demonstrating that disaster risk development and sustainable human development have a core common agenda (Wisner 2003a; UNDP 2004). Thus vulnerability and capacity in the face of disaster risk should be seen as important components of urban sustainability, and as elements of a sustainable urban livelihood (Sanderson 2000). Capacity as 'self protection', in this context, has many connections with the kinds of citizen-based environmental management activities included under Local Agenda 21 (a major practical follow up to the Earth Summit in 1992). Capacity and vulnerability are largely determined by social factors, such as socio-economic status, age, gender, ethnicity, and health, which have distinct spatial dimensions in an urban setting, and which, in turn, are largely determined by access to resources (Wisner/Blaikie/Cannon/Davis 2004: chap. 3).

13.2.2 Megacities, Globalization, and Vulnerability

The urban regions that have emerged in the latter half of the 20th century are huge, encompassing pre-existing cities, spilling over into watersheds, food and fuel producing areas, and developing satellite or 'edge' cities at a rapid rate (Coy/Kraas 2003; Kraas 2003). These new configurations present challenges of planning and administration as well as difficult logistical situations. The protection of lifeline infrastructure and provision of these cities is often problematic during 'normal' times. Urban metabolism (supply of consumables and disposal of waste) becomes highly questionable in disaster scenarios (Mitchell 1999; Fernandez 1999).

Urban size and fragmentation lead to difficulties in planning and administration. However, beyond this obvious challenge to the megacity, there are complexities in the way that different jurisdictions, agencies and - more generally - stakeholders perceive hazards. This gives rise to significant problems in communication and coordination of effort focused on different

stages of disaster management: prevention and mitigation, warning and response, and rehabilitation and recovery (Handmer/Penning-Rowsell 1990; Comfort 1999).

Disaster planners have seldom engaged with the literature concerning 'sustainable cities' (Stren/White/Whitney 1992; Roseland 1997) and 'healthy cities' (Davies/Kelley 1993). Although the IDNDR's intention was to 'mainstream' disaster reduction as part of routine planning, that has still not happened. Disaster management should be indistinguishable from 'normal' urban and regional planning (OAS 1990; IDNDR 1996) but that goal has not yet been attained.

Thus in common with much other work in geography, resource management, public health, among other disciplines, the UNU project sought to change 'normal' urban planning practice. In particular, it attempted to identify ways that municipalities and NGOs can cooperate in capacity building for more resilient cities. This requires recognizing the agency and knowledge of a wide variety of citizens and lay people (Enarson/Morrow 1998; Eade 1997; Wisner 1995; 2004) and translating such knowledge into common language that planners and citizens can share.

13.2.3 Focus on Urban Areas in the Pacific Rim

This chapter focuses on four megacities in the Pacific Rim. This geographical focus is natural given that the Pacific Basin has experienced extraordinary urban growth and is now the host of a large number of megacities and extended urban areas. It also has a history of multiculturalism and international migration, a part of which is illegal. Furthermore, the lands surrounding the Pacific Ocean are regularly exposed to a broad range of natural hazards, including earthquakes, volcanic eruptions, tsunami and tropical cyclones (see below).

The rapid population increase and the growth of very large cities in Pacific Asia has long been a cause of concern for urban scholars and planners (Fuchs/Brennan/Chamie/Lo/Uitto 1994). World wide population growth rates are highest in the coastal zone of the tropics, most affected by cyclones (Hanzhou Declaration 1999). It has been projected that urbanization rates in Asia as a whole will reach 54 percent by the year 2020, up from a mere 23 percent in 1970 (Lohani/Whittington 1996). Nine out of the twenty-five largest urban conglomerations in the world are today located in Pacific Asia (Choe 1998). These include the Tokyo/Yokohama extended metropolis as well as Manila. According to the UN's urbanization prospects 2005 of the 22 mega cities of more than 10 million inhabitants 14 were in the wider Asia Pacific region (table 13.1).

All of the cities in the Pacific Rim are exposed to a gamut of natural hazards (Britton 1992; Mitchell 1992). These include earthquakes, tsunamis, flooding, landslides, volcanic eruptions and subsequent lahar flows, forest fires, and tropical cyclones (typhoons or hurricanes) (Orrick/Bemis/Francis/Goss/Howell/Yurkovich 2002: 19-22). An analysis of earthquake hypocenters shows major concentrations along the Pacific, Philippine and South American Plates (Ogawa 1996). Similarly, most tropical cyclones originate near the equator and affect worst Southeast and East Asia, as well as Central America. China, the largest and most populous country on the Pacific Rim experienced during the 40 years 1949-1990 the following on average each year: 5.6 floods, 6 earthquakes greater than R6 magnitude, 6.9 tropical cyclones, and 7.5 droughts (Jingshen/Gangjian/Gang 1992). All of these are capable of affecting China's cities in a variety of ways. Also linking the countries of the Pacific Rim ever more closely through increased trade and migration (legal and illegal) is the diffusion of new and resurgent diseases such as antibiotic resistant tuberculosis, influ-

enza, cholera, and new diseases such as SARS (Wisner/Blaikie/Cannon/Davis 2004: 197, note 5).

13.3 Introducing the Four Megacities

13.3.1 Human and Physical Geography

Table 13.2 summarizes some striking similarities among these four large urban regions besides their location on (or near)⁴ the Pacific Rim. First is their size. They all fall squarely into the strict definition of 'megacity' with well over 10 million people living in their metropolitan areas. They are all extensive, but Los Angeles far exceeds the others in sprawl, and has the lowest average density. The other three are densely populated, with both Mexico City and Tokyo, respectively, just below and just above one thousand inhabitants per square kilometre of urban space.

Los Angeles is the youngest city region among them, with even its mere 220 years provides a history rich enough to provide several 'root causes' of social vulnerability to disaster. The others are each twice as old, or nearly so, even dating Mexico City from the Spanish conquest and not from its Aztec origins.

All four urban regions contain considerable flood prone flatlands even though Mexico City is the only one without a coastal location. These latter three have over many years augmented their coasts with considerable land fill which shares with the drained lake bed under the historic centre of Mexico City soil conditions subject to subsidence and liquefaction. In all cases there are hills adjacent to or intermixed with these flatter parts. Therefore, despite their differences in climate, in all cases there are times in the year, or particular climate events, when one can expect landslides.

13.3.2 Economic and Political Geography

Three of these urban regions contain a national capital region and the economically primate city of their country. Tokyo is considered to be a 'world city' in terms of financial networks (Castells 1999). The other

4 Mexico City is 300 km from the Pacific, but it is forcefully influenced by earthquakes that occur at a plate boundary in the Pacific off Mexico's western coast. Also, as the national capital of a country with a long Pacific coast line and major economic linkages with other Pacific Rim countries (the US, Canada, Japan, South Korea, Taiwan); it seems appropriate to include Mexico City despite its landlocked condition.

Table 13.2: Comparison of Four Megacities. **Sources:** *Manila and Tokyo:* Fuchs/Brennan/Chamie/Lo/Uitto (1994); Yeung/Lo (1996); Tayag (1999), Velasquez/Uitto/Wisner/Takahashi (1999); *Tokyo:* Takahashi (1998, 1999); Tokyo Metropolitan Government (1995); *Manila:* Tayag (1999); Asian Development Bank (ADB 2000, 2002); Bankoff (2003b); *Mexico City:* Cruz (1993); Gilbert (1994, 1996); Roland/Gordon (1996); Puente (1999a, 1999b); *Los Angeles:* Wisner (1999a, 1999b, 2003a); Bolin/Stanford (1998); General: U.N. (1999).

Characteristics	Greater Los Angeles	Metropolitan Manila	Greater Mexico City	Metropolitan Tokyo
Population	13	11	18	26
Size (000 Km²)	87	15	22	14
Density (Pop/ Km²)	149	733	818	1,857
Age Since Foundation (Years)	220	430	477 (666)	398
Situation	Coastal and inland valleys	Coastal peninsulas between bay and lake	Inland valley on plateau	Coastal, running N and W into hills
Topography	Mix of flood plain, canyon, coastal cliff and estuary	Coastal plain, river flood plain, hilly to East	Centre over ancient lake bed, many ravines to N, W and S, flatter to NE	Flat in much of ward (<i>Ku</i>) area, more relief in <i>Tama</i> area to West
Climate	Semi-arid	Tropical	Semi-arid	Temperate
Political & Economic Importance	Regional economic role, Pacific Rim and Latin America, regional economic and political role in U.S.	Nationally primate and sub-regional economic role in Asia	Nationally primate in economic and political terms, regional economic role in the Americas	Nationally primate in economic and political terms, world and regional economic centre
Per cent Poor	25	40	50	10
Per cent in Informal Settlement or Illegal Migrant	5-10	30	40	2-3
Natural Hazards	Earthquake, fire, flood, landslide	Earthquake, flood, landslide, typhoon	Earthquake, flood, landslide	Earthquake, flood, typhoon
Last Major Disasters	Northridge earthquake in 1994; wildfires in 1995	Payatas garbage dump flood, fire, and landslide in 2000	Earthquake in 1985	Earthquake and fire in 1923

Notes: “*Age since Foundation*”: All mega cities were predated by small settlements, some occupied for a long and undetermined period. In the case of Mexico City two ages are given. The first uses the date of the establishment of the Aztec settlement of Tenochtitlan (1325 or 1345). The second uses the date of the defeat of the Aztecs by Cortez (1524). The banks of the Pasig River in present day Manila were inhabited long before the Spanish colonial period, but the age provided uses the date of Spanish control of Manila (1571). “*Per cent Poor*”: Per cent below locally defined poverty line. Clearly one is dealing with relative and not absolute poverty in these comparisons, however, in all cases among the ‘poor’ there is little or no surplus for financial investments in self-protection because of the relative expense of food, shelter, utilities, and transport. “*Percent Informal Settlement or illegal immigrants*”: There is little squatter or informal settlement in greater Los Angeles or greater Tokyo except for some semi-permanent encampments of homeless individuals and the illegal use of condemned buildings (‘squats’). In area extent and numbers of inhabitants, these are not at all comparable to the large informal settlements in greater Mexico City and greater Manila. However, when one considers the numbers of illegal or undocumented persons in the urban population, a different but related percentage can be estimated for Los Angeles and Tokyo. The commonality between the two measures is ‘illegality’ and the challenge for risk reduction that that produces. “*Last Major Disaster*”: The fire bombing of Tokyo during the Second World War is not included, although more recent than the 1923 earthquake and fire, because it was not triggered by an extreme natural event. While the catastrophic mass movement of solid waste, and subsequent fire, that buried homes and people at Payatas, Manila, is partly the failure of a human artefact (a solid waste dump site), the trigger was heavy rainfall.

three have significant regional economic importance: Mexico City and Los Angeles in the Americas, and Manila in Southeast Asia.

It is because of this regional importance that three of the four are the destinations of considerable numbers of illegal immigrants either in the sense of foreign nations in search of livelihoods or political refuge (Los Angeles and, to a lesser extent, Mexico City and Tokyo) or in the sense of nationals who have come from other parts of the country and now live in illegal or informal settlements (large proportions of the population of Manila and Mexico City).

13.3.3 Time Geography of Hazard

Parts of all four urban regions are prone to earthquakes, floods, and landslides. Coastal gales and other storms can affect all but Mexico City. Wildfires are a hazard in parts of Los Angeles, and to a lesser extent, also in Mexico City. These megacities have long chronologies of disaster, although only Tokyo, like San Francisco, London, and Lisbon, has been almost totally destroyed in the past.

Given the social and physical heterogeneity of these great urban regions, and also because of the long journeys to work endured by much of their populations, the time-place geography of hazard is highly contingent and complex at the micro scale.

13.4 Los Angeles and Mexico City: Specific Comparisons

13.4.1 Shared Geographies of Hazard

Los Angeles and Mexico City both encompass large urban regions, with metropolitan populations of 14 and 18 million respectively. They both spread to fill much of the available land in large regions: the coastal plain and internal valleys that run eastward into foothills and mountains in the case of greater Los Angeles; the Valley Mexico and its surrounding mountain slopes and ravines in the case of greater Mexico City. Both urban regions are fragmented administratively. First, in both cases the urban region is divided among multiple administrative jurisdictions: six counties in the state of California and among three Mexican states (but principally one: the *Estado de Mexico*) and the Federal District. Both urban regions are further divided into municipalities: 116 in the case of Los Angeles County, and 65 *Delegaciones* (delegations) in the case of Mexico's Federal District. Finally, in both

cases, there is no overarching metropolitan government for the whole urban region as exists for greater Manila or greater Tokyo (Wisner 1999a; Puente 1999a).

Both megacities face a similar array of hazards. Among natural hazards they both face earthquakes, flooding, landslides, and urban-wildland interface fires.

Mexico City is affected most seriously by movements in tectonic plates off the western coast under the Pacific Ocean. This wave energy travels inland, where the local soil factors amplify the shaking, especially in the area of the historic centre of the city, which was built on a lake that was drained in the 16th Century. In 1985 at least 10,000 people died in such an earthquake (Wisner/ Blaikie/Cannon/Davis 2004: 281-292). So far the mortality from earthquakes in greater Los Angeles is lower. Fewer than 100 died in the Northridge temblor in 1994, but the economic loss can run into the billions of dollars (Bolin/Stanford 1998). Also, models based on the 1934 earthquake in Long Beach suggest that thousands could be killed in a future large event (RMS 1995).

Flooding in both urban regions is a hazard because of the intense seasonal rainfall and proximity to mountains that have been largely deforested because of development pressures. In both cases there are extensive and ambitious public works designed to channel and control run off, with varying degrees of success. In the case of Los Angeles the storm drainage canals have produced a secondary hazard of their own. Each year a number of children are swept away by powerful waves of water that course down from the hills with little warning (Rigg 1996; ICBO 2003).

Landslides produce economic loss to homeowners in parts of Los Angeles, but a deadly hazard in some areas of Mexico City. Informal, self-built settlement in some parts of Mexico City is situated over centuries-old, disused mines subject to cave-ins that produce sinkholes. In other areas steep slopes are unstable although inhabited by the poor. In yet others rocks fall from ridges and slopes above settled areas are the principle geomorphologic hazard.

Forest and grass fires affect the outer most zones of Mexico City's extensive area; however the population density is quite low in these areas. By contrast, there are a large number of people living among highly flammable Mediterranean, chaparral vegetation in greater Los Angeles. Limited road access increases the risk. During the great fire in Laguna Beach in 1994 nearly the entire town was threatened, and evacuation

by sea was being considered as the fire was finally controlled (Wisner 1999c; Davis 1998: 95-147).

What sets these urban regions apart is Mexico City's proximity to an active volcano and LA's exposure to coastal storms and coastal erosion. Ash fall from eruptions of Popocatepetl volcano reached the southeast of Mexico City in 1994 and 2001. Persons displaced by the eruption in 2001 were placed in shelters in Mexico City. As the metropolitan area grows in the direction of Puebla, directly on the slopes of the volcano, the hazard from future eruptions will increase (CENEPRED 2004).

Coastal gales are a hazard affecting seaward zones in greater Los Angeles, especially during years affected by El Niño. The pier in Santa Monica was washed away in El Niño storms, and high value real estate routinely falls into the sea from the Palos Verde peninsula northwards through Malibu (Glantz 2001).

These two urban regions also face similar technological hazards. Explosions and fires from the refining industry have occurred in both places. Air pollution is a chronic problem in both Mexico City and Los Angeles (Wisner 1999a: 405-409; Puente 1999a; Ezcurra/Mazari-Hiriart/Pisanty/Aguilar 1999). Sewerage and drainage systems in both urban regions are sometimes overcome. In Los Angeles there were large discharges of raw sewage during storms in the late 1980's and 1990's (Davis 1990: 196-200). In Mexico City the deep sewer system put in at great expense in the 1960's serves only the central part of the city. Given the natural problems of drainage on an ancient lake bed, even this limited system cannot always cope with run off, and the majority of residents live in areas where sewage is discharged into the *aguas negras* (black waters) of narrow ravines and streams (Ezcurra/Mazari-Hiriart/Pisanty/Aguilar 1999; Du-Mars 1995: chap. 5).

13.4.2 Shared Sociology of Survival

One tends to think of Los Angeles as rich and Mexico City as poor. However, differences in average per capita income make little difference for the most vulnerable social groups in both places. In both urban regions the working poor spend considerable income on minimally adequate housing and long, expensive journeys to work. Given the neo-liberal trend towards privatization and elimination of social welfare benefits in both the US and Mexico (and especially in California, where the neo-liberal model got its start with a referendum in 1978 that froze public expenditure - the so-called 'tax payer rebellion'), there is limited access

to health care, quality education, and social services for the working poor on both sides of the border (Bolin/Stanford 1998; Wisner 1999a). Tension between authorities and illegal immigrants has grown far worse since the attack on New York's World Trade Towers in September 2001 (Wisner 2003b), despite the fact that a Hispanic mayor of Los Angeles has been elected.

Contrary to expectations, there is probably better access to primary health care for the poor in Mexico City through the system of social security hospitals than in Los Angeles, where the emergency room at USC/County Hospital has become the de facto provider of primary care for a large number of people who do not have private health insurance. Throughout the LA metro region smaller community and church-run hospitals are closing or being sold to Health Management Organizations due to the economics of concentration and privatization of health-care.

The bottom of the socio-economic distribution in Mexico City tends to be immigrants from areas of Mexico inhabited by indigenous groups of people from the south of the country. They are to be found in self-built accommodation in some of the areas of the city with least infrastructure (no drainage, no sanitary system or reticulated water supply) on steep slopes. Their counterparts in greater Los Angeles tend also to be minorities, especially undocumented Hispanic immigrants from Mexico, Guatemala, or El Salvador. They live in areas of the city exposed to highest risk from factory emissions and explosions and floods. They also tend to live in overcrowded tenements that are at risk from fire (often arson) if made of wood, and at risk to earthquakes if they are of the older brick construction. In both Mexico City and Los Angeles there are considerable numbers of homeless youths who are at risk to violence, HIV/AIDS, fires in abandoned buildings, as well as to the other natural and industrial hazards to which all marginalized social groups are vulnerable.

Among these more marginal social groups in both urban regions livelihoods and survival strategies depend on informal networks, casual labour under highly exploitative conditions, many kinds of informal economic activities such as street trading, sale of lottery tickets, etc., and mutual aid. There is mistrust of authorities but a high degree of social solidarity within these social groups. Solidarity is often channelled into the efforts of local NGOs to provide services not provided by official municipal agencies, for example the Pico Union/Westlake Cluster (in LA)

and tenants’ association at Tlatelolco or popular education groups, like Los Olvidados.

Given the social and economic heterogeneity within these two huge urban regions, and their long histories, it is not surprising that politics, too, is diverse.

The Hispanics in California account for more than a third of the state’s population, and since 1999 the state’s ‘non-Hispanic whites’ have been a minority group (BBC 2000). More and more Hispanics are also registered to vote. Thus, especially in some parts of greater LA, including the City of Los Angeles (the largest single city, with four million people), there is an opening for collaboration between municipal technocrats and the leadership of neighbourhood based NGOs. The voters of the City of Los Angeles also approved a change in the city charter that mandates a more decentralized and participatory process of setting local priorities in social services, public works, etc. The City of Los Angeles’ Department of Emergency Preparedness hopes to work with these new neighbourhood councils to spread disaster risk awareness, preparedness, and mitigation of risk.

In Mexico City’s Federal District the election of two successive mayors from parties other than the historically dominant PRI has provided support for programmes that reach out to the marginalized population. The Federal District’s office of civil protection has not gone as far as its counterpart in LA in the direction of linking its efforts with those of other local government departments or involving local neighbourhoods. However, in Mexico City there is a longer history of rigid hierarchy and paternalism to overcome. It is also only very recently that the Federal District even had an elected mayor. Until 1995 the Federal District was governed directly by the central government (which is to say the historically hegemonic, once-ruling party, the PRI) through an appointed governor. Despite these handicaps, the Federal District is trying some impressive experiments such as the collaboration with the tenants’ association at the Tlatelolco high rise apartment complex, and its establishment of a dedicated geological survey team within the office of civil protection. Through its efforts the true magnitude of the landslide, flood, and earthquake hazard in the DF are becoming more widely known.

13.4.3 Contrasting Perceptions of Social Vulnerability

Despite these important similarities in the geography of hazard and the sociology of marginality, the UNU

study found quite different definitions or perceptions of who the highly vulnerable social groups were. Table 13.3 summarizes these differences.

Table 13.3: Groups Perceived by Disaster Management Professionals to be Highly Vulnerable to Disasters (per cent of officials). **Source:** Authors’ field work.

Mexico City	Los Angeles
Squatters (67%), especially Living in ravines Living over ancient mines Living near hazardous industries	Elderly persons (100%)
Children (23%)	Disabled persons (93%)
Legal immigrants (16%)	Persons with special medical needs (86%)
Disabled persons (14%)	Mentally ill (54%)
Elderly (14%)	Illegal immigrants (29%)
Homeless (11%)	Foreigners/ foreign-born (29%)
Mentally ill (5%)	Homeless (21%)
Persons with special medical needs (5%)	Street children (14%)
Illegal street vendors (5%)	People living near oil refineries (7%)
Artisanal fireworks producers (5%)	People living near water pumping stations (4%)
Street children (2%)	People living in mobile homes (4%)

Notes: “% officials”: Percentage of 44 disaster management officials interviewed in greater Mexico City and 28 interviewed in greater Los Angeles. “Legal immigrants”: This includes people from the rural areas of the country where indigenous people live. “Foreigners/ foreign-born”: This was said to be mostly to do with lack of knowledge of English.

In Mexico City the more detailed breakdown by age, gender, socio-economic status was generally thought by officials in both the Delegations of the DF and the Municipalities of the *Estado de Mexico* to be an academic luxury of a rich country. While a small number of the respondents did acknowledge that some of these groups face additional risks or additional problems in recovery from disasters, the consensus was different. Most believed that illegal or informal squatters, who most commonly live in ravines, over the ancient mines in some of the surrounding slopes,

were generally vulnerable. They thought that everyone in such a living situation was vulnerable without finer distinctions. The exception to this concerned a more common belief that children needed special protection.

In greater Los Angeles there was nearly universal acknowledgement of the special vulnerability faced by the elderly, disabled persons, children, and people with special, chronic medical needs (e.g. those on oxygen or ventilators at home or those in need of frequent dialysis). The mentally ill or retarded were also recognized in more than half of the interviews with disaster management officials in greater Los Angeles. A smaller, but significant group of municipalities took the legality of immigrant status, language ability of foreigners or the foreign born, and homelessness to create situations in which people can suffer increased vulnerability to disaster.

13.4.4 Similar Approaches to Knowledge and Planning

Despite differences in the way that social vulnerability is defined and understood by municipal disaster managers, their approaches to planning and to the acquisition of information is similar. Table 13.4 summarizes these data.

Both Mexico City officials and their counterparts in greater Los Angeles involve neighbourhood groups and NGOs in the planning process, but more do so in the Mexico megacity. This difference is due in large part to the history of social and political organization the two urban regions. In Mexico there is a long history of political party patronage and clientelism that manifests itself in the form of a variety of local associations and groups. There is also a tradition of opposition and protest in Mexico that gives rise to other groups.

It is striking, however, that despite claims of involvement of citizens in the planning process, very few municipalities in greater Mexico City actually obtain information about socially vulnerable groups from neighbourhood groups (where, of course, the fine grained and detailed information exists).

At the level of the municipal jurisdiction both sets of officials claim a high degree of inter-sectoral cooperation. In part this turns out in practice to be a matter of legal formality - attending the same planning meetings, signing off on the same planning documents. However, more than half in both cases claim to obtain information from other departments in the

Table 13.4: Knowledge of Vulnerable Groups and Planning of Programmes to Reduce Vulnerability In Mexico City and Los Angeles (per cent of officials). **Source:** Authors' field work.

Mexico City	Los Angeles
Involve neighbourhood groups in planning (71%)	Involve neighbourhood groups in planning (50%)
Obtain information from neighbourhood groups (9%)	Information from neighbourhood groups (21%)
Involve NGOs in planning (43%)	Involve NGOs in planning (21%)
Inter-sectoral coordination at the municipal level (91%)	Inter-sectoral coordination at the municipal level (100%)
Information from other government department in municipal government (68%)	Information from other government department in municipal government (61%)
Information from national agencies (30%)	Information from national agencies (14%)
Experience problems using social data (66%)	Experience problems using social data (71%)

Notes: “*Involve neighbourhood groups...*”: Many of these take the form of groups formed around someone who has taken the free 18-hour course made available to citizens called *Citizen Emergency Response Training (CERT)*. The inspiration for this kind of training came from the experience of spontaneous citizen action after the 1985 earthquake in Mexico City, where LA Fire Department chief Frank Borden had gone as an observer. The course included fire suppression, light search and rescue, first aid, transportation of the injured, communication, and team leadership. “*Involve NGOs in planning*”: One of the six municipalities that involve NGOs is the City of Los Angeles, where there is an active network of 70 NGOs with official status in the planning and emergency response system called the *Emergency Network Los Angeles (ENLA)*. There is a great contrast between a city like the City of Los Angeles and its relationship with NGOs through ENLA, and other, much smaller municipalities that have no process for involving NGOs with the exception of the two national, quasi-governmental bodies, the American Red Cross and the Salvation Army. “*Inter-sectoral coordination...*”: Universal claims of coordination are explained by the legal requirement in California to follow what is known as the *Standard Emergency Management System (SEMS)*, which mandates plans, and exercises that involve multiple sectors and mutual aid contingency arrangement among cities and counties. “*Information from national agencies*”: This was most commonly information from the *National Centre for Disaster Prevention (CENAPRED)* or the *National Institute of Statistics, Geography, and Information (INEGI)*.

same municipal government. This sharing of information goes beyond mere formalism.

A most striking result is how few municipalities take advantage of the many publications and electronic information sources made available by their respective national government agencies. In part this is a matter of lack of financial resources and labour time by understaffed, small municipal offices. In part this is a reflection of the background and lack of specific training in social science of most of those who work on disaster management at the municipal level. In greater Mexico City they mostly have engineering backgrounds or some from the construction industry. In greater Los Angeles they come either from careers in law enforcement or from fire fighting. In neither case do the managers find it easy to use social data.

Municipalities generally have the technical (and possibly the financial) resources for meeting the needs of socially vulnerable groups, but they lack detailed information about them and lack their trust. NGOs (and some neighbourhood groups) have more detailed information about socially vulnerable groups and, because of more frequent and positive contacts; they tend to have their trust. Therefore, the overall conclusion of the UNU study is that municipalities and NGOs/neighbourhood groups need to cooperate. They need to share their strengths and make up for one another's weaknesses. However, such cooperation is hard to put into practice.

13.5 Manila and Tokyo: Specific Comparisons

13.5.1 Shared Geographies of Hazard

Manila and Tokyo both have coastal locations, where flooding is a hazard and typhoons are capable of damaging exposed areas. Long histories in both cases of the reclamation and extension of coastal land with land fills and dense urban encroachment on, even paving over, rivers flowing into their respective oceans exacerbate these hazards.

Bankoff (2003a: 11; 2003b) notes that flooding in Manila was a frequent occurrence during the 19th Century, and that since records were kept, there have been serious floods in 1942, 1948, 1966, 1967, 1970, 1972, 1977, 1986, 1988, 1995, 1996, and 1997. Tayag identifies three triggers of flooding in Manila (1999). Low-lying areas are flooded when the major river systems (the Pasig-Marikina Rivers and San Juan River) overflow, especially when accompanied by high tide.

Such flooding can occur when there is excessive rainfall due to typhoons, to the annual Southwest monsoon, or to showers that cause isolated flash flooding. She notes that flooding in greater Manila is aggravated by poor or non-existent drainage, rapid urbanization, low river capacity due to heavy siltation, dumping of refuse into rivers and the encroachment of settlement into flood plains. Water management in Manila is also complicated by over-pumping of ground water and salt-water intrusion from Manila Bay (Rau 1992: 282).

Located in 'Typhoon Alley', the Philippines suffer most from cyclonic storms. Between 1948-1999 its 780 inhabited islands experienced 200 typhoons (Longshore 2000: 260). Greater Manila has been seriously affected by typhoons in 1937, 1956, 1970, 1972, 1983, and 1995.

Secondary health hazards, especially cholera, dengue, malaria, and measles epidemics have been found to be associated with flood disasters (Relox/Perez/Villareal 1997). Another study found that in the greater Manila region between 1984-1988 "hospital admission of dengue fever cases increased 1-and 2-month after the cyclone passages while gastroenteritis, hepatitis, typhoid fever, bronchopneumonia and tetanus admission decreases after the typhoon" (Relox/Arruejo 2002).

Tokyo also has a long flood chronology. In 1910 nearly the whole of central Tokyo was flooded when heavy rainfall in the Chichibu Mountains caused the Arakawa River to burst its banks. Typhoon Catherine in 1947 again caused the Arakawa to overflow, together with the Tone River, and 300,000 people had to be evacuated (see at: <<http://www.ara.or.jp/asc/english/history/history.html>>). The Tone River flooded again in 1981, 1982, and 1983 (Kishii/Kuzuha/Hayano 2002). Oya and Haruyama (1987: 2) list 26 floods affecting the lowlands of greater Tokyo between 1963-1984 alone. Kumagai and Nojima (1999: 67) acknowledge the high flood hazard in greater Tokyo, but they stress that since 1966 there has been massive investment in structural mitigation (embankments, pumping stations, water gates) and no significant flooding in the lowlands. In fact, reliance on such physical works began in 1911 with public works designed to control the Arakawa River (finally finished in 1930). The result has been a westward shift of flooding from the lowlands into more hilly regions of greater Tokyo (as population has grown in these former rural areas). One trigger for flooding in greater Tokyo is cyclonic storm, especially the spring and autumn 'rain typhoons' that bring large amounts

of rain. Tokyo is further north than Manila, and so it experiences typhoons less frequently, perhaps one every two or three years, with a particularly severe storm hitting every five or six years (Longshore 2000: 200). Although the shape of the coast near Tokyo and normal storm tracks make it unlikely that it would receive a direct hit by a typhoon, wind, rain, and storm surges associated with storms that pass nearby have caused millions of dollars of damage over the years, for instance in 1934, 1945, 1961, 1965, 1969, and 1991 (RMS 1999). This, however, is a matter of economic loss and not lives, homes, and livelihoods lost, as in Manila. The most deadly recent typhoon to affect Tokyo was in 2002, when four people died in the worst storm to strike in fifty years (BBC 2002).

The hills and low mountains that rise, in both cases, from behind the coastal plain are prone to landslides, flash flooding, and also produce run-off that must find its way through densely populated urban cores before discharging into the Laguna de Bay or Manila Bay in one case, or into Tokyo Bay in the other. As we have seen earlier, this is also the case in greater Los Angeles.

Both Manila and Tokyo have experienced rapid growth of population and also in the numbers of industrial facilities, including refining and storage of petrochemicals and other potentially hazardous industries capable of causing explosions and chemical spills during floods and earthquakes. In Tokyo, for example, most middle-class and high income residential areas are in higher areas, and the lower zones are devoted to industrial facilities as well as working class housing. This includes a 40 km long corridor along Tokyo Bay and inland along the Tama River where there are steel mills and chemical plants (Kumagai/Nojima 1999: 65). In Manila there is much chemical and other industrial activity mixed with low income housing along the Pasig River. Complex upland topography combines with a complicated pattern of streams in the plains to produce challenges for maintenance of transportation corridors under extreme conditions. There are many bridges and potential choke points in the transportation systems of both megacities. Even under the best of conditions, transportation is congested.

All of these factors become relevant considering the vulnerability of people, livelihoods, and infrastructure to possible earthquake damage. Tokyo's location near the borders of tectonic plates makes it more prone to earthquake than Manila. There is also a greater value of investment in the built environment in Tokyo than in Manila, so the probability of loss – thus

vulnerability – must also be considered higher. On the other hand, mitigation measures are more developed in Tokyo, and the consequences for low income city dwellers in Manila in the event of a major quake would be more severe. In particular, it is less likely that they would be able to restore their livelihoods. The poor have less to lose, but that little is vital to their well-being, and its replacement is more difficult.

Tokyo had at least six major earthquakes since 1615 (Kumagai/Nojima 1999: 66, citing Matsuda 1993). Ten thousand people died in one in 1855, and the Great Kanto earthquake that shook the region in 1923 claimed 140,000. Fire was a major factor in this death toll, and season of the year and wind speed and direction are associated with this additional, secondary hazard (Kumagai/Nojima 1999: 66-67). Since the rebuilding that followed the Second World War much older, flammable construction has disappeared, but the use of natural gas, propane, and petrochemical products has increased in a considerably larger metropolitan area, where crowded areas persist. Despite much planning attention to possible recurrence of a 1923-scale event, especially attention paid to provision of evacuation areas safe from fire, Tokyo still runs a very high risk of serious death, injury, and massive economic loss in such an event (Takahashi 1999, citing Tokyo Metropolitan Government 1998; Hadfield 1991).

Volcanoes tower above both Tokyo and Manila – Mts. Fuji and Pinatubo – although far enough away that the impact of eruptions would be more disruptive than catastrophic, much as ash fall from the volcano Popocatepetl affects the outskirts of Mexico City.

There are five earthquake source zones under or near Manila, including the Marikina Valley Fault that bisects the city. A moderate intensity earthquake affects Manila, on average, every 15 years, and although relatively rare, very heavy damage (VIII or IX on the Modified Mercalli damage scale) may occur with an interval of 79-350 years (Punongbayan/Coburn/Tayag 1993). Given what has already been said about topography and encroachment into low lying areas, liquefaction is one of the major hazards facing Manila residents in the event of an earthquake, together with ground rupture and shaking, fire, chemical spills, and landslides in outlying areas.

In the 1950's and 1960's, during a period of rapid and relatively unregulated industrial growth, Tokyo suffered considerable air and water pollution. Manila still suffers this fate, more through non-enforcement of environmental law than through its lack. A body of

law also exists in the Philippines since the early 1990's that nominally protects the urban poor from arbitrary or forced displacement without due process and sometimes compensation. However, despite the existence of such law, and legal aid NGOs to help the poor take advantage of it, the power of the state to move people out of their established locations is one of the social hazards affecting low income people (Santiago 1998: 117-120).

13.5.2 Contrasting Sociologies of Survival

If patterns of hazard in Tokyo and Manila are similar, coping with and adaptation to hazard could not be more contrasting. First there is the question of poverty. The contrast is greater than between Mexico City and Los Angeles. In Tokyo, there are, of course, perhaps 5,000 homeless people, mostly men. There are low income people, in relative terms, and some groups of illegal immigrants. However, these amount to a very small proportion of Tokyo's population, unlike the underclass and working poor in Los Angeles. In addition, unemployment in Tokyo is lower than the average for Japan, something that cannot be said for Manila in relation to the rest of Philippines.

The Philippine Commission for the Urban Poor estimated that the number of squatters in Manila grew from 1.65 million in 1982 to 3.5 million in 1993 (Tayag 1999: 5). The Asian financial and economic crisis in the years 1997-2000 saw 3.5 million additional people in the Philippines fall below the poverty line, and trends toward poverty reduction were reversed, leaving a national poverty rate near 40 per cent (Raceles 2003). In Manila livelihoods for people living at or below the poverty line depend on casual labour, petty trading, and many dangerous, informal sector activities such as recycling materials from the huge solid waste dump in Quezon City called Payatas (Gonzales 2003; Vanzi 2003; Asian Development Bank 2000; 2002). On 10 July 2000, after torrential typhoon rains, a mountain of garbage collapsed on the self-built homes of recyclers living nearby and more than 200 people died (Mydans 2000), although estimates of the dead and missing go as high as 700-1,000 (Westfall 2001; Luna 2001). Spontaneous, informal, or 'squatter' settlement is the spatial access and shelter strategy essential to the ability of Manila's poor to secure a niche in the urban fabric, even though this means that many people are forced to choose dangerous (contaminated, flood-prone) locations. Low income people in Manila have limited access to some government and NGO social and health services, and

poor access to sanitary infrastructure. Even for those people connected to Manila's distribution system, some 58 per cent of the water is lost (O'Meara 2001: 341).

Neighbourhood networks and mutual aid based on kinship remain - as in rural areas - the main safety net for the poor. By contrast, in Japan, officially provided municipal and other government services are the main welfare umbrella. Although many elderly people still live with their children in Tokyo, even this vestige of familial bonds and filial piety is disappearing as the population lives longer and longer and as the cost of urban accommodation continues to rise. Social service and advocacy NGOs are less common in Tokyo than they are in Manila, where widespread income poverty is, to some extent, balanced by rich social capital. Volunteerism is on the rise in Japan following the spontaneous outpouring of youthful solidarity with the victims of the Kobe earthquake in 1995. There are groups advocating the rights of people living with disability and other special groups, yet the militancy and impact of such groups are less in Tokyo than in Manila (Heijmans/Victoria 2001; Tayag 1999).

Age structure also affects the sociology of survival in these two cities, and again a large contrast is apparent. The population of Japan is old by comparison to that of Manila, and many of these elderly live with disability and ill health and are highly dependent on social services and, to some degree, their families. Dependency is also an issue in Manila, where economic pressure at home is cited as one of the main reasons why some children live on the street (Bacos/Ramirez/Dorado/Velasco/Barba, nd). Approximately one-third of Manila's population is aged 1-14 years (see at: <<http://www.cityofmanila.com.ph/demography.htm>>).

13.5.3 Contrasting Perceptions of Social Vulnerability

The contrast between Manila and Tokyo is similar to that between Mexico City and Los Angeles, only more extreme. Residents of urban informal settlements in Manila were regarded by the majority of the officials interviewed (87 per cent) to be the social group at highest risk (67 per cent shared this view in Mexico City). The elderly and disabled were universally seen as the groups in Tokyo who are most vulnerable. Indeed, a highly nuanced typology of the vulnerable elderly emerged from interviews there in the 23 central wards.

These differences may well mirror the macroeconomic conditions prevailing in the two cities. As in Mexico City, national patterns of poverty give rise to migration to informal settlements in the countries' major economic centres. Urban marginality results, as well, in many homeless children and youth. These were the second most commonly mentioned in Manila.

Reflecting its role as a destination for many legal foreigners with little knowledge of Japanese, such people were considered potentially at risk by 70 per cent of disaster planners in Tokyo. This has more to do with Tokyo's role as a global business and financial centre and less to do with illegal working class immigration, although there are some of the latter who arrive from mainland China, the Philippines, Bangladesh, Iran and North Korea (table 13.5).

13.5.4 Similar Approaches to Knowledge and Planning

Despite considerable economic and political differences between Manila and Tokyo, there is a similar approach to knowledge of disaster vulnerability and planning. Indeed, all four megacities show the same pattern. They all attempt to involve neighbourhood groups in planning. All four also claim high degrees of inter-sectoral coordination and connections with other jurisdictions within the megacities. None of the four cities are particularly good at involving non-governmental organizations in planning. Finally, disaster planners in all had difficulties using social data.

However, there are important differences within these generally similar patterns. Manila and Tokyo were better at the municipal level in acquiring information about vulnerable groups of people from neighbourhood groups (65 per cent and 57 per cent of municipal level respondents saying they did). In Los Angeles only one in five planners could count on this source of information, and a mere 9 per cent in Mexico City.

Another thing in common in Manila and Tokyo was the existence of legally established, strong, and well-financed metropolitan government structures. Their existence explain the high degree of inter-sectoral and inter-city coordination claimed. This was only diminished with Tokyo's wards by the strict interpretation of privacy laws that prevent one department's sharing of social data with another. Neither greater Mexico City nor metro Los Angeles have metropolitan governments, or even informal consortia, that embrace their entire, and very extensive, urban regions.

Table 13.5: Groups Perceived by Disaster Management Professionals to be Highly Vulnerable to Disasters (per cent of officials). **Source:** Authors' field work.

Metro Manila	Central Tokyo
Squatters (87%)	Elderly persons (100%) Bed-ridden elderly (61%) Elderly living alone (48%) Elderly in general (26%) Dementing elderly (13%)
Street children (71%)	Disabled persons (100%)
Elderly (13%)	Legal foreigners (70%)
Disabled persons (7%)	Infants (39%)
Young children (7%)	Persons with special medical needs (35%)
Others (3%)	

Notes: “% officials”: Percentage of 31 disaster management officials interviewed in Metro Manila action officers responsible for disaster planning in the 16 administrative subunits of Metro Manila plus 5 at primary district (*barangay*) level, and 10 in a variety of government commissions; and 23 disaster management officials in the 23 central wards in the case of Tokyo. “Street children”: However, these respondents believed that they were not responsible for dealing with the vulnerability of street children as their welfare falls under the Department of Social Welfare and Development. Five officials believed that street children are too mobile and transient to be the responsibility of any municipal jurisdiction. “Disabled persons”: In the case of Tokyo this included both physical and mental disability. “Legal foreigners”: Officials mentioned only legal non-Japanese residents who may have difficulty understanding Japanese language warnings and instructions. While the growing presence of illegal immigrants, especially among those doing casual labour, was recognized, no official believed that they were a group of vulnerable people for whom special disaster planning should be done. Likewise, the homeless in Tokyo subway stations, in parks, and along the Sumida River were acknowledged to exist, but they “did not count” for planning purposes (Wisner 1998). “Others”: There were single mentions among the 31 officials (3 per cent) of orphans, students living in boarding houses, women (battered, pregnant, or lactating), mentally retarded (due to drug use), persons in flood prone areas.

Finally, Manila and Tokyo municipalities both used information made available by national level institutions such as Philippine's Presidential Commission on Urban Poverty or Japan's National Land Agency. Nothing like such an uptake of nationally-generated infor-

Notes: *"Involve neighbourhood groups in planning"* (Manila): The 1992 Local Government Code specifies that local citizen groups must be represented in special bodies such as health boards, but not all municipalities have managed to involve neighbourhoods in disaster planning. *"Involve neighbourhood groups in planning"* (Tokyo): There is a centuries' long tradition of urban neighbourhood groups based on ceremonial functions and other more practical activities such as fire fighting. Tokyo's neighbourhood fire brigades date back to the 18th Century. However, many groups are merely formal and not active. Fifty-seven per cent of officials expressed concern about the level of participation of citizens at neighbourhood level, and 83 per cent characterized their ward's neighbourhood groups as "formal." Only four wards (17 per cent) said they had very active neighbourhood groups. *"Involve NGOs in planning"* (Manila): Excluding the Philippine National Red Cross, which is present and active in all municipalities and treated as part of government for planning purposes. *"Involve NGOs in planning"* (Tokyo): The Japanese Red Cross was referred to in eight wards (35 per cent), and *Shakai Fukushi Kyougikai*, an umbrella organization to coordinate social welfare organizations dealing with visual impairment, physical disabilities, and mental retardation in seven wards. However, only five wards claimed to have active involvement of NGOs in their plans. *"Inter-sectoral coordination..."* (Manila): Via the Metropolitan Manila Development Authority and its Metro Manila Disaster Coordinating Council. *"Inter-sectoral coordination..."* (Tokyo): Via the Tokyo Metropolitan Council. *"Obtain information from other departments..."* (Tokyo): Strict interpretation of privacy laws in all but three wards meant that there was very little sharing of information about vulnerable groups of people from one department (e.g. that dealing with the elderly, for example, or the disabled) and the department of disaster planning. *"Obtain information from national agencies"* (Manila): Particularly the Presidential Commission on Urban Poverty and the Department of Social Welfare and Development. *"Obtain information from national agencies"* (Tokyo): The Tokyo Metropolitan Council provides many maps and planning materials, as does the National Land Agency.

mation takes place in Mexico City (ironically, since the national premier National Centre for Disaster Preparedness - CENAPRED - is located in Mexico City). Table 13.6 presents the data on sources of knowledge and planning in Manila and Tokyo.

13.6 Common Problems and Obstacles

13.6.1 Difficulties Facing Municipality/ NGO Cooperation

The starting point of this research project was the hypothesis that non-governmental and community-based organizations (NGOs and CBOs) can provide a vital link between highly vulnerable populations and municipal governments. In the ideal world, such groups would have information about and trust rela-

tionships with marginalized groups of people that the city finds it difficult to understand or to approach. Our research partially supports the hypothesis. However the situation appears more complex than we originally believed. There are at least three complicating issues.

First, most NGOs have their own fairly narrow and well-defined agendas and areas of expertise and concern. In part this is a natural result of how NGOs are formed and remain funded. They carve out niches in the urban ecology. Focused concerns might be housing, legal empowerment, women's rights, sanitation, etc. The problem observed is that such groups see disaster management and the process of vulnerability reduction through the prism of their established agenda. In a more general way, Foreman (1998) has noted the narrowness and inflexibility of NGO agendas as both a weakness and a strength (Benson/Twigg/Myers 2001).

There were a few, predictable NGOs whose mandate specifically concerns aspects of risk communication or more general disaster management, such as the Red Cross in all four cities, or *Emergency Network Los Angeles* (ENLA) and the Salvation Army. Ironically, however, these NGOs have been so fully ‘officialized’ and incorporated into the municipal system of disaster management that they do not function as conduits to and from the poorest of the poor and other special needs groups.

In a similar way, we encountered some specialized disaster-oriented CBOs, such as Tokyo’s neighbourhood fire fighting teams, the neighbourhoods in central Mexico City trained by the Association of Retired Fire Fighters,⁵ and the CERTs in Los Angeles mentioned earlier. These suffer, however, from narrowness of mission and, in the case of Los Angeles, a definite class bias. Most of the roughly 20,000 CERT-trained individuals in the City of Los Angeles are white and middle class.

The second complication concerns politics. In a number of interviews the municipal officials believed that NGOs involved themselves in relief and post-disaster recovery work to further their own political ends. They were not trusted and collaboration suffered. From the NGO side, there was as often a history of antagonism with the government. Mistrust from the NGO side could have deep roots and centre around larger societal issues such as human rights and corruption – giving rise to such epochal changes as the electoral loss of Mexico City by the PRI political party or the use of massive ‘people’s power’ non-violent demonstrations to cause Philippine president Estrada to resign. Mistrust could also be focused on feelings of neglect and social exclusion by the communities served by the NGO, as was the case of the Pico Union Cluster near Downtown in Los Angeles. This is a low income residential district populated by Hispanic immigrants, especially from El Salvador and Guatemala, many of them undocumented. The housing stock comprises five and six storey brick tenements and poorly maintained, subdivided wood-frame Victorians that date from an earlier, more affluent period in this districts’ settlement history.

The third complication concerns continuity and capacity building. In numerous cases, NGOs that had

formed spontaneously in response to disasters such as the 1985 earthquake in Mexico City or the Northridge earthquake in greater Los Angeles did not persist beyond the early stages of recovery. If the whole point of developing a ‘culture of prevention’ is to build networks at neighbourhood level capable of ongoing hazard assessment and mitigation at the micro level, preparedness training, and the identification of vulnerable individuals, then the organizational base is weakened or even lost each time ‘emergent’ NGOs rise and fall in response to specific events.

13.6.2 Problems with Municipal Decentralization

Since the hazardscape of megacities is so diverse, planning and implementation needs to take local variations in hazard, vulnerability, capacity (and thus, risk) into account. Efforts are therefore common to build professional planning expertise at various scales – the megacity’s constituent municipalities, and then, moving as close to the neighbourhood as possible. Sometimes this works well, as in some of Manila’s *barangays*, within the Tlatelolco public housing complex in Mexico City, and in West Hollywood, where there is a vigorous, neighbourhood based Disaster Volunteer Corps. In such circumstances local people assess their own vulnerabilities and their own capacities. They know, house by house, who lives there who may have special health or disability related needs, and who has special knowledge (nursing, construction, etc.) and skill. However, this kind of neighbourhood based comprehensive planning is still too rare. There are a number of problems that block effective decentralization.

Lack of formal coordination is a problem. Only Manila and Tokyo have metropolitan authorities mandated to coordinate and to support “city” level planning. In Mexico, there is such an authority at the level of the 18 cities (*Delegaciones*) that constitute the Federal District, but Mexico City spills out into neighbouring Mexican states. Nothing but the federal government is formally mandated to coordinate efforts at mitigation, preparedness, response, and recovery across the whole of the megacity area. The State of California’s SEMS system legally requires mutual aid arrangements among counties and cities, and being so very large, the City of Los Angeles and LA county do often take a leading role in the urban region, but informally.

Even where coordination and support for decentralization does exist, there is often a failure to take

5 This *Asociacion de Bomberos en Retiro* was unknown to municipal authorities, and was unregistered as an NGO, prima facie evidence that it was not the product to client-patron politics so often encountered among nominally independent NGOs in Mexico City.

Table 13.7: Social Capital and Trust Matrix. **Source:** The authors.

Social Capital(SC)	Trust (T)				
	Interpersonal (T1)	HH vs. CBO (T2)	HH vs. Govern-ment (T3)	CBO vs. Govern-ment (T4)	Government vs. Government (T5)
Knowledge (SC1)	Expertise, memory and mobility	Culture and idiom (class and ethnic differences)	Cynicism and mass media, literacy and criticality	Bottom up vs. top down	Centralism, regionalism and distribution of knowledge resources
Solidarity (SC2)	Duration, contingency and strength	Inclusiveness or exclusiveness (divisiveness?)	Delivery and training	Accountability, delivery, media-tion and control	Electoral manipulation, Ethnic politics
Access (SC3)	Intra-household (e.g. gender) distribution and access	Capture and co-optation; Delivery and transparency	Personal experi-ence, oral History and myths	Credibility and legitimation, organizational culture; Brokers and champions	Mediation and bureaucracy vs. direct networking

full advantage of opportunities. There is great variation among Tokyo’s 23 central wards (cities) and among Metro Manila’s cities in their ability to plan and to conduct outreach to vulnerable groups. The same is true of Mexico City and Los Angeles. In Los Angeles, small, municipalities with little tax base and a poor, often illegal immigrant population are hardly able to maintain essential services let alone conduct sophisticated vulnerability and capacity assessment. Examples are the city of Vernon (Davis 2000a: 191-204) and the city of Compton (Davis 2000a: 137-142).

The most commonly cited constraints cited in the UNU study interviews with municipal level officers were lack of training and lack of resources. Across the four megacities, most of the officers interviewed come from either an engineering background (or the construction industry) or police (or fire fighting). It is rare to find someone with a background in social science, thus the integration of social and physical data in risk analysis does not come naturally to these personnel. They need more training and support. This, however, costs money, and the resource constraint was often mentioned, even in the two more affluent megacities, Los Angeles and Tokyo.

13.6.3 Overview of Issues: On Trust and the Notion of Social Capital

In table 13.7 above we have summarized the key issues that emerge from the cases we have investigated. These are the factors that come into play as five sorts of trust (or its absence) affect the ability to mobilize

and utilize the three kinds of social capital - knowledge, solidarity, and access.

From left to right one finds interpersonal trust, trust between households (HH) and community based organizations (HH vs. CBO), trust between households and government at various levels (HH vs. Government), trust between CBOs and government, and, finally, trust among various branches and levels of government. All these manifestations of trust and distrust influence whether social capital remains hidden or latent or is mobilized and becomes active (Barnes 2002; Beck 1992; Beck/Giddens/Lash 1994; Bujra 2000).

History and memory are playing a major role in determining these trust relations. For example, a long history of racism and police brutality in Los Angeles provides the historical background to suspicion between minority households, especially those with members who are illegal immigrants, and government, and it is a major factor that CBOs need to take into consideration (Davis 1990; 2000b). In turn, such CBOs walk a tightrope in order to maintain their credibility with local government and such household constituents.

13.7 Conclusions

If the municipalities in our study of four megacities are at all typical for the Pacific Rim (we think they are⁶), then urban social vulnerability remains a serious problem as yet insufficiently faced by municipal, metropolitan, or other higher levels of government. Among the problems documented are:

- Fragmented and uncoordinated responsibility for different at risk groups;
- Legal barriers to access to social data;
- Staffing shortage and lack of training in use of available social data resulting in little use of existing sources;
- Limited or ritualistic use of community or neighbourhood groups;
- Limited or sometimes no planning at municipal level for longer term recovery issues;
- Political hostility toward NGOs;
- Funding shortages and high turnover in NGO staff.

The last three of these problems are very common and block the effective use of social capital to reduce risk. Socially vulnerable and marginal groups of people in cities have needs but also capacities. Their local knowledge and coping as well as their needs can be communicated to government agencies through NGOs and CBOs. City agencies have systems of risk reduction that may be of benefit to socially vulnerable groups of people. Here again, it is the bridge, mediation, or interface provided by organs of civil society that can provide access to official risk reduction.

On the positive side, however, we have observed the following:

- Innovative use of existing neighbourhood groups for preparedness or even for hazard and vulnerability mapping; in other words, it *can* be done!;
- Cases of excellent coordination between municipality and NGOs;
- Improvements in risk communication and increased sensitivity on the part of some municipalities to the needs of foreigners, both legal and illegal;
- The exponential growth of CBOs and NGOs during the decades of the 1980's and 1990's, therefore producing a basis - with all the pros, cons and difficulties mentioned earlier - for much deeper and systematic relations between cities and civil society.

Our main conclusion, therefore, is that the social basis for disaster-resilient cities is continued generalized capacity building across the whole of these heterogeneous populations (Eade 1998). Revitalized democratic participation in the governance of cities, better

education systems, employment generation, broader inclusion of women, minorities, and youth all contribute. This may sound like too sweeping a generalization. However, it is no more general than the oft quoted saying that 'earthquakes don't kill people, buildings do' (Bendimerad/Wenzel/Green/Wisner 1999). On the social side, one could say, "governments can't ensure safety unless the people demand it" (Wisner 1995, 2004).

6 For comparative purposes see: Mitchell 1999; IFRC 1998; IDNDR 1996: U.N. Centre for Human Settlement 1996; Parker/Mitchell 1995; Fuchs/Brennan/Chamie/Lo/Uitto 1994; Stren/White/Whitney 1992.

14 Policy Dimensions of Human Security and Vulnerability Challenges. The Case of Urban India

Isabelle Milbert

14.1 Introduction

Cities are now commonly labelled as vulnerable, violent, conflict-prone (Grunewald/Levron 2004) and the list of threats to city dwellers' security is longer every day. Urban insecurity often appears to be linked to economic and social inequalities, gender imbalance, new forms of violence, and political fragility (Wisner 1999; Moser/Rodgers 2005). Environmental disasters are hitting them badly and more frequently (Mitchell 1999; UN/ISDR 2004), not to forget the impact of different types of more pernicious environmental damages in the long term (Satterthwaite 1998).

However, in periods of crisis, cities are also considered by many people as a refuge from drought, floods, or from loss of traditional rural livelihoods. Many environmental hazards result in refugees landing in cities' peripheries and public spaces (see e.g. the role of Kolkata during floods in the Ganges valley). Urban centres often function as safe places in conflicts (Grunewald/Levron 2004). People perceive them as a place where it is at least possible to survive, and where international or national aid is accessible, contrary to remote rural areas.

Therefore, the question is to assess the place of urban centres in the human security debate. Bogardi and Brauch (2005) argued that human security should rest on three conceptual pillars:

- 'freedom from want' by reducing societal vulnerability through poverty eradication programmes (UNDP 1994; CHS 2003);
- 'freedom from hazard impact' by reducing vulnerability and enhancing coping capabilities of societies confronted with natural and human-induced hazards (UNU-EHS 2004); and
- 'freedom from fear' by reducing the probability that hazards may pose a survival dilemma for the people most affected by extreme weather events (UNESCO, HSN) (Brauch 2005: 23).

However, this objective of security is challenged by the extreme vulnerability of a good part (often a majority) of the city's population. The objective of this chapter is to understand how the concepts of security, vulnerability, and resilience interact in the building of public policies, and how some policies aiming at security building may eventually result in endangering even more the most vulnerable population.

This chapter will not cover cities in conflict and their vulnerability to terrorism (Light 2002). It rather concentrates on Indian cities, which appear relatively 'at peace', and on the issues of urban dwellers' security and vulnerability in their interaction with different stakeholders.

The case of India appears particularly heuristic: public policies are democratically elaborated, and security concerns are discussed in a context where no open national or international conflict is declared. The magnitude of the urban poverty issue is certainly a specific character of Indian cities, where 20 to 50 per cent of the population lives in slums (Kundu 2006; Baud/Dhanalakshmi 2007), and where problems related to gangs, violence, and personal safety develop distinctly from Latin American or African cities (Rodgers 2004a).

14.2 The Essential Vulnerability of the Indian Urban Space

Is it possible to define Indian urban centres and population as vulnerable? Nathan (chap. 87) points to the dual characteristics of vulnerability:

on the one side, (...) a tendency to undergo damages, i.e. a state of fragility, or a set of conditions, that raise the susceptibility of a community to the impact of a damaging phenomenon. On the other side, vulnerability is an incapacity to anticipate, cope with, resist to, adapt to and recover from hazards. Vulnerable units are either not resistant, i.e. not capable to withstand the shock (without adapting); and/or not resilient, i.e. not capable

to absorb the shock and adapt to come back to an acceptable state.

Only 27.8 per cent of the total population of India lives in cities (Census of India, 2001). Some of them are among the largest metropolises in the world, in particular Mumbai (16.3 million), Kolkata (13.2 million), and Delhi (12.8 million). In 2001, 36 cities had more than one million inhabitants. From 1991 to 2001, the decennial growth of Bangalore was 37.7 per cent. Delhi grew by 52 per cent, and Surat (2.8 million) registered the highest growth with 85 per cent during the same period of time. 6 to 7 million persons are added annually to the urban population.

A close look at statistics and city environmental situation is disquieting: for instance, 70 per cent of Greater Mumbai area is flood prone, and 75 per cent of the population live in these neighbourhoods (Kapoor 2005: 97). Also these cities appear increasingly vulnerable to industrial and natural disasters, as demonstrated in the industrial disaster in Bhopal (1983), the Ahmedabad earthquake (2001), the tsunami in Chennai (January 2005), and the Mumbai floods (July 2005). A city like Jamnagar in Gujarat, which is a prosperous centre surrounded by petrochemical industry, still has more than 40 per cent of its population living below the poverty line. These cities combine multiple vulnerabilities. Gujarat had barely overcome a drought in 1995 when it was hit by a cyclone in 1998, followed by the earthquake in 2001, and the Hindu - Muslim riots in 2002 (Kapoor 2005: 25).

Risk and vulnerability structure and organize the fragmentation of Indian cities. Safe areas, generally speaking, are bought and built by the organized sector, in line with municipal rules. A number of areas considered as environmentally unsafe, which are not allowed construction, are actually appropriated, and built on by the informal sector. Therefore, to ensure environmental security in informal areas can often be considered as a lost battle. And to wish to rehouse the low income population in safer zones does not correspond to the actual pressures on land and speculation. There is a constant risk that poor urban dwellers would be pushed away, year after year, towards peripheral, ill-serviced and marginal areas (see the debate on Delhi in Dupont/Ramanathan 2007). The cumulative characteristics of vulnerability defined by Nathan (chap. 87 below) become evident: people build slums because of their socio-economical weakness, which prevents them from accessing the formal market; most slums are built on areas with a physical drawback (flood prone, steep slope, under electric wires, along railway lines or highways...), making them

incapable to mitigate a risk or to recover from the impact of a hazard. Their organizational, political, and legal vulnerability is also intrinsically linked to their informal (and thus illegal) status. Technical vulnerability results from the impossibility of using most knowledge or techniques, for financial or political reasons. Psychological, cultural, and organizational vulnerability creates inadequate security paradigms.

Human exposure to anthropogenic and natural hazards is strongly correlated to the economic and social status of the considered urban population. The environmental fragility of many cities is actually quite distinct from one neighbourhood to the other. In some parts of the city, which are well built according to the security standards and rules, a disaster will provoke only financial and material losses. While in the poor areas, a disaster provokes many fatalities, many injured, and the loss of non-insured livelihood assets which are huge if compared to people's earnings, and are not even measurable. The incidence of disasters on city dwellers therefore depends on their socio-economic status, which conditions their neighbourhood, their habitat quality, and their relationship to power. In India, the tendency has been to concentrate investment and management efforts on those parts of the cities which are obviously engines of modernity and economic growth.

Numerous studies have demonstrated the vulnerability of slum dwellers, in terms of exposure to communicable diseases, malnutrition, waterborne diseases, mental health (Parkar/Fernandes/Weiss 2003), and exposure to environmental hazards (Lavigne/Milbert 1983). The informal settlements made of recycled material has been often described (Saglio-Yatzimirsky 2002) and the innovative methodology of mapping lack of services and informal land use has enabled to draw a "mapping of poverty" (Baud/Pfeffer/Sridharan/Nainan 2007). However, much information on the most vulnerable is still missing, concerning for instance, street children or women.

14.3 Security Policies and Human Vulnerability in the Urban Space

Security can be considered as a common good (Gabbas/Hugon 2001). To grant security to all citizens of the national territory is the main justification of the state. This applies to the Westphalian state, and the traditional definition of security, but also to the 'welfare state' and to the very wide definition of human

security elaborated in the Human Development Report (UNDP 1994).

The coordination and implementation of public policies should counter individual vulnerability and facilitate the combination of different factors contributing to improved security. Their long-term purpose is, in theory, to ensure the achievement of this essential common good. This could be achieved through the definition of socio-economic rights, through the implementation of law and order, and eventually through social, economic and urban policies, contributing to the emergence of a welfare state. In developing countries, the failure to build a welfare state has undermined the state as the guarantor of security and strengthened other stakeholders, especially international organizations, municipal bodies, and social movements.

To overcome fragmentation which has placed some urban neighbourhoods on Western standards while others are more vulnerable than even remote rural areas, some authors have focused on vulnerability assessments at the local scale thorough the use of specific indicators aiming at measuring vulnerability at the community scale. For instance, Hahn (2003) suggested several indicators to assess the four types of vulnerability factors proposed by UN/ISDR at the municipal level: physical and demographic as well as social, economic, and environmental vulnerability (Villagran de Leon 2006: 44).

A number of measures have also been proposed to assess the vulnerabilities of cities and neighbourhoods, such as physical vulnerability, using a combination of indicators related to the state of houses, geomorphology, and services. Using census data and GIS systems permits to map and compare communities inside the same geographical region, and even to map some specific components of vulnerability, such as poverty.

14.4 Differential Approaches to Urban Vulnerability and Search for Security

Indian cities are confronted with multiple specific vulnerabilities, or a 'cumulative vulnerability', in the social, physical, infrastructural, and political field. City dwellers are extremely conscious of the difference set by A. Lavell (2004) between two levels of vulnerability: exceptional vulnerability associated with exceptional events, and everyday vulnerability associated with permanent conditions of poor people (health problems, malnutrition, unemployment, income defi-

cits, illiteracy, social and domestic violence, alcoholism, etc...) which limit their development. In urban India, the main problem is that everyday vulnerability is so great and varied, and the social risks faced by most urban dwellers are so numerous and crucial, that there is little social demand for tackling the industrial and natural hazards. Technically measurable risks related to infrastructure, and industrial and natural hazards are considered as a second priority by the population.

14.4.1 Vulnerability, Security and Infrastructure

High population density and the low quality and unequal distribution of infrastructure services are direct causes for many disasters, whether 'low intensity disasters' (cholera, dengue fever...), or brutal eruptions (plague in Surat, floods in Mumbai).

Data on water and sanitation services indicate considerable state-wide variations in Indian cities. There is a strong negative correlation between access to piped water and sanitation, and the state per capita income. For instance, private water taps are available to less than one third of the urban population in Kerala, Bihar, and Orissa. In Bihar and Madhya Pradesh, more than 45 per cent of the urban population has no access to any type of latrine, while this is the case for 15 per cent of the population in Maharashtra (Zerah 2007: 130-131). Sewerage is virtually non existent in Bihar, Madhya Pradesh, Orissa, and Assam (in the North-East and among the poorest and the least urbanized states). The most urbanized and richest states fare better but are still under 50 per cent of serviced dwellings, and the national average is only 22.5 per cent (Zerah 2007: 132). The level of basic amenities decreases with the size of urban agglomerations.

Though there are important improvements in basic amenities such as electricity, water supply, road paving and access to telecom services, the quality of many of them has been declining: "increasing coverage in infrastructure [that] is not matched by improvement in the service level." (Savage/Dasgupta 2007: 50). 90 per cent of the urban water supplied is polluted (CPCB 2000). "Of the total wastewater generated in the metropolitan cities, barely 30% is treated before disposal. Untreated water finds its way into water systems such as rivers, lakes, groundwater and coastal waters" (3iNetwork 2007: 209). Only 72 per cent of solid waste generated by urban areas are collected daily, which leads to increased pollution in public spaces (CPCB 2000).

Infrastructure hazards are concentrated at the interface between the formal and informal part of metropolises. Illegal electricity connections create a high risk, since they are prone to fall on the slum huts connected to them. Water delivery by trucks or even by individual vendors is a common sight in cities such as Chennai, especially in the peripheries. Not only is this water service very expensive (around 10 times costlier than tap water), it also increases the contamination hazard. The health hazard increases even more when a number of slum dwellers end up digging the soil in order to draw their own water with hand pumps. In Delhi, these hand pumps are often distributed as a reward during election campaigns, without any consideration of the fact that groundwater in the city is highly polluted.

Slum dwellers are extremely conscious of the risk involved in utilizing this deficient infrastructure, and they know how much and which way it impacts negatively on their health. But they have no alternative for a living place enabling them to have access to the work market (Milbert 2006).

One of the main infrastructure threats to security in India is linked to road management and traffic, and it is one of the least mentioned by population and officials. In India, the total number of road accidents has gone up significantly from 114,000 in 1970 to 394,000 in 2001 and fatalities have risen from 14,500 to 80,000 per year. The 7 largest metropolitan cities in India (Mumbai, Kolkata, Delhi, Ahmedabad, Bangalore, Hyderabad and Chennai), representing 6.5 per cent of the Indian population, witnessed 16.9 per cent of the total accidents in 2001, 6 per cent of the fatalities and 8.9 per cent of all injuries (Valli 2005: 59). A recent World Bank study shows that the greatest percentage increase in traffic deaths between 2000 and 2020 will occur in South Asia (144 per cent increase), while traffic deaths should decline by around 30 per cent in high income countries¹ (Kopits/Cropper 2003: 30).

14.4.2 Vulnerability and Industrial Activities

The *Union Carbide India Limited* (UCIL) pesticide plant accident in Bhopal in December 1984 has become a symbol of the inefficiency of these regulations, of the collusion of the public and private stake-

holders in relation to risk management, and of the accumulation of carelessness leading to disaster. The decline of the security budget of the plant contributed to the lack of maintenance and workers' security within the premises. Subsequent litigation has shown the superficial character of security controls, combined with the shortcomings of the plant management itself. Public authorities did not properly implement the regulations on industrial pollution controls.²

Officially, 7,000 people died in the following days. Over the last 20 years at least 15,000 more people have died from illnesses related to the gas exposure. Today more than 100,000 people continue to suffer chronic and debilitating illnesses for which treatment is largely ineffective. Again, the victims are the slum dwellers who had built their huts close to the factory, thus forming a large slum around the plant. These neighbouring residents had repeatedly complained that they were suffering from gas leakages, but public authorities had ignored the claims by people who were squatting on the land. Subsequently, after the disaster took place,

the payment of compensation to victims did not ... begin until 1992 and involved numerous problems, including payment of inadequate sums, delayed payments, arbitrary rejection or downgrading of claims. ... The social and economic rehabilitation measures have been poorly implemented and have failed to lessen the impoverishment of already economically vulnerable survivors. Those orphaned and widowed by the gas leak are in a particularly precarious condition.³

India has also developed some particularly hazardous activities. For instance, it is one of the major countries in the ship-breaking industry. It is estimated that this activity produces around 4000 tons of solid and hazardous wastes per annum, which are disposed of on seashores (3iNetwork 2007: 220).

Many Western engineers still complain of the disrespect for security rules and the disinterest for security, comforted by strict hierarchies implying lack of concern for the lowest categories of personnel, even

1 These results are displayed according to the World Bank regional classifications. The global estimate of road traffic fatalities in 2000 is 723,439 (Kopits/Cropper 2003: 35).

2 For background information see: "What happened in Bhopal?", in: *The Bhopal Medical Appeal and Sambhavana Trust*, at: <<http://www.bhopal.org/whathappened.html>>; and the official view of Union Carbide: "Bhopal Information Center"; at: <<http://www.bhopal.com/>>.

3 Amnesty International, ASA 20/005/2005, "Union Carbide Corporation (UCC), DOW Chemicals and the Bhopal Communities in India - The case" (21 January 2005); at: <<http://www.amnesty.org/en/report/info/ASA20/005/2005>>: 2 (1 April 2006).

in the most modern industrial complexes. However, the Bhopal-type disaster has not occurred again. In recent years, experts have noted a change in the social control of accidents in the corporate sector. It seems that safety is becoming an official objective and an indicator of good management, in the same way as the respect of costs, time, and quality. Especially in large building sites, the biggest developers in the construction industry are now getting organized, moving towards a better attention given to the safety of workers on building sites and roads.⁴

Several laws⁵ and urban planning regulations have been formulated to protect the population against hazardous industries. However, their implementation has been lacking. First, as underlined by Lagadec (1981: 578), “law is posterior to events” in the field of industrial risk management. The expert knowledge is neither transmitted to the political level nor to the municipal level, where the implementation is due to take place. Therefore, the authorities in charge of implementing the law are not aware of the implications of changing the practices, and many regulations remain unimplemented.

A second point is the lack of information on these regulations, in particular information for the population. This applies even more to people working in the informal sector. Information is not disseminated, neither on safety regulations (which would be costly to respect), nor on the threats (to avoid a panic among the population). In the immediate periphery of chemical industrial complexes (for instance, in the peri-urban area of Mumbai), toxic fuels run down the lanes where children are playing, between two rows of barracks, dwellings, and informal workshops. In many industries such as the coir industry, toxic products are manipulated with bare hands. In March 2006, in one of Mumbai’s most exclusive locations (Breach Candy), some street vendors were pictured selling fruit and vegetable from containers which had been used for thorium storage. The combination of indifference to security, maintenance, and the persistence of informal sector practices still provokes incredible deficiencies in the security chain.

An education on industrial risks has a cost and necessitates a political impulse, an involvement of the private sector and mediators such as NGOs. “Population cannot be educated through the promulgation of legal regulations, but only through concrete examples” (Lagadec 1981: 588).

14.4.3 Risks Related to Natural Hazards

Indian cities are extremely fragile environmentally: floods in Mumbai and Kolkata, drought in Delhi, tsunami in Chennai, and earthquake in Ahmedabad are but a few recent examples. The natural hazards impact is considerably aggravated by the lack of preparedness of city management and by the fact that they are additional risks.

For instance, in July 2005, heavy rain in Mumbai combined with the very fragile topography of the city⁶ and with the mishandling of tons of solid waste, provoked the flooding of the Mithi River and cut off all major communications within hours. About 6.5 million commuters were trapped in the southern part of the city. Many lives were saved thanks to the courage and solidarity of ordinary citizens. Power was not restored for several days (up to two weeks in some areas). During the first four days after the flood, very few police officers or civic employees were seen in the major flooded areas (Whitehead 2005: 18). Mumbai planners then discovered that they did not even have an evacuation plan, in a city where some neighbourhoods have the highest density in the world. The management of sewer and storm water drainage remains poor. In March 2006, nine months after the disaster, practical prevention measures were still at a preliminary stage. Contrary to municipal regulations, lorries were still using the banks of the river for unloading construction waste, thus contributing to water clogging.

The aggravation of the consequences of floods, landslides, and earthquakes is directly related to the way the urban territory is appropriated by the poorest. Population density, urban growth, and informal buildings have a direct impact on the physical vulnerability and on the ecological niche. Squatters ‘take the risk’ of building on flood-prone land (Mumbai, Kolkata), for the same reasons as they do on sloping areas in La Paz, Quito or Rio de Janeiro. Many huts are built in high risk-prone areas such as roadsides or rail-

4 Interview of Professor Koshi Varghese, IITM, Chennai, January 25TH, 2006

5 See in particular the Dangerous Machines (Regulation) Act, 1983, the Environment (Protection) Act, 1986, the Air (Prevention and Control of Pollution) Amendment Act, 1987, the Central Industrial Security Force (Amendment and Validation) Act, 1999, the Disaster Management Act, 2005.

6 Mumbai is built on reclaimed land as the site was originally made of 7 distinct islands.

way lines (Mumbai), engendering terrible accidents where many lives are lost.

If a neighbourhood is officially labelled as risk-prone, this reinforces the risk that the authorities may destroy the dwellings and clear the area at any moment. It is not sure that the affected families will be relocated, since they often cannot prove how long they have lived there, they belong to the informal sector and have built their houses without permit. “Environmental solutions being offered have an inherent anti-poor bias” (Kabra 2000: 82). Therefore, urban dwellers living in dangerous areas remain quiet and avoid complaining about the degradation of their environment, because they have integrated the official point of view that they have no right to be there.⁷

14.4.4 Overwhelming Social Vulnerability

Social and economic vulnerabilities are so evident and immediate for low income city dwellers that it minimizes the perceptions of other types of vulnerability. Poverty and insecure employment come first, and give way to impressive inequalities inside city boundaries. These inequalities are translated in space by the presence of squatter settlements and slums. In Mumbai, around 50 per cent of the population now live in slums (Landy 2007). The fact that their municipal authorities have launched large programmes of slum destruction only adds to the precarious state of these inhabitants (Milbert 2006).

Unemployment is the biggest risk. The informal sector enables millions of people, especially the youth, to find work in the context of the limited recruitment by the organized sector. In the light of adverse social conditions and in the absence of state provisions, the informal sector can devise *coping strategies* in order to survive, which are based within the family, the community, and social networks (Green 2005: 72; Lautier 2000). The growth of the informal sector may be regarded as a way out of the misery (Milbert 2002), but it keeps people in an insecure livelihood with low salaries, uncertainty of work and competition, and it keeps them out of the formal political negotiating tables. Thus “their needs and liveli-

hood constraints are not taken into consideration when city policies are made” (IFRCRCS 2004: 150). The weight of the informal sector explains partly the uncontrolled drifting of many public policies at the stage of implementation.

Interpersonal violence figures are well below the Latin American figures, which are plagued by statistics on crime, drug trafficking, and gangs (Rodgers 2004b). The Indian statistics on urban violence have been depending in the past on other variables such as ethnic and communal (inter-religious) violence. According to Varshney (2002), differences in ethnic violence between Indian cities, their brutal eruption followed by years of relative peace explains that urban homicide rates in South Asia may vary widely in time and space (see Mumbai after the 1991–1992 riots, Ahmedabad after the 2002 riots). The perception of these vulnerabilities may be on the way to change in Indian metropolises. For a long time, crime and delinquency, which have become crucial socio-political issues in European and Latin American cities, were not perceived as such in Indian cities, where traditional solidarity is still very present. However, a number of categories see their vulnerability increase considerably when they are no more in a position to rely on their village, caste or family ties.

A growing concern for interpersonal violence and criminality is empirically observed, whether in rich or poor areas. It leads to new housing strategies, like gating and guarding (Thieme 2006) in the middle class, while the poor are much more helpless in the face of a rise of interpersonal violence. Night assaults, women and children trafficking, and numerous cases of women molested are reported, in particular in Northern Indian cities. The responsibility or complicity of some individuals belonging to the police has sometimes led to court cases. Among the most vulnerable to these forms of violence are those living with a physical or mental handicap (Parkar/Fernandes/Weiss 2003).

To develop policies supporting human security in such a context represents the most difficult challenge. It would imply a global societal vision, a perfectly efficient planning, a faultless management and an inclusive approach, going beyond traditional social cleavages. In front of deficiencies, some stakeholders are tempted to create gated communities, or privately organized walled cities eliminating the informal sector, its vulnerabilities and risks. This option is considered by many as a non democratic temptation, but is developing rapidly in the periphery of large cities.

7 In other places where the right to shelter is more recognized, such as in Peru or Bolivia, urban dwellers whose houses are at immediate risk also tend to hide it, since exposing it to the public would provoke an immediate fall in their house value, and second because they also might be expelled from their house by the municipality in the name of security (Milbert/Nathan 2005: 12).

Eventually, people fear less natural or man-made, infrastructural or industrial disasters, which are an exceptional event than risks related to livelihoods, social cohesion and essential needs, which are daily risks and concern all family members. In case of disaster, there is hope that the community (local, national, international) might react in a solidarity move, while the management of the 'ordinary' daily vulnerability (access to food, to shelter) has to be coped with in solitude, and often with disdain from the rest of city dwellers. For instance, after the December 2004 tsunami, some NGOs in Chennai were establishing a distinction between the refugees, victims of the tsunami, entitled to aid, food and shelter, and the 'ordinary poor' who tried to access the relief centres.

14.5 The Governance Dimension of the Security Challenge

Globalization is accompanied by a deep transformation of the modalities of power exercise (Milbert 2007), through fragmentation of decision-making, negotiations with stakeholders, cooperative action, and multiplying networks of formal and informal actors (Commission on Global Governance 1995: 4). The question is to know if these new modalities, described under the concept of governance, and apparently improving communication between technical, political and citizens' networks, are favourable to the building of human security.

The Indian political framework has followed the same evolution towards governance. Security matters are still very much at the core of the central government's functions as far as international security, and innovative legislation and regulations are concerned. However, states are also prime stakeholders in legislating and implementing regulations, and decentralization has put a lot of responsibilities in the hands of municipal bodies. International stakeholders are playing an important role in the dissemination of norms and techniques, in coordination with a multitude of new stakeholders such as researchers, consultants and NGOs, all linked together by a number of informal channels. The corporate sector, in relation with these think tanks, is also participating in the elaboration of new internal security rules. Examining governance issues implies to take into consideration some newcomers who are most often quoted as bearers of progress, before looking at the evolution of the implementation of public policies.

14.5.1 International Cooperation and Urban Security

International cooperation agencies have been extremely cautious in their involvement in the urban sector, especially after the Habitat II UN Conference in 1996. The necessity of huge investments, the complexity of urban problems, and the weak visibility of the results are certainly part of the explanation. The Development Banks (World Bank, Asian Development Bank, and Inter American Development Bank) have launched the most important urban projects (Milbert 1999), and to this day they are the most important fund providers in the struggle against urban poverty, including in the field of slum rehabilitation, infrastructure for the poor, and urban and rural employment programmes.

Setting up norms is considered as one of the core tasks of these international bodies. These norms, which would be valid anywhere in the world, are considered as a key element of urban management and of the construction of risk mitigation and resilience. They rely on high level technical expertise and renowned examples, are made easily accessible and widely disseminated (Milbert/Nathan 2005: 15). They propose a number of principles in relation with infrastructure, industrial techniques, land use, pollution, housing construction, and also in the field of inter-institutional coordination and people's participation (see e.g. the Cities Alliance frameworks). Including in the field of human security and social vulnerability in slums, they have brought ideas for strategies to implement recommendations of the IFRC-RCS (2004: 157): "understand what slum dwellers perceive as disasters; explore barriers that constrain people from coping; link measures supporting resilience to income generation; improve relations between municipalities and slum dwellers."

However, these norms that have been adopted internationally often appear unrealistic as they ignore the structure of power and they do not take into account the importance of the informal sector, developing out of the scope of national and international regulations. When most of a city is built without building permits and on non-constructible land, it is nearly impossible to have international norms being implemented.

Most bilateral and UN agencies have shown immediate concern with the theme of disaster mitigation and prevention. The international organizations' preoccupation for these themes is understandable: a number of disasters are naturally falling under their

competence since they ignore borders, whether we consider their origin, their scope or their impact. UNCHS, UNDP, UN/ISDR, WHO, ICRC, and the World Bank and many others (Milbert/Nathan 2005) have developed information systems, planning methods, prevention strategies, and intervention strategies. UNOPS and CRID are good examples of international institutions aiming at developing sophisticated technological tools of simple use, enabling the concerned stakeholders such as municipal authorities to use them in order to build their own interventions.

A lot of international funding has concentrated on disaster management, post-disaster reconstruction and disaster prevention. This introduces several biases. It focuses attention on 'internationally visible' disasters, while thousands of 'small' disasters remain 'silent' and 'slow' (see for instance malaria or lung diseases in Indian cities) and 'local', depending on the number of fatalities and the media coverage: for instance, an encephalitis epidemic is not going to be discussed in the same way in a tourist spot or in a remote area. Also, it seems that some authorities and sometimes even slum dwellers have been relying on the potential of international aid if the risk was to materialize in disasters. Thus the threat perception among the population diminishes, encouraging old habits of neglecting environmental hazards and staying on in an informal habitat in risk prone areas.

14.5.2 The New Role of Decentralized Stakeholders

Since the 19th century, Indian urban local bodies have found themselves in an awkward position: in some cases, they have been only a relay in a vertical political, and administrative hierarchy (see for instance the numerous years without municipal elections in Uttar Pradesh), while in some others, local democracy has functioned (see the case of Kerala, West Bengal or Mumbai). The 74th Constitutional Amendment (1992) aimed at strengthening urban local bodies. It restored democracy and local finance, and transferred to them a number of functions directly related to human security. However, there has been no uniformity in the devolution of functions to urban local bodies across the different states of India, and this is particularly true in the case of urban poverty alleviation. For instance, in Gujarat, the institutions dealing with urban poverty remain dispersed in a number of state-level departments. This lack of clarity is quite detrimental to the efficiency on the field.

Decentralization of responsibilities without adequate financial support and capacity building can also be an additional cause of vulnerability. Many Indian municipal bodies, including fast-growing municipalities, find themselves today in a situation where some of the devolved functions are difficult to implement, for lack of professionally trained staff (see Wisner 2001: 264).⁸ From one city to another, the approach to the management of squatter and slum areas varies widely.

In the contemporary context of decentralization and multiplication of stakeholders in city management (Le Galès 1995), the responsibility and proximity of urban local bodies to city dwellers would imply that they guarantee action, information, and participation at all moments, including during a crisis. However, research conducted in India (Kapoor 2005: 221) demonstrates how deep the mistrust of city dwellers is towards state and municipal authorities as far as security building and risk management is concerned. Numerous testimonies have shown how these institutions proved inefficient and unconcerned in the 1994 Surat plague crisis (Shah 1997) as well as during the August 2005 Mumbai floods. "The urban municipal bodies (...) are cash trapped and riddled with political interference" (Kabra 2000: 82).

Decentralization policies have eventually created considerable differences between cities and have reinforced the role of individuals. In the case of Surat (Gujarat), the plague epidemic in 1994 came as a symbolic and practical consequence of years of mismanagement of the sanitation system. Shah (1997: 610) described a city "plagued" by a chronically sick, corrupt and disinterested administration, which demonstrated its incapacity including at the moment the epidemic broke out. But this crisis worked as a catalyst. Under the leadership of a new municipal commissioner, a number of measures were taken: road widening schemes were initiated, as well as improvements in sanitation, slum rehabilitation, and paving. Toilets were installed and garbage collection doubled. Efforts are being made to address public hygiene, and the population has been active in maintaining their neighbourhoods clean. In the aftermath of the plague, Surat gained the status of the second cleanest city in In-

8 Wisner shows that in the case of the 2001 El Salvador earthquake, only a handful of the country's 264 municipal governments had any professionally trained staff, and that the national government had no wish at all to support municipalities where opposition parties were very strong.

dia. We formulate the hypothesis that there is a link between this last point and the following: Surat is today one of the fastest growing cities in India, economically and demographically.

In times of crisis, local powers are certainly a unique focus of social relations, but they are often marginalized in terms of information, crisis management, and funding. Their duty is to inform, to comfort, and to mobilize a population which can be at the same time apathetic or overreacting, and which is often ridden by divisions and mutual distrust. They should not hide the reality of the risk, but they cannot throw the population into panic.

It is extremely difficult to implement a risk mitigation process in urban agglomerations which have very limited budgets, where mayors and municipal commissioners have short mandates, and where the municipal administration lacks the required technical competence. Thouret and d'Ercole (1996) have shown how disaster strikes harder, with maximum damage, when power shows lack of concern and irresponsibility, leading to a lack of information and preparedness by the population.

14.5.3 Issues Around Social Movements, NGOs, and Popular Participation

There is a consensus that local stakeholders, NGOs, and municipalities should be involved in programmes to reduce different types of risk, and that they should be associated with decision-makers at all levels (Pelling 2003a: 84; chap. 13 by Wisner/Uitto). In Latin America, social movements and NGOs play a crucial role in facilitating access to security for the low-income urban dwellers, for instance in helping them secure access to land security, as was the case in Villa El Salvador in Peru, for instance. But in the case of Indian cities, the needs are so important and numerous, and issues are so complex, that these institutions can play an efficient and visible role on the field only if they come to complement existing policies and funding. For instance, a number of NGOs have specialized in channelling specific public programmes (health, education, livelihoods, minorities, disaster prevention...) to the targeted beneficiaries, who otherwise would not be informed. Another responsibility is located upstream, for instance to inform and document the human security gaps in the slums. A third role is advocacy, using a number of new legal tools (public interest litigation, right to information) enabling representatives of social movements to appeal to the authorities to take a political stand on these issues.

Most disasters, like the Mumbai floods in August 2005, demonstrate the immediate response of traditional mutual help networks, in contrast with the lack of preparedness of the municipal authorities. However, India does not have the technical and financial backing which enables Japanese authorities to combine these self-help traditions, coordinated by neighbourhood assemblies, with huge investment programmes in security systems. In India, the informal character of most of the buildings and activities, and the clientelist relationship between local politicians and city dwellers impede many measures of prevention that would contribute to human security, leading to this statement: "The sheer magnitude of urban risk which combines inadequate infrastructure, poor water and sanitation, pollution, deforestation, high population density, recurrent natural hazards, fragile livelihoods and weak governance - means that the responsibility of building resilience to risk cannot be left to either at risk communities or municipalities alone" (IFRC-RCS 2004: 154).

14.5.4 The Implementation of Public Policies

Indian cities are therefore in a situation where a great number of poverty-related, infrastructure and environmental risks are well assessed, and even in some cases disasters would be predictable, while most authorities have still to establish the chain of public policies related to this reality. Anti-poverty measures are also identified at the national and international level, but at the local level implementing them constitutes a challenge to the social order for local elites. Also, many authorities fear that pro-poor policies might encourage more migration from rural areas and from poverty-ridden states such as Bihar, and they hope that slums would constitute a repellent to further migration.

Security is not a given factor: it is also enhanced through power games existing between different urban stakeholders, those who benefit from transformations and those who bear the consequences of degradation (Mackinnon 1999: 47). In a chapter on "Urban Governance - Agent of Disaster", the *World Disaster Report 2004* recalls that "poor governance keeps slum dwellers vulnerable, because it denies them access to the kind of support, such as credit or basic services, that they need to help enhance their resilience to risks" (IFRC-RCS 2004: 150).

For instance, slum rehabilitation is a well-known method of improving livelihoods of slum dwellers and reintegrating them into the economic urban flow. But

this would mean selling the land (public or private) on which slums are installed, without taking into account the speculative price they might reach. Therefore, in many cities, authorities prefer to clear slums and install new upper middle class housing and offices. In these cases of clearance, only a minority of slum dwellers are entitled to relocation, taking into account Indian complex rules and standards. Some buildings under construction in the periphery of Mumbai (Mankhurd) which are meant to provide for future relocation will undoubtedly create new, unforeseen social and economic problems.

Thus, public policies may constitute a direct blow to human security, and directly cause disaster for tens of thousands of the poorest urban dwellers. In Delhi and Mumbai, large-scale clearance operations took place since 2000; 90,000 dwellings were destroyed and 450,000 people made homeless within six months in Mumbai during 2005 (Bunsha 2005). Brutal, overnight evictions provoke the destruction of all their belongings for populations among the most vulnerable, as well as the loss of their livelihoods and their social life, not to speak of public health and the right to shelter issues.

The main problem for slum dwellers is that they cumulate all vulnerabilities and remain with a very small number of assets, while the urban environment is itself at risk, until the point when disaster is bound to strike. Many public policies have been adding to this vulnerability, through slum clearance, nonrecognition of the informal sector, and marginalization in polluted areas. Although, from the political point of view, this slum population is often active, the persistence of these situations raises the issue of their social and economic rights as citizens. They can also be considered as extremely resilient socially, since these appalling economic and environmental life conditions have not led to the development of more violence.

However, if asked, Indian authorities would reaffirm their constant concern for a number of elements constitutive of human security. They have tried to better target the very poorest, and to provide more social welfare in the rural areas, considering that both rural and urban policies are intrinsically linked. For instance, original and very large-scale public policies have been elaborated to avoid food shortages. They are quite widespread and much appreciated also in cities (Landy 2007). Also, requests for security are often understood by authorities in terms of 'fight against anti-social elements'. It remains that the informal neighbourhoods of cities have not yet been prioritized.

After many years where most slums were not taken into consideration by town planners, the Master Plan 2015 of Bangalore identified "shadow areas", defined as areas that have accumulated shortages with regard to the physical and social infrastructure. These areas were identified through a mix of several available indicators: lack of supply of water, insufficiency of schools and teachers, prevalence of slums... The results showed that the majority of the peripheral areas and about one third of the area under the jurisdiction of the Bangalore Municipal Corporation could be considered "shadow areas" (3iNetwork 2007: 66).

Although many programmes were officially geared at slum dwellers (water, sanitation, women's education), they could never overcome the gap between organized and informal settlements. To this day, 90 per cent of India's land titles are weak (3iNetwork 2007: 63). Now a new challenge started with the launching at the national level of the *Jawaharlal Nehru National Urban Renewal Mission* (JNNURM), created in 2005, which explicitly prioritizes infrastructure investments in favour of the poor urban population, and creates new methodologies of implementing policies in contractual agreement with the states and urban local bodies.

14.6 Conclusion

Indian cities and urban dwellers, even in a context of rapid economic growth, remain vulnerable to industrial, infrastructural, natural and social risks. So far, public policies have not been able to bridge the gap between a relatively well-protected organized sector and informal sector workers who are cumulating vulnerabilities. This is translated in physical terms in Indian cities, which today are getting increasingly fragmented spatially, along the lines of their social, economic and environmental vulnerability.

Several Indian cities, such as Mumbai, Kolkata, Delhi, Chennai, Bangalore and Hyderabad now rank among the largest and most dynamic urban centres in the world. But security in all its senses has become a key element in the fierce international competition for foreign investment and industries location. Therefore, while these cities belong to the network of the global economy (Taylor 2004: 30), they still remain at its periphery. Shortage of services, environmental threats, and the persistence of urban poverty have an impact on development dynamics and social cohesion. They are now becoming priorities of the central government, in close relation with states and urban local bodies.

15 Interactions between Conflict and Natural Hazards: Swords, Ploughshares, Earthquakes, Floods and Storms

Ben Wisner

15.1 Introduction: Violent Conflict and Natural Hazards: Definitions and Approaches

There are many ways violent conflict complicates, confuses, and obstructs the efforts of planners, engineers, and others to assist people in protecting themselves, their livelihoods, and their built environments from natural hazards. For example, civil war and the so-called 'war on drugs' in Colombia have displaced more than a million rural people, who have sought a more secure existence on the edges of large cities such as Bogota.¹ This influx of unemployed, poor people into highly dangerous locations where they squat in self-built houses in steep ravines, adds a great deal to the challenge faced by emergency management planners. Although some very important innovations in earthquake and landslide preparedness and mitigation have come out of Colombia in the past decade,² the sheer numbers of people displaced by violence threatens to overwhelm efforts to implement such innovative designs and programmes.

Beginning in the 1990's application of knowledge that could prevent loss from natural hazards was frequently blocked, deflected, diluted by violent conflict and its aftermath. A year after the tragic tsunami that affected Sri Lanka and ten other countries, the Tamil Tigers and the Sri Lanka government had still not concluded an arrangement for sharing relief and recovery assistance.³ Thus, as ambitious as it might seem, a dialogue needs to be fostered between the disciplines of peace research and disaster research for the benefit of both sides.⁴

Peace research and disaster research have similar and, at some times, overlapping histories. Briefly, peace research began as a discipline in the 1970's in part out of dissatisfaction with 'realist' approaches to international relations that take the necessity of war or the threat of war for granted in international relations. Instead, peace research drew on a venerable, centuries-long tradition of concerns with social justice and non-violent conflict mediation to produce a positive notion of peace.⁵ It sought the root causes of war and other forms of violent conflict in what are con-

1 Two million people have become internally displaced in Colombia since 1985; 300,000 alone in 2000. Rural health services have been destroyed. In urban areas these displaced persons live in very dangerous places. This is a recipe for increasing exposure to flood, landslide, earthquake, and epidemic disease. See: Médecins Sans Frontières 2001. *The Top Ten under Reported Humanitarian Crises of 2001*; at: <www.msf.org/content/page.cfm?articleid=7B5D6023-75EA-415A-80CC71C8E6B90DCF>. In addition, the majority of the displaced in Colombia are children, Afro-Colombians, and poor women. Only 20 per cent of these internally displaced persons have received any aid from the Colombian state, and even that has been 'minimal and short term' (A. Lopez, "Talking Sense on Colombia", American Friends Service Committee, Philadelphia, September, 2001; at: <<http://www.afsc.org>>: 7).

2 Wilches-Chaux, G./Wilches-Chaux, S., 2001. *¡Ni de Riesgos!* (Bogotá, Colombia: Fondo Para la Reconstrucción y Desarrollo de Eje Cafetero); at: <<http://www.ejecafetero.gov.co>>; Omar Dario Cardona, "Low cost, locally based repair and retrofitting of non-engineered, rural structures" [in Spanish] (Bogota, Colombia: University of Los Andes); at: <http://www.radixonline.org/knowningvsdoing2htm#>.

3 BBC News, "Sri Lanka suspends tsunami deal", 15 July 2005; at: <http://news.bbc.co.uk/1/hi/world/south_asia/4685291.stm>.

4 Other specialists are taking up the daunting subject of war and peace, for example, in the context of public health: Krug/Dahlberg/Mercy/Zwi/Lozano (2002); Murray/King/Lopez/Tomijima/Krug (2002); Cahill (1999); Wisner/Adams (2003); and in the field of food security Cuny/Hill (1999); Macrae/Zwi (1994).

ventionally considered 'normal' economic and political power relations.

Peace research approached a definition of violence and conflict from a broad perspective. Drawing from this research tradition, the analysis that follows treats several manifestations of violence:

- *Organized activity intended to kill or harm others.* Only one-to-one, interpersonal violence is excluded from the analysis that follows, although strictly speaking even domestic violence has been shown to be correlated with natural disaster occurrences.⁶ Organized violence takes the form not only of state vs. state war but increasingly as the activity of war lords, urban gangs, and mobs.
- *Use of the threat of violence to displace or coerce others.* In situations where rural or urban people live in fear of organized violence, they may be forced to forfeit their assets and leave their homes. Even when they remain, their behaviour may be constrained and coerced.
- *In addition, in peace research Galtung (1967, 1968) introduced the concept of 'structural violence'.* This describes entire economic, social, and political systems whose normal functioning produces and reproduces hunger, ill health, and premature death primarily via the structural maintenance of inequalities and inequities. More generally, these 'structures' deny people the ability to exercise their capacities.⁷ This is a powerful concept, and its invocation by peace researchers has had much the same motive as attempts within

disaster research to develop 'integrated' frameworks of understanding.

- *Finally, historical memory of violence and its post-traumatic consequences* even when the actual use of violence or threat of violence has subsided. Historical memory may affect the ability of groups of people to generate the trust required to implement disaster reduction measures. One should understand the term 'post-traumatic consequences' in a broad sense that includes the individual mind and body, domestic and social relations (including trust), as well as the longer term impacts on livelihoods, the natural environment and resources, and on the built environment. Thus in numerous ways recovery from violent conflict may face similar challenges on a similar time scale as recovery from catastrophic disaster.⁸

This broad definition of violent conflict is in keeping with the way in which the United Nations and its specialized agencies and others have guided the evolution of the concept of 'security.' A narrow preoccupation with 'international security' from a politico-military point of view characterized this concept when the U.N. was founded in 1945 (Bothe 2008; Brauch 2008a; Oswald 2008; Waever 2008). Whereas today the U.N. Development Program, among others, recognizes many interrelated aspects of 'human' security:

5 See the discussion of the sub-fields of peace studies and their origins in the *Guide to Graduate Programs* produced by the Peace and World Security Studies Program (PAWSS) at Hampshire College; at: <<http://pawss.hampshire.edu/students/grad/#2>>. There the earliest roots of peace studies are traced to various religious views of non-violence and concerns with social justice. The field is also subdivided into these focal areas: Conflict Resolution and Negotiation, Citizen Participation in Socioeconomic Development, Arms Control and International Security, Law and more recently also human and ecological security and sustainable peace.

6 Gillis Peacock/Morrow/Gladwin (1997); Fran H. Norris, "Disasters and Domestic Violence", in: U.S. Department of Veterans' Affairs, National Center for Post Traumatic Stress Disorder, Fact Sheet; <http://www.ncptsd.va.gov/facts/disasters/fs_domestic.html> (4 July 2005).

7 Galtung (1969); compare Sen's (2000) notion of development as freedom.

8 The time dimension of recovery in both these circumstances is poorly understood and little researched. Certainly the well-known overlapping bell-shaped curves that Haas/Kates/Bowden (1997) found to fit recovery from the 1906 San Francisco earthquake and the 1972 earthquake in Managua, Nicaragua cannot be generalized (see one critique of later use of this model in Wisner/Blaikie/Cannon/Davis (2004: 353-363). Generally the length of time required for full psycho-social, economic, and environmental recovery from catastrophic events has been underestimated. This may be because of a desire on the part of the donor community and recipient governments to 'move on' and to re-establish minimum conditions for international trade and 'business as usual' as soon as possible. However, consider the continuing low level violence (social banditry) in post-war situations such as Cambodia, Guatemala, and Somalia long after peace agreements. In a similar way, donors and affected nations are reluctant to admit that in certain respects recovery may simply not occur. Some households never regained rural livelihoods following the Sahel drought and famine in the late 1960's or in the wake of hurricane Mitch (1998) in Honduras and Nicaragua. It is likely that some large proportion of those who survived the Asian tsunami may never again engage in fishing or farming (see Wisner/Walker 2005).

economic security, food security, health security, environmental security, personal security, community security, and political security (Brauch 2005; see chap. 74–96 in part IX of this vol.).

Disaster research shares peace research's impatience with excessively narrow definitions. Current thinking about integrated disaster management grew out of dissatisfaction with a narrow approach that focused primarily on the hazard and not on vulnerability of the people and systems affected by a hazard. In addition, this earlier 'hazard' – as opposed to 'vulnerability' – approach tended to be inspired by the 'top down', 'command and control' style of cold war civilian defence.⁹ By contrast, the vulnerability approach to integrated disaster management tries to balance participatory, or 'bottom up' use of local knowledge and capacity for risk reduction with 'top down' technical expertise.

Digging deeper, one can also see that the emphasis on social justice and the root causes of conflict one finds in peace research are also there in the search for root causes of disaster vulnerability (Wisner/ Blaikie/ Cannon/Davis 2004; Wisner 1993, 2003). In this way, Tony Oliver-Smith (1994: 31) called the 1970 earthquake that destroyed the town of Yungay, Peru, a "500 year earthquake." What he meant is that the vulnerability of the people of Yungay can be traced back many years to the destruction by Spanish conquest of the ancient Inca system of architecture and land use, which was risk-adverse and exposed the Inca population to less risk from natural hazards. Likewise in Guatemala City people referred to the 1976 earthquake as a 'class quake', demonstrating that people on the street were aware that the majority of the homes destroyed were those of the poor Mayan squatters who had built on the steep waste land in the city. In this manner, integrated disaster risk management seeks out root causes for vulnerability just as peace research probes the root causes of violent conflict.

At the beginning of the 21st century there is a growing consensus that human beings have a right to

security and development as an extension of their right to life (Uvin 2008; Katselis 2008; Sending 2008; Klingebiel/Roehder 2008). A rights-driven approach to both development work and the practice of integrated disaster management must see violent conflict as a major obstacle to achievement of those rights.¹⁰

15.2 Violent Conflict and Disaster: Scientific, Moral, and Policy Challenges

It is important to note the scale and human cost of violent conflict in relation to the human loss from natural hazards. Disasters, especially those that seem to be principally caused by natural hazards, are not the greatest threat to humanity. Despite the lethal reputation of earthquakes, epidemics, and famine, a much greater proportion of the world's population has had its lifespan shortened by events that are often unnoticed: *violent conflict, endemic disease, and hunger* – conditions that pass for normal existence in many parts of the world, especially (but not only) less developed countries (LDCs). Occasionally earthquakes have killed hundreds of thousands, and very occasionally floods, famines, or epidemics have taken millions of lives at a time. But to focus on these alone (in the understandably humanitarian way that outsiders respond to such tragedies) is to ignore the millions who are not killed in such events, but who also face grave risks. Many more lives are lost in violent conflict and to the preventable outcome of disease and hunger.

If one totals deaths during the 20th Century (1900–1999) from violent conflict, disasters triggered by a natural event, epidemics, and accidents (road, rail, air, industrial), it is violent conflict that accounts for 62 per cent of these 424 million deaths. By contrast, rapid-onset disasters such as earthquakes and volcanic eruptions account for only 2 per cent; whilst epidemics take 12 per cent as their share.¹¹

U.N. Secretary General, Kofi Annan (2001: xix), put these multiple threats to human security into perspective in 2001 when he wrote:

We know that we cannot be secure amidst starvation, that we cannot build peace without alleviating poverty, and that we cannot build freedom on foundations of

9 One of the earliest authors to call attention to the distinction between 'hazard' and 'vulnerability' paradigms in disaster research was Kenneth Hewitt in his essay, "The Idea of Calamity in a Technocratic Age" (Hewitt, 1983). See also: Hewitt (1995, 1998); O'Keefe/Westgate/Wisner (1976). On the history, and possible resurgence, of the command and control paradigm in the U.S., see: David Alexander, "Do *you* want to be commanded and controlled? Reflections on modern emergency management"; at: RADIX website, *Latest Additions*, 6 February 2003; at: <http://www.radixonline.org>.

10 James K. Boyce, "Let them Eat Risk? Wealth, Rights, and Disaster Vulnerability", Political Economy Research Institute (PERI), Working Paper 4, University of Massachusetts Amherst, 2000; at: <http://www.umass.edu/peripdfs/WP4.pdf>.

injustice. These pillars of what we now understand as the people-centred concept of 'human security' are inter-related and mutually reinforcing.

Violent conflict poses challenges to scientists and planners who attempt to anticipate 'surprises' and other kinds of complications and uncertainties that can accompany natural and technological hazard events. War and other kinds of violent conflict, therefore, are a serious addition to difficulties in applying an integrated approach to disaster management. These violent conflict-induced complications can be seen in all phases of the disaster management cycle. Efforts at integrated mitigation, prevention, and preparedness are made more difficult by past, present, and possible future violent conflict. For example, early warning may be impossible under conditions of violent conflict. Goma, a city of 500,000 in the eastern part of the Republic of Congo, had no public warning of a perilous volcanic eruption in 2002.¹¹ There was at the time simply no municipal government since the city was under the control of a rebel army contesting the authority of the central state in Kinshasa. Response capacity may also be reduced under conditions of violent conflict. Fire fighters were

stoned and shot at when they responded to fire during the uprising in Los Angeles in 1991. Relief, reconstruction and recovery are all subject to additional requirements and possible limitations when they confront pervasive violent conflict or its aftermath in addition to the effects of the natural or technological hazard event (e.g. drought, flood, epidemic, explosion, or chemical release). For example, a refinery burned for many days uncontrollably during the bombing of Belgrade which was part of NATO's intervention in the conflict on Bosnia and Kosovo.

During the 1990's many violent conflicts broke out in various parts of the world, and many civilians were killed, maimed (especially by land mines), injured, deliberately mutilated, starved, occasionally enslaved, and displaced by the belligerent parties. So great has been the need for humanitarian relief in these conflict and post-conflict situations that some normal development assistance has been diverted, and opportunities for self-generated development delayed or destroyed, further worsening the position of marginal and vulnerable populations in the long term. Furthermore, there has been confusion among development agencies, including non-governmental organizations (NGOs) about how to act in regard to:¹³

11 See Wisner, Blaikie, Cannon and Davis (2004: Chap 1, Table 1.2) who used diverse sources in estimating these numbers, which, especially for the earlier part of the century and for specific kinds of conflicts, must be considered only as roughest approximations. For estimates of deaths due to war and political violence the author is most grateful to Kenneth Hewitt, Wilfred Laurier University, Canada, for time spent in personal communication and consultation on these matters during July 2002. Hewitt's (1997) book: *Regions of Risk* and an earlier article (Hewitt 1994) were also helpful as well as Sivard (2001) and M. White: "Wars, Massacres and Atrocities of the Twentieth Century Wars" (1999); at: <<http://users.erols.com/mwhite28/war-1900.htm>>. *Drought and famine death statistics* are based on the author's approximate calculations that expand on the official reports that are regarded as a gross underestimates, since entire famines, such as the 'Great Leap Forward Famine' in China (1959-1961, which may have killed 30 million people (Yang 1996; Becker 1996; Heilig 1999) are omitted from official data bases. *For other disaster mortality statistics* the author relied on the EM-DAT data base by CRED and OFDA (at: <www.cred.be/emdat> (11 July 2002). *Traffic accident statistics* came from the *World Disaster Report 1998* (IFRC 1998: 20-31). *Estimates of deaths due to HIV-AIDS* rely on Barnett and Whiteside (2001).

ern Congo (2002) mentioned above. In 2005, the way conflict has complicated recovery from the tsunami in Sri Lanka is a vivid example.¹⁵ At the same time, in Zimbabwe resilience to drought has been undermined by chaotic years of farm nationalizations and famine relief denied to opponents of the ruling party.¹⁶

15.3 Interaction of Violent Conflict with Natural and Technological Hazards and Management Efforts

Violent conflict interacts with natural hazards and technological hazards in a wide variety of ways.

15.3.1 Violent Conflict as Root Causes of Social Vulnerability

In violent conflict situations today 90 per cent of the casualties are suffered by civilians. This contrasts with around 50 per cent during the Second World War and only 5 per cent during the First World War (Wisner/Blaikie/Cannon/Davis 2004: 3–5). In addition to death and injury, the civilian population often finds its normal livelihoods disrupted, leading many into more hazardous means of obtaining the necessities of life. Women and children are particularly affected by these stresses (Wiest, Mocellin, Motsisi 1994). Prostitution as a desperate means of livelihood combined with rape and sexual slavery has contributed to the explosion of HIV/AIDS in some parts of Africa (Wisner/Blaikie/Cannon/Davis 2004: 185–192). In extreme cases famine (Wisner/Blaikie/Cannon/Davis 2004: chap. 4) may be the result as in Bengal in 1943, Biafra (the Ibo-speaking breakaway territory of south eastern Nigeria) in 1969, Cambodia in the mid-1970's,

Angola and southern Sudan in the 1980's and 1990's, and Darfur, Sudan in the early 2000's.

15.3.2 Institutional Weaknesses: Past Violent Conflict and Natural Hazards Producing a Downward Spiral

This is evident in the case of Central America where Guatemala, Nicaragua, Panama, and El Salvador all have societies shaped by violent conflict. In the case of El Salvador, few of the elements of the 1992 peace accords had been implemented when hurricane Mitch hit the region in 1998. Contentious issues concerning land tenure and reform of the police and judiciary bear directly on social welfare and economic development. These issues were still not settled when two earthquakes struck in January and February 2001, killing more than one thousand people, injuring more than eight thousand and causing damages valued at \$2.3 billion. Forty per cent of the country's health centres were destroyed and one-third of the schools. 150,000 homes were destroyed another 185,000 damaged (Wisner 2001).

Because of institutional weaknesses, El Salvador was unable to make effective use of the international assistance for multi-hazard mitigation made available by the Stockholm group of donors to the whole region affected by hurricane Mitch. Had it done so, damage and loss from the 2001 earthquake might have been less (Wisner 2001). Since then the poorest rural population has suffered hail and drought, both devastating food crops, as well as the collapse of the world price for coffee. Small farmers and landless labourers have suffered most. Caught up in a similar vicious spiral, half a million poor rural Nicaraguans have crossed the border into Costa Rica seeking work. These immigrants are likely to live in places and in conditions that expose them to risks such as flooding, landslides, and disease.

Such a mass movement of poor people may be interpreted as motivated by a 'pull factor', namely economic opportunity, and not the 'push factor' exerted by violent conflict (Loescher 1993: 16–17). To some extent, that is true; however, one has to place the economic and institutional weaknesses of Nicaragua and other countries in the context of long histories of civil war.

15 By contrast, the tsunami seems to have provided an opening for mediation by Finland in the decades' long violent conflict between the Free Aceh Movement and the government of Indonesia, and a peace agreement was announced in July, 2005 (see: "Indonesia, Aceh Rebels Reach Deal", in: *Japan Times*, 18 July 2005, p. 1).

16 BBC News: "WFP Warns of Zimbabwe Food Crisis", 1 July 2005; at: <<http://news.bbc.co.uk/1/hi/world/africa/4639909.stm>>, in which World Food Programme director, James Morris, is quoted: "the greatest humanitarian crisis we face today [is] not in Darfur, Afghanistan or North Korea, but in southern Africa... [where, as in Zimbabwe] a lethal mix of Aids, recurring drought and failing governance is eroding social and political stability."

15.3.3 Displacement of Large Numbers of People in War and Other Violent Conflicts Leading to New Risks.

There were 9.2 million refugees in the world in 2005, down from roughly 10 million official refugees in the world in 2003 and 12 million in 2002.¹⁷ These numbers exclude ‘internally displaced’ people who have not crossed a national border while seeking refuge. Most of these refugees are fleeing violence. In many cases they face new risks that include exposure to disease and unfamiliar hazards in new rural or urban environments.

Deadly outbreaks of cholera and other communicable diseases affected displaced persons who fled the genocide in Rwanda and, earlier, the civil war that led to the creation of Bangladesh (Wisner/Blaikie/Cannon/Davis 2004: 176-177); Wisner/Adams 2003). In Alexandra Township in Johannesburg, South Africa, refugees from the civil war in Mozambique were among the poorest residents who lived in locations most highly exposed to flash flooding (Wisner 1995).

In addition, when international refugees are finally repatriated to their home countries, they often end up in new locations – not their original homes, and these locations are sometimes hazardous. In this entire situation, women, children, and the elderly are among the most vulnerable people (Diaz 1994: 49-50; Turshen/Twagiramariya 1998; Walker 1994; Moser/Clark 2001).

15.3.4 Violent Conflict Interfering with Relief and Recovery Assistance

The civil wars and instances of violent conflict in Africa during the 1980’s and 1990’s often challenged the ability of humanitarian agencies to provide essential relief to the civilian population. In Sudan UNICEF was able to negotiate ‘corridors of tranquillity’ during its so-called ‘Operation Lifeline Sudan’ (Minear 1991). However, more commonly arrangements for relief and recovery assistance have been ad hoc, unreliable, and rapidly changing, as they have been more recently in Afghanistan, Iraq, and Darfur in Western Sudan. Worse than this, there is some evidence from case

17 United Nations: “Global number of refugees dropped 14 per cent in 2002”, 20 June 2003; at: <<http://www.hrea.org/lists/refugee-rights/markup/msg00346.html>>; UNHCR: 2004 *Global Refugee Trends*, Geneva: UNHCR (17 June 2005); at: <<http://www.unhcr.ch/cgi-bin/texis/vtx/events/opendoc.pdf?tbl=STATISTICS&cid=42b283744>>.

studies, mostly in Africa so far, that middlemen and war lords actually profit from and wish to perpetuate a ‘relief economy’ in which they are able to trade relief goods they steal or divert for guns or use relief aid they come to acquire to ‘buy’ support among civilians (Keen 1994; Duffield 2002).

15.3.5 Difficulty for Participatory Methods Empowering and Engaging Socially Vulnerable Groups During Violent Conflicts

This effect of violent conflict is a particularly important challenge to ‘integrated disaster management’. An integrated approach to disaster management has much in common with what the UNDP calls a ‘developmental’ approach to humanitarian assistance.¹⁸ In both cases the goal is not only to address the specific crisis at hand – an earthquake, flood, factory explosion, or a violent conflict – but to do so in a way that builds capacity to mitigate or to prevent a future occurrence. In both cases, the role of local knowledge and capabilities is important; hence participatory methods based on trust are vital tools (Wisner (1995, 2003).

But in violent conflict situations people are less inclined or able to take part in such ‘bottom up’ efforts – be they directed toward preventing damage from future natural hazards or toward peace-making. In the case of the work by the Red Crescent Society with Palestinian refugees, there has been some success in empowering ordinary people in the assessment of their own vulnerabilities, capacities, and resources in a systematic way. However, this is likely to be an exception that proves the rule that under intensely violent conditions participatory and developmental approaches are very difficult (IFRC 2002: chap. 6).

It is important in this context to make a clear distinction between ‘conflict’ and ‘violent conflict.’ The author’s position – shared by many who work in the field of development studies and peace research – is that the process of sustainable human development is necessarily conflictual (Wisner 1988: chap. 1-2). That is, human beings have different objective material interests as well as subjective understandings of their needs. However, the vast majority of these conflicts are resolved directly by local mechanisms of negotiation and mediation.¹⁹ Such conflicts are normally

18 UNDP, n.d.: *Building Bridges Between Relief and Development* (New York: UNDP): at: <<http://www.undp.org/erd/archives/bridges.htm>>.

non-violent. These are verbal dispute-based conflicts whose resolution logical reasoning-based arguments, persuasion and debate as well as negotiation and bargaining work to a large extent. By contrast, violent conflict tends to by-pass or even to shut down local mechanisms for conflict resolution.

15.3.6 Difficulty of Applying Existing Knowledge for Mitigation of Risk from Extreme Natural Events during Violent Conflict

Over the past three decades a very large knowledge bank has grown as regards preparedness, mitigation, warning, and response to natural and technological hazards. Flood and cyclone warning systems have improved (Zschau/Kueppers 2002). So also have early warning systems of food emergencies based partly on satellite surveillance of pasture and croplands and partly on field data routinely reporting market prices and the nutritional status of children.²⁰

However, violent conflicts disrupt the communication necessary to make application of this knowledge effective. Advances in hydrological modelling and the use of current information and communication technologies (ICTs) make management of large river basins feasible. But tensions among the 12 nations within the basin of the Nile make common management difficult, even in the absence of overt warfare. The same could be said of other large river basins such as those of the Mekong, or the Euphrates.²¹

It is not only current violent conflicts that complicate the practice of integrated disaster management. A long history of conflicts, as for example in southern Africa, leaves behind weak infrastructure and institutional arrangements. Such a history may have played a

role in the breakdown in communications from authorities in Zimbabwe and Zambia who released water from dams on the Zambezi River that took Mozambicans downstream by surprise during the floods in 2000 (Christie/Hanlon 2001).

15.3.7 Violent Conflict Diverting National and International Financial and Human Resources from Mitigation of Disaster Risk

On the national scale a good example is Ethiopia. During its state vs. state war with Eritrea during the 1990's, Ethiopia let its national famine early warning system deteriorate. Resources were used for war and not for such social investments as maintenance of the food monitoring system that had been put in place following the famines of the 1980's. In 2003 the Ethiopian government was 'surprised' by a widespread food emergency that it should have been able to detect much earlier (Westing 1999).

On the international scale, donor attention was so fixated on post-war Afghanistan and Iraq that little attention was given to a fulminating combination of HIV/AIDS, flood, and drought in southern Africa, among other 'under-reported' humanitarian emergencies,²² a distortion of course compounded by donor fixation by the Asian tsunami in 2004. It was only in 2005 with the G8 meeting in Gleneagles (UK) and the massive, international 'Make Poverty History' citizen movement²³ that donors began to redress this distorted focus.

15.3.8 Violent Conflict Destroying Infrastructure and Intensifying Natural Hazards: Flooding, Drought, or Epidemic Disease

Among the infrastructure targets in recent conflicts have been irrigation systems, dams, levees, roads, bridges, water treatment plants, refineries, pipelines, and electricity systems. Such destruction may rapidly erode public health and also throw large numbers of people into unemployment. Both these effects increase a population's vulnerability to future hazards.

23 See: Make Poverty History; at: <http://www.makepovertyhistory.org/>.

In the case of Iraq, the destruction of water treatment and distribution systems, drainage and sanitation facilities, and electricity supplies during the first and second wars in that country contributed to health hazards that cost the lives of more than half a million children. During the first Gulf War, the U.S. destroyed electricity supplies, shutting off power to hospitals and water treatment facilities. This began a series of disastrous events that undermined public health. Transportation networks were also targeted, so that distribution of food and other essential items to Iraq's primarily urban civilian population was disrupted. As a result, there were 47,000 avoidable child deaths within eight months of the 1991 war (CESR 2003; Savage 2002).

The effect of sanctions during the years following the first Gulf war added to these initial stresses on the most vulnerable groups of civilians. Iraq's rank in the UNDP's Human Development Index fell from 96 to 127. That fall set an unenviable record as the most rapid decline in human welfare in recent history. Between 1990 and 1999, Iraq's under-five mortality rate increased by more than 150 per cent to 131 per 1000 live births (Savage 2002a: 4). By 2005, occupied Iraq had still not been able to restore its basic infrastructure due to frequent terror attacks and instability. Twenty per cent of the cost of contracted reconstruction work goes for private security for the work force and consulting engineers.

15.3.9 Violent Confrontations Impacting on Vegetation, Land, and Water, and Undermining Sustainable Development

The use of depleted uranium as shell casings by U.S. and British forces during the two wars with Iraq have contaminated large areas of northern Kuwait and southern Iraq with radioactive dust (Westing 2003). In 2005, the date crop in Iraq was at risk from insect infestation because insecticide dusters had been destroyed in the wars. Chemical defoliants were used by the U.S. in Southeast Asia during the Vietnam War. In such cases there may have been long-lasting health and economic effects (Westing 1972, 1976, 1989).

Unexploded explosives and land mines make some agricultural land unusable in post-war regions, where there are on-going efforts to remove land mines in 90 countries (Westing 1977, 1980a, 1984, 1985).²⁴ Water has also been contaminated by acts as diverse as sabotage of oil terminals by Saddam Hussein in 1991 and the aerial spraying of coca fields by the U.S. during its so-called 'war on drugs'.²⁵ In addition, the

presence of large numbers of displaced persons and refugees in dense concentrations can cause local de-vegetation and soil erosion (chap. 9 by Rechkemmer; Black 1998).

15.3.10 Poorly Managed Disasters Creating, Prolonging, or Exacerbating Violent Conflicts

The nine points reviewed so far have focused the impact of violent conflict on the vulnerability of people to natural hazards and the ability to manage or cope with natural hazards. However, poorly managed disasters may also create the conditions for violent conflict. Popular discontent with government response may lead to short term rioting or to longer term attempts to change the regime. Regime change following disasters cannot be caused by mismanagement or perception of mismanagement in a clear cut way because of time lag and the existence of grievances and contradictions prior to and after the extreme event in question.

For example, the Sandinista rebellion was well underway when Managua was destroyed by an earthquake in 1972. It took another seven years for the Somoza dynasty to be overthrown in that country; however, widespread disgust at perceived looting of international relief funds and allocation of reconstruction contracts to Somoza cronies contributed to an increase in support for the Sandinistas. In a similar way, mismanagement of the earthquake in Mexico city and its aftermath in 1985 is cited by many observers as the 'beginning of the end' of the PRI hegemony first in the capital city (in 1997) and then in the nation (in 2000).²⁶

24 The *Land Mine Monitor Report 2002* documents some progress in de-mining and in destruction of land mines, but it also indicates that there are still 230 million land mines in the arsenals of 94 countries; at: <<http://www.icbl.org/lm/2002/findings.html>>.

25 Documentation of the environmental and health consequences of the Indo-China wars and first Gulf War are available in Austin and Bruch (2000a). A longer-term perspective of the role of chemical weapons is available in Russell (2001).

26 Bell Gale Chevigny: "A Shock to the System", in: *AlterNet* (19 September 2005); at: <<http://www.alternet.org/katrina/25516/>>, citing Poniatowska (1995). Also see Richard Olson: "The Mexico City 1985 Earthquake Disaster and Emergent Organizations: A Case Study", Natural Hazards Research and Applications Workshop, Boulder, CO, July, 2000; at: <<http://www.colorado.edu/hazards/workshop/2000/s37.html>>.

There are other ways disaster can affect violent conflict. The so-called ‘complex emergencies’ in Africa almost always involve drought or another natural trigger for food insecurity in populations that have little resilience. Such violent conflicts are often prolonged by the ability of belligerents to loot or obtain partial control over emergency food aid with which they barter for weapons or feed their fighters (Keen 1994; Duffield 2002; Smillie/Minear 2004: 108–114).

The question remains, do disasters triggered by extreme natural events actually cause violent conflict? Some scholars believe there is evidence that natural resource scarcity may cause violent conflict (Homer-Dixon, 1999). The examples most often produced concern water, arable land, pasture, and forests, and there is controversy over the relative importance of scarcity versus formal (state) and informal institutions, norms, and power.²⁷ Although the range of natural events that may trigger disasters certainly includes drought, and others such as coastal storms and locust plagues may temporarily deny people arable land or pasture, the causal nexus is not clear. Prolonged drought in Australia is not associated with violent conflict on any large scale, while in Somalia or northern Kenya it may. Why is this? The answer probably lies in the domain of institutions that are used to cope with water shortage. Also it is very important to distinguish between livestock raiding as a form of violence normally limited by cultural norms (FAO 2001a) and inter-state conflict over water rights (Ohlsson 1998/99).

15.4 Practical Implications and the Way Forward

A series of international conferences have defined ‘integrated disaster management’ as a set of risk reduction efforts that proceed by “integrating risk policy making with infrastructure development, communication, social networks and economic and financial

planning.”²⁸ In an urban context this implies “integrating disaster/risk policy making with urban development, land use, communication networks, economic/financial planning, human security, cultural heritage preservation and institutional realities.”²⁹ Above all, an ‘integrated’ approach to disaster management is “a multidisciplinary approach ... involving not only scholars ... but also practitioners in ... public policy making at the national and community level, and community and NGO representatives.”³⁰ The United Nations also has asserted a strong link between disaster risk reduction and sustainable development (UN/ISDR 2002).

What should be clear from the previous section is that violent conflict affects in very specific ways each and every element in these definitions of integrated disaster management. So, in the face of such systematic blockage of such efforts in times of war, other situations of violent conflict, and often in post-war conditions, what can be done?

An analysis of these practical implications can be divided into two parts – those regarding humanitarian practice and those concerning professions whose practice is prevention and mitigation of hazards.

15.4.1 Providing Disaster Relief

The first group of professionals face a task of coordination, negotiating the complex issue of civil-military relations mentioned earlier as well as the challenge of providing assistance in ways that contribute toward local capacity in the future. The United Nations has laid out the basic requirements for effective humanitarian assistance. These are a set of ‘core protection principles’ adopted by the U.N. Security Council in 2002.³¹

- *Access to Vulnerable Populations:* Facilitate safe and unimpeded access to vulnerable populations as the fundamental prerequisite for humanitarian assistance and protection.

27 See critiques of Homer-Dixon by McDonald (1999), Hartmann (2003), Hartman/Hendrixson (2005) and a better balanced, holistic view of the relationship between environment and security provided by the research programme on Global Environmental Change and Human Security (GECHS); at: <<http://www.gechs.org/>>. The Crisis States Research Centre at the Development Studies Institute, London School of Economics also takes a much more nuanced approach to the origins and consequences of violent conflict; see: <<http://www.crisisstates.com/>> and their four key themes at: <<http://www.crisisstates.com/themes/index.htm>>.

30 *ibid.*

31 U.N. Security Council, 2003: “Plight of civilians in armed conflict remains considerable, grave problem, USG for Humanitarian Affairs tells Security Council”. 20 June; at: <<http://www.reliefweb.int/w/Rwb.nsf/s/C0BB61CED9D0B67885256D4B00722621>>; see also Annan (2002).

- *Separation of Civilians and Armed Elements:* Maintain the humanitarian and civilian character of camps for refugees and internally displaced persons.
- *Justice and Reconciliation:* (1) Put an end to impunity for those responsible for serious violations of international humanitarian, human rights and criminal law. (2) Build confidence and enhance stability within the host state by promoting truth and reconciliation.
- *Security, Law and Order:* Strengthen the capacity of local police and judicial systems to enforce law and order.
- *Disarmament, Demobilization, Reintegration and Rehabilitation:* Facilitate the stabilization and rehabilitation of communities.
- *Small Arms and Mine Action:* Facilitate a secure environment for vulnerable populations and humanitarian personnel.
- *Training of Security and Peacekeeping Forces:* Ensure adequate sensitization of multinational forces to issues pertaining to the protection of civilians.
- *Effects on Women:* Address the specific needs of women for assistance and protection.
- *Effects on Children:* Address the specific needs of children for assistance and protection.
- *Safety and Security of Humanitarian and Associated Personnel:* Ensure the safety and security of humanitarian, United Nations and associated personnel.
- *Media and Information:* (1) Counter occurrences of speech used to incite violence. (2) Promote and support accurate management of information on the conflict.
- *Natural Resources and Armed Conflict:* Address the impact of natural resource exploitation on the protection of civilians.
- *Humanitarian Impact of Sanctions:* Minimize unintended adverse side effects of sanctions on the civilian population.

15.4.2 Preventing Future Disasters

Those professionals whose prime concern is integrated disaster risk management – and not management of conflict and protection of civilians in conflict situations – may also draw some other implications from the foregoing analysis.

- *First, they should design early warning systems and other programmes for risk reduction in ways*

that are robust even under the stresses of violent conflict.

Joanna Macrae, coordinator of the Humanitarian Network run by the Overseas Development Institute in Britain, has noted that in many countries the challenge is not this or that crisis, but more or less continuous “chronic political emergencies” (Macrae 2001: 156). She denies that in most cases there is a clear-cut ‘post-war reconstruction’ phase during which development-as-usual can be practiced. She sees a much more chaotic situation.

Therefore, if the application of knowledge from engineering, earth science, hydrology, meteorology, public health and other disciplines is to be long-lasting and effective, contingency plans for the resilience of systems in the face of political instability and even violent conflict have got to be built in from the beginning. A corollary is that early warning systems and other risk reduction ‘technologies’ cannot simply be additions and provided from the top-down by specialist expatriates or centres of excellence. Technologies, systems, and designs for a safe society must be developed in partnership with end users who know the demands and stresses of the real environment in which these innovations will have to be implemented. Among those stresses is violent conflict.

- *Thus, a second implication is that capacity needs to be built deeply among the end users and stakeholders.*

An example of such an approach is the flood early warning system set up with assistance of Swedish SIDA in one river basin in Guatemala. It does not rely on warning messages from the capital city or an academic institution. Trained villagers take stream flow measurements and monitor rainfall with simple instruments and send their observations to the local town using solar powered radios. In the town, other trained volunteers use software on a lap top computer to model the flood hazard and give the warning. During hurricane Mitch in 1998 no one was killed in this part of Guatemala, despite flash flooding that killed hundreds elsewhere in the country and thousands in Honduras and Nicaragua.³² A very similar system also saved lives in northern Honduras during Mitch (Wisner/Ruiz/Lavell/Meyreles 2005).

The effects of violent conflict and its long-term consequences must also be faced by practitioners in more developed countries (MDCs). People fleeing violent conflict such as illegal immigrants and asylum-seekers, who find themselves in large cities in Europe, North America and elsewhere may be highly vulnera-

ble to natural hazards, but they are very difficult for professionals to contact. This is because of language difficulties as well as a lack of trust. In the case of the World Trade Center, possibly as many as 500 illegal immigrants, many of them from war-torn areas of Latin America, were killed.³³ In the aftermath of the 1994 Northridge earthquake in Los Angeles, illegal immigrants avoided hospitals and recovery services for fear of deportation (Bolin/Stanford 1998, 1998a).

- *The third implication is that efforts should be made to implement and institutionalize risk reduction and disaster management systems in ways that address disparities and grievances that may lead to violent conflict.*

This point may be considered more controversial than the first two. One might ask if this is where specialist engineers and the like should not cross the line into 'political' activity. In answer to this doubt, one should consider the fact that the cycle of poverty and marginalization is often perpetuated by drought, flood, crop pests, human and livestock disease. Health professionals who find themselves working in similar circumstances are sometimes the first to link peace making with health,³⁴ so why not consulting engineers, agronomists, or foresters? If, for example, one is in the situation of a consulting engineer, for example, giving advice about a large city's water supply, is this not the perfect opportunity to suggest an extension of the system into the low-income squatter settlement adjacent to the city centre? If one begins to look for opportunities to use risk reduction to reduce or eliminate disparities that are among the root causes of violent conflict, it is surprising how many opportunities there are. Among these opportunities are the occa-

sions where similarity in human suffering faced by two hostile countries provides a window of opportunity for diplomatic breakthroughs or at least humane contact. Ilan Kelman has begun to collect such examples as the exchange of relief aid between Turkey and Greece - erstwhile enemies - on the occasion when they both suffered earthquakes within a brief period. Kelman refers to these openings as 'disaster diplomacy'.³⁵

15.4.3 Recovery from Disaster

To date there has been little cross fertilization and collaboration among specialists working on post-conflict recovery and those planning and facilitating post-disaster recovery. They have lessons and approaches to share. Two generalizations suggest themselves.

- *Post-conflict recovery has been concerned with building trust and communication and institutions with too little emphasis on physical infrastructure and livelihoods.*

In his review of post-conflict development programmes in El Salvador, Boyce found that something as basic as land for farming had been neglected (Boyce 1996) although this balance is slowly being reassessed (Maiese 2003).

- *Post-disaster recovery has tended to dwell on the 'bricks and mortar' aspects of economic and infrastructural reconstruction with not enough emphasis on building trust, communication, and institutions.*

These 'softer' psychological and social aspects of recovery have been slow to enter a domain usually controlled by engineers and economists but it is slowing developing (Wisner/Blaikie/Cannon/Davis 2004: 253-266; Natural Hazards Center 2001).

15.5 Conclusion

War and violent conflict certainly complicate the challenges of integrated disaster management in a number of ways. However, professionals can take these complications into account in order to increase the chance that policy advice, programming, project planning, design, and training activities will be robust enough to

32 The Guatemala examples is documented in IFRC (2002: 52). The author is grateful to John Twigg, Benfield Greig Centre for Hazard Research, University College London for reminding me of this case study. For more on the potential of the ICTs, and their robustness (due, in large part, to their decentralized use), see Ben Wisner, 'Disaster Preparedness and Response: Why is the Phone Off the Hook?', Invited paper for the European Telecommunications Resilience & Recovery Association Inaugural Conference (ETR2A), Newcastle-upon-Tyne, UK, 11-13 June 2003.

survive the chaos of violent conflict situations. More ambitiously, it is also possible that integrated disaster management can help to reduce the social and economic disparities – especially the differential exposure to disaster risk – that divides people in fragile societies and can lead to violent conflict. Finally, the common humanity that unites people, no matter what their professional disciplines or national origins, call them to support the United Nations and to work for peace at a time when unilateralism and so-called pre-emptive war threaten to tear up the fabric of world order.

Disaster reduction work in the 21st Century should not lose its ability to be inspired by such large visions, nor should practitioners lose the courage to speak truth to power in pursuit of the vision of a peaceful, just, and sustainable world.

16 AIDS as a Human Security Challenge

Nana K. Poku and Bjorg Sandkjaer

16.1 Introduction

The causes of human insecurity and suffering in the contemporary world are a major concern of this volume. If security is concerned with the achievement of basic human needs (CHS 2003), then HIV/AIDS poses the foremost challenge to the attainment of security in Africa. Though the exact mechanisms through which the epidemic is unfolding are not fully mapped and understood, it has a non-linear impact on state-society relations. As such, it serves to aggravate existing weaknesses by curtailing the range of options open to policymakers for expanding economies and achieving stated development goals sufficient to arrest underdevelopment on the continent.

In the most heavily affected countries the ramifications of HIV/AIDS are evident in the deterioration in social welfare indicators, such as life expectancy, literacy and primary school enrolment that had been improving for several decades. HIV/AIDS is reducing the capacity in all social and economic sectors, as a result of the mortality and morbidity of highly skilled and experienced people who cannot be replaced quickly or easily, but only after long periods of training and skill acquisition. General levels of education fall as enrolments decline among children who lose parents as a result of HIV/AIDS. In some hard hit communities, the epidemic is leading to a retreat into subsistence production in agriculture as a result of reductions in the economically active population. In turn, these declines in economic activity are reducing levels of tax revenue, which lowers the capacity of the public sector to undertake its functions at a time of dramatically increased demand for public services in health, education and training.

The net effect of the proceeding processes is the systematic erosion of the ability of all affected societies to safeguard the stock and flow of vital human capacity needed to sustain socio-economic development and political stability. The ability of nations, therefore, to improve the well-being of their citizens, build strong and

stable societies, and expand opportunities for all is threatened by the HIV/AIDS. The situation is complicated because many high HIV prevalence countries (especially in Africa) were performing poorly before HIV/AIDS gained a foothold.

The issue as to how HIV/AIDS affects society and in the process undermines its ability to sustain the vital human capital needed for sustained human development in Africa is the core preoccupation of this chapter. Using a human security framework (16.2), the chapter charts the rise of the HIV epidemic (16.3), explores the impacts of AIDS (16.4) and, based on primary research, postulates the possible ramifications on sustained human development in the years to come (16.4).

16.2 Human Security and HIV/AIDS

In the context of globalization, the threats posed to many people are of a wider variety, of lower intensity and less well-defined than what was previously perceived as security threats. Human security provides a framework for understanding these threats as they affect ordinary people and communities, rather than posing direct threats to states. Concomitant with this is a recognition that globalization brings into sharp focus the ways in which different categories of people are marginal to the states in which they live and the various forms of insecurity confronting them. It follows that human security represents a conscious attempt to relocate the security discourse, to move it from the impersonal terrain of inter-state relations and to embed it in a global social structure composed of humanity. In the process, the concept enables the analyst to challenge the notion of two separate worlds in which domestic security is set against the contrasting insecurity in the global political arena.

The *United Nations Development Programme* (UNDP) puts the position this way: "The concept of security has for too long been interpreted narrowly: as security of territory from external aggression, or as

protection of national interest in foreign policy or as global security from threat of nuclear holocaust ... forgotten were the legitimate concerns of ordinary people who sought security in their daily lives" (UNDP 1994: 22). The UNDP critique is clear and powerful. By placing the poor, the disadvantaged, the voiceless, the underrepresented and the powerless at the core of the security agenda, the human security discourse recognizes that for the majority of the people in the world, apparent 'marginal' or 'esoteric' concerns - such as environmental, food and economic security - are far more real and immediate threats to their daily survival than interstate wars.

Currently, most analysts, following the 1994 UNDP definition, agree that human security encompasses both 'freedom from want' and 'freedom from fear'. 'Freedom from want' describes a condition of existence in which basic material needs are met, and in which there is a reasonable expectation that protection will be afforded during any crisis. Similarly, 'freedom from fear' describes a condition of existence in which human dignity is realized, through protection from poverty and violent threat. The human security agenda, therefore, is concerned with the protection of human life and dignity in the modern world.

Nowhere has the importance of this agenda been more strongly embraced than in Africa. Here, the human security agenda offers a powerful voice for a coalition of actors to demonstrate in the most dramatic way the exposure of vast numbers of people, not only to the dangers of violence from contending bands of warriors and bandits in a manner reminiscent of medieval times, but also to hunger and disease on a cataclysmic scale. Here, the level, numbers and intensity of civil conflict spreading across the continent illustrate the lack of 'freedom from fear'. In 2005 over half the countries on the continent and twenty per cent of the population were affected by conflict (World Watch Institute 2005). During the previous decade over six million people were estimated to have died and over twenty million displaced as a direct result of conflict (Médecins Sans Frontières 2005). Human rights abuses in Angola, Ethiopia, Nigeria, or Zimbabwe, genocide in Rwanda or Sudan, and a whole range of outrages against civilians on all sides in the wars of Liberia and Sierra Leone are all cases in point. Progress on one front is so often accompanied by regression on another; as a faint glimmer of hope begins to emerge in the appalling conflicts in Sudan with the signing of the Comprehensive Peace Agreement and the Darfur Peace Agreement, the situation in So-

malia deteriorates, threatening to draw in Ethiopia (Rupiya/Nhema 2008).

Whatever the cause, it is the innocent - not necessarily aligned with any side - who suffer in their millions. The conflicts over the remains of Sudan, which has driven 1.5 million people from their homes (UNHCR 2006a), particularly highlight the plight of a population without protection from external or internal forces and yet at the same time falling prey to the remnants of the very state that was once supposed to be their protector. For millions of Africans therefore, the chief security threat is often the very government under whose sovereignty they live, either through the use of power and oppressive policies, or as a result of the governments' incapacity to sustain the infrastructure of life for the vast majority.

According to recent data from the *African Development Bank* (AfDB), some 80 per cent of the 'low human development' countries - these are countries with high population growth rates, low income, low literacy, and low life expectancy - in 2005, were located in Africa (AfDB 2005). There are only ten African countries in the middle category - Algeria, Botswana, Egypt, Gabon, Libya, Mauritius, Morocco, Seychelles, Swaziland and South Africa, five of which have a combined population of just 4.6 million - Mauritius, Seychelles, Botswana, Gabon and Swaziland. The remaining 43 countries on the continent are in the low human development category. There are 55 countries in this latter category, which means African countries account for a staggering 78 per cent of the countries classified as having attained low human development globally. Even more telling, is that, of the 30 countries with the lowest human development indices, 26 (or 87 per cent) are African.

The same report's celebrated headline growth of 3.5 per cent in GDP in 2005 compared to 3.2 per cent in 2004 (AfDb 2005) belies the systematic decline observable in real per capital GDP growth from 1.0 per cent to 0.8 per cent in the same period. In developmental terms, this means that the combined economies of Africa actually shrunk by 0.2 per cent in 2005. All other regions are already outperforming Africa, and efforts to redress this poor performance over the past two decades have not been successful. In 2004, for example, the average *Gross National Product* (GNP) per capita in the *Organization for Economic Co-operation and Development* (OECD) countries was \$28,086 compared with \$528 in Africa (OECD 2006). This means that the industrialized countries are roughly 51 times wealthier than African states. Assuming that the OECD countries could stop

stretching this development gap further, and hoping that African economies could grow at an annual rate of 3.5 per cent over the coming years, it would still take the continent some 135 years to reach today's level of wealth enjoyed by OECD countries.

Not surprisingly, poverty has increased at a faster rate on the continent than anywhere else in the world. With just over a tenth of the world's population, the continent is home to one third of the world's poor persons. Four of every ten of its inhabitants living in what the World Bank (2000: 12) classifies as 'a condition of absolute poverty.' More worrying still, as the only continent in the world, Africa has experienced an *increase* in poverty and hunger over the last fifteen years or so (figure 16.1). The number of people living on less than a dollar a day increased from 227 million in 1990 to 313 million in 2005, and the very poor are getting poorer. In the same period, the number of hungry people also increased in Africa, by a staggering 34 million. Of the children under five in sub-Saharan Africa who are underweight, the proportion decreased somewhat (from 32 to 31 per cent from 1990 to 2003), but in absolute terms, the numbers rose from 29 million to 37 million (UN 2005).

Figure 16.1: Percentage of Africans living on less than a dollar a day. **Source:** Authors, using data from UN (2005).

If current trends continue, by 2015 Africa will account for 50 per cent of the poor of the developing world [up from 25 per cent in 1990] (World Bank 2005). During the 1990's the region experienced a decline in GDP per capita of 0.6 per cent per annum, and because economic growth was highly skewed between countries, approximately half the total population is actually poorer in 2004 than in 1990. Income and wealth distributions are extremely unequal in many countries, and with improved growth rates such ine-

qualities are likely to increase rather than to diminish (World Bank 2003).

Whatever the causes of Africa's crisis, about which there is quite legitimately a considerable debate, it is hard to escape the fact that governments on the continent have largely failed in their duty of care to their citizenry. As a result, Africa now stands as the most marginal continent in the world. If we remove territorial boundaries from our cognitive map, we are left with a picture of a people across the continent attempting to meet their basic needs within the hostile and unpredictable environment of violence and political instability. Households are striving to secure these needs in conditions of extreme adversity, as governments and state managers either fail to, or are unable to, pursue policies that would ensure their protection for entrenched poverty.

Figure 16.2: Number of People Living with HIV/AIDS in Sub-Saharan Africa. **Source:** Authors, calculated using data from the World Bank (2005).

A tragic manifestation of this failure has been the states' inability to protect ordinary people from both 'freedoms from fear' (violence) and 'want' (poverty). The resulting fragmentation and dislocation of societal structures has made millions of Africans vulnerable to contracting HIV/AIDS. By all accounts, the African continent has been the most severely affected by the HIV/AIDS epidemic (UNAIDS/WHO 2006). With just over 14 per cent of the world's population, the continent is home to about 60 per cent of all people living with HIV - 25 million at the end of 2005. During the same year an estimated 3 million people in the region were newly infected with HIV, while 2 million died of AIDS - joining the estimated 20 million Africans already claimed by the epidemic. A quarter of the people in the region infected with HIV are young (aged 15-24 years) and three quarters of those are girls and young women. As the epidemic matures, the prevalence rates are expected to more or less plateau towards 2020. However, this does not necessarily mean that the epi-

Figure 16.3: Impact of HIV/AIDS on population growth for selected southern African states. **Source:** Authors, using data from UN/DESA Population Division (2005).

demographic has 'slowed down'. Prevalence measures the proportion HIV infected in the population at a given time, and this will be a function of the number of infections, but also of the number of AIDS deaths. Stable prevalence may mask a situation where the number of new infections offsets the number of deaths – not a 'slowed down' epidemic at all! However, as a measure of proportion infected prevalence does provide a useful measure, and as can be seen in figure 16.2, the number of HIV infected in Sub-Saharan Africa (SSA) is projected to steadily increase to just above 30 million in 2020 (see chap. 17 by Benz).

In the majority of southern African countries, at least one in six adults is currently HIV positive and the likelihood of a 15-year-old woman dying before the end of her reproductive years is expected to quadruple from around 11 per cent in the early 1980's to over 40 per cent in 2010 (Ngoma/Le Roux 2008). If it is assumed that five people within an immediate African family are directly affected by the death of a family member from HIV/AIDS, then some 200 million Africans are closely affected by the epidemic. To this number one needs to add those less directly affected in extended families, colleagues at work, close friends in faith and other communities – perhaps a doubling of those directly affected to give a total of some 200 million at the lowest estimate. A staggering proportion of Africa's people – possibly half the entire population – feel the effects of the epidemic.

As a result of these demographic changes, there will be fewer people, especially in the productive 20 to 50 year old age groups, to attend to social reproduction and contribute to the management of national affairs whether in government, business, reli-

gious or social life. The growing number of HIV/AIDS-related illnesses and deaths in society will quickly undermine achievements in reducing death rates. Estimates made earlier in the epidemic's history projected some slowing of population growth rates. However, as the epidemic has become more intense and extensive, experts estimate that countries in southern Africa will experience a loss of population, as more people die than are being born (figure 16.3). By 2010, it is predicted that the population of Botswana, South Africa and Zimbabwe will decline by about 1 per cent per year. Without AIDS, the population would have grown by between 1.0 and 2.0 per cent in these countries (UN/DESA Population Division 2005).

AIDS-related deaths are occurring especially among young and middle-aged adults, between the ages of 24 and 50. Women tend to die in the younger age brackets (20–35 years old) while men tend to die in the older age brackets (30–45 years old). Infants, too, are dying at an increasing rate because they acquire HIV/AIDS before they are born or shortly thereafter. In 1990 infant mortality in Zimbabwe was 54; in 2005 the rate had risen to 62. In Kenya, infant mortality in 1990 was 67, in 2005 it was 69. Without AIDS infant mortality would have continued to decline in both countries (UN/DESA Population Division 2005).

As infants and young adults die at increasing rates, overall life expectancy will dramatically decline (figure 16.4). As of 2005, life expectancy in Botswana was less than half of what it would have been without AIDS. In Zimbabwe, life expectancy is 40 years instead of 69 as it would have been in the absence of AIDS. Seven sub-

Figure 16.4: Impact of HIV/AIDS on life expectancy at birth, 1970-2015. **Source:** Authors, using data from UN/DESA Population Division (2005).

Saharan African countries (Angola, Botswana, Lesotho, Malawi, Mozambique, Rwanda, and Zambia) have life expectancies below 40 years. Each of the countries, except for Angola and Mozambique, would have had an estimated life expectancy of 50 years or more without AIDS (UN/DESA Population Division 2005).

The epidemic is restructuring the population. Age distribution in societies is changing dramatically, with fewer infants, young children and young adults than would be the case without HIV/AIDS. The implications are several. Fewer children mean a smaller pool of future human resources to take part in national development. Older adults will be proportionally more numerous and will have to take on new responsibilities to care for children and generate income. There will be fewer young and middle-aged adults to provide income and raise families. Families, businesses and nations will have a smaller number of adults to count on for leadership and management.

16.3 Impact of HIV/AIDS on Sustainable Development

A strong feature of Africa's HIV epidemic is that it clusters within families, often resulting in both parents being HIV-positive, and in time falling sick and dying. Given the overall levels of poverty, most families have a reduced capacity to deal with the effects of morbidity and mortality: these include the cost of drugs - when available - to treat opportunistic infections, the cost of transport to health centres, reduced household productivity through illness and diversion

of labour to caring roles, loss of employment through illness and job discrimination, funeral and related costs, and so on. In the longer term most households never recover even their initial level of living, since their capacity is reduced through the loss of productive family members through death and the sales of any productive assets they once possessed. As a result, a true process of immiseration is now observable in many parts of Africa, particularly in southern Africa. This image from a field worker in Zambia illustrates the challenge:

In the field you are often led into somebody's home. The first thing that hits you is that the patient will be on the floor. If that household was not poor before HIV/AIDS infected somebody, then by the end of the first few years, poverty will come to the household as all of their assets are sold off to pay for healthcare. Children have been taken out of school - daughters, particularly - to become caregivers. Invariably, the person you have come to see will be on the floor without a blanket or a pillow. If you look around that mud hut for food, you won't see it, and you won't smell people cooking. There is no food (Poku 2005: 24).

There is thus enormous strain on the capacity of families to cope with the psychosocial and economic consequences of illness, such that many families experience great distress and often disintegrate as social and economic units. Even where they do not, by eliminating the breadwinners - often both parents - the process further exposes the rest of the family members to poverty, which then increases their chances of contracting the virus. This is particularly so for young women, who will often be forced to engage in com-

Figure 16.5: Women in Parliament 2004. **Source:** Population Reference Bureau (2005).

mercial sexual transactions, sometimes as casual sex workers, as a survival strategy for themselves and their dependants.

Indeed, the need to integrate gender issues is nowhere more essential and urgent than in the programme and activities on HIV/AIDS. This is because women play a central role in the economy and society of countries in the region, and their capacity to do so is being undermined by HIV and AIDS. An old Chinese proverb states that 'Women hold up half the sky', but in the case of African women they possibly hold up a larger share than this. The centrality of women's social and economic role is not at all reflected in either their representation at the political level, in parliaments or cabinets, nor in the senior ranks of company managers and executives; certainly not in their share of ownership of wealth or their levels of income. Taking the example of parliaments, despite an increase, women are still under-represented in political decision-making structures in both North Africa and Africa south of the Sahara (16.5).

However, despite the lack of reflection of women's centrality in these measures, they are the backbone of social and economic life: they account for an overwhelming share of agricultural labour, especially in the non-measured sectors of agriculture; their domestic work involves essential activities such as water collection, fuel-wood gathering, food processing, processing of agricultural commodities for sale such as beer brewing; they also are responsible for the upbringing and socialization of children, including the passing on of essential skills to the next generation; and they undertake the care of household members, especially the sick, a task which has ex-

panded dramatically in the era of HIV/AIDS. All of these activities undertaken primarily by women are threatened by the HIV/AIDS epidemic, and the consequences for society are extremely serious.

A note of caution must be entered here: to acknowledge the synergistic relationship between poverty and vulnerability to HIV is not to conclude that AIDS itself is a nutritionally based disease. Equally, it is important not to deny that HIV is sexually transmitted across the African continent and causes AIDS. The argument is rather that any disease in Africa, however transmitted, must be placed in the context of the continent's human insecurity. The epidemic compounded a downward spiral whereby existing social, economic and human deprivation produces a particularly fertile environment for the spread of HIV. In turn, the HIV epidemic compounds and intensifies the deprivation already experienced by people across the continent. In this sense, AIDS is more than a disease. It is also much more than a public health crisis. AIDS in Africa is a development crisis of the highest magnitude.

One of the most widely used indicators of development is the Human Development Index of UNDP. This is an unweighted index of three variables: life expectancy, a measure of purchasing power per capita, and educational attainment. It is argued that such an index is a preferable indicator of development and as a broader aggregate is better than GDP as a measure of human progress. All three components of the HDI are affected by the HIV epidemic. Life expectancy is reduced, possibly very significantly by HIV/AIDS due to increasing levels of under 5 and adult mortality. As also is the rate of GDP growth through decline in the

savings and investment rates, and reductions in the labour force [both in quantity and quality]. It is also the case that educational attainment is worsened by lower rates of educational attendance due to falling enrolment of children affected by HIV/AIDS, together with attrition of educational personnel due to losses of teachers, administrators etc. which has adverse consequences in terms of the educational capacity.

Data on components of the HDI vary in quality and comprehensiveness between countries in the region and this causes problems in making comparisons in terms of the HDI. For some countries, such as Botswana, which has good surveillance systems for HIV and for other indicators such as educational enrolment, the HDI probably measures well what is happening to human development - including the impact of HIV/AIDS since this will be reflected in data relating to economic growth, life expectancy and education. This may be less true for other countries within the region where data is less comprehensive and may not in all cases reflect what is actually happening to the three variables in the HDI.

Nevertheless, with these caveats it is still instructive to review the trends in the HDI for member countries as another indicator of the impact of the HIV epidemic on sustainable development (see table 16.1). Countries with an HDI value above 0.500 fall into the 'medium development group' and those below into the 'low development group'. On the basis of 2006 levels of the HDI a significant proportion of the countries in the region fall into the latter category, reflecting high levels of poverty, low levels of literacy and low and falling life expectancy.

A comparison of the changes in the levels of the HDI for individual countries between 1995 and 2006 is instructive: of the nine countries for which there is data, no less than six of them show declines in the value of the HDI. For the three countries that do not show a decline (Tanzania, Malawi and Mozambique) there are sound reasons for doubting the quality of the underlying data used in constructing their HDI values. Data revisions that are under way for these three countries will almost certainly lead to a revaluation of their HDIs which will confirm a worsening of their human development performance over the past decade.

What is less evident from the levels of the HDI is what has been happening to the relative ranking of the various countries, and here there have been significant changes - in large part due to HIV/AIDS. Every country, apart from Angola, suffers a fall in its HDI rank between 1996 and 2006 (table 16.1). The changes

Table 16.1: Human Development in selected African countries. **Source:** UNDP (2006).

Country	HDI ranking – 2006	HDI value – 1995	HDI value – 2006
South Africa	107	0.714	0.695
Namibia	122	0.610
Swaziland	125	0.615	0.577
Botswana	126	0.653	0.572
Zimbabwe	128	0.597	0.551
Lesotho	132	0.574	0.535
Tanzania	151	0.422	0.440
Zambia	153	0.468	0.433
DRC	155	0.431
Angola	161	0.403
Malawi	163	0.362	0.400
Mozambique	170	0.310	0.322

in rankings over such a short time are in a few cases very significant. For example Botswana moves from a rank of 71 in 1996 to 126 in 2006 [largely a reflection of the large decline in life expectancy], while South Africa also shows a decline over the same period from 100 to 107. The other two countries where significant declines have taken place in relative human development are Zambia and Swaziland, for reasons which are also largely related to the effects of HIV and AIDS, although in the case of Zambia the decline also reflects sharply falling GDP per capita due mainly to non-AIDS related causes.

16.4 HIV/AIDS: The Biggest Development Challenge

The importance of human capital for the achievement of sustainable development is recognized by all development practitioners. In part this capital is the outcome of social processes undertaken privately, usually by families, and in part it is the outcome of formal activities undertaken by the state in the public education and training system, and private institutions such as enterprises and churches. Whatever the source of the investment in human capital it is essential for the processes of development. Because the HIV epidemic is concentrated in the working age population, both men and women, and may be affecting disproportionately those with better education and skills, there is

occurring in many African countries an immense loss of human capital. Both the stock of human capital is suffering attrition, but so is the flow of those who are educated and trained.

These developments have consequences for all forms of social, economic and political activity, and thus will have implications for the totality of human development. It is therefore logical to expect HIV/AIDS to further intensify poverty in many countries on the continent. Until recently, the most common method for projecting this effect was to estimate the effects by projecting the impact of the epidemic on Gross Domestic Product (GDP) (Kambou/Devarajan/Over 1992; Cuddington 1993; Cuddington/Hancock 1994; Abt Associates 2000; Arndt/Lewis 2000; Whiteside/Sunter 2000; Arndt 2002; Barnett/Whiteside 2002, Drouhin/Touzé/Ventelon 2003). This work typically found that HIV/AIDS will reduce economic growth but only by modest amounts. It is now, however, widely accepted that the method of projection has an important shortcoming as it does not take fully into account the reduction in welfare due to the loss of family members. Recent work attempts to address these shortcomings by using a broader definition of welfare that includes the monetary value of the changes in life expectancy along with per capita income.

Key among these works is a World Bank study which argued that after allowing for inter-generational losses of human capital (and knowledge), the projected macroeconomic effects of HIV/AIDS will be severe (Bell/Devarajan/Gersbach 2003). To illustrate the dynamics of this impact, take the case of a family on an island that is affected by AIDS. Most economic models that were used to project the impact of the epidemic would project that the survivors would enjoy higher per capita income. However, this result neglects the welfare of the family members who died on account of AIDS and the (likely) lower welfare of the surviving members. Especially important are the following two effects: First, the loss of human capital cripples the capacity of countries to develop an effective response to the HIV/AIDS. Because the education sector and the health sectors are keys to implementing prevention programmes in school and providing medical care, the loss of human capital increases the odds that the HIV/AIDS epidemics will remain stronger and last longer than otherwise. Second, the increased mortality among those meant to pass on information erodes the transmission of knowledge across generations. Over time declining human capital and lower investment combine to re-

duce the productivity growth on which long-term per capita income growth depends. This in turn reduces the children's ability to invest in their children's education and so on.

These inter-generational effects were already widely noted, especially in relation to the effects of HIV/AIDS on agriculture.¹ The study mentioned above, however, represents a watershed for the World Bank: to this point, its research had concluded that the macroeconomic impacts of HIV/AIDS would be limited (Ainsworth/Over 1994; Arndt/Lewis 2000; Bonnel 2000). The recent research cannot, however, be the last word. Under conservative assumptions, the conclusion is then that Africa's mortality changes already imply an economic cost of HIV/AIDS equal to 15 per cent of 2000 GDP. This translates into a decline in income of 1.7 per cent per year from 1990 to 2000 (Bloom/Canning/Jamison 2004), which exceeds previous estimates based solely on the loss of output due to the epidemic. In the case of a typical African country with a prevalence rate of 20 per cent, recent estimates from the Commission on HIV/AIDS and Governance in Africa suggests that GDP could be 67 per cent less than otherwise at the end of a twenty-year period. One implication of this is that high prevalence countries will sink into greater poverty.

The process above raises the following social and fiscal challenges for sustainable development in developing regions. First is the threat of worsening inequality: if the children left orphaned are not given the care and education enjoyed by those whose parents remain uninfected, there will be increasing inequality among the next generation of adults and the families they form. Social customs of adoption and fostering, however well established, may not be able to cope with the scale of the problem generated by a sharp increase in adult mortality, thereby shifting the onus onto the government. The government itself, however, is likely to experience increasing fiscal problems and so be unable to fully finance this additional task. Second, by killing mainly young adults, AIDS seriously weakens a country's tax base, and reduces its ability to finance public expenditures, including those aimed at accumulating human capital, such as education and health services not related to AIDS. In this way, the damaging impact of HIV/AIDS on economic growth over

1 See for details: FAO (1996); Decosas (1996); Cohen (1997); du Guerny (1999); UNAIDS (1999, 2001); McPherson (2001, 2002a); Piot/Pinstrup-Andersen (2002); de Waal (2002); Somerville (2002); Stokes (2003); Hertford (2003)

the longer run is intensified. As a result, national finances will come under increasing pressure. Slower economic growth means slower growth of the tax base, at the same time as governments face growing demands to treat the sick and care for orphans. It will also distort development spending on other areas, since it will be necessary to use valuable resources in 'defensive' or socially unproductive ways.

With such potentially devastating economic effects, the mitigation of the epidemic becomes as important as controlling the spread of the disease itself. But in a context where access to health care is already low, the delivery of mitigation services looks set to pose, perhaps the most daunting challenge of all. In the absence of HIV/AIDS, the population group aged 15–49 accounts for about 20 per cent of all deaths. But with AIDS the mortality rate of the adult population increases sharply. How much the mortality rate increases has been a subject of considerable debate in Africa due to the lack of adequate statistics on the causes of death. In the absence of such data two alternative methods exist. The first is to project the AIDS-related increase in mortality on the basis of a mathematical modeling of the epidemic. Applying this approach to *sub-Saharan African* (SSA) countries suggests that HIV-related deaths represented 30 per cent of all deaths during the period 1996–2001.² An alternative method is to estimate the increase in mortality directly from the excess deaths that can be attributable to AIDS. In the case of South Africa, this method indicates that about 27 per cent of the deaths recently observed in South Africa were HIV-related (Groenewald/Nannan/Bourne/Laubscher/Bradshaw 2005), which is quite consistent with the first approach.

The reason why HIV/AIDS has such an impact on mortality can be understood from the typical characteristics of the HIV epidemic. In a typical African country adult mortality was around 7 per 1000 before the advent of HIV/AIDS. A stable 7 per cent HIV prevalence rate (average for SSA) would therefore increase the death rate of the whole population by about 20 per cent.³ For the more heavily infected countries with an HIV prevalence rate of 20 per cent, the increase would be much larger of the order of 80

per cent⁴. Quite clearly, the impact on health services is likely to be substantial. If as an approximation, one assumes that the demand for health care is proportional to mortality rates, the demand for health services would increase by about 20 to 80 per cent in sub-Saharan Africa.

If antiretroviral treatment delivers its promise of longer lives, it will substantially increase the numbers of people living with AIDS. An important reason is the increase in life expectancy made possible by antiretroviral drugs. Figure 16.6 shows the increase in the number of people treated with antiretroviral drugs under two assumptions. The first one is that the percentage of people with access to treatment would increase from 8 per cent of those in need of treatment to 80 per cent over the long-term. The second one is that treatment would extend lives. If lives are extended by three years, the number of people under treatment would increase from 300,000 in 2004 to 6 million in sub-Saharan Africa by 2015. But if treatment provides a gain of ten extra years of life, the number of people under treatment would reach 9 million over the long-term.

Figure 16.6: Number of Adults Receiving Antiretroviral Treatment in sub-Saharan Africa. **Source:** Simulation based on Salomon/Hogan/Stover/Stanecki/Walker/Ghys/Schwarländer (2005). It is assumed that the per cent in need receiving ART increases from 8 per cent in 2004 to 80% in 2012 and remains at 80 per cent until 2025.

- 2 Bradshaw/Groenewald/Laubscher/Nannan/Nojilana/Norman/Pieterse/Schneider/Bourne/Timaues/Johnson (2003).
- 3 Under the assumption that the median time from infection to death is 10 years, adult mortality would increase by 7 per 1000 or 100 per cent. As the group aged 15–49 typically accounts for 20 per cent of number of deaths in the absence of AIDS, the aggregate mortality would increase by 20 per cent.

- 4 With an HIV prevalence of 20 per cent, adult mortality rises from 7 to 27 deaths per 1000 or 386 per cent, which translates into a 77 per cent increase in the total demand for health services.

16.5 AIDS and Instability

The AIDS epidemic provides a powerful reminder of how the demilitarization of security thinking in global politics should, in no way, be mistaken to imply that the issues at stake have any fewer ramifications for state security and – in some cases – survival. These harrowing statistics of prevalence, mortality and demographic changes only indicate the wider reach and impacts of the epidemic. If it is assumed that five people within an immediate African family are directly affected by the death of a family member from HIV/AIDS, then some 200 million Africans are closely affected by the epidemic. To this number needs to be added those less directly affected in extended families, colleagues at work, close friends in faith and other communities – perhaps a doubling of those directly affected to give a total of some 400 million at the lowest estimate. Thus a staggering proportion of Africa's people – something like half of the entire population – personally feel the effects of the epidemic.

As many countries are still in a relatively early stage of the HIV epidemic, the long term political ramifications are unclear, but it is possible that it might act as a destabilizing force in many countries. Already, in some countries the epidemic poses, with increasing immediacy, the challenge of how democratic transitions can continue amid prevalence levels as high as 10, 20, and 30 per cent of adult populations. Participation is affected through two channels: morbidity and mortality. Increasing mortality among the electorate has the immediate effect of reducing the number of people who can vote. Through morbidity large sections of people are disenfranchised either because they are ill themselves or are looking after family members, friends or community members who are incapacitated by the epidemic. It follows that if political participation is adversely affected by the epidemic, then so will legitimacy, accountability and the ownership of political processes and outcomes over the *longue durée*.

That the epidemic is concentrated in regions already undergoing tenuous economic transitions only heightens the risk of state failure. As the human resources and capacity of government ministries and agencies are lost to HIV/AIDS, the ability of the state to carry out its functions is impaired (figure 16.7). To date, one of the most significant inquiries into the impact of HIV/AIDS on governance systems is the work of the UN *Commission on HIV/AIDS and Governance in Africa* (CHGA). CHGA found that HIV/AIDS undermined the capacities of local and district

governments, through loss of both staff members and volunteers. The fact that local and district political organizations personal leadership of one or a handful of energetic and well-networked individuals leaves them highly vulnerable to the loss of such key staff members. By the same token, the pandemic may witness reduced readiness to participate in all forms of public life including elections. There may also be pressure on local organizations, such as community-based organizations to focus on the pressing requirements of AIDS care, so that other important activities – for example human rights education – are scaled back or abandoned.

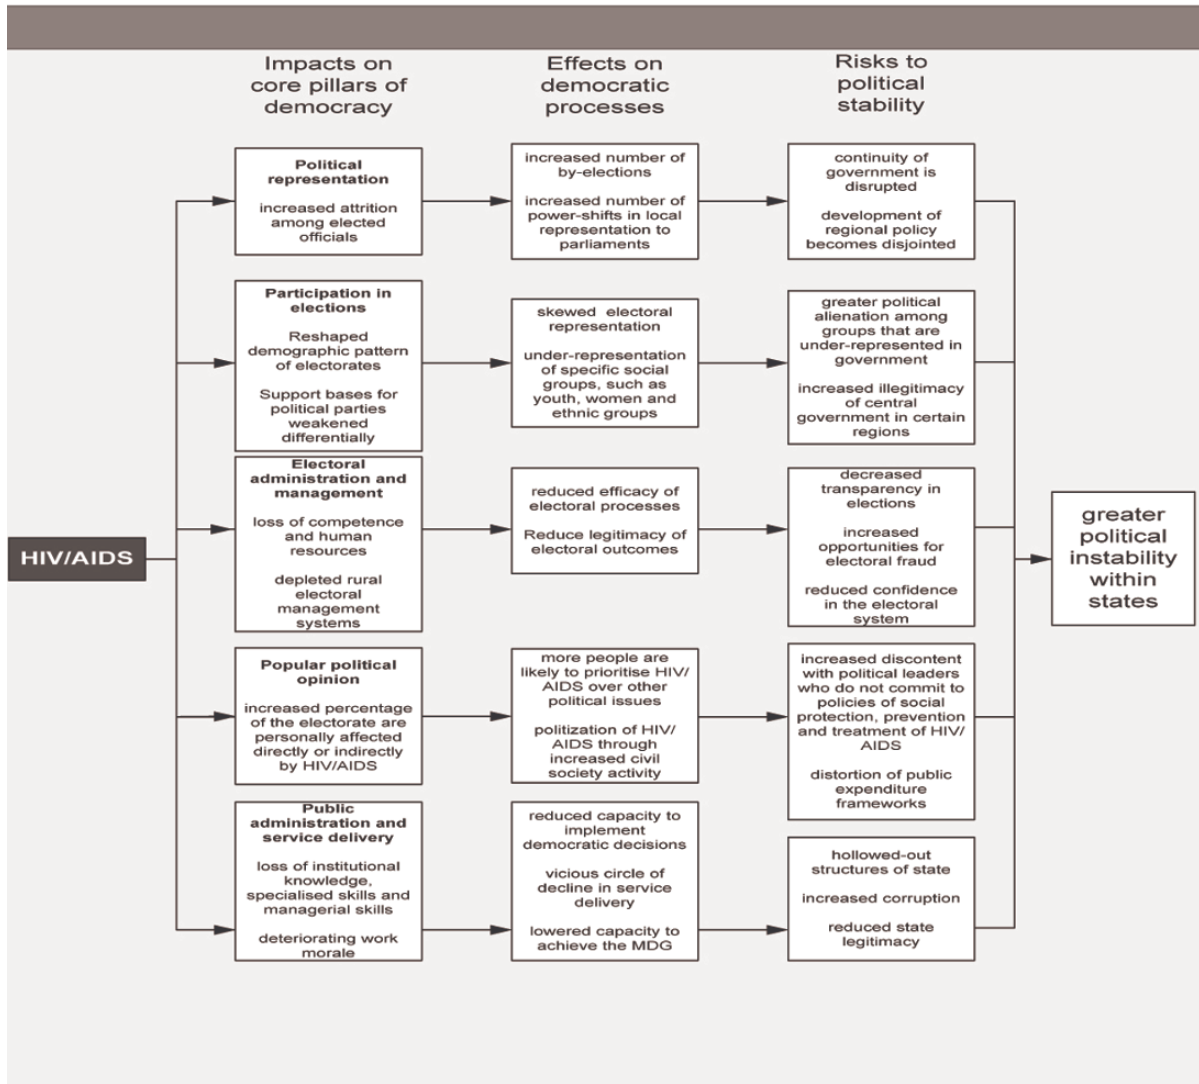

What the CHGA findings confirm is that, across the continent the structures of government remain, but the ability to govern is diminished. Some authorities refer to this situation as the 'hollow states hypothesis'. The concept refers to the existence of state systems, but the inability of the state to fulfil its stated responsibilities and functions. It implies a weak state, without the ability to provide sustained leadership across society. It further implies a state relying largely on the support of those who receive some benefit from its existence. Finally, it implies a form of governance in which the state is unable to adequately interact with citizens through democratic institutions.

In many African countries, the losses of human capacity are likely to leave states less capable of protecting and providing for their citizens, thus failing a core function of effective governance, with ramifications for both political legitimacy and stability in the years to come. But, just as the epidemic endangers pillars of nation-states, so too does it strike at the pillars of international stability and governance. A more direct security threat is that AIDS induced weak states may become havens for new enemies of global order. Such states give extremist groups freedom of operation, with dangerous consequences for global order.

16.6 Conclusion

Slowly and belatedly, we are awakening to the full implications of the HIV/AIDS epidemic in Africa. As the data and analysis provided in this chapter clearly demonstrate, this is an epidemic like no other. It is quite simply the most important issue in sub-Saharan Africa for the coming decade, bar none. It has already set in motion processes that will transform the continent's political, economic and social structures for ever, destabilizing societies and eroding human security. Sadly the world, and in particular, African govern-

Figure 16.7: Conceptual framework for impacts of HIV/AIDS on democratic processes. **Source:** The authors.

ments are simply not set up to deal with the ramifications. There is a conspicuous reluctance by institutions, both African and donor, to develop institutional mechanisms for dealing with the challenge. There is a tendency for HIV/AIDS to become an add-on to other ‘more urgent’ demands. There is also a well-demonstrated tendency to discount the darker ramifications of the epidemic, especially in view of the fact that other disasters (notably famines) have repeatedly failed to kill the huge numbers of people predicted by the media and some relief agencies.

It is all too increasingly apparent, however, that HIV/AIDS is different: the figures are real, and there cannot be the rapid ‘bounce back’ to a version of normality quickly afterwards. The impact of AIDS on human resources and institutional capacity means that it

will be necessary for African governments and their development partners to prioritize ruthlessly. Although the proximate cause of the epidemic is sexuality, the underlining societal causes are much broader and familiar. Across Africa, poverty structures not only the contours of the pandemic but also the outcome once an individual is infected with HIV. Thus, until poverty is reduced there will be little progress with either reducing transmission of the virus or creating an enhanced capacity to cope with its socio-economic consequences. This will require some political courage, and the sacrifice of some other ideals and aspirations.

The next step has to be the development of policies and programmes that address the interrelationships between poverty and development and actually

to put in place those activities that can make a difference for development outcomes. Central to these activities are programmes that address poverty today so as to facilitate socio-economic development tomorrow. Herein lays Africa's predicament: how to achieve the sustainable development essential for an effective response to the pandemic under conditions where the epidemic is destructive of the capacities essential for the response – namely, killing the most economically productive members of the continent's people. Simple answers to this problem do not exist, but recognition of its nature is a step towards its solution.

Policy makers, donor organization and institutions on the continent, such as the African Union, need to focus their energies on doing just two or three things, each of them relevant to combating the epidemic, rather than trying to do everything from industrial development to judicial reform. This is not a blueprint for abandoning social development in favour of HIV/AIDS programming. On the contrary, the political energies required for overcoming the epidemic can be drawn from these other, longer-established social agendas. A symbiosis between long-standing demands such as education, food security or local democracy and HIV/AIDS will enable both aims to be met.

Sophia Benz

17.1 Introduction

It is increasingly argued that HIV/AIDS might threaten the internal and external security of severely affected societies, for example through the loss of military personnel,¹ through rising crime rates associated with the increasing number of AIDS orphans,² and especially through its destabilizing economic impact.³ Thus, HIV/AIDS can be viewed as an indirect cause of conflict due to its direct impact on social, political, and economic variables decisive for the outbreak of conflict. Although various studies have explored this issue⁴, the question whether and how far AIDS may affect political stability, lead to state failure, or even to

the outbreak of conflict requires empirical examination in the coming years as the epidemic unfolds and the necessary AIDS-death data become available.

However, what can be empirically analysed at this point is the reverse-causal effect or the question whether conflict experience impacts on HIV-prevalence rates. Below, the key arguments of a study will be introduced which examines decisive mechanisms linking HIV/AIDS and conflict experience.⁵ In addition, main results of the corresponding quantitative analysis are presented before some policy conclusions are drawn from these results.⁶

In accordance with the theme of this book the overall aim is to illustrate how HIV/AIDS as a health issue interacts with conflict or war experience. Recognizing the HIV/AIDS epidemic as a non-traditional threat to security highlights the importance of a widened and deepened definition of security. In addition, debating and analysing the links between HIV/AIDS and political instability helps to answer the question

5 The term ‘conflict’ refers to the concept of ‘armed conflict’ as defined by Gleditsch/Wallensteen/Eriksson/Stollenberg/Strand (2004): “Armed conflict is a contested incompatibility that concerns government and/or territory where the use of armed force between two parties, of which at least one is the government of a state, results in at least 25 battle-related deaths” (Gleditsch/Strand/Wilhelmsen 2004: 3). For the purpose of analysis armed conflict is later categorized into ‘minor armed conflicts’ with at least 25 battle-related deaths per year and fewer than 1,000 battle-related deaths during the course of conflict, ‘intermediate armed conflicts’ with at least 25 battle-related deaths per year and an accumulated total of at least 1,000 deaths, but fewer than 1,000 per year, and ‘wars’ with at least 1,000 battle-related deaths per year (see Gleditsch/Strand/Wilhelmsen 2004: 4).

6 The extended version of this study is available at: <<http://www.ub.uni-konstanz.de/kops/volltexte/2005/1473>> and has been submitted to the University of Konstanz in partial fulfilment of the requirements for the MA degree in Politics and Management (Diplomarbeit). The statistics package used is: STATA 8.0, 6.0.

as to how far health initiatives can be used as peace initiatives, as well as the question of how far peace initiatives might play a role in improving overall health. As the results of the quantitative analysis indicate that countries' prior conflict involvement significantly correlates with higher HIV-prevalence, this supports the importance of health interventions in conflict and peacekeeping settings. In addition, these results suggest that peace initiatives have a vital role in promoting health and indirectly contribute to stop the HIV virus from spreading.

17.2 The Theoretical Argument

Theoretically, the study is based on the 'Jaipur Paradigm', enlarged by a micro-foundation as well as a conflict dimension. The Jaipur Paradigm is a social epidemiological approach which explains differences in the progress of HIV/AIDS epidemics through variations in countries' socio-economic susceptibility and vulnerability to the disease.⁷ According to this approach, countries' susceptibility and vulnerability is determined by only two factors: their level of wealth and the degree of social cohesion or income inequality.⁸ Elsewhere it is argued that at least one dimension of the social cohesion concept (a strong civil society protecting human rights) associates with less vulnera-

bility to HIV-infection. Separatism, fragmentation, and marginalization decrease the capacity for action of socially isolated individuals living in areas with low social capital.⁹ In addition, health information and innovative behaviour (e.g. condom use) may also diffuse more rapidly in communities that are cohesive and whose members trust each other. At the individual level, social capital may influence health behaviour by establishing social identities and societal norms, which are collectively negotiated and which promote healthy behaviour, trust, and respect. Others argue that members of cohesive and trusting communities are more likely to experience high levels of perceived self-efficacy and empowerment, which increases the likelihood that they will engage in health-protective behaviour. Finally, social capital may also lead to the development of and accessibility to health care services.¹⁰ Thus, social capital facilitates collective action and eventually leads to policies which are more likely to benefit and protect all citizens.

Empirical evidence derives from a study by DeHoltgrave and Crosby (2003) that examines poverty, income inequality, and social capital as predictors of state-level AIDS rates in the US. Social capital is found to be the strongest predictor of both STD and AIDS rates, and the authors conclude that membership in social organizations protects against risky sexual behaviour. Although a study from South Africa that examines only the civic participation aspect of social capital suggests that the type of organization to which one belongs makes a difference (Campbell/Williams/Gilgen 2002), there is support for the 'Jaipur Paradigm' in the HIV/AIDS literature and for the thesis that levels of social cohesion, social capital, wealth or income inequality correlate with HIV/AIDS.¹¹

According to the Jaipur Paradigm, especially poor countries with little social cohesion face high levels of susceptibility to HIV-infection and high levels of vulnerability to its impact. These countries often experi-

7 Susceptibility refers to the level of risk for HIV-infection in a particular social environment, defined as those aspects of a society which make it more or less likely that an epidemic will develop. In contrast, vulnerability refers to those aspects of a society which influence the likelihood that an epidemic will have a serious impact on social and economic organizations (Barnett/Whiteside/Decosas 2000: 1099).

8 The concept of social cohesion refers to (1) the absence of latent social conflict (in form of income inequality, racial/ethnic tensions, disparity in political participation or other forms of polarization), and (2) to the presence of strong social bonds or high levels of "social capital" (Kawachi/Berkman 2000: 175). Thus, cohesive societies are those that are richly endowed with stocks of social capital, which is associated with informal sociability, social trust, civic involvement in public affairs, high levels of volunteerism, and the existence of a vivid community organizational life. The authors of the Jaipur Paradigm themselves note that social cohesion may be an expression of cultural homogeneity, it may be the product of good governance and a strong civil society, it may be related to a prescriptive religious culture, or it may be the result of a controlling authoritarian political system or military dictatorship (Barnett/Whiteside/Decosas 2000: 1100).

9 See Putnam's measure of social capital as described by DeHoltgrave/Crosby (2003): "The measure is a combination of 14 variables that span the domains of community organizational life, involvement in public affairs, volunteerism, informal sociability, and social trust" (DeHoltgrave/Crosby 2003: 62).

10 See: Mann (1999); DeHoltgrave/Crosby (2003: 62); Kawachi/Berkman (2000: 179-180, 184-185); Campbell/Williams/Gilgen (2002: 51); Deneke/Faltis/Hildebrandt/Trojan (1991); Poundstone/Strathdee/Celentano (2004: 26).

11 See: Over (1998); Mahal (2001); DeHoltgrave/Crosby (2003); Kawachi (2000).

ence civil war or economic collapse, and although it may take time for the epidemic to develop, it will eventually reach very high levels. Their lack of social cohesion and an unequal distribution of wealth render an effective response difficult. Thus, HIV-prevalence levels are also predicted to remain high.

Although the 'Jaipur Paradigm' greatly improves our understanding of the AIDS epidemic by adding this decisive socio-economic explanatory dimension, the approach is not without its weaknesses. It has been especially criticized because it lacks a sound micro-foundation and only implicitly assumes that the level of wealth and social cohesion is somehow causally related to the HIV-transmission, and therefore individual risk behaviour. Interpreting a population-based association between socio-economic variables and national HIV-prevalence, and inferring a causal effect on individual-level processes is, however, problematic.

Therefore, a micro-foundation is added by relying on socio-psychological approaches that state that individual health risk behaviour is determined by the following factors: the individual's perceived threat or susceptibility to the disease, the individual's cost benefit calculation as benefits of taking a preventive action need to outweigh the perceived barriers or costs, and finally demographic, socio-psychological, and structural factors (or environments) which act as external barriers or motivators to individual risk behaviour. The specific application of this approach to the AIDS epidemic is the so-called "AIDS Risk Reduction Model".¹² This model argues that in order to change risk behaviour individuals need to move across three stages: first, they need to recognize and label their behaviour as high risk. This phase is influenced by the individual's knowledge of sexual activities associated with HIV-transmission or aversive emotional states such as high levels of distress. Already at this point it becomes clear that these variables are negatively affected by conflict experience. Secondly, individuals need to commit themselves to reduce high-risk behaviour. This is for example influenced by the perceived costs and benefits of behavioural change, the perceived self-efficacy as well as social factors (such as group norms and social support). Again, these variables are negatively affected by conflict experience. Finally, there comes the 'taking action stage', which is influenced by prior experiences with problems and solutions, informal or formal help (e.g. from social

networks), the individual's level of self-esteem or the resource requirements of acquiring help. Again, conflict experience negatively impacts on these factors. Additionally, this stage is heavily influenced by the sexual partner's beliefs and behaviour and the individual's ability to communicate verbally with this partner. Thus, it becomes clear that especially conflict-related rape acts as a massive barrier.

Socio-psychological models include an important component of reasoned action. However, these approaches also leave room for external (macro-) factors to influence actions and the cost/benefit calculations of individuals. These external variables, among them the macro-variables of the 'Jaipur Paradigm', become decisive in linking macro-environments to individual health risk behaviour.

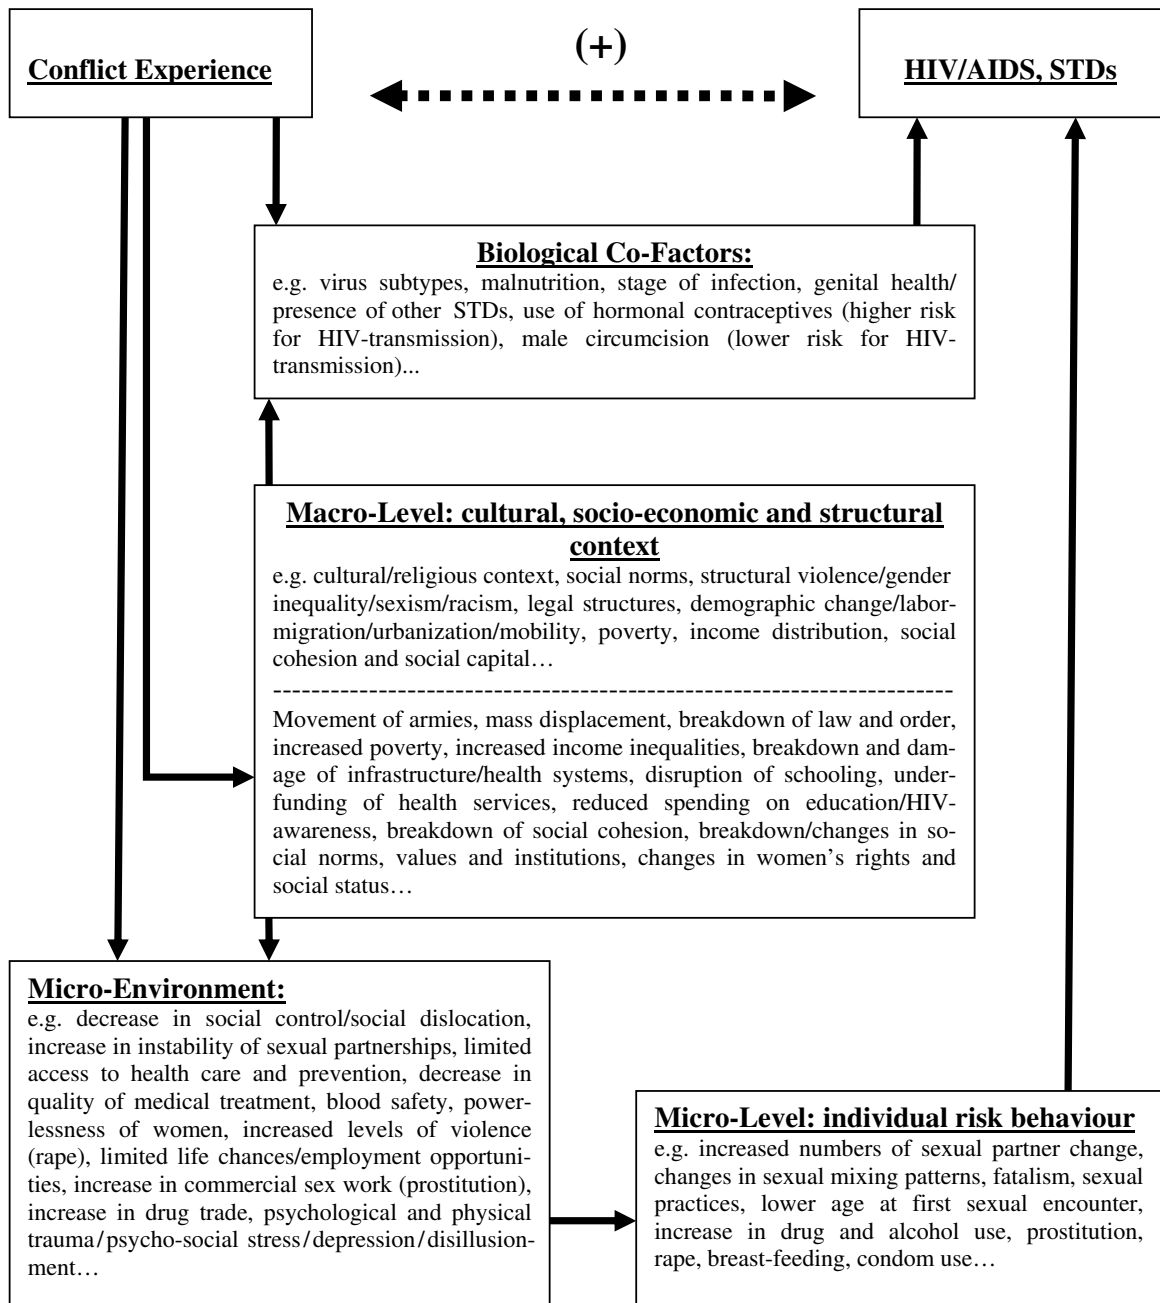

Taken together, it is assumed that there are four types of determinants of the epidemic: (1) *macro-environmental factors* (wealth, income distribution, or conflict experience), (2) *micro-environmental factors* (access to health care or level of social control), (3) *behavioural factors* (sexual mixing patterns and condom use) and (4) *biomedical co-factors* (stage of the epidemic, existing virus subtypes, STDs). It is further argued that factors at different levels of analysis interact. Changes in macro-level conditions affect micro-environments of individuals that affect lifestyle and individual health risk behaviour.

Finally, conflict experience fits into the 'Jaipur Paradigm' because it not only results in the breakdown of all social cohesion and poverty, but also because it impacts on societies' susceptibility and vulnerability to HIV/AIDS independently of its effect through wealth, social cohesion or income distribution. Thus, there exist a wide range of macro effects which are associated with conflict involvement. Most importantly, conflict results in increases in the disparity in income, in the breakdown of social cohesion, and declining levels of wealth. The mobility of populations (soldiers, refugees, Internally Displaced Persons (IDPs)) increases, health care and education systems break down, are damaged or at least under-funded, and social values rapidly change (e.g. women's status as they become refugees). In addition, institutions, law, and order break down, and biological co-factors of transmission (malnutrition, presence, of other STDs and the existence or emergence of virus subtypes) become prevalent.

These changes at the macro-level affect micro-environments of individuals in several ways. People face refugee existence associated with individual depression and increasing levels of violence and powerless-

12 For more information see at: <http://www.cominit.com/hiv aids/change_theories.html>.

Figure 17.1: The Final Theoretical Model. **Source:** Benz (2005).

ness of women. They face decreases in social control and increases in commercial sex work, but at the same time decreasing access to health care and deteriorating health care systems, a lack of preventive health education or increases in drug trade. This in return impacts individual health risk behaviour. Drug and alcohol use increase, sexual mixing patterns change, sexual partnerships become unstable, the number of different sexual partners increases while condom use

becomes less likely, and rape increasingly occurs. At the macro level high national HIV-prevalence rates may be observed. Figure 17.1 once again summarizes the theoretical model, which explains the linkage between conflict involvement and HIV-prevalence levels.

In summary, the three identified main mechanisms linking conflict experience with high HIV-prevalence are the effect of conflict on infrastructure, the effect of conflict experience on civilians who become

uprooted and face increased risk of HIV-infection, and third, the so-called ‘Trojan Horse Hypothesis’, which directly links the spread of HIV/AIDS to the mobility of soldiers. Only the latter of these mechanisms shall now be described in detail.

17.3 ‘Trojan Horse Hypothesis’: HIV in the Military

Although data indicate wide country specific ranges, they indicate significantly higher HIV-prevalence rates among the armed forces. In South Africa, for example, 60 per cent to 70 per cent of military personnel are infected; at a military police base in northern KwaZulu-Natal, a 90 per cent infection rate was found (Kirk 2000). Others mention infection rates among the military in Malawi of 75 per cent and in Zimbabwe of 80 per cent - approximately three times as high as average rates among the adult population (ICAD 2001: 2). Even in peaceful Botswana, one in three members of the military have been tested HIV-positive (UNAIDS/WHO 2004a: 176). Estimates of HIV-prevalence among the military in Angola and the Democratic Republic of Congo range between 40 per cent and 60 per cent (VanBeelen 2003: 6). The same author notes that 50–60 per cent of all beds in the Kenyan Armed Forces Memorial Hospital are occupied by military personnel with HIV/AIDS-related infections and that at least 6–10 soldiers die each week as a result of AIDS.

Data from a rural blood bank in Mozambique revealed that 39 per cent of military blood donors were HIV-positive, compared to 15 per cent of non-military donors (VanBeelen 2003: 7, 6). The proportion of reported HIV-cases in the military is also comparatively high in El Salvador (Wollants/Schoenenberg/Figueroa/Shor-Posner/Klaskala/Baum 1995: 129) as well as Cambodia and Thailand (Carballo/Frajnzgier 2001: 19). Although HIV-prevalence levels in the military forces are still low, HIV-prevalence in military recruits also alarmingly increases in Vietnam (Gorbach/Ryan/Saphonn/Detels 2002: 41). The government of Ethiopia found that only 5.5 per cent of tested military personnel were HIV-positive, which is less than the national prevalence of 10.6 per cent. However, Renaud (2002) points to the hidden factor that most soldiers had been screened prior to entry into the army and those with HIV had been rejected. In addition, the length of stay in the military averaged only 10 months, meaning that the HIV-positive conscripts had become infected very fast (Renaud 2001: 15).

The UN summarizes that even during peacetime, soldiers have STI rates two to five times greater than those of civilian populations. Those rates can rise up to 50 times higher during armed conflict (UNAIDS 1998: 3). Where data are available, this leads to figures such as 20 to 40 per cent HIV-positive soldiers in Sub-Saharan African countries, with rates of 50 per cent to 60 per cent in a few cases where the virus has been present for over 10 years and average adult prevalence is already very high (UN 2001c: 2; Nogoma/Len Roux 2007). Accurate figures on infection rates of various rebel groups and militias do not exist but may be expected to be high. Over (1998) finds that for the average developing country, reducing the military size from 30 per cent to 12 per cent of the urban population would reduce sero-prevalence among low-risk urban adults by about one per cent (Over 1998: 48).

High susceptibility of military forces to HIV-infection has been attributed to their work environment,¹³ their relatively low levels of maturity combined with high levels of testosterone (Fourie/Schönsteich 2001: 7), their high levels of sexual activity (VanBeelen 2003: 6), and the military’s professional ethos, which tends to excuse or even encourages risk-taking on and off the battlefield, also in regard to sexual behaviour (UNAIDS 1998). Additionally, aggressiveness is often abetted by high levels of alcohol and drug consumption (Fourie/Schönsteich 2001: 7). Trauma and brutalization caused by day-to-day experience of violence, frustration, apathy, loneliness, and dispiritedness have also been identified to lead to an increase in sexual violence (ICAD 2001; Hankins/Friedman/Zafar/Strathdee 2002: 2246; Smith 2002: 11).

This is supported by a UN study (2001: 2) and the finding that young men who staff armed forces are main perpetrators of sexual abuse and exploitation in settings of war and conflict. Thus, sexual violence and rape committed by soldiers e.g. in Sierra Leone, Rwanda, and Liberia¹⁴ become an important factor linking HIV/AIDS and conflict. Systematic mass rape used by regular and state armies as a weapon against civilians during wartime has also been undertaken in Uganda, Bosnia, Mozambique, Sri Lanka, Burma, Somalia, and the Democratic Republic of Congo.¹⁵

13 E.g. deployment to unsettled areas with exposure to socially disrupted settings where STIs may abound, a high possibility of infection through wounds and contaminated blood, etc. (see: Goyer 2001: 13).

14 See: Amowitz/Reis/Lyons/Vann/Mansaray/Akinsulure-Smith/Taylor/Iacopino 2002; Astill 2000; Donovan 2002; Swiss/Jennings/Aryee/Brown/Jappah-Samukai/Kamara/Schaack/Turay-Kanneh 1998.

Among the objectives are spreading terror and fear, inflicting psychological damage, disabling the enemy by destroying the bonds of family and society, or even ethnic cleansing (Shanks/Schull 2000: 1153). Systematic sexual molestation, mutilation, and rape of women and girls during the Rwandan genocide were integral to the plan to annihilate the Tutsi population. "Among the weapons of choice calculated to destroy while inflicting maximum pain and suffering was HIV. Eyewitnesses recounted later that marauders carrying the virus described their intentions to their victims: they were going to rape and infect them as an ultimate punishment that would guarantee long-suffering and tormented deaths" (Donovan 2002: 17). In the capital of Rwanda, HIV-prevalence among pregnant women from rural areas rose up to 24 per cent in 1995, which is said to be a result of rape and displacement during the 1994 genocide.¹⁵ The UN estimates that between 250,000 and 500,000 rapes were committed, gang rape was common, and that there were many incidences of women being abducted and held for long periods as sex slaves. Of the women who survived these attacks 70 per cent are estimated to have been infected with HIV (AI 2004: 3, 6). Burma is mentioned as another example, where soldiers' practice of raping ethnic minority women in conflict areas has attributed to the spread of HIV (Burkhalter 2002: 3). In addition, HIV-infection is also found to be strongly associated with the movements of military personnel and rape in Liberia (UNAIDS/WHO 2002: 35), as well as in Nigeria and Uganda (Fleshman 2001; Van der Heijden 1997; Smallman-Raynor/Cliff 1991).

A related problem is the growth of local sex industries in response to demand from military bases. As military service often includes lengthy periods spent away from home, personnel are looking for ways to relieving loneliness, stress, and the build-up of sexual tensions. It is also mentioned that the military culture uses the purchasing of sex as part of bonding among soldiers (VanBeelen 2003: 6). In addition, military personnel bring a degree of steady income into impoverished rural areas where men are off fighting or

have fled. This can translate into an increase in the number of women who turn to prostitution to survive during and after conflict.¹⁷

The UN study warns that even in peacetime, the likelihood of unsafe commercial sex appears to rise in the presence of military bases and units (UN 2001c: 2). Evidence comes from Cambodia (UNAIDS 1998), Sierra Leone (UNAIDS/WHO 2002: 35), or Thailand (VanLandingham/Suprasert/Sittitrai/Vaddhanaphuti/Grandjean 1993). The potential for the spread of the HIV-virus from the prostitutes over soldiers into the population of non-prostitutes is considerable, because men visiting prostitutes often have non-prostitute partners.¹⁸ Machel (1996) and Elliott (1996) both find that even children become victims of prostitution following the arrival of peacekeeping and foreign military forces. Female child soldiers, who are forced to be 'wives' or sex slaves to one or several boys or men in their unit in Sierra Leone, Liberia or the Democratic Republic of Congo are particularly vulnerable to STIs, HIV, and unwanted pregnancy through rape and sexual exploitation (Renaud 2001: 6).

These described mechanisms illustrate how the HIV-virus uses combatants as 'Trojan Horses' to spread itself among the civilian population surrounding military bases and to enter low-prevalence areas. Given the fact that HIV-prevalence levels within the military forces are extremely high, especially increasing prostitution and rape committed by soldiers become decisive mechanisms linking HIV/AIDS and conflict experience. In agreement with Robert Shell, the hypothesis that HIV is spread by troops is called the 'Trojan Horse Hypothesis' (Shell 2000: 12, 2002). In general, the mobility of soldiers during warfare results in a mix of people with high- and low-risk behaviour that otherwise might not mix. Thus, armies moving between high- and low-prevalence countries become primary vectors for transmitting the disease, and serve as a 'bridge population'.¹⁹ Thus, the pres-

15 See ICAD (2001: 2); Salama/Laurence/Nolan (1999); Human Rights Watch (1995); Shanks/Schull (2000: 1153); Swiss/Giller (1993); Swiss/Jennings/Aryee/Brown/Jappah-Samukai/Kamara/Schaack/Turay-Kanneh (1998); Smith (2002: 8); Swiss (1999); Wax (2003); Elliott (1999). See also McGinn (2000) for an overview on case studies regarding sexual violence in conflict settings.

16 See at: < <http://www.unaids.org/security/Issues/conflict.html>>.

17 See: Hankins/Friedman/Zafar/Strathdee (2002); Goyer (2001: 16); Astill (2000); Machel (1996: 34, 35); UNAIDS/WHO (2002: 35); UNAIDS (1998).

18 See: VanLandingham/Suprasert/Sittitrai/Vaddhanaphuti/Grandjean (1993: 311); see also: Lowndes/Alary/Meda/Gnintoungné/Mukenge-Tshibaka/Adjovi/Buvé/Morison/Kanhonou/Anagonou (2002) for evidence on Benin.

19 This is not a new phenomenon. The military has played a significant role in the spread of other infectious diseases in the past, such as the Influenza Epidemic of 1918/1919 or the spread of Smallpox and Syphilis in the fifteenth and sixteenth century (see: Shell 2000: 9).

ence of armies recruited from high-prevalence countries has an immense impact on domestic HIV-prevalence rates in areas of conflict. However, soldiers recruited from low-prevalence countries (e.g. Angola) but posted in areas where HIV-prevalence is high (e.g. Congo) also spread the disease in their communities when returning home.²⁰ Considering the determination that a soldier's sero-status is a major consideration in being demobilized or mustered out, there is urgent need to recognize this serious public health threat. Definitely, similar logic applies to returning refugees and internally displaced people (DeHulsters/Barreto/Bastos/Noya/Folgosa/Fransen 2003: 77; UNAIDS/WHO 2004; Williams/Martin 2002; Spiegel/Nankoe 2004: 22).

Based on the above it appears reasonable to expect that conflict involvement leads to a difference in countries' HIV-prevalence rates. More specifically, the main hypothesis of the following quantitative analysis states that prior conflict involvement associates with high HIV-prevalence levels.

17.4 Modelling HIV-Prevalence: A Quantitative Analysis

The dependent variable of the corresponding quantitative analysis is therefore adult HIV-prevalence as the percentage of the whole adult population (15–49 years old) estimated to be HIV-positive and alive by the end of 2003.²¹ The HIV-data are taken from the UNAIDS/WHO report on the global AIDS epidemic, released on 15 July 2004. The estimates of late 2003 are presented with ranges (low and high estimates), called 'plausibility bounds'.²² This should reflect the uncertainty in estimates and provides an additional test for the robustness of the coefficients of the conflict variable.

The key independent variable is 'prior conflict involvement' which proxies many of the previously mentioned variables associated with high HIV-prevalence rates (such as increasing prostitution, rape, and mobility of refugees and soldiers). The indicators refer to data compiled by Gleditsch, Wallensteen, Eriksson, Stollenberg, and Strand (2004), and measure the number of conflicts involved, the number of wars, intermediate and minor conflicts involved, the duration

of conflict involvement, the time since the last conflict involvement, and conflict involvement of neighbouring states. As conflicts taking place before 1995 can hardly be linked to people still alive and tested HIV-positive at the end of 2003, they have been excluded from the analysis.

Results of the bivariate analyses indicate significantly higher mean HIV-prevalence for countries which have been involved in conflicts and for countries surrounded by neighbours with high war involvement. Additionally and surprisingly, countries with a medium duration of conflict involvement show a significantly higher mean HIV-prevalence compared to the group of countries with a very short or long duration of conflict involvement. This points to a non-linear effect. Therefore, it might be that initially, HIV-prevalence is increasing with the duration and intensity of conflict involvement (due to increasing prostitution, rape, mobility of soldiers, or collapsing health and education infrastructure).

However, very extensive and intense conflict involvement might be associated with again declining HIV-prevalence due to isolating side effects. It can be argued that very extensive and intense conflict involvement 'quarantines' countries, "limiting people's exposure to the outside world and, consequently, to carriers of HIV". Angola, Liberia, Sierra Leone, and southern Sudan belong to the group of 'war-torn'

20 This has been the case with Nigerian peacekeepers returning from Sierra Leone and Liberia (see Alban et al. 2000) or with returning South African veterans and exiles (see: Shell 2000: 7, 12).

21 The age range (15–49 years old) captures those who are in their most sexually active years. While the risk for HIV-infection continues beyond 50 years the vast majority of people who will become infected are likely to have done so by this age. Thus, it is necessary to point out that the data used exclude HIV-positive adults over the age of 49 who might have become infected during the study period. However, most of the developing countries with particularly high HIV-rates (where this could have resulted in the exclusion of a large number of people) have life expectancies lower than 49 years. Thus, this age cut should not be too problematic as the total number of adults over the age of 49 who are HIV-positive and still alive, is expected to be very low. Additionally, HIV-positive children aged 0–14 are also not covered by the data. However, most of them are likely to have acquired the virus via mother-to-child-transmission. As the mothers' infection might be associated with conflict related factors and as mothers are most likely over the age of 15 and, therefore, already captured by the data, the exclusion of children is a means of avoiding double counting.

22 For more information on the estimation and application of the plausibility bounds, see: Grassly/Morgan/Walker/Garnett/Stanecki/Stover/Brown/Ghys (2004) or Walker/Grassly/Garnett/Stanecki/Ghys (2004).

Box 17.1: Functional Form of a Multiple Regression Analysis

The analysis applied is based on a simple multiple regression equation of the following functional form:

$$Y = b_1 * x_1 + b_2 * x_2 + \dots b_k * x_k + c + e, (1)$$

where Y is the true dependent variable, the b's are the regression coefficients of the corresponding x (independent/control) terms, c is the constant or intercept, and e is the error term reflected in the residuals.

countries with nevertheless low HIV-prevalence relative to surrounding countries due to conflict-related isolation (UNAIDS/WHO 2004a: 178, 180; Spiegel/Nankoe 2004: 324). Other factors, particularly related to very extensive and intense conflict experience that might reduce the pace of infection are decreasing casual sex associated with trauma and depression, the long-term disruption of sexual networks, increasing death rates among high-risk groups (soldiers) or heavy involvement of international humanitarian aid agencies.

The conducted multiple regression analysis models this assumed non-linear, inverse u-curve relationship. Other statistical problems, such as bivariate- as well as multivariate-multicollinearity, have also been taken care of. Additionally, the underlying structure of the HIV-data and heteroscedasticity both require a transformation of the dependent variable. Missing data have been replaced, eleven cases needed to be dropped²³, and the final sample contains 197 countries. Additionally and to allow for the isolation of the impact of conflict involvement, factors previously shown to affect HIV-prevalence must be controlled. Thus, the final statistical model explains HIV-prevalence through countries' education levels, their level of wealth and income inequality, the pace of urbanization, the lagged HIV-prevalence rates, a youth bulge variable, a cultural context variable, the key independent variable which is prior conflict involvement, its squared term in case of non-linearity, and finally the proportion of neighbours involved in war.²⁴ Additional information on data sources as well as measurement of all variables included in the analyses is given in Table 17.2 in the Annex.

23 Deleted cases with missing values on more than six out of fourteen indicators used to measure the control variables are: Aruba, Bermuda, Channel Islands, Faroe Islands, French Polynesia, Greenland, Isle of Man, Liechtenstein, Mayotte, Virgin Islands, and West Bank and Gaza.

24 For more information on technical details, as well as the theoretical justification for the inclusion of the control variables see at: <<http://www.ub.uni-konstanz.de/kops/volltexte/2005/1473>>.

17.5 Does Conflict Experience Significantly Correlate with Higher HIV-Prevalence?

Generally, R²-values of the models given in Table 17.1 in the Annex are very high, which indicates that the models explain up to 68.57 per cent of the variation in HIV-prevalence. Results also clearly indicate that countries' own prior conflict involvement exerts a statistically significant and positive effect on HIV-prevalence. The expectation that the type of conflicts involved (wars, intermediate or minor conflicts) is important with regard to its impact on HIV-prevalence cannot be supported. Instead, involvement in all types of prior conflicts significantly correlates with higher HIV-prevalence. The comparatively strong effect of the number of minor conflicts on HIV-prevalence might be explained by the fact that low intensity conflict involvement is correlated with a medium duration of conflict involvement, which itself correlates positively with HIV-prevalence.

Secondly, any type of a country's own conflict involvement exerts a much stronger (and positive) effect on HIV-prevalence at home compared to a much weaker (and negative) effect of neighbouring war involvement on HIV-prevalence in bordering nations. For instance, increasing the proportion of neighbours involved in war by one standard deviation would result in a decrease of HIV-prevalence at home by only -0.13 standard deviations, whereas increasing a country's own number of conflicts involved by one standard deviation increases the transformed dependent variable (HIV-prevalence) by 0.43 standard deviations (see Model 6, Table 17.1 in the Annex). This points to the importance of intra-state, conflict-related mechanisms, such as increasing mobility of soldiers and internally displaced people, or increases in the incidence of rape and prostitution. The spread of HIV to neighbouring countries via international, war-related effects, such as refugee flows, might be less important. International spillover effects might be offset by the isolating effect of neighbouring war involvement, as mobility and trade between countries is reduced and the spread of the virus across borderlines is hin-

dered. Negative economic spillover effects are probably already captured by the variable measuring the level of wealth.

There is also preliminary support for the inverse u-curve relationships between the duration of conflict involvement and HIV-prevalence, and between the peacetime since the last conflict involvement and HIV-prevalence. However, intense conflict involvement (in terms of battle deaths and measured through the number of wars a country has been involved in) is associated with a steadily increasing HIV-prevalence. Thus, it is rather extensive conflict involvement (in terms of duration) instead of intense conflict involvement (in terms of battle deaths), which exerts a significant, non-linear effect on HIV-prevalence. This is explained by the fact that particularly long-term conflict involvement is associated with isolating effects and a delaying impact on the spread of HIV-infection, which might not be the fact in cases of frequent and intense, but relatively short war involvement.

Finally, highly significant and positive coefficients are found for the lagged HIV-prevalence variable, which indicates strong temporal dependence in HIV-data. Results also indicate that the higher the proportion of males aged 15–49 years, the lower HIV-prevalence levels are. This might be explained by a problem of reverse causation: although the existence of a large sexually active and highly at risk population increases societies' susceptibility to the disease, young adults are also most likely to die of AIDS. As expected, the higher the level of education the lower HIV-prevalence levels are. However, the effect of education on HIV-prevalence remains comparatively weak. This might be due to the presence of other variables in the same specification (e.g. level of wealth or urbanization) which partly capture the effect of education. The strength of the effect of income inequality on HIV-prevalence is comparable to the strength of the effect of the education variable. Again, coefficients are highly significant even when mediating variables (e.g. the level of poverty, educational attainment or levels of urbanization) are controlled. This supports a contextual effect of income inequality on HIV-prevalence. The coefficients of the cultural variable measuring the proportion of Muslim or Jewish population are also highly significant and show the expected negative sign. Higher levels of urbanization are generally correlated with higher levels of HIV-prevalence. However, the pace of urbanization seems to make a difference. In particular, rapid urbanization might be associated with lower HIV-prevalence because it avoids long periods of short-term rural-urban labour migra-

tion. High levels of per capita health expenditures are not significantly correlated with lower HIV-prevalence, which might again be due to an endogenous relationship. That means although high levels of health spending might be related to lower HIV-prevalence due to better prevention and controlling options, the level of HIV-prevalence vice versa affects the level of health spending.

Last but not least, tests of robustness as well as robust regression results support these outcomes. For example, using low estimates of HIV-prevalence to measure the dependent variable or using a smaller sample ($N=151$), which excludes those countries for which HIV-data are missing, does not change the significant results found for the conflict variables. The strength of effects only slightly changes. There are also no signs of bias in the data due to systematic missing cases. A corresponding measurement error hypothesis which states that the level of uncertainty in HIV-estimates correlates with the fact that countries have been involved in conflict could not be supported. Results from robust regression analysis also further support the main hypothesis. The exclusion of identified multivariate outliers does not result in a significant change in the values of regression coefficients.²⁵ Instead, R^2 -values drastically increase and the coefficients of the conflict involvement variables stay or become even more significant. Again, and beside the lagged HIV-prevalence rates, the conflict variable contributes most to the predictive power of the models. Illustrating the relative strength of this effect requires a comparison of the so-called standardized beta-coefficients. This reveals that for example the exclusion of the dummy variable measuring a country's own war involvement from the analysis would reduce the R^2 -values and predictive power of the models by as much as 11.41 per cent, whereas an exclusion of the variable measuring the proportion of Muslim or Jewish population only results in a reduction of R^2 of about nine per cent. Excluding the variables measuring the level of health expenditure, the pace of urbanization, income inequality, the level of education, the proportion of young male adults or neighbouring war

25 Identified 'multivariate outliers' (cases with an unusual combination of values on the dependent as well as independent variables and a value of cook's $D > 4/\epsilon(N)$) in every of the 12 calculated robust regression analyses are Somalia, Laos, Zimbabwe, Lesotho, Botswana, Swaziland, the Maldives, and Vanuatu. North Korea has been identified as a multivariate outlier in nine, the Philippines in seven, Pakistan in four, and Sri Lanka in two out of the twelve robust regression analyses.

involvement would reduce the R^2 -values by only four to six per cent. Alone the lagged HIV-prevalence rates add more predictive power to the model than the conflict variable.

17.6 Policy Implications and Conclusions

In general, these results have important implications for AIDS forecasting and control in countries which have been involved in conflicts. The significant effect found for conflict involvement on HIV-prevalence confirms the importance of key health interventions in conflict and peacekeeping settings. Especially countries recovering from armed conflict need to integrate responses to AIDS in their recovery programmes (e.g. in humanitarian assistance or demobilization programmes). For example, there is urgent need to test outgoing but also incoming military personnel, as well as to counsel and prepare HIV-positive soldiers for demobilization and a return to civilian life. Confidential or voluntary counselling and testing in armies and peacekeeping forces needs to be expanded, health care for soldiers needs to be improved, and secrecy, stigma, and shame that cloak the epidemic particularly in the army need to be offset. However, uniformed services can also be excellent agents of change and an important human resource to build on for advocacy and social mobilization efforts through HIV/AIDS prevention training (UNAIDS 2002; UNAIDS/WHO 2004a: 177). They are generally perceived as role models, particularly for young people in their society. In addition, the military has strong traditions of organization and discipline, which gives them an 'organizational' advantage in the fight against HIV/AIDS.

More specifically, these results indicate that HIV/AIDS treatment and prevention programmes in conflict or post-conflict settings should focus on countries which have been involved in a large number of different conflicts, and on countries with a medium duration of conflict involvement. Particularly the impact of less intense forms of conflict involvement on HIV-prevalence should not be underestimated.

With regard to its effect on HIV-prevalence, it also seems to be of importance how development takes place. Increasing levels of urbanization are expected to be positively correlated with HIV-prevalence rates. However, the pace of urbanization seems to make a difference. Similarly, increasing income levels are negatively correlated with HIV-prevalence rates. How-

ever, the level of income inequality is also of importance. And finally, rising education levels are also expected to be associated with lower HIV-prevalence – as long as this does not result in increasing income inequalities.²⁶

In summary, it is important that structural interventions be developed with a view to the socio-economic and political determinants of HIV-risk, as well as the macro-impacts of AIDS epidemics. However, political scientists rarely study the linkage between politics and health, and "(...) there is [also] massive disinterest amongst AIDS researchers in such macro-analyses of the epidemic" (Altmann 1999: 561). Others mention that the potential of structural interventions for HIV-prevention has received only limited attention to date although in practice, many individual-level interventions have only had limited impact at the population level (Myer/Morrioni/Susser 2003: 191).

26 See also Whiteside/Hickey/Ngcobo/Tomlinson (2003: 35–6), who agree with the conclusion that there is not a simple causal relation between the epidemic and poverty/development. According to them, part of the answer may also lie in the type of economic growth (rapid or slow, equally or unequally distributed).

18 Preparing for Low-Frequency, Extreme Natural Hazards: Contributing to Human Security by Enhancing 'Freedom from Hazard Impact'

Janos J. Bogardi, Jörn Birkmann, Niklas Gebert and Neysa J. Setiadi

18.1 Introduction

In contrast to daily risks, low-frequency but extreme natural hazard events are often seen as the lowest priority risk (Cannon 2006). However, the fact of increasing extreme natural events in the light of global environmental and climate change (IPCC 2007) implies that there is an emerging necessity to get prepared for hitherto low-frequency, but extreme hazard events. The occurrence of mega-disasters such as the Indian Ocean Tsunami in 2004 and Hurricane Katrina in 2005 demonstrated the horrifying impacts of such extreme hazard events on the people exposed causing a tremendous threat to human security. High death tolls with large numbers of *Internally Displaced People* (IDP) and the destruction of critical infrastructures causing social disruptions and long term development retardation are the consequences.

On the other hand, it has opened a window of opportunity to promote preparedness even in regions which have not experienced extreme hazard events in the last decades.

Enhancing human security by promoting preparedness and resilience of societies confronted with natural hazards is an important step forward meeting the challenge of "freedom from hazard impact" as one of the three dimensions of human security (Brauch 2005: 23; 2005a). In contrast to frequent hazards and risks that people face and might experience daily, getting prepared for low-frequency, extreme hazard events is a major challenge (18.3).

The chapter examines these challenges and outlines new approaches on how natural hazards and global environmental change can be assessed with concepts of human security. In this regard, a key concept is vulnerability (18.2). The chapter presents a case study assessing community preparedness to tsunami, which shows that even communities which have not

experienced any major tsunami event for decades are getting prepared (18.4). The preparedness assessment takes into consideration: knowledge and attitude (awareness), policy and guidelines, emergency planning, warning system and capacity mobilizing resources. The results underline that individuals and households already have a good knowledge of the tsunami, whereas the actions and coping capacity in terms of emergency planning and resource mobilization are still insufficient. Important preparedness activities were carried out initially by NGOs and later on also by the local government.

Overall, the chapter shows the difficulties of raising awareness and getting prepared for low-frequency, but extreme hazard events and shows, drawing on the example of the city of Padang in Sumatra, where these activities are currently being carried out. The assessment approach also provides insights for measuring preparedness even in regions which have not experienced a major hazard event for decades (18.5).

18.2 The Concepts 'Human Security' and 'Vulnerability'

18.2.1 The Human Security Concept

UNDP (1994: 23) defined human security as "safety from such chronic threats as hunger, disease, and repression and protection from sudden and hurtful disruptions in the patterns of daily life." In the wake of a new wave of dramatic crises at the turn of the millennium, the report *Human Security Now* (CHS 2003), launched by the Commission on Human Security at the 2000 UN Millennium Summit, proposed a new, people-centred security framework. Hence, human security is no longer regarded as a function of a state's ability to counter external threats by military means

(CHS 2003: 2f). Accordingly, two visions have emerged to address major challenges for tackling human insecurity: 'freedom from want' (economic and societal security dimension) and 'freedom from fear' (political security dimension) (CHS 2003: iv). Although the protection of societies from environmental hazards was already mentioned in UNDP's (1994: 23) conceptualization of 'freedom from want', the environmental dimension is not addressed in depth. In the light of global environmental change, the increase in extreme natural events – such as floods, droughts, heat waves, storms, etc. – and the growing number of *Internally Displaced People* (IDP) due to natural hazards (Lambert 2002; Lonergan 1998), Bogardi and Brauch (2005) argue that human security should encompass three conceptual pillars: 'freedom from fear', 'freedom from want', and 'freedom from hazard impact' (Brauch 2005: 23).

Under the conditions of global environmental change, and especially climate change (IPCC 2007), the former ideas of being able to control or steer nature are revealed as a false perception of security. New security paradigms are needed that take into account the global nature of environmental change as well as the complexity of coupled human-environment systems (non-linear processes). Among other things, this implies that focusing on the hazard alone is not sufficient. In the past few decades the mainstream of scientists and practitioners felt confident of being capable of managing extreme natural events with the help of what they assumed to be sophisticated technical means of protection. However, particularly the predicted impacts of climate change – such as sea-level rise, e.g. for countries like Egypt (Nile Delta) or the Maldives (UNDP 2006a: 57) – show the serious limitations of previous technical security measures. Therefore it is necessary to shift the focus from the hazard paradigm to the prevention and reduction of the vulnerability of societies confronted with natural hazards.¹

Although vulnerability research to sudden-onset and creeping hazards can still be considered as a relatively new research field for many disciplines, and particularly as a transdisciplinary concept (Bohle 2007), different scientific communities have developed their own understanding of what vulnerability stands for as a scientific concept (Brauch 2005; Birkmann 2006; Thywissen 2005).

While in development research and in the social sciences the 'livelihood framework' (Chambers and Gordon 1992, DFID 1999; chap. 36 by Bohle) and the model of the 'double structure of vulnerability' (Bohle 2001) were developed and used as key concepts to better understand and frame the vulnerability of societies to natural hazards, the disaster community mainly adapted frameworks which focus on vulnerability as a solely negative characteristic which increases the likelihood of harm and damage (Davidson 1997; Bollin/Cárdenas/Hahn/Vatsa 2003).

In contrast, the 'double structure of vulnerability' by Bohle (2001) outlines that vulnerability does not only encompass fragility; it also implies an internal side of being able to cope with the impact of extreme events. The livelihood framework puts emphasis on the examination of potential root causes, particularly the lack of access to certain assets on the part of some people (for an in-depth discussion of the livelihood approach, chap. 36 by Bohle).

Interestingly, a third school has broadened the picture and even views vulnerability as a characteristic within coupled human-environment systems. This approach defines exposure and resilience as components of vulnerability (Turner/Kasperson/Matson/McCarthy/Corell/Christensen/Eckley/Kasperson/Luers/Martel-lo/Polsky/Pulsipher/Schiller 2003).

A fourth school, illustrated by the holistic approach to vulnerability and risk, considers exposure and susceptibility, socio-economic fragilities and lack of resilience as vulnerability components. It uses complex system dynamics to represent vulnerability within a risk-management cycle (Cardona 1999, 2001; Carreño/Cardona/Barbat 2004, 2005a, 2005b).

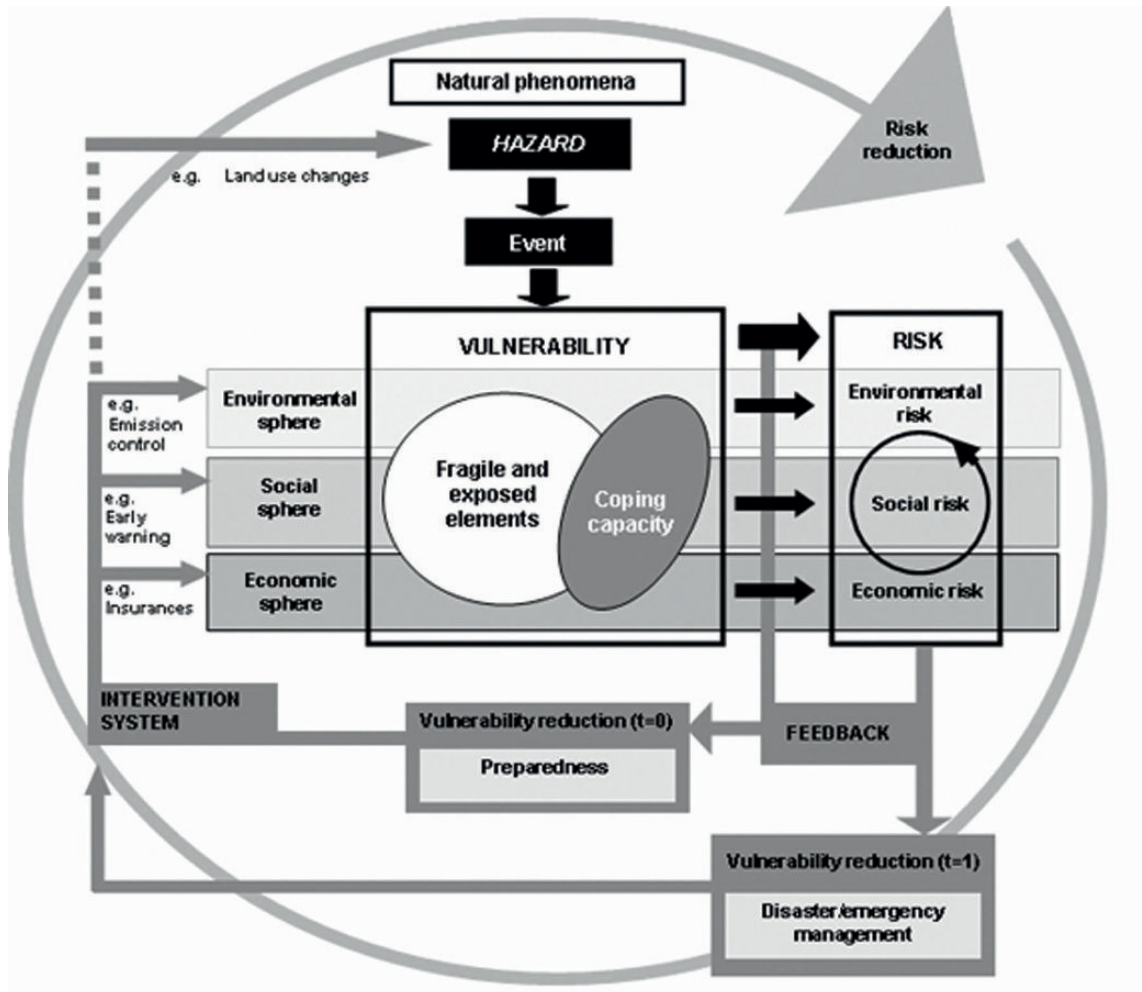

UNU-EHS conceptualized vulnerability as encompassing exposure, susceptibility and coping capacity. Moreover, it is important not to limit the analysis of vulnerability to one dimension, such as economic vulnerability. Rather, it is crucial to link vulnerability reduction and sustainable development by integrating a social, an economic and an often overlooked environmental dimension into the framework for vulnerability assessment (see figure 18.2).

18.2.2 The BBC Conceptual Framework for Social Vulnerability

The acronym 'BBC' is linked to conceptual work done by Bogardi/Birkmann (2004) and Cardona (1999/2001), which served as a basis for this approach. It emerged from three discussions on: a) how to link vulnerability, human security and sustainable

1 For details see the website of the United Nation University, Institute for Environment and Human Security, Bonn (Germany); at: <www.ehs.unu.edu>.

Figure 18.1: The BBC conceptual framework. **Source:** Birkmann 2006: 34, based on Bogardi/Birkmann (2004) and Cardona (1999, 2001).

development (Bogardi/ Birkmann 2004; Birkmann 2006: 34); b) the need for an integrated approach to disaster-risk assessment (Cardona 1999, 2001; Carreño/Cardona/Barbat 2004, 2005a, 2005b); and c) from the broader debate on developing causal frameworks for measuring environmental degradation in the context of sustainable development (e.g. OECD 1992: 6; Zieschank/Nouhuys/Ranneberg/Mulot 1993: 144).

The BBC framework understands vulnerability as a dynamic process, which goes beyond the estimation of damage and the probability of loss. It promotes a problem-solving perspective by simultaneously analysing probable losses and the deficiencies of various exposed susceptible elements (e.g. social groups) and their coping capacities as well as potential intervention measures (feedback-loop system) within all three key spheres of sustainable development (social,

economic and environmental spheres; see Birkmann 2006). The BBC framework – as a meta-framework – outlines two potential ways of reducing disaster risk and vulnerability: first through preventive measures, and second through disaster management.

Preventive measures are generally introduced before events strike societies; these could range from raising awareness, moving people out of hazardous zones, or improving the resilience of households or environmental services to hazard impacts (actions in $t=0$). However, we have to acknowledge that the public media and also political responses often focus solely on disaster management as a way of improving disaster preparedness. As seen in the case of Hurricane Katrina, the international media reports primarily on disasters and disaster management, rather than on potential options to reduce vulnerability before hazard events strike a specific region at risk. Although

disaster-management capacities are important for limiting the impact of catastrophes and managing the crisis, the BBC conceptual framework shows the essential role of anticipating risk and taking actions before hazardous events might cause a disaster ($t=0$) (see figure 18.1). The improvement of disaster- and emergency-response capacity ($t=1$) is necessary; however, it is merely one part of the picture and often occurs at the end of the chain (Birkmann 2006). Instead, forward-looking and pro-active interventions are needed (preparedness, mitigation) in order to reduce vulnerability.

18.3 Preparedness and Risk Priorities

Mega-disasters such as the Indian Ocean Tsunami in December 2004 and Hurricane Katrina in 2005 in the United States dramatically revealed the need for better preparedness on the part of households exposed to low-frequency natural hazards. However, can one really prepare people for these events? Increasing the preparedness of people to hazards which they have not yet experienced in their life times is a major challenge for research, development planning and disaster-risk reduction.

One precondition for societies to be capable of developing pro-active intervention tools and becoming prepared for future hazards and environmental changes, such as the various impacts of climate change, is to perceive a potential hazard and the vulnerable conditions as a risk to its society. Although the authors view risk mainly as a result of the interaction between a hazard and vulnerable conditions (e.g. UN/ISDR 2004), another crucial question for human security is: How are risks perceived and judged?

Various groups of actors perceive and judge risks differently due to differences in knowledge (e.g. awareness through experience), education and cultural norms and values, leading to the conclusion that the perception of risk is socially filtered (Jungermann/Slovic 1997: 201).

The Indian Ocean Tsunami and the current efforts to establish effective early warning systems in Indonesia² and Sri Lanka demonstrate the fact that preparedness measures are seen as an important element to reduce the potential catastrophic impact of extreme natural phenomena, such as earthquakes and tsuna-

mis. Sudden-onset hazards, such as tsunamis, floods or hurricanes, receive much attention in the media, particularly if they cause a disaster.

Nevertheless, there are still major gaps between international media reporting and the effective preparedness and awareness of people exposed particularly to low-frequency but extreme hazardous events. In the political arena one can still observe that major funding and actions often only take effect after a disaster has occurred, rather than beforehand. Besides the necessity to change the political response away from reaction to preparedness and adaptation, it is equally important to address the individual preparedness of people exposed to low-frequency but extreme hazard events.

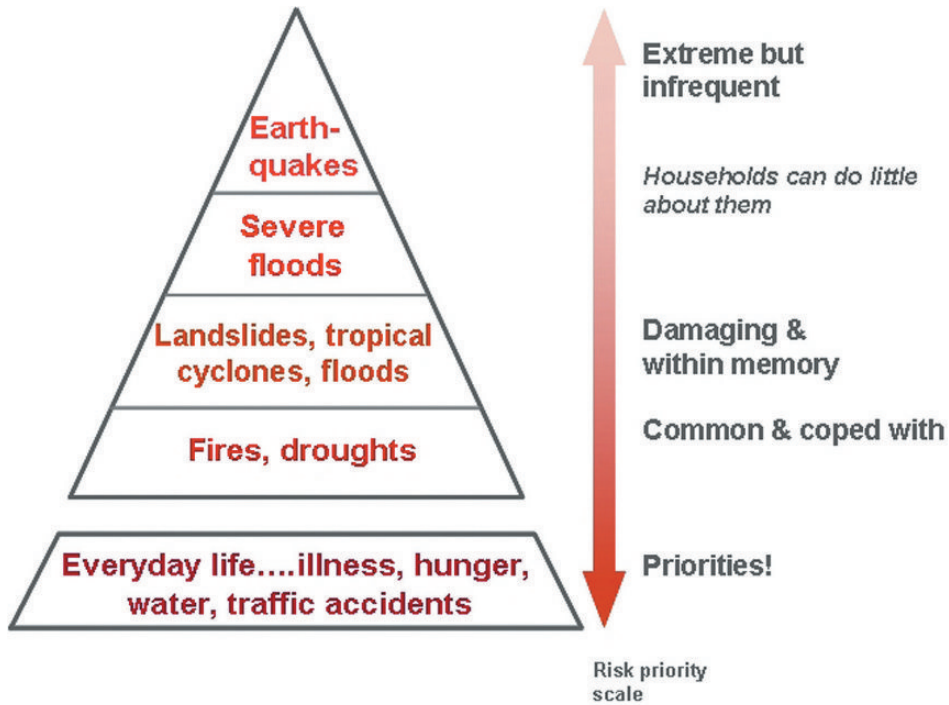

Especially in developing countries, and particularly in rapidly growing cities such as Jakarta, Dhaka or La Paz, the poor and the most vulnerable households are still settled in high-risk zones. The awareness and preparedness of these groups is often lacking. Even if they have some knowledge regarding potential consequences of low-frequency hazards, one has to consider that poor households, particularly in developing countries, often face various risks at once; consequently, natural hazards are only one component of their daily exposure to risks.

Cannon (2006) concludes that natural hazards are often not at the top of people's priorities. Therefore, changing people's perception of risk - and in turn their behaviour - is essential, but in reality very difficult. This is true with respect to low-frequency natural hazards, but also for more frequent hazards (e.g. flooding) that people simply learn to cope with (Cannon 2006).

Cannon argues that households might be capable of doing very little about extreme - but infrequent - natural hazards, such as strong earthquakes and tsunamis. "In most places for most people (whether in California, Florida or Vietnam or Philippines etc.) the most important division is between the benefits of a location for the pursuit of everyday life and livelihoods, and the risks that affect and threaten those livelihood assets on a regular basis. Thus, all over the world hundreds of local risk assessment surveys carried out by NGOs, e.g. Red Cross/Crescent, people hardly ever mention the risks higher up the hierarchy, and will emphasis everyday risks. They prepare for and cope with shocks and hazards such as illness, hunger, water shortage rather than preparing for low-frequency events" (Personal Communication, Cannon 200). Figure 18.2 exemplary illustrates that e.g. severe floods, landslides, tropical cyclones, etc., which might

2 See for details the website of the German-Indonesian Tsunami Early Warning System (GITEWS) project at: <www.gitews.de>.

Figure 18.2: The Risk Hierarchy. **Source:** Adapted from Cannon (2006: 11). Permission was obtained from the copyright holder.

cause major damage, are placed in the middle of the hierarchy and are classified as being present in collective memory; they are not, however, necessarily seen as a priority. In addition, the authors argue that the priority setting of households in terms of risk reduction and the ability to cope correlates with the frequency, magnitude and experience of various shocks and hazards.

Changing people’s perceptions of risk is crucial in order to take action to mitigate the impacts particularly of low-frequency but severe natural hazards, such as tsunamis. According to the logic of the risk hierarchy it is difficult to increase awareness and preparedness with regard to low-frequency but extreme events, thus more research is needed to explore how to prepare people exposed to low-frequency natural hazards.

It is interesting to note that, particularly after the devastating Indian Ocean Tsunami (December 2004), awareness raising and preparedness activities are being undertaken in communities which have not experienced a major tsunami within the last 100 years. Such case studies are an interesting laboratory for concepts of human security, disaster-risk reduction and sustainable development, since, generally speaking, awareness and preparedness for low-frequency

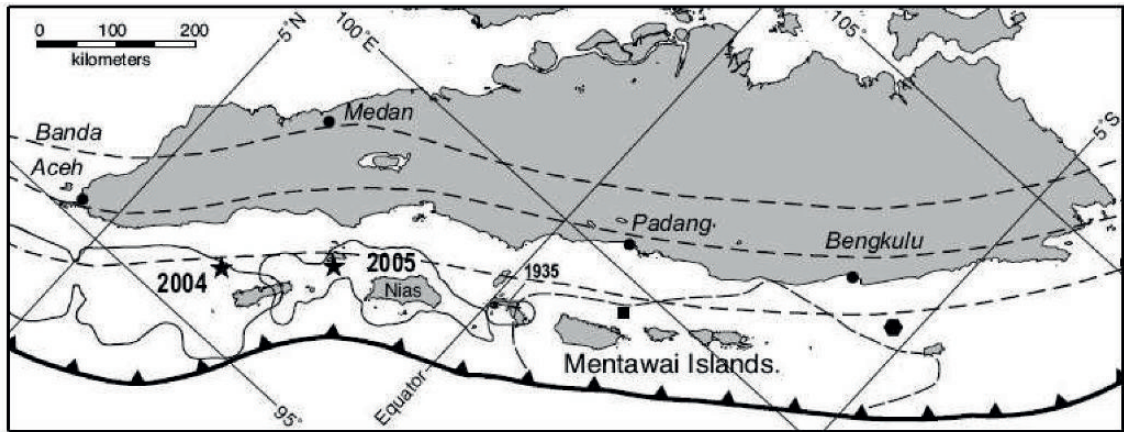

hazards – particularly hazards which have not been present in the lifespan of one generation – are rare.

Additionally, a major challenge is the selection of appropriate mitigation and preparedness measures against these low-frequency but extreme events in the context of fragile livelihoods. Birkmann and Fernando (2008) outline in their study on revealed and emerging vulnerabilities in Sri Lanka after the December 2004 tsunami that also new vulnerabilities were generated by inappropriate intervention and mitigation strategies. They come to the conclusion that more emphasis has to be given to local assessments and context specific mitigation and preparedness measures. The challenge of identifying and developing appropriate mitigation and preparedness measures after the devastating Indian Ocean Tsunami – also in communities which were slightly affected – will be illustrated in a case study focusing on the assessment of awareness and preparedness undertaken in the city of Padang in Indonesia. The city of Padang is highly exposed to future tsunami risks in Indonesia. Its citizens experienced a major tsunami in 1833 for the last time.

The analysis of awareness-raising and preparedness activities to the low-frequency hazard in Padang will address the following questions:

- How prepared are people with regard to hazards they did not experience?

Figure 18.3: Map of recent and plausible future sources of Sumatran tsunamis. **Source:** Borrero/Sieh/Chlieh/Synolakis (2006: 19674). Permission was obtained from the copyright holder.

- What are the sources and stakeholders that contribute to increased awareness on the part of people to these low-frequency hazards?
- What are the potential indicators and criteria to measure the level of preparedness?
- What are the major challenges for building resilience to low-frequency hazards?

18.4 Case Study: Preparedness for Tsunami Risk in Padang City, Indonesia

The impact of the 2004 tsunami on the Aceh coast of Sumatra has evoked widespread concern about a similarly devastating tsunami on other populated Indonesian coasts. Although the island of Sumatra encompasses a shore line of 4,868.9 km³, of which only about 600 km (13 per cent) was heavily impacted by the December 2004 tsunami (Shofiyati/Dimiyati/Kristijono/Wahyunto 2005), the mega-disaster and its echo in the international and national media also created awareness in communities that had not faced major damage. The city of Padang is seen today as a future hotspot of tsunami risk. It is one of the most plausible localities for a tsunami of disastrous proportions in the near future (Borrero/Sieh/Chlieh/Synolakis 2006; figure 18.3).

Padang is the third biggest city in Sumatra with a population of about 800,000. It is the capital city of the West Sumatra Province of Indonesia. It is situated directly on the coast of the Indian Ocean and is highly

exposed to potential tsunamis in the future. Padang city has experienced various natural disasters, such as floods, landslides and storms. Although no major tsunami has impacted Padang within the last 170 years (Natawidjaja/Sieh/Ward/Cheng/Edwards/Galetzka/Suwargadi 2004), concerns on tsunami occurrence have risen in the community after the traumatic tsunami of 2004 in the neighbouring Aceh province. It is estimated that 50 per cent of Padang's population live in the areas with an elevation of 0–5 meters above sea level and would be severely affected by a major tsunami impact (BPS 2004). The critical infrastructures, medical services, schools, public offices, as well as transportation networks, are also often constructed parallel to the coastline; this results in high exposure to potential tsunami waves. The recent earthquake happening in southern Sumatra in September 2007 with the magnitude of 8.4M_w⁴ and its several shocks thereafter caused observable damages and also small tsunamis in some areas in Padang. This triggered panic among the population (UNOCHA 2007). This event has once more demonstrated the necessity of the city of Padang to prepare itself for low-frequency but extreme natural events.

18.4.1 Assessment of Community Preparedness to Earthquake and Tsunami

A methodology to measure community preparedness for earthquakes and tsunamis was developed and tested by UNESCO and the *Indonesian Science Insti-*

3 Wikipedia online (2007): "Sumatra"; at: <<http://id.wikipedia.org/wiki/Sumatera>> (15 April 2007).

4 USGS website; at: <<http://earthquake.usgs.gov/eqcenter/eqinthenews/2007/us2007hear/>> (12 September 2007).

tute (LIPI) in co-operation with other scientific and local institutions⁵ (Hidayati/Permana/Pribadi/Ismail/Meyers/Widayatun/Handayani/Bustami/Daliyo/Fitranita/Nagib/Ngadi/Kumoro/Rafliana/Argo 2006). Besides the city of Padang, the methodology and assessment approach for community preparedness were tested in *Kabupaten Aceh Besar*, as an example of a region having experienced the tsunami in December 2004, and *Bengkulu*.

In the context of the community-preparedness assessment, the following definition of preparedness is used:

Measures which enable governments, organizations, communities and individuals to respond rapidly and effectively to disaster situations. Preparedness measures include the formulation of viable disaster plans, the maintenance of resources and the training of personnel (Carter 1991: 213).

It focuses primarily on the capability to carry out an emergency action and a fast response, which encompasses the sequence of actions a moment prior to the event or during the event (disaster management). These actions and activities include early warning (warning dissemination and response to the warning), action during the event – such as rescue, saving assets, evacuation, action immediately after the event, such as search and rescue (SAR), evacuation, temporary shelters, emergency treatment, public kitchen, emergency aid, damage assessment and a recovery plan for the critical infrastructure.

Through participatory approaches, involving various stakeholders such as government agencies, academics and NGOs, five critical factors were identified as the most important parameters for the assessment of community preparedness (Hidayati/Permana/Pribadi/Ismail/Meyers/Widayatun/Handayani/Bustami/Daliyo/Fitranita/Nagib/Ngadi/Kumoro/Rafliana/Argo 2006: 13–14):

1. *Knowledge and attitude towards disaster risk*

Knowledge is considered as a main factor and key for preparedness. Particularly the experience of the 2004 tsunami in Aceh and the 2006 tsunami in Pangandaran, southern Java, showed the importance of knowledge on natural hazards. For example, during the sudden low tide, a lot of people in the coastal area in Aceh ran to the sea to gather up

fish, rather than understanding the threat of the formation of a tsunami wave.

2. *Policy and guidelines*

Relevant policies that significantly influence preparedness comprise budgeting, organization, human resources and important facilities for public education, emergency planning, early warning and resource mobilization. These should be available in the form of regulations with clear job descriptions and operational procedures.

3. *Emergency plan*

Emergency plans are especially important regarding evacuation and search and rescue in order to minimize the number of victims.

4. *Warning system*

The warning system contains warning and information dissemination. This should also be supported by training and simulation of an appropriate response.

5. *Capacity to mobilize resources*

This means resources in the form of human resources, as well as financial resources (funding) and physical resources (facilities); the capacity to mobilize them is also considered to be a crucial factor.

In order to gain a better understanding of community preparedness, different stakeholders were identified and categorized. Based on the level of significance, responsibility and sensitivity, the stakeholders were divided into two groups: (1) main stakeholders (individual/household, government, school community); and (2) supporting stakeholders (community institutions, NGOs, professionals, private sector).

The assessment encompassed a combination of quantitative, qualitative and participative methods. The quantitative method focused on a questionnaire-based survey. The questionnaire contains a set of indicators for all five parameters, to be derived as indices for each parameter (knowledge and attitude, emergency planning, etc.). The index value was calculated using the following equation:

$$\text{Index} = \frac{\text{total score of the parameter}}{\text{The maximum score of the parameter}} \times 100$$

A composite index for each stakeholder – and eventually for the city – was calculated using a weighing system. The community preparedness level was categorized based on its index value. The values below 54 show insufficient or no preparedness, the values between 55 and 64 means that the community is almost prepared, and values above 65 show sufficient or high preparedness. In the following section, we focus on

5 The local institutions involved are academies such as *Institut Teknologi Bandung (ITB)*, *Andalas University* in Padang, and *Bengkulu University* in Bengkulu. This study was also supported by the UN/ISDR.

major findings of the assessment of preparedness at the household and at the government (disaster management) level.

18.4.2 Household Preparedness

Overall, the household survey encompassed 2,800 respondents in Padang city. The respondents were households living in several subdistricts close to the sea, with different levels of assessment framework, taking into consideration five parameters: (1) knowledge and attitude, (2) policy and guidelines, (3) emergency planning, (4) warning system, and (5) capacity of resource mobilization. For households, the parameter of policy and guidelines does not apply (see box 18.1).

Box 18.1: Household questionnaire content. **Source:** Authors based on Hidayati/Permana/Pribadi/Ismail/Meyers/Widayatun/Handayani/Bustami/Daliyo/Fitranita/Nagib/Ngadi/Kumoro/Rafliana/Argo 2006. Summary of the authors based on components of the study's questionnaire.

- (1) Knowledge and attitude
 1. Definition of natural disaster
 2. Cause and indications of earthquake and tsunami
 3. Characteristics of seismic and tsunami resistant structures
 4. Response to strong earthquake and sudden low tide
 5. Source of information about earthquakes and tsunami
- (2) Emergency planning
 6. Action to rescue from the earthquake and tsunami
 7. Availability of emergency plan and equipment, such as evacuation route and places, emergency bags, simulation/exercise
- (3) Warning system
 8. Awareness of availability of a warning system in the region
 9. Response after receiving the warning
- (4) Resource mobilization
 10. Participation in preparedness activities
 11. Possession of savings, insurance, or land/house in other places
 12. Availability of relatives/friends to help in case of disaster

The overall results of the household-preparedness level are displayed in figure 18.4 differentiated according to the three different hazard zones. The hazard zoning was created by KOGAMI, an NGO that is actively involved in disaster-preparedness activities in Padang. The subdistricts were classified into three hazard zones according to their elevation above sea level: (1) prone zone (< 5 m), (2) alert zone (5–10 m), and (3) safe zone (>10 m). The preparedness evaluation shows that both the parameters of 'knowledge and attitude' as well as 'warning system' have relatively high values in all three zones. However, this knowledge does not seem to manifest itself in actions or in terms of the parameters 'emergency plan' and 'resource mobilization'. In general, the households in the hazard-prone zone show higher preparedness in plans and actions than the households in other zones

18.4.2.1 Knowledge and Attitude

The survey revealed that the knowledge of the individuals about natural disasters in general was good. Questions like "What natural event can cause a tsunami?", "What are the indications of a tsunami?", "What would you do if there was a sudden low tide?" were answered correctly by the majority of respondents. Additionally, a higher level of education correlated with higher values on the knowledge parameter (see figure 18.5).

Interestingly, the questions of "What is a natural disaster?" and "What are the reasons for a natural disaster?" implicitly capture the perception of natural disasters. For instance, in Aceh Barat, many people believed that the 2004 tsunami was a punishment from Allah for man's evil deeds and that it would not happen again in their lifetimes as long as they followed God's law. This attitude might have important implications for disaster preparedness activities. In Aceh Barat, the religious leaders were involved in approaching the people to get them prepared using a religious approach. However, this did not seem to be the case in Padang.

It is also important to examine the main source of information about tsunamis. Most of the people had heard about tsunamis from the media (TV, radio and newspapers). The survey also shows that social networks are an important source of information. About 77 per cent of the respondents acquired knowledge about the tsunami from their friends, family and neighbours. Differences were observed regarding the sources of information in the three zones, as shown in figure 18.6. In the prone zone, more people received information from posters, brochures, seminars, as

Figure 18.4: Indices of the household preparedness level in three different hazard zones. **Source:** Own figures based on data from Hidayati/Permana/Pribadi/Ismail/Meyers/Widayatun/Handayani/Bustami/Daliyo/Fitranita/Nagib/Ngadi/Kumoro/Rafliana/Argo (2006). well as from the government and NGOs, in contrast to the alert and safe zones. This might be due to the activities undertaken by NGOs - particularly KOG-AMI - and the local government to promote disaster preparedness on the part of those highly exposed to tsunami.

In order to promote and ensure awareness and knowledge on tsunami risk in the long term, particularly the role of schools in disaster education needs to be strengthened. The results of the assessment of the institution ‘school’ still showed a low level of preparedness. Presently there is no written education policy that supports the integration of preparedness for nat-

Figure 18.6: Sources of information about tsunamis and earthquakes from specific sources. **Source:** Own figures based on data from Hidayati/Permana/Pribadi/Ismail/Meyers/Widayatun/Handayani/Bustami/Daliyo/Fitranita/Nagib/Ngadi/Kumoro/Rafliana/Argo (2006). ural disasters into the school curriculum. Another possible approach to long-term knowledge transfer in the community for such an extreme event (tsunami) is through storytelling and folk songs, as was practiced in Simeulue Island (Yogaswara/Yulianto 2006).

18.4.2.2 Coping Capacity in Terms of Individual Capacity and Actions

Besides the improvement of knowledge about tsunami, special preparedness measures are undertaken – particularly by the households in the prone zone – such as developing a family evacuation plan (51 per cent). Some households (23 per cent) in the prone zone were also planning to resettle to a safer location. However, the preparedness in terms of the current availability of an emergency plan and equipment was in general insufficient.

The capacity for financial resource mobilization was relatively low and insurance did not appear to be a known measure for the households (only 19 per cent of the respondents had insurance), while the social network seems to be a valuable asset. About 75 per cent of the respondents stated that they had friends/relatives who were ready to help them in case of disaster (Hidayati/Permana/Pribadi/Ismail/Meyers/Widayatun/Handayani/Bustami/Daliyo/Fitranita/Nagib/Ngadi/Kumoro/Rafliana/Argo 2006).

18.4.3 Government Level - Disaster Management

18.4.3.1 Policy and Guidelines

Policy regulations supporting disaster management exist at the city level to a certain degree. In Padang there are ongoing efforts with respect to disaster-mitigation policies, whereas action plans and technical guidelines are not yet available. The coordinating unit for disaster management (*Satlak PB*) in Padang still existed as an *ad hoc* unit with only limited authority to develop and implement technical guidelines. Commitment in the form of funding allocation for disaster management was not yet in evidence. In addition, the land-use plan for the city of Padang for the period 2005–2015 contained a commitment to disaster preparedness, and yet it had not taken into account tsunami and earthquake-related aspects. .

18.4.3.2 Emergency Planning and Early Warning System

Although the policies and guidelines still need to be improved, the emergency planning parameter of the government of Padang city was considered ‘good’, since it was proven to contain all the elements of an emergency plan (see box 18.2). In contrast, the availability of these elements at the *Kecamatan* level was still incomplete.

Early warning technology is planned for Padang city using sirens and buoys. The sirens are to be installed in the telecommunication towers and buoys

Box 18.2: 14 indicators for assessing emergency planning for the city government. **Source:** The authors.

1. Hazard map and evacuation map
2. Evacuation places
3. Buildings prepared for temporary rescue locations
4. Disaster command centre
5. Operating procedure from command centre
6. Disaster-management training in command centre
7. Storage of emergency materials
8. Procedure and plan of materials provision in emergency
9. Search and Rescue team (SAR)
10. Evacuation system/ambulance in SAR unit
11. Electricity supply for emergency
12. Communication network for emergency
13. Water supply for emergency
14. Heavy equipment

will be used for warning the public. This is not yet optimal since the *Kecamatan* government had no access to the early warning system of the city government. Also no agreed mechanism exists for disseminating warnings to the community. (Hidayati/Permana/Pribadi/Ismail/Meyers/Widayatun/Handayani/Bustami/Daliyo/Fitranita/Nagib/Ngadi/Kumoro/Rafliana/Argo 2006).

18.5 Conclusions

The presented assessment in Padang defines ‘preparedness’ as a bundle of measures that enables a rapid and effective response to disaster situations, focusing primarily on saving lives and dealing with the immediate impacts caused by earthquakes and/or tsunamis. Thus, mirroring the conceptual set-up and results of the preparedness study in Padang against the concept of human security and the BBC-framework, the study does not primarily focus on disaster prevention orientated at the goal of ‘freedom from hazard impact’. According to the BBC-framework the main focus of the study was the analysis of disaster management capacities related to preparedness within the event ($t=1$). By comparison, the BBC conceptual framework focuses on a more pro-active approach to risk reduction and defines preparedness in a broader sense, which entails the reduction of vulnerability and the implementation of adaptation strategies before an event strikes the community ($t=0$). The assessment of options for introducing preventive measures ($t=0$), e.g. moving parts of a city out of its exposed zone, do not only aim at sav-

ing lives but also saving disruptions of sustainable livelihoods as desired outcomes of a preventive intervention system $t=0$ (BBC-framework). In this context the accepted residual risk for low frequency - high impact hazards is a matter of political negotiation. By promoting a culture of disaster prevention rather than solely emergency and disaster management, the intersections of all three dimensions of human security become evident: Preventing the loss of livelihoods (instead of solely lives) also has effects for achieving ‘freedom from fear’ and ‘freedom from want’. In this sense appropriate vulnerability assessments indirectly refer to state service delivery deficiencies by identifying economic, environmental and societal deficiencies (deprivation) and inequities (entitlements, power relations) as well as capacities that constitute a society’s human insecurity to hazard impacts. Hence, vulnerability assessments can be a strong tool for providing information about the qualitative state and intersections of all three dimensions of human security. Both vulnerability and disaster preparedness assessments can act as a basis for long-term resilience strategies developed by exposed communities to low frequent, but extreme natural hazards, such as tsunamis.

Nevertheless, managing change and promoting a culture of resilience is not an easy task. Awareness is a precondition for change, preparedness a precondition for mitigating the effects of disasters but they are not sufficient to meet the goals of human security. When people face various risks in their everyday struggle to secure their livelihoods, the incentive and the effort to bring about societal change in awareness, preparedness and prevention should come from civil institutions and governmental authorities rather than from the people themselves. Therefore, managing institutional change (new norms, laws, and policy instruments, informal rules) to prevent governance failures and to improve societal capacities to achieve sustainable risk reduction requires the introduction of specific instruments like institutional learning and institutional memories. However, the role of the state as a change manager poses a dilemma between its service delivery obligation and capability, since particularly in developing countries, also decision-makers and government administration have only very limited capacities, and resources to set up and implement appropriate prevention activities (exposure reduction, land use change), for example due to the chronic lack of financial resources and due to their lack of change management capacity. Thus, tackling the root causes of human insecurity by promoting good (local) governance is also essential for pursuing ‘freedom from hazard impact’.

The example of the city of Padang illustrates these difficulties towards 'freedom from hazard impact'. Due to the fact that sustainable prevention requires a substantial societal reconfiguration, it is an ambitious goal and needs time. Therefore, creating a culture of resilience requires as a first step the promotion of awareness and also preparedness. NGO (KOGAMI) has started the effort to raise awareness among its citizens and to address the importance of being prepared for tsunami risks in the future. Thus, the case study for Padang shows that civil society has the potential to generate problem solving capacities, to transform structures, and to help to promote a culture of disaster preparedness. A functioning civil society and a democratic system, where organized actors are able and allowed to articulate their interests, are key to sustainable risk reduction and for achieving human security. Due to increased public awareness and consequently public pressure - e.g. generated by NGOs like KOGAMI, as well as by the media and international activities - also the city administration of Padang realized the importance of getting prepared for a tsunami. Further research is needed to explore the linkages and correlation among the degree of awareness, and the level of preparedness and prevention in Padang and Indonesia ($t=1$ and $t=0$; BBC-framework).

Moreover, the general perception that low-frequency hazards are a matter one can do only little about must be reconsidered. This means mega-disasters can also create the momentum for change, if other regions are getting prepared. In this regard, measuring and assessing awareness and preparedness is a challenge and a prerequisite for improving the promotion of disaster resilient communities and a starting point for strengthening human security in facing natural hazards.

The current situation in Padang, and also in Indonesia, provides hope that these processes of promoting disaster preparedness will continue, while, by contrast, in Sri Lanka - particularly in East Sri Lanka - the civil war increases the vulnerability and the lack of recovery and preparedness after the mega-tsunami 2004.

18.6 Recommendations

Based on this analysis, the following recommendations may be drawn:

- Getting prepared for low frequency, but extreme natural hazards requires knowledge and awareness about existing risks. Continuous and long-term

risk communication is an essential means to build risk perception and aid preparation for not-experienced events. Governments and other social institutions should emphasize integrating disaster preparedness into day-to-day decision-making. Institutional capacity-building measures should be implemented by government agencies and non-government organizations involved in disaster management and public education.

- In order to reduce disaster risk in the long term, adaptation strategies are crucial. This implies, for example, that preparedness strategies should be integrated into land-use planning.
- Indicators for community preparedness assessment still need to be improved and used more frequently. Locality factors to be assessed should not be limited solely to disaster management aspects; rather, they need to take into consideration the susceptibility and coping capacity of the people at risk.
- Early-warning systems are important measures to reduce the risk of natural hazards. However, in order to ensure that the early warning chain is working, consideration of the situation of the respondents is crucial. In-depth knowledge of the characteristics of the people exposed and various vulnerable groups needs to be obtained through a vulnerability assessment. This information and local knowledge need to be made available for building better early warning systems. In the context of tsunami preparedness, e.g. an early warning system for Indonesia (GITEWS) is currently being developed and, in addition to this, the project 'Last-Mile' develops a decision support system for better evacuation in a tsunami case for the city of Padang.⁶
- Although both projects also significantly address the technical issues of warning systems, it is important to note that particularly UNU-EHS is responsible for carrying out sub-national and local vulnerability assessments (for more detail see website UNU-EHS). This will hopefully ensure that the design of early warning systems, as well as the development of evacuation plans, takes the most crucial component into account: the most vulnerable groups and people who should respond appropriately to a future early warning.

6 For the GITEWS-project see www.gitews.org, for information on the "Last Mile" project please contact Neysa J. Setiadi.

19 Environmental Refugees and Environmental Distress Migration as a Security Challenge for India and Bangladesh

Imtiaz Ahmed

19.1 Introduction

People move, but not always voluntarily. Involuntary movement of people, particularly across national borders and for reasons of political, religious, racial or ethnic persecution, is what constitutes a refugee population. Currently, the UNHCR figure shows that there are 9.2 million refugees, although the total 'population of concern' to UNHCR totals over 19 million, and this in addition to refugees includes asylum-seekers, returnees, internally displaced persons, and stateless people (UNHCR 2005: 2). This figure however does not include the people who have been uprooted for environmental causes and have ended up having a fate similar to those of conventional refugees. Critics maintain that there are 25 million people worldwide who have been uprooted for environmental reasons, that is, from floods, toxic spills, desertification, hydroelectric projects, soil erosion, land degradation, and other environment related disruptions (Myers 1993; Raina/Chowdhury/Chowdhury 1997; Baker 2001). The latter figure is evidently higher than that for conventional refugees. And it is this group of people - uprooted and impoverished or as Essam El-Hinnawi maintains, 'those who had to leave their habitat, temporarily or permanently, because of a potential environmental hazard or disruption in their life-supporting ecosystems' - who have earned the dubious distinction of being called 'environmental refugees' (El-Hinnawi 1985). The plight of such refugees, particularly with respect to their birth in Bangladesh and later on their crossing over to India, and the subsequent security challenges they pose for both India and Bangladesh, is what we intend to highlight in this chapter.

The chapter is divided into eight sections. Section one is the introduction (19.1). Section two addresses the meaning of environmental refugees, more specifically how they are different from migrants and conventional refugees (19.2). Section three reflects on the

issue of distress migration from Bangladesh to India, focusing particularly on the so-called 'illegal' flow of people (19.3). The environmental problems faced by Bangladesh and how they contribute to distress migration, including the flow of environmental refugees across the border, will be highlighted in section four (19.4). Section five will take up the fate of environmental refugees as 'stateless persons', particularly in the backdrop of the fact that both Bangladesh and India tend to disown them as citizens of their respective countries (19.5). Section six will then take up the issue of India's policy of fencing or barbed wiring the borders to stop the flow of what it regards as 'illegal' migrants from Bangladesh (19.6). The issue of what is to be done will be taken up in section seven, while the final section will include some concluding remarks (19.7 and 19.8 respectively).

19.2 Conceptualizing Environmental Refugees

Floods, famines, and large families combine and create an environment not conducive to the sound and sustainable habitability of human life and living. But the gap between such direct ecological factors (save, of course, the issue of large families) and the consequences of modern development is not that great. There is a growing literature which suggests that many of the environmental problems that we are now facing have resulted from *man-made* structures (Jacobson 1988; Durning 1989; Renner 1989; Shiva 1989; Kritz 1990; BMU 2002; Brauch 2002; Simms 2003). Even in the case of acts of God, like floods and droughts, often the dire consequences are the result of crude human exploitation of nature. Put differently, modern (*mal*) *development* often leads to environmental insecurity. The latter could be further divided into three. The first is the lack of 'water security,' or more precisely, the lack of having fresh

water, which results from the drying up of rivers and waterbeds, although at times it could result from excessive flood waters and water logging, including sea level rise from global warming (Pielou 1998; Ahmed 1999a; Brauch 2002; Brown 2004).¹ Often the lack of water security leads to conflicts or 'water wars' (de Villiers 1999; Shiva 2002). The second is the want of 'land security', related directly to the degradation of soil and the incapacity of the population to harvest any further. The last one is the lack of 'food security,' arising partly from a combination of water and land insecurities, and partly from the excessive growth of population and lack of employment (Sen 1981; Dreze/Sen/Hussain 1995; Brown 1998). If the country is small in size, the situation becomes even more precarious because the victims cannot move to other parts of the country. Consequently, they end up becoming 'environmental refugees' in neighbouring states, which often leads to conflicts not only between the sending and receiving states but also between the people of the receiving state and those who have joined them as environmental refugees.

Environmental refugees often carry the burden that is otherwise implied in the word 'refugee'. In fact, once the victims, whether arising from political persecution or environmental insecurity, become refugees there is no way to distinguish the actual experience that they go through. All of them in reality *live a life* of a refugee, that is, in constant fear, uncertainty, and immense poverty. Moreover, if the victims are compelled to leave their original habitation for reasons of land or food insecurities, it becomes almost impossible for them to return to their home unless effective measures are taken to ensure their survivability. In such a situation, 'the compulsions to flee', 'fear to return', or even 'crossing international borders' - the existing international criteria for becoming a refugee - remain no less pressing factors for the birth and growth of environmental refugees.

Environmental refugees, however, differ from migrants or migratory trends normally found in history. The UNHCR is also clear on this:

Millions of people have been forced to leave their homes because the land on which they live has become uninhabitable or is no longer able to support them. ... The terminology for describing environmentally in-

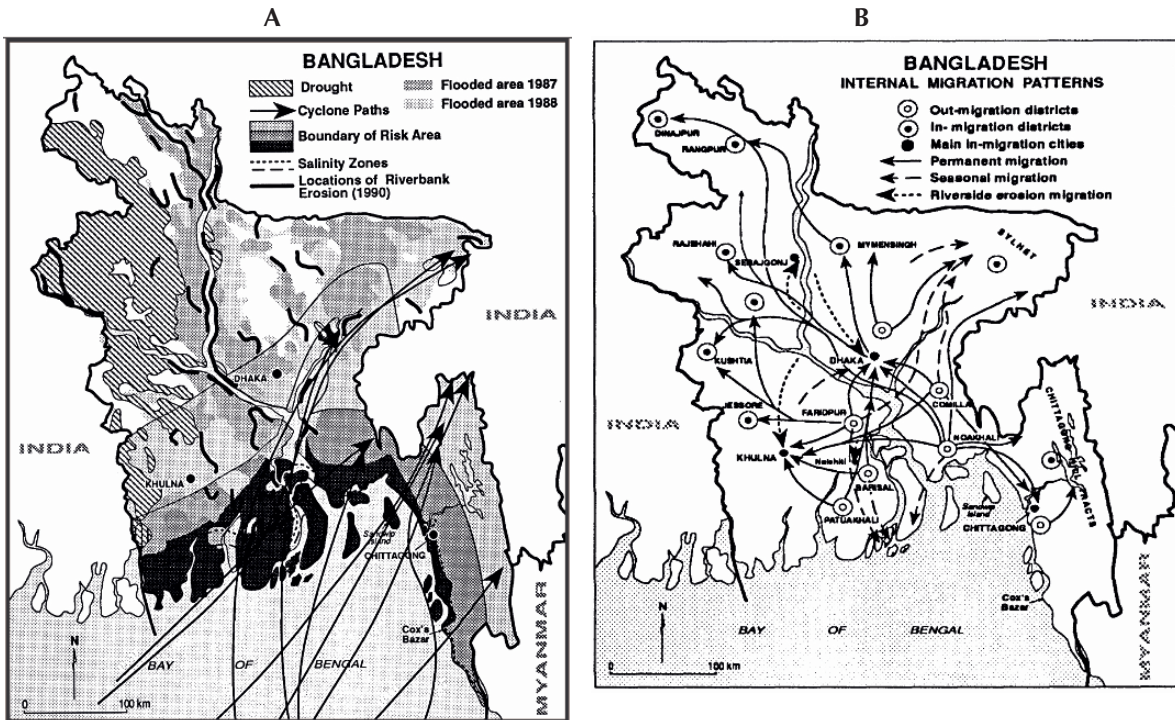

duced migration is controversial. For many observers, 'migration' does not convey the fact that the people affected are *forcibly* uprooted. To call them refugees seems to convey more accurately that they left their homes involuntarily, for reasons not of their own choosing (UNHCR 1993; Black 2001).

But then some continue to use 'migrants' and 'refugees' interchangeably. There is, however, a need to maintain the distinction between the two lest the term 'refugee' be diluted and made economic and taken to mean some historical patterns of population movement. In fact, the UN Convention on the Protection of the Rights of All Migrant Workers and their Families is quite precise in its definition of migrant worker: "a person who is to be engaged or has been engaged in a remunerated activity in a State of which he or she is not a national" (Pkhakadze 2005: 67). Just as precise is the definition provided by the UN Department of Economic and Social Affairs: "A person who moves to a country other than that of his or her usual residence for a period of at least a year (12 months), so that the country of destination effectively becomes his or her new country of usual residence. From the perspective of the country of departure the person will be a long-term emigrant and from that of the country of arrival the person will be a long-term immigrant" (Pkhakadze 2005: 67). There is, indeed, no sense of involuntariness on the part of the person in both these definitions, which is otherwise a critical marker for a 'refugee'. In the case of environmental refugees the involuntariness arises not from political persecution, as would be the case with conventional refugees, but from environmental disruptions, including man-made (mal) developmental interventions and structures. There is also a need to distinguish between 'legal' and 'illegal' migrants. While the former stands for those who had crossed the border with valid documents, the latter generally refers to those who had either crossed the border *without* valid documents or were previously legal migrants but have now 'overstayed' the period for which valid documents were issued to them.² Problems however arise when there is no *legal migration regime*, not even provisions for work permit or options for changing citizenship be-

1 In the case of Bangladesh there is a gruesome prediction that 17% of its land will disappear by 2100 because the sea level would in all probability rise by a metre as a result of global warming, giving rise to even greater water insecurity. See: Brauch (2002).

2 One good example of 'legal' migrants would be the Bangladeshi workers, now numbering more than a million, in the Middle East, Southeast Asia, Europe, and North America. The 'overstayers' (that is, following the lapse of the period for which valid documents for temporary residency and work permit were issued) would fall into the category of 'illegal' migrants, the discussion of which however is beyond the scope of this chapter.

Figure 19.1: Maps of Bangladesh, **A:** Climate-related Natural Events, and **B:** Internal Migration. **Sources:** A: Ericksen/Ahmad/Chowdhury (1996: 264); B: Ericksen/Ahmad/Chowdhury (1996: 245). Permission was obtained.

tween the concerned countries. In such cases the concept of ‘illegal’ migration becomes a misnomer. The environmental distress migration from Bangladesh into India is a good example in this context.

19.3 Distress Migration from Bangladesh to India

Bangladesh’s precarious situation, conditioned greatly by natural calamities and underdevelopment syndrome, is well known. Floods, famines, large families coupled with the possibility of sea level rise have driven people from one place to another, not only within the country but also across international frontiers (see figure 19.1). According to Lester Brown, “Even a one metre rise in sea level would inundate half of Bangladesh’s riceland, forcing the relocation of easily 40 million people. In a densely populated country with 144 million people, internal relocation would not be easy” (Brown, 2004: 2). In fact, one finds the number of people crossing over to India increasing during periods of environmental disasters. In 1974–1975, for instance, when Bangladesh was devastated by a combination of flood and famine, one witnessed heavy ‘illegal’ flow of people to India. According to estimates provided by the Indian census, the

number of people who had crossed the border ‘illegally’ from Bangladesh to India totalled 1,729,310 in 1961–1971 and 559,006 in 1971–1981 (Gupta/Chakrabarty/Bandyopadhyay 1994: 3). The latter figure, however, excludes Assam, which according to one semi-official estimate is around 600,000 in 1971–1981 period (Franda 1982: 235). This figure probably is too high, but then even if we add them, the total ‘illegal’ flow of people does not exceed that of 1961–1971.

Although the post-independence ‘illegal’ flow of people to India is not high, particularly compared to the 1961–1971 periods and also in the context of the 4096.70 km Indo-Bangladesh border, it has already caused great alarm amongst the Indians, particularly in the political and intellectual circles. In this connection, Sanjoy Hazarika pointed out:

Out-migration from Bangladesh over the years has had a severe impact on the ethnic, linguistic, religious, economic, and ecological fabric of northeast India and West Bengal, regions that share a common frontier with Bangladesh. ... India views the migrants as a potential security risk, whatever their reasons for migrating. Intelligence reports indicate that illegal migrants are pliable and easy to use in smuggling, in trans-border gangs, and in information-gathering for extremist groups (Hazarika 1993: 55).

Table 19.1: Reasons for leaving Bangladesh (multiple responses). **Source:** Author's Survey (1997).

Response	Khulna-Sathkhira	Rajshahi	Dinajpur	Nilphamari	Total (%)
Lack of environmental security					67.0
Poverty	19	29	12	33	23.25
Better Accommodation	16	23	15	19	18.25
Ecological	7	8	4	5	6.0
Livelihood	42	10	2	24	19.5
Minority insecurity	0	11	19	0	7.5
Social (Property-related, violence; marriage; prostitution; etc.)	16	11	16	14	14.25
Smuggling	0	8	0	0	2.0
Better education	0	0	8	5	3.25
Join relatives	0	0	24	0	6.0

This has further been complicated by the suggestion that the post-independence flow of people is the result of religious persecution, directed mainly against the Hindus. In support of this contention, Amalendu De pointed out that the Muslim population in Bangladesh had increased from 76.9 per cent to 88.3 per cent in 1951-1991 periods, whereas Hindu population during that period had dropped from 22.0 per cent to 10.5 per cent (De 1994: 1). This suggested that the Hindus in bulk, suffering from insecurity, had left Bangladesh for India.

But a closer exposition of the population flow reveals something else. Table 19.1, for instance, shows that a high percentage of people leave Bangladesh for reasons of environmental insecurity, which includes, amongst others, poverty, lack of accommodation, direct ecological factors, and lack of decent livelihood.

Looking at the high percentage of the population flow from the Khulna-Sathkhira and Rajshahi regions (western Bangladesh), one is led to believe that water insecurity is mainly responsible for producing refugees. In this context, the case of the Ganges water dispute, particularly the Farakka Barrage and how it has led to the drying up of Bangladesh in the winter season, is well known.³ As Ashok Swain pointed out:

It is true that the Ganges water dispute is an excellent case study of an inter-state conflict where two state-

actors are striving to acquire scarce water resource by rationally calculating their interest in a zero-sum situation. However, the resulting environmental destruction in a vast region of Bangladesh has added another important dimension to it. The loss of agriculture, closure of industries and navigation facilities, drop in fish catching, dying of valuable forest resources, disappearance of land due to river bank erosion and devastating floods, have no doubt, resulted in the loss of source of living of a large number of populace in Khulna and some parts of Rajshahi region of Bangladesh, which seem to necessi-

Figure 19.2: Map of Bangladesh. Source: Georgia Tech Bangladesh Student Association; at: <www.gtbsa.org/?p=bd>. Permission was obtained.

tate their migration from the homeland in the pursuit of their survival (Swain 1996). While Swain’s contention can hardly be brushed aside, it would be folly to think that the Farakka alone is responsible for the flow of environmental refugees, and that there is no such movement of people from

other areas of Bangladesh. Table 19.2 provides a clear indication that the matter is not that simple: The high flow of environmental refugees from Rajshahi and Khulna regions to India can definitely be blamed on Farakka. But then, Dhaka, Thakurgaon, and Faridpur also have a high flow of people to India,

and none of these areas are directly affected by the withdrawal of water at Farakka (figure 19.2). There are other environmental disruptions reproducing environmental refugees. I will have more to say about this shortly.

Again, one must not have the impression that the flow of environmental refugees is linear, that is, simply from Bangladesh to India. In fact, a sample survey of the squatting population, numbering around 180 in the city of Dhaka showed that 1.11 per cent of the squatters came from regions other than Bangladesh, mainly from Myanmar and India (see Jahan/Khan/Akter/Parvin/Khatun/Zaheda 1996: 19). The forced eviction of the Rohingyas from Myanmar and the regional and global security implications of their protracted status as a refugee or stateless community certainly fall in the category of conventional refugee studies (Ahmed 2004). But then environmental issues such as drought during the winter season in the Arakan region of Myanmar has further complicated the situation, forcing many Rohingyas to cross over to Bangladesh in search of work and humanitarian support (Ahmed/Dasgupta/Sinha-Kerkhoff 2004). Not so different is the flow of people from West Bengal (India) to Bangladesh during the time of excessive flooding, as has been the case with the flood in 2000 when several hundred Indian nationals took refuge in Bangladesh (Ahmed 2002: 434). That some of them would slip into the mega capital city of Dhaka and end up as environmental refugees cannot be ruled out. Environmental disruptions reproducing environmental refugees therefore are multilayered and complex. Let me return to the case of Bangladesh.

19.4 Environmental Reasons for Distress Migration

It is important to keep the complex combination of insecurities (water, land, and food) in mind lest one starts believing that the resolution of the Ganges water dispute would stop the 'illegal' flow of people across the border. In fact, even after the signing of the Farakka Agreement between Bangladesh and India in 1997, the flow of environmental refugees did not stop. Anyone familiar with the situation, particularly the areas of concern, knows very well that such a thing is not going to happen. There are other, and equally critical, environmental factors operating here as well.

Let us take the case of the 1998 deluge, for instance. A serious concern throughout the 1998 flood period has been the lack of work for many of the af-

ected, particularly of the able-bodied people. This is indeed an irony, for while there is so much work to be done in the affected areas, many of the affected are practically without work for months! At one point of time, there was lack of work in almost all of the affected areas, from Kurigram to Kishoreganj, Comilla to Chapai-Nawabganj, Gaibandha to Gopalganj. And this continued to be so as late as November (that is, 4–5 months after the flood first began), although the extent of the no-work syndrome was greater in the most affected areas that mostly border the banks of the mighty Brahmaputra and Jamuna.

At the time of flooding, however, the testimony of having no work on a massive scale, somewhat ironically, lies in the low price of essential goods. The price of rice in Kurigram, for instance, came around Taka 14 per kg, markedly lower than the price of rice in Dhaka or even in Benapole (around Taka 20 and 24 per kg respectively). While in normal circumstances this would have been a cause for celebration for the people of Kurigram, it was actually the result of the no-work syndrome or the lack of purchasing power that had prevailed for many months in those areas.

But why is there no work to be found? I guess a part of the answer lies in the governmental introduction, albeit under pressure from international donors and the modernist scientific community, of a new cropping pattern in the country, which effectively replaced the age-old method practised in Bangladesh. As Nazrul Islam noted,

The cropping pattern [in Bangladesh] was intricately adjusted to the deltaic conditions. Through a process of natural selection, the people of Bangladesh developed the amazing varieties of *bona aman*, which can grow twenty feet tall or even higher to withstand deep flooding. These miraculous paddy stalks just float in water and can grow up to a foot in twenty four hours just to keep pace with the fast rising level of flood water. These capabilities of *bona aman* are yet to be matched by anything produced by modern plant breeding. Bangladeshi farmers also developed *ropa aman* to adjust to the brief time period that is usually available between *aus* harvest and arrival of floodwater (Islam 1999: 86).

With the introduction of the High Yielding Variety (HYV)⁴, the flood centric varieties, like *bona aman* and *ropa aman*, became less attractive and less financially rewarding to the farmers. The HYV, given its de-

4 It may be mentioned that the area under HYVs increased from 14 per cent in 1973 to 54 per cent in 1993. Moreover, over 90 per cent of the *boro* crop is now in HYVs.

Table 19.3: Incidence of Distress Selling (percentage of villages). **Source:** Sen/Hashemi/Ahmed (1998); also Ahmed (1999b: 38).

	Whether Distress Selling Increased Compared to the Normal Period					
	Land		Domestic Animal		Other Assets	
	Yes	No	Yes	No	Yes	No
Severe	59.0	41.0	87.1	12.9	73.8	26.2
Moderate	59.8	40.2	87.9	12.1	71.8	28.2
Normal/No Affect	44.2	55.8	73.5	26.5	56.3	43.7

pendence on fertilizers and controlled irrigation, can hardly survive in the midst of big floods. Since many of the affected, under active governmental support, left the former cropping pattern for the latter, it is not surprising that they are left without work, and consequently with meagre purchasing power once the flood comes in and drowns their HYV crops. In a situation like this, they can do one or two of the following things.

Firstly, they could start using their savings. The governmental machinery is absolutely inefficient in this respect, particularly when it comes to the issue of savings of and for the poor. In Bangladesh, this task has been performed with some success by the non-governmental organizations (NGOs). In fact, this is precisely what the major NGOs, including the *Grameen Bank*, opted for, providing the long-time borrower full access to her/his past savings. But then again, this has an obvious limitation, for the volume of such savings for each individual or household is not that great.

Secondly, they could take up distress selling. In a nationwide field survey on 15,467 villages carried out by members of *Nagarik Durjog Mokabila Udyog* (a civil response body formed during the flood), it was found that the incidence of distress selling was considerably high at the time of the flood (table 19.3).

Since there is no governmental plan to offset such selling or even regulations for receiving fair price by the distressed seller, often a severe flood comes as a boon to the moneylender and those in the position to buy such things. At times, the highly governmentalized banking system (both public and private, with the possible exception of the trustee-managed *Grameen Bank*) accelerates this process by demanding collateral from the affected persons.

Finally, they could migrate. This could be of two types, internal as well as external. In October, a random survey conducted by a non-governmental organization found that 9 per cent of the village households in the flood-affected areas are totally looked after by

women, implying that their husbands had left the villages in search of work.⁵ Hossain Zillur Rahman (1998) carried out a survey on the floating population of Dhaka and found out that 20 per cent of them were recent migrants. Of the immigrants, fifty-two per cent indicated 'lack of work,' while eight per cent mentioned 'prevailing hunger situation' as reasons for coming to Dhaka. But this is only one side of the migration.

At times, with unprecedented floods in both Bangladesh and India (particularly in West Bengal and Assam), migration criss-crosses both ways. Given the prompt availability of international relief in Bangladesh, one should not be surprised if some distressed people from West Bengal or Assam are found crossing over to Bangladesh. This is precisely what happened during the flood in West Bengal (India) in 2000 as indicated earlier.⁶ And the case no doubt remains the opposite when relief fails to reach the flood-affected border areas of Bangladesh timely and substantially. Moreover, it is not unlikely that population pressure on this side of the border and well-established networks on the other side of the border would lead more Bangladeshis to settle in India than the other way round.

But the above mainly pertains to the issue of water insecurity arising from massive flooding. The 'drought factor' is no less precarious. Take again the case of HYV and the need for pesticides and controlled irrigation. Much of the success related to HYV production, as Peter Rogers pointed out, rested on the "shift from dependence on high-risk monsoon crops to reliance on low-risk irrigated crops grown in the dry sea-

5 Oxfam, Dhaka, conducted the survey during the 1998 flood.

6 In 2000 the flood in West Bengal (India) forced several hundred Indian nationals to take refuge in Bangladesh. BDR (Bangladesh Rifles, the border security force) took care of Indian nationals numbering 2,382 who stayed in relief camps. Less is known about those who did not make it to the relief camps. See: Ahmed (2002: 434).

son from November to May” (Rogers/Lydon/Secler/Pitman 1994: 17). But this shift could be made possible mainly by combining HYV cultivation with expanded irrigation using groundwater and shallow tube wells (STWs).

Excessive pumping of groundwater, particularly in the dry season and that again if it continues for two consecutive seasons, could bring disaster by emptying the aquifers and making the groundwater table to fall. Critics believe that the fall of the groundwater table is the main cause for the dramatic increase of arsenic in water in Bangladesh.⁷ It is not difficult to see that HYV cultivation could lead to land degradation not only for the use of fertilizers but also, and at times more importantly, for having the bad luck of not being accompanied by sufficient river-inundation for replenishing the underground aquifers. The consequence is quite predictable and that is, once land becomes degradable the farmers react almost in the manner of facing an excessive flood. Many end up as internally displaced persons at home or as environmental refugees across the border. The plight however does not end there.

19.5 Environmental Refugees as Stateless Persons

In the case of population movement between Bangladesh and India there is a specific scenario. Indeed, those who cross the border for environmental reasons and are referred to as environmental refugees turn overnight into stateless persons! But why ‘stateless’ when evidence suggests that they have all moved ‘illegally’ from Bangladesh into India or, as is the case with a section of the squatters in Dhaka, from India into Bangladesh? The case of the latter, that is, impoverished and uprooted Indians moving into Bangladesh is less known and is also numerically insignificant, therefore it is less taken up in public fora. As for the former, the government of Bangladesh has consistently denied any ‘illegal’ movement of people from Bangladesh into India. Indeed, in the midst of governmental politicking, with the Bangladesh government disowning the environmental refugees as ‘citizens’ of the country and the Indian government calling them ‘illegal migrants’ and taking measures to push them out of India, the victims of environmental disruptions, including (*mal*) *development*, end up losing protec-

tion from both countries. In this context, one Indian critic noted:

There is already in India a strong feeling against ‘outsiders’. If it is Bangladeshis (i.e. the so-called illegal migrants from Bangladesh) in Assam, it is Chakmas (i.e. the hill people who had crossed over to India in 1960s following the construction of Kaptai Dam in the Chittagong Hill Tracts in Bangladesh) in Arunachal who arouse xenophobic passion. There is no official confirmation of Operation Pushback under which innocent citizens have been taken away from their homes in the dead of the night, their heads shaven, driven to the Indo-Bangladesh border under humiliating conditions, and then ‘pushed’ across without any proof of illegal migration or any agreement with the Bangladesh government....

A disturbing feature of the current situation is the virtual silence and even complicity of the Indian government. No official effort has been made to demystify the greatly exaggerated figures of Bangladeshi migration. Instead, alleged Bangladeshis have been summarily deprived of ration cards, struck of electoral rolls, and threatened with deportation, apart from harassment by the police and communal elements in the lower level of the bureaucracy (Navlakha 1997: 357–358).

The bulk of the environmental refugees, in fact, end up as stateless persons, always in constant fear of being caught and sent to jail in India or worse, pushed back into Bangladesh where the Bangladesh security forces are all the more ready to stop their entry and push them back to India.

This is precisely what had happened with the *Bedes* (a community of snake-charmers), although the latter could hardly be dubbed as environmental refugees. The case however is an eye-opener, for it only showed the plight of the impoverished and somewhat uprooted *Bedes* trying to cross the border without valid documents. In fact, the *Bedes*, being a nomadic community, kept on crisscrossing the Indo-Bangladesh border without valid documents since the time of partition, but in February 2003 they suddenly found themselves trapped in “no-man’s land” for neither India nor Bangladesh would allow their (re) entry (Chattopadhyay 2003; Ganguly/Saksena 2003). After six days of being ‘huddled together in the severe cold’ and without food (figure 19.3) and following international concern and civil uproar in both India and Bangladesh, the issue was finally resolved, albeit without the world knowing how, as one critic commented:

To the relief of the two States, the 213 people stranded in the no man’s land between Bangladesh and India at Satgachi in Cooch Behar vanished mysteriously on February 6 (in 2003). They had been there for a week, India saying they were illegal immigrants and should be

7 See: Islam (1999: 88); see also UNEP (2001: 4); Chowdhury (2001: 67–89).

pushed back and/or not allowed entry. Bangladesh refused to accept that they were its citizens, demanding proof and refusing to 'take them back'.... And then on the morning of 6 February, the BSF (India's border security force) found that the group of 213 had disappeared. Everyone breathed a sigh of relief. The Indian external affairs minister surreally commented: "Snake charmers cannot spoil our relations. We can get over these problems if Bangladesh acknowledges the fact and decides to talk" (Samaddar 2004).

No one could tell whether they ended up becoming Indians or Bangladeshis or remained as *Bedes* as ever! Indeed, this became all the more difficult because the Bangladesh government 'strongly refuted' the Indian government's claim that the former had formally accepted the snake charmers (Ramachandran 2005: 3). The fate of the environmental refugees, in the light of their being denied citizenship by both India and Bangladesh, remains no different.

Figure 19.3: A snake charmer among the 213 people stranded at Satgachi, West Bengal, pleads for food, on February 4, 2003. **Source:** *Frontline*, 20,4 (February 2003): 15-28. Permission to reproduce the photo was obtained from the copyright holder.

It may be pointed out that, save for Sri Lanka, none of the South Asian countries ever took formal measures to grant citizenship to the stateless.⁸ In this connection, one may cite the fate of earlier (pre-1971) en-

vironmental refugees - the Chakmas and Hajongs in Arunachal Pradesh (India). While having arrived in India from the erstwhile East Pakistan (now Bangladesh) in 1964 following the construction of the Kaptai Dam, the Chakmas and Hajongs in Arunachal Pradesh still remain 'stateless' after over 40 years, and this despite having a Supreme Court ruling in their favour. In fact, in the *National Human Rights Commission vs. State of Arunachal Pradesh*, the Supreme Court of India, while referring positively to the content of Section 5 (1) (a) of the Indian Citizenship (Amendment) Act, ruled in 1996 that the Chakmas and Hajongs fulfilled the requirements of the Act. The Court then affirmed the right of these people to apply for citizenship and ordered the state government to take necessary steps to facilitate their registration. Despite this overwhelming *legal* backing, the Chakmas and Hajongs still remain stateless and are increasingly the targets of the local population as well as of the state government. Currently, the plight of environmental refugees is even more severe.

19.6 A Fence to Contain Environmental Refugees?

The Indian government under the supervision of the Ministry of Home Affairs decided to fence the entire Indo-Bangladesh border at an estimated cost of Rs. 1,134 crore.⁹ The project is stipulated to end by March 2007. The fencing of Bangladesh will include a combination of actual border fencing (2409 km) and border roads (797 km). The actual border fencing will be at its maximum (1021 km) in West Bengal and the least in Assam (71.5 km). Tripura, Mizoram and Meghalaya will have 736 km, 400 km, and 198 km of fenced borders respectively. Fenced and cordoned, where will the environmental refugees go now (figure 19.4)? Critics, however, have already pointed out: "No number of barbed wires, fences or machine guns...can stop the movement of the desperately poor to where they think they may find food and shelter" (Swami 2003). Moreover, a photojournalist from Guwahati (India) once told me that it takes only Rs. 10 (the cost of a pair of scissors) to cut through the fencing of Rs. 1,134 crores! But then he went further and said: "Who is exploiting whom? Since the so-called 'illegal immigrants' are exploited heavily by the locals (low wages, more work hours, inhuman living conditions, and the

8 Under the Grant of Citizenship to Stateless Persons Act, No. 5 of 1986, the government of Sri Lanka is obliged to grant citizenship to 469,000 persons of Indian origin, and also to any residue of stateless persons of Indian origin in Sri Lanka. For a detailed exposition of the citizenship laws of South Asian countries, see, Ahmed 2002-2003.

9 One crore = ten million.

Figure 19.4: Indian government's construction of fence on Indo-Bangladesh border. **Source:** BBC News/South Asia, Tripura, Tuesday, 28 June, 2005; at: <www.bbc.com>; Photos by Bapi Roy Choudhury. Permission was obtained from the copyright holder.

like) it is time that Bangladesh demand compensation from India for their time and labour!”¹⁰

Samir Guha Roy of the Indian Statistical Institute, Kolkata, however, finds the estimates of ‘illegal’ Bangladeshis in India “motivatedly exaggerated”. After cross checking population growth and decline rates of the Indian States as well as that of Bangladesh, Roy goes on to state:

A close examination of demographic statistics proves conclusively that it is not the refugees from Bangladesh but the influx of migrants from neighbouring Indian states that has caused West Bengal’s population problem.... A break-up of the estimated total immigrants of 16 lakh or so during 1981–91 reveals that the share of the Bangladeshi migration to West Bengal was 9.1 lakh. The rest i.e. 7 lakh constitute inter-state movements. In other words an annual average of 91 thousand Bangladeshi nationals might have crossed the international border during the decade but how many of them were identified and pushed back is not known. It is possible that a portion of these immigrants returned on their own to their place of origin.¹¹

Speaking on the issue of deportation and almost extending Roy’s contention, Hannan Mollah, the CPI (Marxist) member, once commented in the Indian Parliament that “most of the Bengali-speaking people being deported from Maharashtra had gone to Maharashtra from Howrah and other districts of West Bengal”. Furthermore, he alleged that “usually police demanded rupees 2000 to 2500 from each of the detained Bengali-speaking people for their release. If they failed to give that amount the police kept them behind the bar for 10 to 15 days following which they were taken to border and pushed into Bangladesh” (Ahmed 2005). But the issue of internal migration could hardly dissuade the pro-Indian state scholars

from suggesting the incredible influx of the Bangladeshis. As one recent commentator stated:

This foreign trip is probably the cheapest in the world. For less than Rs. 2,000, including the cost of your ‘tour operator,’ you can actually buy yourself a safe passage and a future in India – if you are Bangladeshi. What’s more, for some small change, you cannot only settle down in whichever part of India you choose to but also be counted as part of a vote bank. Since a Bangladeshi national is culturally similar to a Bengali, he or she can easily pass off as an Indian, an identity that’s quickly fortified by fictitious ration cards that cost as little as Rs. 200. Illegal Bangladeshi immigration has grown manifold over the years. Police estimates – and there are few to come by – peg the total number of illegal immigrants in India at over a crore. Ideally, a strict vigil at the borders is called for to ward off infiltration and nip the problem in the bud.¹²

Environmental refugees are now reified in terms of ‘police estimates’ and ‘over a crore’ figures. This is not to suggest that there is no ‘illegal’ flow of people, although the term ‘illegal’ here, as indicated earlier, is a misnomer. There could be illegality only when there is something legal. In the case of Bangladesh and India, and also Pakistan, save marriage (if we were to believe Sushma Swaraj and the BJP [Bharatiya Janata Party, the main opposition party] even Sonia Gandhi fails to fulfil the criteria of citizenship in full), there can be no legal migration. Both the Nehru-Liaquat Pact of 1950 and two decades later the Mujib-Indira Agreement of 1972 have territorialized and frozen the issue of citizenship. The 1972 agreement, in fact, made 25 March 1971 as the cut off point for considering citizenship between India and Bangladesh.

Migration in South Asia otherwise has meaning only in the sphere of *illegality*. Interestingly, in the

case of India there is one novel exception, and that is, the Gurkhas of Nepal who join the Indian Army have the option of claiming Indian citizenship.¹³ So much for democracy and people's power over governments and institutions! But more importantly, not to have any movement of people or migration across the Indo-Bangladesh border would be unnatural. India and, for that matter, also Bangladesh would turn sterile and die if the flow of people between these two countries ever stopped. And since the door of legality is practically shut off the only option for the environmental refugees is the hazardous journey across the barbed-wire fences aided by none other than criminal elements and even non-state militant groups. The latter only adds to the insecurity, indeed, not only of the person in plight but also of the state and the region.

19.7 What is to be Done?

In view of the collapse of environmental security, it is quite clear that the politically constructed modern

majoritarian state has lost its will to support and nurture the material aspirations not only of the minority community but also of a sizeable section of the majority community. Indeed, threatened by water, land, and food insecurities, the members of both majority and minority communities are willing to risk the life of a 'displaced person' or 'refugee' than live a life of an imbecile in the place they were born and brought up. This is, indeed, a great tragedy. In this context, it is high time for the public and the politicians alike to rethink development, to find ways to ensure a living condition that is free from man-made disasters and the ruthless exploitation of nature.

It is difficult to offer a precise plan for rethinking development. The best we could do is to point out the things that are required to be nurtured here. In order to make 'development' more indigenous, for instance, there ought to be more creative efforts in combining water and people, the two resources that Bangladesh has in plenty (Razzaque 1981).

One such effort, indeed, could be in the area of *mud-housing*, where creative intervention could resolve not only the housing problem in a more environment-friendly manner, but also lead to the proper dredging of the river beds which could greatly reduce

13 The author is grateful to Admiral (ret.) Ramadas for sharing this information.

the possibility of floods during the rainy season. But this is only one aspect of the problem related to development. Serious imaginative interventions are required in the field of industry, transportation, state security, and other modern sectors if the rethinking development agenda is to be materialized.

Immediate and imaginative interventions are also required in the border areas. In fact, the refugee flow will continue if one side of the border remains weak and poor, while the other side remains relatively better off. It is important, therefore, that identical socio-economic, environmental, and even educational projects are undertaken on both sides of the border to meet the immediate demands of the people residing there. On this matter, NGOs on both sides of the border must participate freely, for the chances of their success are more than the highly structured governmental interventions.

There could also be Indo-Bangladesh *civil watch groups* to monitor population movement across the border. Such groups may be government sanctioned for them to have some credence and access to confidential information, including the power to interview and investigate, in the border areas. It may be mentioned that given the paramount role of the border security forces of both India and Bangladesh, often poor and marginalized civilians are fired upon and killed while crisscrossing the border. The yearly toll of such deaths is indeed tragic. According to a report published by *Odhikar*, a human rights organization in Bangladesh, 76 Bangladeshis, mostly peasants and cattle breeders, were killed by the BSF and Indian miscreants in the border area in 2004 (Ahsan 2005). In April 2001 the BDR (Bangladesh Rifles) also fired upon Indian security forces and killed 16 of their soldiers. Indeed, quite astonishing is the fact that while civil groups of both India and Bangladesh are very active in critiquing governmental *internal* policies, they remain suspiciously silent when it comes to inter-state relations and *external* policies. Given the magnitude of the issue, including the rise in the number of environmental refugees, a greater role of civil groups alongside the government could lessen the tension and killing in the border area.

I also think that it is high time to look for alternatives in resolving water insecurity, for example, building 'water catchment' for conserving water when the latter is plenty (i.e. during rainy season, floods, etc.). If this can be made viable, and there is no reason why it should not, given the level of technological development on water catchment, it would surely take away much of the dependency syndrome that Bangladesh

so acutely suffers from when dealing with the issue of water sharing with India. It may not be out of place to point out that the Ganges as a whole is fast drying up for reasons of modern development and increasing population pressure. I do not foresee a time in the recent future when the Ganges will have plenty of water to share around. I do see a politics, however, on the question of sharing the Ganges, which, I believe, is more catered towards reproducing a pro-majoritarian or inversely communalized hegemony in both India and Bangladesh. In this context, water catchments could bring an end to such politics, making development more central to the demands and livelihood of the people.

Moreover, there is a need for revitalizing the culture of *living with floods*. With the frequency of big floods coming down to a decade there is an urgent need to reorient our present mode of living into something that is more flood or water centric. Imtiaz Ahmed, Ajaya Dixit, and Ashis Nandy (1997: 10-11) have tried to highlight this need for reorienting our life and living, while working together on a *South Asian Manifesto on the Politics and Knowledge of Water*. As we collectively maintained,

Till now, the approach to water management and water development has been fragmentary. Not only has it dealt with sea, river and groundwater separately, it has been 'land-centric'. Water management, we believe, should centre on water; it must be based on the recognition of the wholeness of water and its intrinsic function in nature. A comprehensive view also demands critical interventions in the curricula at all levels of education. The principal challenge is, therefore, to integrate the global and the local, to alter the structure and nature of current decision-making models, and the educational context within which they are generated, not only to accommodate a plurality of views, but also to generate options that would reflect the larger reality of water in nature and human society.

The range of activities that can be expected from such reorientation of things is immense. Not only will it provide a space for including a more sensible and topographically relevant cropping system, something that we have discussed earlier, but also a mode of settlement based on the long lost principle of 'dig-elevate-dwell'. The latter refers to a practice in Bengal going back over thousands of years where people in order to construct houses first dug ditches and then used the excavated earth to elevate the land. Houses were then constructed on this elevated land (Islam 1999). In the process, they also succeeded in making new ponds and dredging the silted canals, particularly during the dry season, which must have worked to their benefit

at the time of flooding. It is high time that we make use of this age-old wisdom, albeit with proper innovations to meet the current state of living.

The reorientation of things will also allow us to reinvent and rebuild the much required water-based communication system, flood-free housing structures, flood-time schooling, and many more. Only a timely investment in a culture of *living with floods* would allow the Bangladeshi to transform the current curse that so frequently accompanies the floods and make our life more liveable in the midst of the not-so-natural floods. Since the current government is ill equipped to carry out such an investment, the onus of carrying out this immense task lies with all those concerned and the affected millions.

Finally, there is also the need to *democratize* development. This could come in two ways. First, we need to effectively and creatively make use of the diverse or pluralist understanding and practices of development that is so much present at the international level, even within the World Bank itself. In practical terms, what we need is a thorough knowledge of whatever is taking place in both developed and developing countries. This will put us in a position to effectively bargain for our own development strategies whenever we are fed up with one particular policy prescription provided by international donors. Creating development lobbies in the developed countries, both at government and grassroots levels, falls within the range of this activity. At the same time, there is a need for greater donor responsibility, particularly on the part of the developed countries, including the World Bank. This is because often their developmental initiatives, including the building and financing of large dams and newer irrigation measures, as indicated in the case of Bangladesh, go on to create environmental insecurity and environmental refugees. Second, we need to provide space for alternative development scenarios to be practised in Bangladesh. In this context, 'Yunusonomics' (i.e. the economics and developmental practices of Muhammad Yunus of Grameen Trust) needs to be further explored and brought into mainstream discussion, including the building of alternative economics curricula at the primary, secondary, and tertiary levels on the basis of his paradigmatic vision and experience.

19.8 Concluding Remarks

Several conclusions can easily be reached. From a conceptual perspective, with regard to environmental dis-

tress migration and environmental refugees, and not to mention the crisscrossing of people along the Indo-Bangladesh border, 'security' can no longer be defined in military terms, not even within the familiar 'realist' notion of national security. In fact, 'environmental security' along with 'human security', 'social security', and 'gender security' has now come to inform and influence the understanding of security not only within the national domain but also regionally and internationally. Even the concept of 'environmental refugees' has now attained more specificity, understood and defined differently from conventional refugees and migrants. This is a healthy sign for it creates space to opt for policies qualitatively different from those practised in containing and eradicating problems arising from conventional refugees and economic migrants.

From a theoretical vantage point, the relationship between environmental distress migration and environmental refugees is hardly linear. Rather, the two are product of a complex structure consisting of (mal) development, environmental disruptions, population growth, lack of space, and an obsession with national security. The projected impacts of climate change, including global warming and the rise in sea level, have the potential of further exacerbating the plight of environmental refugees. The multifaceted nature of the problem makes it clear that segmentalized and fragmented interventions would do little to redress the situation. What is required is a comprehensive approach keeping the complexity in mind.

What do these results imply for policy options? Given the widespread lack of familiarity of policymakers on issues related to the environment and also at times serious lack of attention towards the impoverished and uprooted segment of the population, there is a tendency on the part of the state machineries to fall back on the age-old 'realist' resolution of the problem. India's policy of fencing its border with Bangladesh to contain environmental refugees or what it deems as 'illegal migrants' is a good case. But such a policy while (probably) helpful in containing a military threat or a known enemy requiring quarantine can prove immensely destructive when the 'threat' is non-military and the quarantine not only impossible, rather an act more against a friend than anything close to an enemy. Apart from having a psychological bearing on the people of an otherwise friendly country, the barbed-wiring of the border creates further hardship for environmental refugees. This calls for an innovation in policymaking in the age of environmental insecurity and post-nationality. Indeed, nothing

short of creative and bold interventions would stop the reproduction of environmental refugees and the state of insecurity arising out of it.

Thomas Homer-Dixon and
Tom Deligiannis¹

La Paz (Bolivia). Bolivia's president declared a state of emergency today, following a week of widening unrest that left three people dead in fresh clashes between police and demonstrators. The move came after a week of protests over rising water rates, unemployment, and other economic difficulties plaguing the Andean country of eight million people.²

Nairobi (Kenya). Fourteen people were killed and 13 seriously injured in Tana River District, Eastern Kenya, on Sunday when tensions between Orma and Pokomo communities over the use of land and water resources erupted into violence. . . . Some 70 people have now been killed over the last year as a result of repeated clashes between the communities, and Pokomo elders have claimed that the Orma have been accumulating firearms in preparation for more attacks.³

Santiago Xochiltepec (Mexico). All over the state of Oaxaca, where a quarter of the breadwinners earn less than \$5 a day, people fight over who owns the land, the water, the trees. In the absence of governmental authority these disputes become deadly. The killing of 26 men from Santiago Xochiltepec, population 650, took place Friday night on a darkening dirt road outside Las Huertas, population 700. The attackers lay in ambush with automatic weapons.⁴

Kafr Kila (Lebanon). [Here] on this scarred frontier of enemy states, water is everything, and Lebanon's plans to pump water from Wazzani Springs has set off a new round of tension with Israel. . . . Last month, Mr. Sharon issued his most explicit threat. Should Lebanon start pumping water from the Wazzani, the Prime Minister said at a cabinet meeting: "we shall have to take measures."⁵

20.1 Introduction

Scarcities of vital environmental resources – especially of cropland, fresh water, and forests – are contributing to significant violence around the world. These *environmental scarcities* rarely cause wars among countries, but they do generate severe social, economic, and political stresses inside countries. When combined with certain other factors, these stresses, in turn, boost the likelihood of sub-national insurgencies, ethnic clashes, and urban unrest.

Such internal or *civil* violence is particularly harmful to developing countries, because they tend to be far more dependent on environmental resources and far less able to buffer themselves from the social impacts of environmental scarcities. While instability, dislocation, and mass violence may affect poor countries most, policymakers and citizens in the industrialized world ignore it at their peril. It can harm rich countries' national interests by threatening their trade and economic relations, entangling them in complex humanitarian emergencies, provoking distress migrations, and undermining the political cohesion of key regions, which can then become havens for transnational terrorism.

These issues were examined in detail between 1989 and 1998, when the University of Toronto, working with several American organizations and foundations, brought together over 100 experts in fifteen

1 This chapter summarizes the research of the Toronto Group, conducted during the 1990's. An earlier version of this chapter by Thomas Homer-Dixon originally appeared in Kennedy/Riggs (2000).

countries to participate in three major research projects.⁶ The research of this ‘Toronto Group’, as it has become known, studied the links between scarcities of environmental resources – especially of cropland, fresh water, and forests – and mass violence, including insurgencies, ethnic clashes, urban unrest, and rural banditry.

This chapter provides an overview of the Toronto Group’s research findings about how environmental scarcity can contribute to causing conflict. The first part of the chapter places the work of the Toronto Group into the context of research since the end of the Cold War on revised conceptions of security, outlines the research questions that guided the project, and lists the Group’s key findings (20.2). Part two provides an overview of why renewable resources are crucial for the livelihood survival of hundreds of millions of people globally (20.3). Part three outlines the Toronto Group’s conception of environmental security – how demand, supply, and distributional dimensions of human interaction with renewable resources can lead to scarcity and undermine human well-being (20.4). Two types of social effects from environmen-

tal scarcity are particularly important, according to the Toronto Group – resource capture, and ecological marginalization. These social effects are described in part four, with illustrations taken from some of the Toronto Group’s case studies (20.5). Part five describes the linkages between the social effects of environmental scarcity outlined by the Toronto Group and different types of sub-national violent conflict, placing these links into the context of the core causal model of the Toronto Group (20.6). This section also asserts the highly contextual, and highly interactive nature of environmental scarcity-conflict linkages. Part six acknowledges that societies often overcome scarcities through technological or social change, but goes on to argue many societies either lack the capacity to alleviate the impact of environmental scarcities, or that environmental scarcities can actually undermine a society’s ability to apply needed ingenuity (20.7). The chapter concludes with recommendations to address the impacts of environmental scarcity (20.8).

20.2 Toronto Group’s Research and Debates about Environmental Security

The Toronto Group’s research emerged from both the calls for a redefinition of security concerns to include the environment in the last decades of the Cold War, and the rethinking of security policy that took place among scholars and government officials following the collapse of the Soviet bloc.⁷ Throughout much of the Cold War, security thinking was largely the concern of academics and specialists in government security establishments. While their focus was mainly on the use of military force as an instrument of national policy, policymakers often used a much more expansive definition of security than security studies scholars.⁸ At various times, the consequences of environmental scarcities and population change were evaluated at the highest level of the US security bureaucracy during the Cold War.⁹ However, these issues were often a component of general or regional assessments of security considerations, and were overshadowed by the perceived military threat from the USSR. Greater concern among security thinkers about the consequences of population growth and human-in-

6 The first project on *Environmental Change and Acute Conflict* (1990–1993) was jointly sponsored by the American Academy of Arts and Sciences in Cambridge, Massachusetts, and the Peace and Conflict Studies Program of the University of Toronto. It brought together a team of forty experts from four continents to conduct a preliminary study of the links between environmental stress and conflict. The second project on *Environmental Scarcities, State Capacity, and Civil Violence* (1993–1997) followed directly from the first. It sought to determine if scarcities of cropland, forests, water, and other renewable resources are decreasing the capabilities of governments in the developing world and, if so, whether this raises the probability of widespread civil violence such as riots, ethnic clashes, insurgency and revolution. The third project on *Environment, Population and Security* (1994–1996) was a joint effort of the Peace and Conflict Studies Program and the American Association for the Advancement of Science in Washington, DC. It gathered, evaluated, and disseminated existing data on causal linkages among population growth, renewable resource scarcities, migration, and violent conflict. Additional details about the work of the Toronto Group, case studies, and thematic papers can be found at the University of Toronto’s Trudeau Centre for Peace and Conflict Studies, at: <<http://www.trudeaucentre.ca/research-pioneeringresearch.html>>; the key summative publications of the project include the following: Homer-Dixon (1991, 1994, 1999); Homer-Dixon/Blitt (1998); Schwartz/Deligiannis/Homer-Dixon (2001).

7 The discussion in this section is particularly focused on the North American context of debates about security and the expansion of security to include environmental concerns.

duced environmental change evolved with both the growth of the environmental consciousness in the 1970's and the reduction of Cold War tensions in the late 1980's.¹⁰

The end of the Cold War stimulated a vigorous debate about the nature of threats in the post-Cold War era, and the future direction of security thinking. A number of scholars questioned the traditional focus on issues surrounding the use of conventional and nuclear military power; this work built upon the pioneering arguments of a small number of scholars from the 1970's and 1980's.¹¹ These revisionist voices argued that newly emerging or overlooked threats like ethnic conflict, economic decline, environmental degradation, emerging infectious diseases, or the proliferation of nuclear, biological, and chemical weapons, demanded greater attention from security studies scholars, and that the concern with questions of conventional and nuclear conflict had led to overly narrow definitions of 'security'.¹²

Debates among practitioners and scholars about the definition of security and the place of the environment in that definition remained fluid throughout the

1990's. In the United States, a concerted, and largely inconclusive, effort was made at the time to integrate concerns like the environment into national security policymaking in order to take advantage of the favourable political climate in Washington, DC.¹³ Consensus also remained elusive among scholars. The divide expanded beyond traditionalist and revisionist views defining security. Instead, scholarly opinion displayed a continuum of views - from those adamantly opposed to expanding the scope of research to encompass issues outside of the practice of conventional and unconventional war, to those who accepted an inclusive view of the nature of threats like environmental scarcity and the types of conflict in the post-Cold War era worthy of concern.¹⁴ Some traditionalists within the field were afraid of diluting the focus of security studies, while others refused to accept that environmental issues had any bearing on research about the use of military force.¹⁵ Deudney (1999: 189, 192-194) for example, argued that thinking of environmental change as a national security threat would create a "conceptual muddle rather than a paradigm shift, ...because the traditional focus of national security - inter-state

8 The historical record of US national security policy thinking during the Cold War is a good example - and probably represents the general trend, rather than a case of American exceptionalism. The working definitions of "national security" used by policymakers in the US were generally expansive during most of the Cold War, compared with those used by North American security studies scholars. US policymakers regularly included issues such as economic threats in their reviews of threats to national security, for example (see Leffler 1992). Baldwin (1995: 121-122) notes, however, that expansive working definitions of national security used by most scholars at the start of the Cold War appeared to give way to concerns surrounding the military instruments of statecraft as the Cold War reached its height in the 1950's and 1960's. Useful reviews of thinking among security studies scholars during this period include Prins 1991, Walt, 1991, and Baldwin 1995. An excellent discussion of the meaning of national security to US policymakers during the early Cold War period can be found in Leffler (1992).

9 On concerns about population growth in the third world, see: Connelly (2000, 2001). As well, US documents on the concern over population issues and water scarcity can be found in, US Department of State (1999); at: <http://www.state.gov/www/about_state/history/vol_xxxiv/index.html>. The documents released in the FRUS volume are only a small sample of those currently available to scholars in US archives.

10 Dabelko (2003) provides a good overview of these developments.

11 Seminal early arguments about redefining "security" can be found in Brown (1977), Ullman (1983), and the World Commission on Environment and Development (1987). A thorough account of these developments can be found in Dabelko (2003, chap. 2 and 3). Challenges during the 1990's to the traditionalist views of Walt (1991) can be found in Kolodziej (1992). In addition to Baldwin (1995), other articles from the 1990's exploring whether conventional interpretations of "security" should be enlarged, include Wyn Jones (1995), Krause (1996), Lipschutz (1996), and Betts (1997). An overview of this thinking, including reviews done by North American governments, is provided by Florini and Simmons (1998).

12 Scholarly work from this period arguing for the place of the environment in security concerns includes Stoett (1994), Perelet (1994), Stern (1995), Dabelko/Dabelko (1995), Matthew (1995), Dabelko (1996), Pettiford (1996), Shaw (1996), Dabelko/Simmons (1997), Matthew (1997). Dabelko (2003) also provides a comprehensive overview of this thinking.

13 These developments are covered in detail by Dabelko (2003).

14 This analysis was reflected by the scope of discussions on the direction of security studies during a roundtable on "Security Studies for the 21st Century", held at the 40th Annual Convention of the International Studies Association, Washington, DC, 18 February 1999.

15 On the fear of the dilution of security studies, see Betts (1997: 27).

violence – has little to do with either environmental problems or solutions”.

Some of the most pointed critiques, however, come from scholars in environmental studies and development studies. Most acknowledged that the diversity of research in the nascent field of environmental security displayed a healthy interest in academic and policy-making circles about the role of the environment. However, some feared that the consequences of *securitizing* the environment far outweighed the benefits of wrapping a package of environmental concerns with the environmental security concept.¹⁶ Concerns also arose about the wisdom of opening environmental problems to military institutions dominated by a culture of secrecy, and eager for new roles and missions with the evaporation of the Soviet threat.¹⁷ As well, some worried that the multifaceted nature of the term ‘environmental security’ exposed it to far too much rhetorical and political abuse.¹⁸ Instead of debating about threats to environmental security, Conca (1998) argued that policymakers in the developed world should focus on the root causes of destructive global environmental change – our own wasteful, high-consuming industrial societies (Conca/Princen/Maniates 2001). Similarly, Dalby (1996, 1999a, 2000, 2002) warned that the use of the term ‘environmental security’ could perpetuate the exploitative patterns of economic relations and resource use that underlie many of the world’s environmental woes (Peluso/Watts 2001). To Deudney (1999: 202), melding existing concerns about national security with environmental problems was misguided because such an approach bolstered the state-centric concept of nations now dominant in world politics, while simulta-

neously threatening to undermine the most important challenge to this traditional system – the construction of an emergent ‘earth nationalism’ necessary to deal with global ecological problems. Apprehension ran deep among this group of critics about the misappropriation of the idea of environmentalism.

Critiques of the term environmental security thus emerged from an unlikely alliance between some traditionalist scholars in security studies and their ideological opposites in development and environmental studies. General fears about the misapplication by policymakers of conceptions of environmental security link these critical voices together.

Among those scholars who accepted an expanded focus for security studies to include issues related to the environment, by the mid 1990’s many began to regularly employ the term ‘environmental security’ to describe their field. According to a survey by Geoffrey Dabelko (1996), topics examined under the ‘environmental security’ domain included:

1. Environmental degradation or depletion as a threat to human health and human well-being stemming from competition with disease causing micro-organisms; from declining standards of living; from declining agricultural outputs; from increased pollution; from increased ultraviolet radiation; and from economic instability and decline;
2. Environmental degradation or depletion stemming from military preparation for armed conflict; from the conduct of armed conflict; and from the disposal of military waste;
3. Environmental scarcity as a cause of political instability or violent conflict;
4. Institutional infringement on the principle of sovereignty to mitigate environmental degradation;
5. Military and defence intelligence institutions monitoring and enforcing international environmental agreements; gathering, analysing, and disseminated scientific data on the national environment; responding to mitigate environmental crises and disasters; implementing environmental sustainability programmes; guaranteeing access to natural resources; spinning off environmental cleanup technologies; and protecting national parks and reserves.¹⁹

The sheer diversity of definitions and research agendas encompassed under the term ‘environmental security’ no doubt led to the environment being one of the most contested topics in the debates about expanding the traditional focus of security studies.

16 See Deudney (1990), Levy (1995), Dokken/Graeger (1995), Waever (1996), Elliott (1996), Graeger (1996), Lipschutz (1996) Gleditsch (1998). A number of important European scholars were particularly prominent among this group.

17 This concern has probably lost much of its impetus in the wake of terrorist attacks in the United States in 2001.

18 For example, Ken Conca (1998: 40) argued that, “Despite its weak performance on environmental cooperation, the [Clinton] administration has undertaken a concerted effort to repackage the environment as a security issue. Although sometimes touted by environmentalists as a way to generate attention and action, the linking of environmental problems to national security and ‘strategic’ American interests is deeply troubling. It distorts the problem, blurs underlying responsibility, legitimizes coercion, and diverts attention from where action is most badly needed.” See also Conca (1994).

Compared to the vast array of conceptual and thematic issues involved in the expanded domain of environmental security, a number of researchers in the early 1990's chose to focus instead on the narrower goal of identifying the causal linkages between environmental change and violent conflict. These scholars side-stepped debates about including environmental change as a *security* concern in favour of further research on the evidence and nature of a causal connection between environmental change and violent conflict. Two projects were particularly prominent in the 1990's: the Zurich-based Project on Environment and Conflict (Bern-Zürich Group), led by Günther Bächler and other scholars from the Swiss Peace Foundation and the Centre for Security Studies and Conflict Research; and a series of studies headed by Thomas Homer-Dixon of the University of Toronto's Peace and Conflict Studies Program (Toronto Group).²⁰ Both the Bern-Zürich Group and the Toronto Group explored a large number of individual case studies in order to map the linkages between environmental change and violent conflict. Information exchange was common between the two projects, though direct cooperation was limited by the fact that each pursued different approaches to exploring environment-conflict linkages. The Bern-Zürich Group assembled a typology of environmental conflicts "inductively drawn from a set of about 40 area studies" (Bächler 1999:

35), while the Toronto Group explored a small number of hypothesized connections between environmental scarcity and conflict through several case studies (Homer-Dixon 1991, 1994, 1995a).²¹ In the end, the findings of the Bern-Zürich Group and the Toronto Group are complimentary and reinforce each other about the positive relationship between human-induced environmental change and violent conflict (see chap. 21 by Mason, Hagmann, Bichsel, Ludi and Arsano).

The Toronto Group's projects did not aim to identify all the factors that cause violent conflict around the world, but rather sought to determine whether a specific factor - environmental scarcity - can be an important cause of violent conflict. The research of the Toronto Group was guided by three key research questions (Homer-Dixon 1999: 6). First, can environmental scarcity contribute to violent conflict? If yes, how can it contribute to conflict? And, finally, is this contribution important? These questions frame the summary of the Toronto Group's work below.

The Toronto Group's findings can be summarized by seven points:

1. Environmental scarcity is a significant cause of violence in developing countries.
2. The links between environmental scarcity and violence are usually indirect; therefore, scarcity's role as a cause of violence is often not recognized.
3. Environmental scarcity is neither a necessary nor sufficient cause of violence (there is, in fact, no identifiable, non-trivial necessary and sufficient cause of any type of human violence); rather, environmental scarcity is always one component of a complex, multivariate set of causes. The relationship between these causes is invariably synergistic.²²
4. The response of political, social, and economic systems to such stresses is almost always nonlin-

19 The diversity of research perspectives in the new field of environmental security at that time is well represented in the Woodrow Wilson Center's *Environmental Change and Security Project Report*, which published its first report in 1995 under the editorial guidance of P.J. Simmons. Geoffrey Dabelko became editor in August, 1997, and has since then continued to present a broad diversity of environmental security concerns in the Project's publications. The full text of all volumes is available online at: <http://www.wilsoncenter.org/index.cfm?topic_id=1413&fuseaction=topics.publications>. In one form or another, Dabelko (2003) traces the intellectual roots of most of these 'expanded' concerns to the late 1960's.

20 The ENCOP project produced a number of publications. See Bächler (1999); Bächler/Böge/Klötzli/Libiszewski/Spillmann (1996a); Bächler/Spillman (1996b, 1996c). Although Homer-Dixon was the lead researcher in the environmental scarcity research project centred at the University of Toronto, over 100 experts from 15 countries also participated in various stages of three separate research projects. Details of the work of the Toronto Group can be found at the website of the University of Toronto's Trudeau Centre for Peace and Conflict Studies: <<http://www.trudeaucentre.ca/research-trudeaucentreresearch.html>>.

21 See: Bächler/Böge/Klötzli/Libiszewski/Spillmann (1996a); Bächler/Spillman (1996b, 1996c) for explanations of ENCOP's research approach and the results of their case studies. Bächler (1999) provides a synthesis of ENCOP's findings. Chap. 2, in particular discusses their methodological approach in the context of other environment-conflict literature. The Toronto Group's methodological approach is outlined in Homer-Dixon (1991, 1994).

22 The Toronto Group's view of the causal role of environmental scarcities is discussed in greater detail in Schwartz/Deligiannis/Homer-Dixon (2001), and Homer-Dixon (1999): 104-106 and 169-176.

ear, and therefore predicting the specific incidence of violence is usually impossible.

5. The violence that environmental scarcity helps cause tends to the sub-national, diffuse, and chronic; outright 'resource wars' are unlikely. Nonetheless, this violence may have significant security implications for the United States and Western countries.
6. This violence may also disrupt a society's adaptive mechanisms, contributing to downward, 'locked in' spirals of economic crisis, institutional disintegration, and further political violence.
7. The incidence of such violence will increase in the future, because a large fraction of the world's population will remain dependent on renewable resources for day-to-day needs; because interacting demand, supply, and distributional pressures will produce an inexorable worsening of local resource scarcities; and because national economic, political, and social institutions in the South are often too weak to provide an effective collective response.

In many cases, critics of the Toronto Group's work (and critics of similar work elsewhere) have grossly misrepresented the Group's findings and conclusions, often labelling them as simplistically Malthusian. They have implied, and sometimes stated explicitly, that the Toronto Group has proposed deterministic, mono-causal models of the relationship between environmental stress and violence.²³ The reality is very different: the Toronto Group's arguments are complex, subtle, and probabilistic.

23 Notable critiques of the Toronto Group's work can be found in Levy (1995), Deudney (1999), Barnett (2001), Gleditsch (2001), Goldstone (2001a), Le Billon (2001), Peluso/Watts (2001), de Soysa (2002). Responses from the Toronto Group to various critiques can be found in Homer-Dixon and Levy (1995/1996), Homer-Dixon (1999), Schwartz/Deligiannis/Homer-Dixon (2001); Homer-Dixon (2003). Additional commentary and debate about the work of the Toronto Group can be found in the various issues of the Woodrow Wilson's *Environmental Change and Security Project Report*, which can be accessed online at: <http://www.wilson-center.org/index.cfm?fuseaction=topics.home&topic_id=1413>.

20.3 Critical Role of Environmental Resources

Scholars have long considered that negative impacts on standards of living or quality of life might play a role in instigating civil violence and revolutions.²⁴ The Toronto Group's research into environment-conflict linkages began by hypothesizing that human pressure on natural resource endowments and the patterns of use of those resources could impact on a society's material well-being and thus contribute to the outbreak of violent conflict.²⁵ The key roles played by these resources for billions of livelihoods around the world are briefly outlined below.

Those of us living in the developed world may easily forget that the well-being of about half of the world's population of 6.5 billion remains directly tied to local natural resources (MA 2005; chap. 3 by Lee-mans). Rural areas are home to about two-thirds of

24 Useful reviews of literature on the causes of revolution, including the role of material well-being or grievance factors, can be found in Foran (1997), Goldstone (2001b). The *Political Instability Task Force* (PITF) (formerly known as the State Failure Task Force) also explores the impact of quality of life indicators as a part of a general causal model of conflict, and has empirically tested variables to represent quality of life indicators, such as infant mortality, for several years. This variable is discussed in various reports of the PITF, which can be found online: <<http://globalpolicy.gmu.edu/pitf/index.htm>>.

25 Homer-Dixon (1991) surveyed the existing research theorizing about environment-conflict linkages, and proposed a preliminary analytical framework and research agenda to explore the possible relationships. Using this framework, and drawing on the literature of conflict theory, he suggested several hypotheses about how the social effects of human-induced pressure on renewable resources could contribute to conflict. Homer-Dixon (1991: 78): "I propose that poor countries will in general be more vulnerable to environmental change than rich ones; therefore, environmentally induced conflicts are likely to arise first in the developing world. In these countries, a range of atmospheric, terrestrial, and aquatic environmental pressures will in time probably produce, either singly or in combination, four main, causally interrelated social effects: reduced agricultural production, economic decline, population displacement, and disruption of regular and legitimized social relations. These social effects, in turn, may cause several specific types of acute conflict, including scarcity disputes between countries, clashes between ethnic groups, and civil strife and insurgency, each with potentially serious repercussions for the security interests of the developed world."

the world's poor, and most depend on agriculture for a substantial portion of their livelihoods (IFAD 2001, WRI 2005)²⁶; a large majority of these people are smallholder farmers, including many who are subsistence or semi-subsistence farmers (which means they survive, in large part, by eating what they grow). Biomass fuels like wood, charcoal, straw or dung are the main source of energy for over 2.5 billion people – over 40 per cent of people on the planet, and more than 50 % of people in developing nations; at least one billion more rely on such fuels for a part of their primary energy needs (IEA 2006; Homer-Dixon 2000; Lamb 1995). Over 1.1 billion people lack access to clean drinking water; many are forced to walk far to get what water they can find (MA 2005).²⁷ About 1.5 billion people rely upon wild fish for their main source of protein; however, three quarters of the world's fish stocks are either fully exploited, overexploited, or significantly depleted (FAO 2004).

The livelihoods of billions of people around the world depend upon renewable resources like cropland, forests, fish, and water supplies. Unlike non-renewable resources such as oil and iron ore (Klare 2001), renewables are replenished over time by natural processes. In most cases, if used prudently, they should sustain an adequate standard of living indefinitely. Unfortunately, in many regions where people rely on renewables, they are being depleted or degraded faster than they are being renewed. From Gaza (Homer-Dixon/Blitt 1998) to the Philippines (Kahl 2006) to Honduras (Stonich 1993), the evidence is stark: aquifers are being overdrawn and salinized, coastal fisheries are disappearing, and steep uplands have been stripped of their forests leaving their thin soils to erode into the sea.

Currently, the human population is growing by about 1.2 per cent a year on a base of just over 6.5 billion (UN 2005). This figure peaked at about 2 per cent between 1965 and 1970, and has fallen since then. In recent years, fertility rates have dropped surprisingly fast in most poor countries; women are having,

on average, significantly fewer children. But it is wildly premature to declare, as some commentators have, that the problem of the population explosion is behind us. The largest cohorts of girls ever born have yet to reach their reproductive years, which ensures tremendous momentum behind global population growth. So even under the most optimistic projections, the planet's population will expand by almost a third, or by about two billion people, by 2050, with most of this growth eventually concentrating in the urban centres of a handful of developing countries (see chap. 12 by Lutz).

The real economic product per capita is also currently rising by about 1.0 per cent a year.²⁸ Combined with global population growth, the Earth's total economic product is therefore increasing by about 2 per cent annually. With a doubling time of around thirty years, today's global product of about US \$ 30 trillion should exceed US \$ 50 trillion in today's dollars by 2025.

A large component of this two-thirds growth will be achieved through yet higher consumption of the planet's natural resources. In the absence of significant changes to current policies, a further decline in the total area of high-quality cropland will occur, along with the widespread loss of remaining primary forests (MA 2005; FAO 2006a). By 2030, about 2.7 billion people will still rely upon biomass for their primary energy needs (IEA 2006). A continued degradation and depletion of rivers, aquifers, and other water resources, and the further impoverishment of wild fisheries may also be observed (MA 2005).²⁹

Regional scarcities of renewable resources are already affecting large populations in poor countries. But during the last two decades, global environmental problems, especially climate change and stratospheric ozone depletion, have received more attention in the popular media in the industrialized world. The social and economic impacts of these global atmospheric problems, in particular of climate change, may eventually be very large, but these impacts will probably not

26 Measuring poverty is tricky and controversial. One measure counts those people worldwide who consume less than one dollar a day – they are dollar poor (in constant dollars). By this measure, in 2001, between 1.1 billion and 900 million poor people live in rural areas (IFAD 2001, MA 2005), while about 2.7 billion live on less than \$ 2 dollars per day (WRI 2005).

27 MA 2005 reports that, "Water scarcity affects roughly 1–2 billion people worldwide. Since 1960, the ratio of water use to accessible supply has grown by 20 % per decade."

28 Estimates vary depending upon which dates one uses to calculate the average and whether or not one only uses GDP data or some other composite estimate. According to data listed by Van den Berg (2002), between 1820 and 1998, real GDP per capita increased at around 1.3 % per year. If one only examines the period 1950 to 1998, however, the real GDP per capita growth rate was around 2 %. Criticisms about the usefulness of using GDP to measure material wellbeing have led the UNDP to develop the Human Development Index instead (see UNDP 2006).

Figure 20.1: Supply-induced scarcity. **Source:** The authors.

- A human-induced decline in the quantity or quality of a renewable resource leads to worsening supply-induced scarcity.
- Unsustainable human impacts on resources reduce the overall size of the resource pie over time – the pie gradually gets smaller.
- Continual cropping of the same field without rotating crops, for example, will gradually erode the productive capacity of the field by depleting certain necessary minerals and organic matter in the soil. Its productive capacity will be diminished.

be decisively clear till well into this century. And climate change is most likely to have a major effect on societies (Brauch 2002, 2003; Schwartz/Randall 2003, see chap. 59 by Dalby/Brauch/Oswald and chap. 98 by Oswald/Brauch/Dalby in this volume), not by acting as an isolated environmental pressure, but by interacting with other long-present resource pressures, such as degraded cropland and stressed water supplies. While global atmospheric problems are important, policymakers, the media, and the public in rich countries should focus more of their attention on regional environmental scarcities of cropland, water, and forests in poor countries.

20.4 Sources of Environmental Scarcity

The Toronto Group limited its research on environment-conflict linkages to renewable resources that are essential for rural livelihoods. Research on the impact of human-induced pressure on these frequently limited renewable resources is thus different from work

done by the ‘abundance school’ of environmental conflict researchers, who have mostly explored the impact of ‘greed’ conflicts over locally abundant, but globally scarce resources (often non-renewables) like minerals, precious metals, oil, and high value timber.³⁰ The findings of the abundance school are complimentary to the research of the Toronto Group, but describe different types of human-environment relationships, with somewhat different processes operating to generate instability and conflict.³¹

The impact of human-induced pressure on renewable resources is encapsulated by the Toronto Group in the tripartite term environmental scarcity (Homer-Dixon 1999).³² Environmental scarcity is caused by the degradation and depletion of renewable resources (e.g. a specific tract of cropland), the increased demand for these resources, and/or their unequal distribution. Population growth and increased per capita resource consumption can cause depletion and degradation, which can in turn produce a decrease in total resource *supply* or, in other words, a decrease in the size of the total resource ‘pie’.

29 The Millennium Ecosystem Report noted that, “The use of two ecosystem services – capture fisheries and fresh water – is now well beyond levels that can be sustained even at current demands, much less future ones. At least one quarter of important commercial fish stocks are over-harvested (high certainty). From 5% to possibly 25% of global freshwater use exceeds long-term accessible supplies and is now met either through engineered water transfers or overdraft of groundwater supplies (low to medium certainty). Some 15–35% of irrigation withdrawals exceed supply rates and are therefore unsustainable (low to medium certainty)” (MA 2005: 6).

30 See: Ballentine/Sherman (2003); Collier (2000); Collier/Elliott/Hegre/Hoeffler/Reynal-Querol/Sambanis (2003); de Soysa (2002); Le Billon (2001, 2001a); Renner (2002); Ross (2003).

31 Efforts by de Soysa (2002) to characterize environment-conflict research as a debate between ‘greed’ or ‘grievance’ perspectives is thus erroneous, since the different types of conflict describe different human-environment interactions, and they can often operate in the same region, and at the same time.

32 See Homer-Dixon (1999: 47–72), for a full description of the theoretical development of the idea of environmental scarcity.

Figure 20.2: Demand-induced scarcity. **Source:** The authors.

- Demand-induced scarcities are caused by the effects of population growth, which reduces a resource's per capita availability by dividing it among more and more people.
- More people means that you have to divide the pie into smaller and smaller slices for everyone.
- Increased consumption is also a cause of demand induced scarcity, whether as a result of higher demand in local markets or from distant markets

But population growth and changes in consumption behaviour – either locally or in distant markets – can also cause greater scarcity by boosting the *demand* for a resource. So if a rapidly growing population depends on a fixed amount of cropland, the amount of cropland per person – the size of each person's slice of the resource pie – falls inexorably. In many countries, resource availability is being squeezed by both these supply (figure 20.1) and demand (figure 20.2) pressures.

Scarcity is also often caused by a severe imbalance in the distribution of wealth and power that results in some groups in a society getting disproportionately large slices of the resource pie, while others get slices that are too small to sustain their livelihoods.

Such unequal distribution – or *structural* scarcity (figure 20.3) – is a key factor in virtually every case where scarcity contributes to conflict. Often the imbalance is deeply rooted in institutions and class and ethnic relations inherited from the colonial period. Often it is sustained and reinforced by international economic relations that trap developing countries into dependence on a few raw material exports and facilitates the capture of these resources by local, national, or international elites. It can also be reinforced by heavy external debts that encourage countries to use their most productive environmental resources – such as their best croplands and forests – to generate hard currency rather than to support the poorest segments of their populations.

Some critics have argued that by including distributional issues in its definition of environmental scarcity, the Toronto Group makes the concept so broad that it becomes useless. For instance, conflicts solely

over the distribution of resources cannot, according to this criticism, be classed as environmental conflicts. The argument is misguided. Uneven distribution of resources never acts on its own as a cause of conflict: its impact is always a function of its interaction with resource supply and demand. Indeed, resource distribution is only important because the resources people want are in finite supply. The Toronto Group found that problems of declining resource supply and rising resource demand were always intimately entangled with uneven resource distribution (Schwartz/Deligianis/Schwartz 2001: 275–276). Demand linkages can often be traced to global resource markets and high levels of consumption by consumers in the developed world. But the impacts of these linkages are often expressed through interactive scarcity impacts in developing nations.

If the causes of violence are to be explored, a resource's *absolute* supply is not interesting. What we should investigate, rather, is the resource's supply *relative to*, first, demand on the resource, and, second, the social distribution of the resource. The relationships between supply and demand and between supply and distribution determine people's actual experience of scarcity, and under any practical hypothesis, it is these relationships that influence the probability of violence. For this reason the Toronto Group included demand and distributional aspects in its definition of environmental scarcity.

Figure 20.3: Structural scarcity. **Source:** The authors.

- Environmental scarcity is often caused by a severe imbalance in the distribution of wealth and power that results in some groups in a society getting disproportionately larger slices of the resource pie, whereas, others get slices that are too small to sustain their livelihoods.
- Such unequal distribution – or what Homer-Dixon calls structural scarcity – is a key factor in virtually every case of scarcity contributing to conflict examined by the Toronto Group

20.5 Resource Capture and Ecological Marginalization

In the past, analysts and policymakers have usually addressed these three sources of scarcity – supply, demand, and structural – independently. But the Toronto Group’s research shows that they interact and reinforce each other in extraordinarily pernicious ways. Two patterns of interaction are particularly important: *resource capture* and *ecological marginalization*.

Resource capture occurs when powerful groups within a society recognize that a key resource is becoming scarcer (due to both supply and demand pressures) and use their power to shift in their favour the regime governing resource access. This shift imposes severe structural scarcities on weaker groups (Homer-Dixon 1999).³³

In Chiapas, Mexico, for instance, worsening land scarcities, in part caused by rapid population growth, encouraged powerful landowners and ranchers to exploit weaknesses in the state’s land laws in order to seize lands from *campesinos* and indigenous farmers. Gradually these peasants were forced deeper into the state’s lowland rain forest, further away from the state’s economic heartland, and further into poverty. In the mid-1990’s, Zapatista insurgents rose against land scarcity and insecure land tenure. The insurgency rocked Mexico to the core, helped trigger a peso cri-

sis, and reminded the world that Mexico remains – despite the pretences of the country’s economic elites – a poor and unstable developing country (Homer-Dixon/Blitt 1998).

In the Jordan River basin, Israel’s critical dependence on groundwater flowing out of the West Bank – a dependence made acute by a rising Israeli population and salinization of aquifers along the Mediterranean coast – has encouraged Israel to restrict groundwater withdrawals on the West Bank. These restrictions have been far more severe for Palestinians than for Israeli settlers. They have contributed to the rapid decline in Palestinian agriculture in the region, and, ultimately, to rising frustrations in the Palestinian community (Homer-Dixon/Blitt 1998).

Ecological marginalization occurs when grave inequality in resource distribution joins with rapid population growth to drive resource-poor people to exploit ecologically marginal areas, such as upland hillsides, areas at risk of desertification, and tropical rainforests (Homer-Dixon 1999).³⁴ Higher population densities in these vulnerable areas, along with a lack of the capital and knowledge needed to protect local resources, causes local resource depletion, poverty, and eventually further migration, often to cities.

Ecological marginalization affects hundreds of millions of people around the world, across a wide range of geographies and economic and political systems. We see the same process in the Himalayas, Indonesia,

33 See Homer-Dixon (1991, 1999: 74–77), for a theoretical description of the development of this idea.

34 See Homer-Dixon (1991, 1999: 77–79), for a theoretical description of the development of this idea.

Central America, Brazil, India, China, and the Sahel (Stonich 1993; Homer-Dixon 1999; Suliman 1999).

For example, in the Philippines an extreme imbalance in cropland distribution between landowners and peasants combined with high population growth rates to force large numbers of the landless poor into interior hilly regions of the archipelago. There, the migrants used slash and burn agriculture to clear land for crops. As more millions arrived from the lowlands, new land became hard to find; and as population densities on the steep slopes increased, erosion, landslides, and flash floods became critical. During the 1970's and 1980's, the resulting poverty drove many peasants into the arms of the communist New People's Army insurgency that had a stranglehold on upland regions. Poverty also drove countless others into wretched squatter settlements in cities like Manila (Kahl 2006).

20.6 Links to Civil Violence

Unequal resource distribution, expanding populations, and land degradation spurred decades of social instability in highland Peru, and helped cause the Sendero Luminoso insurgency (Mitchell 1991). Scarcity-induced resource capture by Moors in Mauritania ignited violence over water and cropland in the Senegal River basin, producing tens of thousands of refugees (Homer-Dixon 1991; see also chap. 51, 54 by Kipping). In Haiti, forest and soil loss has worsened a persistent economic crisis that generates strife and periodic waves of boat people (Homer-Dixon 1999). And land shortages in Bangladesh, exacerbated by fast population growth, have prompted millions of people to migrate to India – an influx that has, in turn, caused ethnic strife in the state of Assam (Homer-Dixon 1999; see chap. 19 by Ahmed).

In South Africa, severe land, water, and fuel wood scarcities in the former black homelands have helped drive millions of poor blacks into squatter settlements around the major cities. The settlements are often constructed on the worst urban land, in depressions prone to flooding, on hillsides vulnerable to slides, or near heavily polluting industries. Scarcities of land, water, and fuel wood in these settlements provoke inter-ethnic rivalries and violent feuds among settlement warlords and their followers. This strife jeopardizes the country's transition to democratic stability and prosperity (Homer-Dixon/Blitt 1998).

In the state of Bihar, India, skewed land distribution has combined with rapid population growth and

significant soil degradation to produce some of the country's most crippling shortages of cropland. As a result, the last three decades have seen vicious conflicts between marginal farmers and landless labourers, on one side, and middle and upper caste farmers who still own relatively abundant land, on the other. The cycle of violence has polarized Bihar's society and progressively weakened its institutions, from its court system and universities to its financial and agricultural bureaucracies. As the second most populous state in the country, Bihar's chronic political crisis reverberates in the national capital, New Delhi, and has contributed to instability in the country's governing coalition.

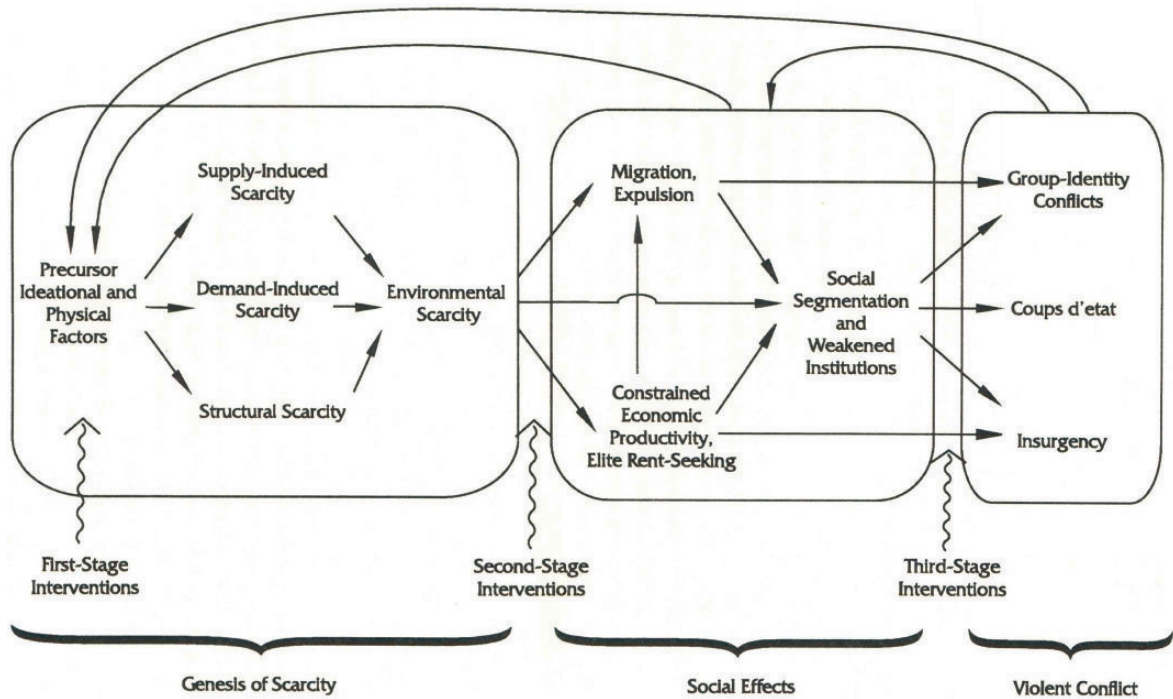

In Pakistan, shortages and maldistribution of good land, water, and forests in the countryside have encouraged millions of the rural poor to migrate into major cities, such as Karachi and Hyderabad. The conjunction of this in-migration with high fertility rates is causing city populations to grow at an astonishing 4 to 5 per cent a year, producing fierce competition – and often violence – among ethnic groups over land, basic services, and political and economic power. This turmoil exacts a huge toll on an already struggling national economy (Homer-Dixon/Blitt 1998).³⁵

Close study of such cases shows that severe environmental scarcity can produce a number of identifiable 'intermediate' social effects: it restricts local food production, aggravates poverty of marginal groups, spurs large temporary or permanent migrations, enriches elites that capture resources, deepens divisions among social groups, and undermines a state's moral authority and capacity to govern. Marginal groups that directly depend on renewable resources find themselves trapped in a vice between rising scarcity on one side and institutional and policy failures on the other. In many cases, these social impacts are aggravated and amplified by weak or dysfunctional governance capacities in developing states. These long-term, tectonic stresses can slowly tear apart a poor society's social fabric, causing chronic popular unrest and violence by boosting grievances and changing the balance of power among contending social groups and the state.

Figure 20.4 illustrates the Toronto Group's core model of causal links between environmental scarcity and violence. Environmental scarcity is mainly an *indi-*

35 Details of many of these cases can be found on the website of the Trudeau Centre for Peace and Conflict Studies.

Figure 20.4: The Toronto Group's Core Model of the Causal Links between Environmental Scarcity and violence.
Source: Homer-Dixon (1999).

rect cause of violence. It contributes to harsh social effects - from worsening poverty and massive migrations to deeper cleavages among ethnic groups and weakened states - that in turn help produce violence. Scarcities can also trigger adaptive responses by subsistence or semi-subsistence farmers that in turn worsen or exacerbate social tensions. Analysts often interpret these social effects of environmental scarcities as the conflict's principal causes, thus overlooking scarcity's influence as an underlying stress.

Moreover, environmental scarcity is never a sole or sufficient cause of such crises. It always interacts with other economic, political, and social factors - which the Toronto Group calls 'contextual factors' - to produce its effects. In the Filipino case (Kahl 2006), for example, the lack of clear property rights in upland areas encouraged migration into these regions and discouraged migrants from conserving the land once they arrived. And President Marcos's corrupt and authoritarian leadership reduced regime legitimacy and closed off options for democratic action by aggrieved groups.

The key contextual factors that can interact with environmental scarcity to produce violence fall into two categories: those that influence the adaptability or resilience of a society when faced with severe environmental scarcity, and those that influence the likeli-

hood of violence should adaptation fail. The former category includes the efficiency of a society's markets (especially whether market prices reflect the true scarcity of environmental resources), the administrative and political capacity of the state (especially its economy from outside influences), the abundance and quality of the society's social capital, and the strength of cultural sentiments of responsibility to the commonweal (Homer-Dixon 1999: 114-125). The latter category includes the character and depth of ethnic and class divisions within a society; the concept of justice held by groups challenging the state; the resources and organizational capacity of challenger groups, political elites, and the state; and quality of leadership within challenger groups and the state (Homer-Dixon 1999: 142-147).

Since the relationship between environmental scarcity and such contextual factors is interactive, it is often impossible to determine the relative weight or power of environmental scarcity as a cause of violence in specific cases. But this does not mean that environmental scarcity is always an unimportant cause. A large proportion of the world's population is almost completely reliant on local cropland, water, and forest supplies for its daily existence. Sceptics (Gleditsch 2001) usually underestimate the extent to which much of humankind still depends on its natural environ-

ment and therefore underestimate the social stress that environmental scarcity can cause.

Although contextual factors are often critical to the development of violence, policymakers must realize that they can neither adequately understand nor respond to many important cases of civil violence around the world – like the Filipino insurgency or the chronic instability in Haiti – if they do not take into account the *independent causal role* of environmental scarcity. Some sceptics (Levy 1995, Gleditsch 2001, Peluso/Watts 2001) claim that environmental scarcity's contribution to conflict merits little attention, because scarcity is wholly a result of political, economic, and social factors, such as failed institutions and policies. Since these factors are the ultimate causes of conflict, policymakers trying to prevent conflict should focus on them and not on scarcity (Homer-Dixon 1999: 17–18).

But the Toronto Group's research has identified three reasons why such arguments are incomplete at best (Homer-Dixon 1999: 16–18, 104–106; Schwartz/Deligiannis/Homer-dixon 2001: 278). *First*, environmental scarcity often reciprocally influences the political and economic character of social systems – as, for example, when it stimulates resource capture by powerful elites or competition among narrow social coalitions that impedes institutional and policy reform. This reciprocal influence can affect the very contextual factors – market structure, state capacity, strength of social capital, and the like – that interact with environmental scarcity to cause violence. *Second*, environmental scarcity is partly a function of the character of a society's physical environment – whether, for instance, that environment is robust or fragile – a factor that is, in important respects, independent of human activities. And *third*, if severe environmental damage becomes irreversible or requires many decades to repair, it can become a permanent source of social stress; even if the political and economic factors that originally contributed to the damage are fixed, it remains an independent burden on the society.

In the end, the Toronto Group concluded that environmental scarcities help generate chronic, diffuse, subnational violence. In other words, it helps generate violence that is mainly *internal* to countries. This is not the type of violence that analysts commonly assume will occur when critical resources are scarce – that is, simple-scarcity 'resource wars' among countries, in which scarcity directly stimulates one country to try to seize the resources of another. Instead, the Toronto Group's research led them to conclude that two categories of internal violence were most likely

stimulated by environmental scarcities: first, scarcity would deepen social cleavages and stimulate population migration, leading to ethnic clashes; and secondly, scarcity would affect economic productivity and, in turn, people's livelihoods, the behaviour of elite groups, and the ability of states to meet these changing demands, thereby helping to cause increasing civil strife like insurgency, banditry, and coups d'état (Homer-Dixon 1999: 5, 136–148).

Recent events have also led us to revise somewhat our earlier dismissal of the impacts of environmental scarcities on localized conflicts. As the news reports highlighted above illustrate, we have come to appreciate the pernicious impact of small scale, localized violence that have strong links to environmental scarcity. Although often lacking the visibility of national insurgencies, these local conflicts, multiplied many times over around the world, are maiming and killing significant numbers of people and destabilizing many developing states. In some cases, these disputes are encouraged and manipulated by elites to further their own corrupt rule (Kahl 2003, 2006).

These various manifestations of environmentally-induced sub-national violence are exactly the kinds of violence that bedevil conventional military institutions. Globally, conventional armies are pinned down and often utterly impotent in the face of inter-ethnic violence or attacks by ragtag bands of lightly armed guerrillas and insurgents. Analysts frequently fail to see that environmental scarcity is a contributing factor behind many of these conflicts. This may become a more powerful influence in coming decades because of larger populations and higher per capita resource consumption rates.

Although this internal violence may not be as conspicuous or dramatic as wars among countries, it can have broad implications. The changing nature of the international system – heightened economic interdependence, easier long-distance travel, and increased access to arms – makes previously insignificant regions of interest to policymakers. Crises in small countries, such as Haiti, often create serious foreign policy difficulties for developed countries, and large and significant countries – including Pakistan, China, India, and Indonesia – are not immune to the severe stresses environmental scarcity generates.

Major civil violence within states can affect external trade relations, cause refugee flows, and produce humanitarian disasters that call upon the military and financial resources of developed countries and international organizations. Countries destabilized by civil violence often fragment as they become enfeebled

and as peripheral regions are seized by renegade authorities and warlords. Their regimes might avoid fragmentation by becoming more authoritarian, intolerant of opposition, and militarized; they might also try to divert attention from domestic grievances by threatening neighbouring states.

20.7 Limits of Adaptation

Sceptics often respond that environmental scarcity rarely contributes to conflict, because human societies show great capacity to adapt to resource scarcity, especially through market mechanisms (Simon 1996). When a resource becomes scarce, its price increases, which encourages conservation, substitution, and technological innovation. Scarcity also encourages institutional adaptations, such as changes in property rights that raise incentives to conserve and innovate and that reduce the hardship scarcity produces.

It is true that scarcity often stimulates useful technological and social changes. Yet a society's ability to adapt to rising scarcity depends on the relationship between its requirement for ingenuity³⁶ to respond to this scarcity and its supply of ingenuity (Homer-Dixon 1999: 107–126). Societies in which requirement outstrips supply face an *ingenuity gap* (Homer-Dixon 2000); they will be unable to adapt adequately to environmental scarcity and will, consequently, be vulnerable to scarcity's harsh social effects, including economic dislocation, migrations, social cleavages, state weakening, and – ultimately – violence.

In the next decades, population growth, rising average resource demand, and persistent inequalities in resource access ensure that scarcities will affect many environmentally sensitive regions with unprecedented severity, speed, and scale. Ingenuity requirements will therefore rise rapidly. But this situation need not lead to crisis, since, by changing prices and incentives, scarcity often does stimulate a flow of ingenuity sufficient to meet the rising need.

But there are several reasons why this beneficial response may not occur in some poor societies. The prerequisites for effective adaptation to scarcity often do not exist: states are weak, bureaucracies incompetent, judicial systems corrupt, research centres under-

funded, and property rights unclear. Markets often do not work well: prices in most developing countries – especially for water, forests, and other common resources – do not adjust to reflect accurately rising scarcity, and therefore incentives for entrepreneurs are inadequate. Low levels of education, technological capacity, and financial capital also depress the supply of ingenuity. Finally, environmental scarcity can actually undermine the ability of developing societies to generate social and technical solutions to scarcity. Under certain circumstances, scarcity mobilizes narrow coalitions and powerful elites to block the institutional reforms that could reduce the scarcity's broader social impact.

Positive economic, social, and technological responses to environmental scarcity are therefore not guaranteed. Some societies will adapt well, others will not. In coming decades, worsening environmental scarcities in many regions will further exaggerate the world's already gaping differentials between rich and poor societies and between the powerful and weak people within those societies. The world's wealthy regions should not assume that they will be able to wall themselves off from turmoil in societies that do not adapt well to scarcity. We are living cheek by jowl on this planet now. We are all next-door neighbours.

20.8 Recommendations

We are passing through a moment in history when political and economic events are fluid, and social structures are more malleable than they have been for decades. This situation provides opportunities for reform of our economic, political, and social systems, but it also presents dangers. Many of the choices we make during the next years – even small ones – will have large consequences far into the future. And the future is sometimes not as distant as it seems: well over one third of the people currently alive will still be alive in 2050. The children around us today will live with the consequences of the decisions we make today.

Each case of environmentally induced conflict is complex and unique: each has a specific ecosystem, history, culture, economy, set of actors, and set of power relations among these actors. Policy tools available in one case will not be available in another, for wholly idiosyncratic reasons. Successful policy intervention therefore requires customization based on a careful analysis of the character of the specific case and of the policy tools available in that case.

36 *Ingenuity*, as used here, consists of ideas for new technologies and new and reformed institutions. The requirement for ingenuity refers to the new ideas and institutions required to overcome the impacts and effects of environmental scarcities. (Homer-Dixon 2000).

Yet it is possible to make four general points about policy interventions in this area. *First*, there is no single solution or ‘magic bullet’ that will always break the links between environmental scarcity and violence. The causal systems in question encompass huge numbers of interacting variables; interventions must therefore operate at many points to capitalize on these systems’ natural synergies. Policymakers need to implement a broad and integrated set of responses at the international, regional, national, and community levels.

Second, early intervention is generally better than late intervention. If policymakers wait till widespread violence has broken out, it will probably be too intractable, too complex, and too charged with emotion to resolve. In addition, environmental scarcity tends to produce diffuse and sub-national violence of a kind that our conventional military institutions do not, in general, handle well. Policymakers should therefore emphasize proactive interventions that break the early links in the causal chains described here.

Third, policy responses do not have to be capital-intensive: they can be simultaneously effective and relatively inexpensive. Examples include greater support for non-governmental organizations that are rehabilitating local environmental resources, and for research on crops that can grow with eroded soil and polluted water.

Fourth and finally, effective policy interventions will not necessarily be unique or special. The analysis above simply presents another set of reasons for a range of interventions – from selective debt relief to enhancement of indigenous technical capacity – that many experts have long believed necessary to produce humane and rapid economic development in poor countries around the world.

21 Linkages Between Sub-national and International Water Conflicts: The Eastern Nile Basin

Simon A Mason, Tobias Haggmann, Christine Bichsel, Eva Ludi and Yacob Arsano

21.1 Introduction¹

Water conflicts in transboundary rivers systems have been the object of a growing literature and ongoing debates among scholars of political science, international relations and political geography. The subject is approached from two main angles: 1) if, how and under what conditions does water scarcity lead to violent conflict or even war (Starr 1991; Homer-Dixon 1999; Libiszewski 1999; Toset/Gleditsch/Hegre 2000; Lonergan 2001)?² 2) how can international rivers be managed and water conflicts be mitigated (Trolldalen 1992; Biswas/Kolars/Murakami/Waterbury/Wolf 1997; Waterbury 2002; Wolf 2000, 2002a)? The 'water wars' hypothesis that partly shaped the first question could not be substantiated and should therefore be dismissed. There is an increasingly wide consensus that water scarcity does not lead to war (Allan 1997; Trondalen 1997; Wolf 1998; Amer/Arsano/El-Battahani/Hamad/Hefny/Tamrat 2005). Water scarcity, however, may be a politically destabilizing factor that can lead to political tensions and hinder sustainable development. Violent conflicts over scarce water are

more likely to be found on the sub-national level than on the international level (Wolf 1998). This article focuses on the second question, how conflicts over the use of scarce water resources can be mitigated. The aim of the article is to improve the transformation of international river conflicts through the systematic assessment of the linkages between the local, national, international and global level. *Linkages* refers to the interaction between the system (e.g. international river conflict) and its sub-system (e.g. local conflict) and super-system (e.g. global food market). The main argument of this chapter is that these linkages are often neglected in the analysis of international river conflicts, based upon which faulty mitigation strategies are then initiated. One exception is the article by Giordano et al (2002). According to these authors, there is a link between interstate and intrastate relations over water resources, but the nature of this link and the degree to which it is present varies considerably by country and region (Giordano/Giordano/Wolf 2002). The linkage approach seems to be especially relevant in river basins characterized by two factors, first, where some of the riparian countries experience water stress (i.e. less than 1700 m³/person and year) and due to this they import food from the global market, and second, where weak economies and political instability make the management of water conflicts difficult. The Nile, Euphrates, Jordan, and Senqu are examples. The Nile Basin is used in this article to demonstrate the proposed conceptual approach. This linkage approach to conflict is in line with the reconceptualization of security after 1990. Security studies were 'deepened' to no longer exclusively focus on the national state as the key actor, but rather to highlight the interaction between the local, national, international and global actors and levels.

The present chapter is in part a continuation, in part a major refocusing of the 'Swiss group's' research on environment and conflicts that began with the Environment and Conflicts Project (ENCOP) in 1992

1 The research for this paper was carried out within the Individual Project 7 (Environmental Change and Conflict Transformation) of the Swiss National Centre of Competence in Research (NCCR) North-South: Research Partnerships for Mitigating Syndromes of Global Change, co-funded by the Swiss National Science Foundation (SNF) and the Swiss Agency for Development and Cooperation (SDC).

2 Examples of water conflicts and management events are listed in these two databases: 1) Wolf, Aaron T., 2000: "Transboundary Freshwater Dispute Database, International Water Events Database 1948-1999", International Events 2000, Oregon State University, at: <<http://ocid.nacse.org/cgi-bin/qml/tfdd/eventsearch.qml>>; 2) Gleick, Peter, 2000: "Water Conflict Chronology", September 2000 version, at: <<http://www.worldwater.org/conflict.htm>>.

(Baechler/Böge/Klötzli/Libiszewski/Spillmann 1996). ENCOF's *environmental induced conflict* definition focused on the degradation of the environment as a cause of violent conflict – similar to the first question above. Subsequent research projects focused on how to deal with conflict (also non-violent) over the use of resources and the environment – similar to the second question above.³

The reason for the conceptual refocusing after ENCOF was due to the limitations of its definition in relation to questions of multi-causality and the systemic nature of conflict (Mason/Spillmann 2003) and the problems related to the assumption that the 'environment' determines human behaviour (Hagmann 2005). Some of the case studies of ENCOF, e.g. Libiszewski (1995) on cooperation over the Jordan River, had already moved on from the original environmental induced conflict hypothesis (Libiszewski 1992: 13). Thus the refocusing of research from 'environmentally induced conflicts' to the 'management of conflicts over the use of resources and the environment' was influenced by case study findings that pointed to the need of better understanding the relationship between (non-violent) water and land use conflicts and cooperative sustainable development (Baechler/Spillmann/Suliman 2002; Arsano 2004; Mason 2004; Arsano 2005). Research showed that armed conflicts are more directly related to non-renewable resources such as oil, and 'lootable' resources such as diamonds or coltan, rather than to the degradation of the environment or scarcity of water or land (Ross 2004). Nevertheless, there is also continuity in the 'Swiss group's' approach. This mainly entails a process-tracing, case study methodology (Schwartz/Deligiannis/Homer-Dixon 2001) and close cooperation with academics and practitioners in the actual case study regions.

The *conflict transformation approach* towards water and land use that replaced the environmentally induced conflict paradigm is presented in Baechler (2002) and Mason (2004). A conflict transformative approach sees the development potential in conflicts, conflict is a 'transforming agent for systemic change' inherent in all societies, manifest on all levels of social interaction (Lederach 1995: 18). Its key tenets in this context are: 1) the need for direct participation of af-

ected actors in the conflict management process, 2) approaches from the natural and social sciences need to be combined in transdisciplinary research, and 3) any results developed in the participatory approaches need to be institutionalized.

After some nine years of research using the conflict transformation approach in relation to water and land conflicts, lessons have been learned concerning the participatory approach. The publications of Amer, Arsano, El-Battahani, Hamad, Hefny, and Tamrat (2005), Arsano and Tamrat (2005), Hamad and El-Battahani (2005), as well as of Hefny and Amer (2005), are examples of joint research and conflict analysis of an international river basin carried out by researchers and practitioners from the region. The second and third points on transdisciplinarity and institutionalization are still underdeveloped. Further open questions are: 1) The conflict transformation approach has not yet sufficiently addressed the question of how to deal with power asymmetries between conflict actors and the role of 'oppression' in conflict (Deutsch 2002), and 2) The approach has not adequately addressed the linkages between different conflict system levels. The last point is addressed here as it is missing in a large number of conflict case studies (Homer-Dixon/Blitt 1998) and statistical analyses of conflicts using aggregate country data (Toest/Gleditsch/Hegre 2000).

The chapter is structured as follows: first we introduce our conceptual model with its *physical* water linkages between the sub-national, national and international systems of an international river basin, and its *political* conflict/cooperation linkages between the same levels. The conceptual model is then applied to the case of the Nile Basin in the following section. The article concludes with a summary of the advantages of the linkage approach when attempting to mitigate water conflicts.

21.2 The Linkages Approach: Addressing Physical and Non-Physical Links

Competition over freshwater in international river basins affects three interdependent levels. First, the natural river basin can be viewed as a system, where riparian countries of the same basin agree, dispute and/or negotiate over who gets which quantity and quality of water, in the following referred to as the *international level*. Second, the riparian countries and regions represent subsystems, where different sectors

3 These projects included: *Environment and Conflict Management* (ECOMAN) 1996-1999; *Environment and Cooperation in the Nile Basin* (ECONILE) 1999-2004 and NCCR North-South "Environmental Change and Conflict Transformation" 2001 ongoing.

and territorial units compete for their share within these countries. We refer to this as the *sub-national level*. Third, global food production and markets can be seen as a super-system, in that water scarce countries import water in the form of food ('virtual water') and thus mitigate water related tensions on the regional or national level, this is called the *global level*. In terms of conflict analysis, the allocation of water between and within countries raises the question how forms of cooperation (or conflict) on the international level reinforce conflict (or cooperation) on the sub-national level and vice versa. A central question is whether and through which pathways water and conflicts and cooperation over scarce resources are transferred - 'shifted' - from one level to another, and what the implications are for conflict mitigation.

Conflicts can be differentiated according to their intensity ranging from 'competition' to 'violent conflict' as well as a number of other criteria according to the outcomes, actors, level or scale, duration or the issues involved in conflict. While a number of definitions have aimed to grasp violent environmental conflicts (Libiszewski 1992; Homer-Dixon 1999; Gleditsch 2001), here a more generic definition is adopted focusing on conflict prevention and transformation. We define environmental conflicts as interactions between at least two actors (individuals or groups) over the use of natural resources and the environment, where at least one of the actors is negatively affected by this interaction, and the other actor intended or ignored these negative impacts that resulted from his/her actions (adapted from Coser 1956; Trolldallen 1992; Glasl 2002). This follows a conflict analysis⁴ approach, encompassing different levels of intensity between interdependent actors involved in resource use, in this case, freshwater in transboundary river basins. Conflicts over the use of resources and the environment need to address both the socio-economic and political dimensions and the physical, ecological dimensions, thus our distinction between physical and non physical linkages.

The relationship between the content and the context is a key question in a systems approach (Bateson 1972: 518). The relationship between the international

river conflict (the 'content') and the sub-national or global conflict/cooperation (the 'context') is referred to as *linkage*. The delineation of what is content and context entails subjective elements, as the observer is part of the system observed (von Foerster 1981). The acknowledgement of this key aspect clarifies many misunderstandings regarding conflicts in relation to the environment. Dalby (2007), for example, states that violence in relation to the environment is a matter of "... the control of relatively abundant resources in poor economies." If the system boundary is delineated on a global level, a resource such as gold, diamonds or oil is not abundant, but scarce, else there would be no incentive to gain control over it. Regarding water, it is relatively abundant on the global level, but relatively scarce in numerous regions. Thus, the subjective delineation of a system decides if a resource is scarce or abundant, rather than the physical availability of the resource.

What are the *physical linkages* between the systems of an international river basin?⁵ This article focuses on water quantity; this means water for food, as 70 per cent of the world water withdrawal is used for food production (SEI 1997). The linkages between the sub-national and international arenas are all related to the transport of water, either in the form of water or in the form of food, i.e. 'virtual water' (Allan 1997). It takes about 1000 litres to produce 1 kg of bread, and 15000 litres to produce 1 kg of beef, thus transporting food is a very efficient way of transporting water (Allan 1997; Yang/Zehnder 2002; Yang/Reichert/Abbaspour/Zehnder 2003). All stakeholders in a river basin are related to each other in an upstream-downstream relationship as they are dependent on the same water as it flows from source to river mouth. Physical water linkages may either be natural, as water rains and flows downstream, or influenced by human behaviour, if water is diverted, dammed, withdrawn or transported as food.

What are the *socio-economic and political linkages* between the systems of an international water basin? Dyadic relationships between actors competing for water uses in river basins are empirically observable on different, politically and historically constituted

4 The goals of conflict analysis are a structured approach to conflict dynamics, a full understanding of the critical issues or 'breaking points' that determine the course of conflict, the identification of optimal opportunities for intervention, the determination of adequate intervention steps, and the understanding of escalation and de-escalation phases (Fisher/Abdi/Ludin/Smith/Williams/Williams 2000).

5 A river basin is the area of land from which all surface run-off flows through a sequence of streams, rivers and lakes into the sea at a single river mouth, estuary or delta. Directive 2000/60/EC of 23 October 2000 establishing a framework for Community action in the field of water policy (Water Framework Directive). In: *EEA multilingual environmental glossary*, at: <http://glossary.eea.eu.int/EEAGlossary/R/river_basin>.

levels; namely in local, national and international arenas. To simplify, the article distinguishes between sub-national and international and global 'water conflict systems'. The first includes non-state and state actors of the same national territory while the latter refers to conflict between different national governmental (and sometimes non-governmental) organizations. The third level concerns the political economy of global food markets. These water conflict systems are characterized by the involvement of diverse actors, from intergovernmental bodies to local communities and by varying degrees of cooperation and conflict intensity, from interstate tensions over water allocation to acute conflict over property rights between villagers. In addition to water as a physical resource linking actors of different levels, the transfer of non-material and symbolic resources (e.g. political legitimacy or the cultural-religious meaning of rivers) relate these different levels with each other in interdependent conflict systems (see also McGinnis 1999). On a more abstract level, these material and non-material linkages are shaped by principles concerning *how* the resources are transferred from one level to another. Governance, for example, including policies, regime type and opportunities for political involvement, link the different water conflict arenas by structuring the behaviour and strategies of actors. Such structuring factors influence actors confronted with the choice of adopting means to defend their resource-related interests.

Thus, the political linkages between conflict and cooperation over water resources on the sub-national and international levels can be conceptualized as three distinct, yet often complementary key processes in interdependent conflict systems. Firstly, conflicts and cooperative relations between actor groups over resources can be *transferred* from the sub-national level to the international level and vice versa. Thus for example conflict on the international level 'spills over' - is transferred - to conflict on the sub-national level. A second form of linkage is when conflicts are *transformed* into cooperative relations.⁶ A third form of linkage is when cooperative relations *escalate* into non-violent or violent conflicts. The linkages should not be understood in terms of linear cause and effect, but in terms of circularity and dynamic processes - transfer, transformation, escalation - leading to changes in the conflict system which in turn is shaped by a number of context and proximate factors.

6 Terminology refers to 'conflict transformation' approaches (Bush/Folger 1992, Lederach 1995, Reimann 2001).

21.2.1 Factors Influencing Linkages

Past empirical research has identified and studied a number of factors significantly influencing the dynamics of international river conflicts and cooperation. These can be divided into context factors, that are harder to influence directly, and the more malleable proximate factors, directly influencing water relations between and within riparian states. *Context factors* include the natural availability of water resources⁷, the level of economic and political integration and existence of non-environmental conflicts in the region⁸, the symmetry of power between riparian countries⁹, the number of riparian states¹⁰, the economic development of the riparian states and the world market for agricultural products (Durth 1996; Allan 1997; Marty 2001; Wolf 2002a). *Proximate factors* include: national policies affecting water management and water allocation to different sectors¹¹, international policies, the institutional¹², legal setting in the river basin, and the form of extra-basin involvement, and political participation of different actor groups on the sub-national and international level related to water management and allocation (Delli Priscoli 1996; Trondalen 1997; Libiszewski 1999; Wolf 2002a; Mason 2004). From the standpoint of conflict mitigation, proximate

7 Water dependency is calculated as the percentage of internal renewable water resources of the total actual renewable water resources, i.e. dependency on rainfall outside of a state's territory. See: AQUASTAT, *FAO's Information System on Water and Agriculture*, at: <<http://www.fao.org/ag/agl/aglw/aquastat/main/index.stm>>.

8 The more non-environmental conflicts, the more difficult it is to resolve water conflicts, as tensions between the countries are already sensitive. Examples are given in: Mason/Spillmann (2003).

9 According to Frey (1984), conflict is more likely if the downstream riparian state is highly dependant on water and is powerful in comparison to the upstream riparian state. Recent developments in the Nile Basin and Euphrates/Tigris basin contradict this argument, however. The downstream country is always geographically weaker. A powerful downstream country (economically, diplomatically and militarily) can partly compensate the geographical weakness. This may lead to power symmetry that can enable cooperation, as in the Nile Basin. An upstream country (e.g. Turkey), that is also economically more powerful than the downstream country (Syria, Iraq), has little incentive to cooperate, and the downstream country has little leverage to influence the upstream country.

10 The more riparian states, the harder the coordination task. This is one reason why Egypt is interested in a unified Sudan.

Figure 21.1: Countries of the Nile Basin. The Nile Basin includes two main sub-basins: the Eastern Nile Sub-basin (Egypt, Ethiopia, Eritrea and Sudan) and the Equatorial Lakes Sub-basin (Burundi, Dem. Rep. of Congo, Egypt, Kenya, Rwanda, Sudan, Tanzania and Uganda). The country borders do not represent officially recognized country borders. **Source:** From Amer et al., 2005 © EAWAG, Duebendorf, 2005; reproduced with permission of Eawag.

factors are of special interest to our analysis as they are less static than context factors and are (partly) explicative of the dynamics of conflict and cooperation in different water conflict arenas. The proximate and

context factors only *implicitly* influence the linkages between an international system and its sub- and super-system. The following case study focuses *explicitly* on the factors influencing the linkages in an international river basin. First, the Nile conflict on the international level regarding the water allocation between the countries in the Eastern Nile Basin is presented, as is typically done in international river case studies.

12 Wolf (2002a: 15) remarks that "... it is when the rate of change within a basin exceeds the institutional capacity to absorb that change when we find tensions".

Then two water conflict/cooperation linkages are explored: 1) linkage between the sub-national and the international systems through projects planned on the international level but implemented on the sub-national level, and 2) linkage between the global food market system and the international river system, through the trade in 'virtual water'.

21.3 International Conflict and Cooperation in the Eastern Nile Basin

The Nile River is shared by ten countries (Egypt, Sudan, Ethiopia, Eritrea, Tanzania, Uganda, Burundi, Rwanda, D.R. Congo, and Kenya, figure 21.1) and is home to more than 160 million people; its population is growing by 2-3 per cent per year. Measured at Aswan, the Nile River has a yearly flow of 87.1 km³/year¹³. 86 per cent of the Nile's water at Aswan stems from the Ethiopian highlands in the Eastern Nile Basin, the rest originates mainly from the watersheds of the equatorial lakes (Waterbury 2002). Many countries in the Nile Basin are highly dependent on the Nile's water, as they are situated in an arid or semi-arid region. More than 95 per cent of Egypt's water stems from the Nile, this means that it depends on rainfall outside of its territory. Egypt has therefore always closely observed Ethiopia's water development plans. Ethiopia's irrigation plans are of great concern since they could reduce the water flow in the Nile. Currently, Ethiopia's economic capacity does not yet allow full implementation of its irrigation plans (Mason 2004). Rain-fed agriculture, upon which Ethiopia's food production depends at the moment, is un-

reliable because of the unpredictability of the seasonal rains.¹⁴

The national capacity to address the water development needs of the Nile countries is limited. The civil war in Sudan, civil war in Ethiopia and the interstate war between Ethiopia and Eritrea during the second half of the 20th century are indications of the political instability in the region. On the international level, the absence of a basin-wide water agreement has caused tensions between the riparian states and hindered access to international development support. Egypt and Sudan uphold the validity of the 1959 agreement that was signed by these two countries¹⁵; the upstream countries, however, do not consider it to be relevant for them. Many international development banks require the consent of downstream countries before financing development projects on international rivers, thereby protecting the geographically weaker downstream states. A lack of consent from the downstream states can hinder development upstream, one of the main concerns of Ethiopia.¹⁶ The conflict between Egypt and Ethiopia over water rights is at the core of the Nile conflict in the international arena. Sudan, the country between Egypt and Ethiopia plays an important role in the Eastern Nile Basin, as it is dependent on good relations with both countries. Recent developments towards cooperation in the Nile

11 Negative externalities resulting from industrial or municipal pollution are generally easier to mitigate than those resulting from irrigation, as water is consumed. A water treatment plant can improve the water quality, but water that is consumed in irrigated agriculture is lost through evapotranspiration. Irrigated agriculture is responsible for 70 per cent of the global water withdrawal, while the industrial sector consumes 20 per cent and the municipal sector 10 per cent only (SEI 1997). Water used for hydroelectric power production (HEP) can also lead to conflicts. Since water used for HEP is a question of timing and not one of absolute quantity, it is generally less contentious than large irrigation schemes.

13 See: SHI, 1999: *World Water Resources and Their Use*, State Hydrological Institute (SHI), Russia and UNESCO, at: <http://espejo.unesco.org.uy/part%604/_1_africa/index.htm>, 1 January 2002.

14 The periodic fluctuations in the Nile's flow is demonstrated by the two extremes of 1916 with a water flow of 120 km³/year, and 1984 with a flow of 42 km³/year measured at Aswan (Collins 1990: 402).

15 Agreement between the Republic of the Sudan and the United Arab Republic for the full utilization of the Nile waters signed at Cairo Egypt, 8 November 1959. Food and Agriculture Organization [cited 15 March 2002], at: <<http://www.fao.org/docrep/W7414B/w7414b13.htm>>, 2 July 2002.

16 "Although the need has always been there, Ethiopia has failed to develop its water resources to feed its needy population, mainly because of a lack of the required financial resources. Policies of international financial institutions like the World Bank, which have made it difficult for upper riparian countries to secure finance for development projects without the consent of the downstream riparian countries, have a significant contribution in this regard. (...) The downstream riparian states, therefore, have maintained the right to veto the development endeavors of the upstream states. As a result, upper riparian countries are naturally left with little choice other than to resort to a reciprocal measure of unilateralism", Lemma, S., 2001: "Cooperating on the Nile: Not a Zero-sum Game", in: UN Chronicle, vol.,1. (March): 65, at: <<http://www.un.org/Pubs/chronicle/2001/issue3/0103p65.html>>, 4 July 2002.

Basin resulted from Egypt accepting a discussion on a basin wide legal framework, and Ethiopia accepting a start for cooperation on a project by project basis (Mason 2004). The Nile Basin Initiative (NBI) was launched in Dar es Salaam in February 1999 by the Basin countries as a transitional forum to facilitate these cooperative efforts with the aim of a binding basin-wide institution in the future.¹⁷

21.3.1 Linkage Between Sub-national and International Systems

Many plans to augment the total amount of available water in the Nile Basin through supply-side¹⁸ projects hinge around the evaporation losses in the Sudd swamps¹⁹ in Sudan or in the swamps of the Baro-Akobo/Sobat, on Ethiopian territory. Through canals, the retention time of water in the swamps can be reduced, and less water is then lost to evaporation.²⁰ The two examples, the historic one in Sudan and the planned one in Ethiopia are presented below.

As part of the agreement of 1959 between Sudan and Egypt on the 'Full Utilization of the Nile Water', the two countries decided to build the Jonglei Canal I and share the net benefit of 4.7 km³/year water (3.8 km³/year measured at Aswan) equally between each other (Collins 1990: 317). 267 km of the 300 km long Jonglei Canal were built, when the bucket wheel used to dig the canal was destroyed by the Sudan People's Liberation Army in 1983, the year the second civil war broke out (Collins 1990: 401). Economic, political and historical disparities between the North and South, actor groups channelled by ethnic and religious differences, and competition over the access to water, land and oil are some of the factors fuelling this war (Suliman 1999c). John Garang, later to become head of the Sudan People's Liberation Army, wrote his PhD at Iowa University on the Jonglei Canal, mainly criticiz-

ing the limited development strategies, which would make it benefit Northern Sudan and Egypt, rather than the local populations where the project was to be implemented (Collins 1990: 383). The project did not have the support of many groups in South Sudan and it was also debatable internationally, since the impacts on the environment²¹ and local population were unclear (Howell/Lock/Cobb 1988).

In summary, there was no compensation for the water that was to be 'transported' from the local Sudd area in South Sudan to the North Sudan and Egypt. Furthermore, the local communities were not involved in the planning process. Water that evaporated and was thus part of the sub-national eco- and social-systems was to be used in the North, without sufficient compensation and political participation. Thus cooperation between North Sudan and Egypt over water, neglecting the needs of people in South Sudan, escalated into conflict on the sub-national level.

In the framework of the Nile Basin Initiative, the 'Baro-Akobo Multi-Purpose Water Resources Sub-Project' in Gambella, south-western Ethiopia on the Ethiopian-Sudanese border is planned (NBI 2001). The three countries, Egypt, Sudan and Ethiopia have agreed on building a canal through the swamps of the Baro-Akobo River, allocating the additional water to Egypt and Sudan, and allocating an equal amount from the Blue Nile River to Ethiopia.²² It seems that some lessons were learnt from the Jonglei Canal experience, one of the main ones being that the project has to benefit the people directly affected and that they need to be involved in the planning process. Thus besides increasing the water yield, the multi-purpose project aims at the production of hydroelectric power and irrigation projects, by which livelihoods and income opportunities in the sub-basin shall be enhanced. Broad stakeholder consultation and involvement in the identification, planning and design phases are planned. The preparation of the project is estimated to cost 3 million USD, and the implementation to be more than 400 million USD (NBI 2001: 25-26).

Some questions remain, however. In the Gambella national regional state that would be affected by the Baro-Akobo/Sobat project nothing has been done so

17 NBI, 2002: Nile Basin Initiative, About the NBI, History of NBI, Update Nov. 2002, at: <<http://www.nilebasin.org/>>.

18 Supply side water management indicates efforts to increase the water available for withdrawal. Demand-side management indicates efforts to increase intra- or inter-sector efficiency, to make better use per unit of water withdrawn.

19 19200 km² in 1980 (Howell/ Lock/Cobb 1988).

20 Projects on the Upper White Nile to build canals through the wetlands of Sudan are estimated to be able to increase the total amount of available water by 18 km³/year (Jonglei I: 3.8, Jonglei II: 3.2, Machar Marshes: 4, Bahr el Ghazal: 7 (Whittington/McClelland 1992).

21 Whittington and McClelland (1992) calculated the opportunity costs of the Jonglei Canal I project at 500 million USD per year or about 5 billion USD lump sum, suggesting that international agencies could pay for the upkeep of Europe's most important southern range for migratory birds.

22 Interview with an Ethiopian academic, Addis Ababa, April 2001.

far regarding land re-allocation since the overthrow of the Derg regime in 1991. Pastoralists view land and other natural resources including water as communal property in pastoral areas and all the communities have equal rights to use land, which are controlled and managed by identifiable groups at the local level. The communities have established their own socially accepted rules to use and manage resources collectively even if these are not formally recognized by the government. As 85 per cent of the Gambella people are directly dependant on the Baro-Akobo river system for cultivation, livestock production and other supplementary food collection such as fish, any project planned at the international and national level will have a direct impact at the sub-national and local level.²³ In addition to regarding linkages between the local and national level, there are also conflicts between different actors on the local level (e.g. between agribusiness vs. small land-holders). The power asymmetry between the stakeholders on the local level greatly shapes these conflicts, as different actors have different interests and means regarding land and water use, depending on their access to financial, political and human capital.

In view of the Jonglei canal experience, the linkage approach must be considered in future water development projects. If water is channelled and taken out of the local system, how can the local people be compensated and included in the decision making process? Since the systems of property rights are different (communal property managed at the local level on the one hand, and government or private property rights for agro-businesses on the other hand), classical compensation in the form of land or money is not likely to satisfy the local needs adequately. As there are already tensions between the local groups in the area, as well as between the local lowlanders and the formal government of Gambella, who are linked to the central government of Ethiopia, the Baro-Akobo project could escalate already existing conflicts²⁴ if it is not planned and implemented with utmost care.

21.3.2 Linkage Between the Global and International Systems

Already today 15 km³/year are imported into the Nile Basin from the global system in the form of 'virtual water', i.e. water embedded in food (Mason 2004). As water becomes scarcer, it may be reallocated between sectors according to its highest economic value, an example of inter-sector efficiency increase. Food is imported, for example, allowing for less water to be used in the agricultural sector. This saved water can then be used in the industrial sector where it yields a higher economic return. Table 21.1 shows that Egypt is the main cereal importer into the Nile Basin, with 130 kg per capita and year. Egypt produces about 60% of its cereals and imports the rest, mainly from the USA (Yang/Zehnder 2002). While the virtual water strategy makes economic sense in the case of Egypt, potential negative effects on Egypt's social and political stability (decreasing employment in the agricultural sector) must be considered.

The situation is different for Ethiopia that imports food as food aid, not because it is water scarce, but because its weak economic and political situation have hindered the use of its available water resources. Egypt on the one hand, and Sudan and Ethiopia on the other hand, demonstrate that different strategies are required for a country to be food secure. If a country experiences physical water scarcity²⁵ like Egypt, virtual water is an important part of the solution (see Table 21.1). If a county experiences economic water scarcity, like Sudan and Ethiopia, virtual water is not an adequate strategy; rather the institutions and infrastructure to use the primary available water resources should be developed. While food aid in Ethiopia (about 11% of national cereals production) helps household food security in rural Ethiopia, inappropriate food aid interventions may increase dependence on the household and national level. Mid-term strategies include stabilization of agricultural yields, long-term strategies involve diversification away from rainfall dependent livelihoods (Devereux 2000).

23 Interview with Moges Shiferaw, Zurich, June 2003.

24 Ethiopia: The Gambella Conflict - Structures and Prognosis, 2004. Wirenet independent analysis, practical management, UK. at: <<http://www.unhcr.ch/cgi-bin/texis/vtx/publ/open-doc.pdf?tbl=RSDCOI&cid=4186616c4&page=publ>>.

25 Countries experiencing 'physical water scarcity' do not have enough primary water resources to feed their population. Countries suffering from 'economic water scarcity' have sufficient water resources to meet their additional primary water supply, but need additional storage and conveyance facilities to make use of the naturally available water. Most of these countries face severe financial and development capacity problems (International Water Management Institute at: <<http://www.iwmi.cgiar.org>>).

Uganda	30%	Civil strife in parts, drought	3.14	0.404	24.8

In summary: Water is brought into the Nile system in the form of food, and it is compensated for, i.e. Egypt pays for it, and farmers in the USA are interested in exporting cereals. There is economic participation of those involved, e.g. the American farmers, and political participation through their government in shaping world trade regulations. Thus the transfer of water from the global system into the international Nile system transforms the conflict between the countries of the Nile and makes cooperation possible. If Egypt would have to be self-sufficient by growing its own food for a growing population and remain dependent on the waters of the Nile for this, then the tensions towards the upstream countries would be much greater. Virtual water explains why water scarce countries do not go to war (Allan 1997). However, Egypt is also concerned about becoming too dependent on food exporting countries, and any political strings tied to such imports. To ease such concerns, various ideas have been proposed: a regime that buys the

wheat and sells to water scarce counties without geopolitical strings attached (Ohlsson 1999: 239) or a private company that does the same thing (Yang/Zehnder 2002).

One more water conflict mitigation strategy deserves mention here, as it can ease the need for moving water across the local, national and international systems. This strategy concerns demand-side management, i.e. increased efficiency in irrigation or rain fed agriculture. There is greater benefit per unit of water withdrawn or unit of rain that has fallen, if less water has to be withdrawn and thus upstream-downstream conflicts both on a sub-national and international level can be eased. According to Egyptian estimates, an additional 20.9 km³/year could be made available through recycling water, by changing irrigation techniques and adopting water efficient crops and cropping patterns (El Quosy/Tarek 1999: EGY-18.8). This is equal to 30% of the water that is being used at present in Egypt (Mason 2004).

21.4 Conclusions

The Eastern Nile case indicates that the success of international river development projects depends to a large degree on how people are affected by such projects on the sub-national level can be compensated and involved in the decision making process. The difficulties involved with such supply-side projects need to be carefully assessed in relationship to the alternative opportunities of demand-side projects. Examples of demand-side projects in the Nile case are increased efficiency in irrigation in Egypt, greater yields by developing rain-fed agriculture in Ethiopia, or the possibility for economically strong countries such as Egypt to import food from the global market. Concerning the transformation of international river conflicts in general, and the Nile river in particular, the linkage approach calls for dialogue processes between grassroots and government actors ('vertical dialogue') and between governments ('horizontal dialogue'), long term demand-side management through increased efficiency and inter-sector reallocation of water, stabilization of the world food markets, and adequate compensation mechanisms for peoples directly affected when water is taken out of a sub-system.

The two elements of (economic) compensation and political participation are central to the linkage approach - similar to Allan's (2003a) fourth and fifth water management paradigms. A key result of our case study, therefore, is the following hypothesis: If water is taken out of a system (physical linkage) without compensation and without the participation of the people directly affected (economic and political linkage), conflict escalates or is transferred across the systems. Inversely, water conflicts are transformed or cooperation is transferred across systems, when water is brought into a system or is withdrawn and compensated, and this compensation happens with the participation of the people affected. This hypothesis needs to be tested in other river basins to verify its generality.

More generally, the article argues that environmental conflicts always deal with physical and non-physical dimensions. These are thus the two types of links researchers and practitioners need to focus on. Generally, a 'deepening' of security studies is understood as focusing on other actors besides the nation state. The approach presented here goes a step further, rather than only focusing on further actors (e.g. human security instead of national security), there are indications that security studies need to focus on the *links* between the actors (and their respective levels), rather than just on the actors themselves. Specifically

regarding environmental security, the relations between the physical and non-physical linkages should be highlighted. For water and land resources, the concept of 'virtual' land and water is helpful to trace the physical linkage throughout their entire 'life-cycle'. People eat virtual land and water when they consume food. This can be part of the solution, i.e. in physically water scarce countries, that import food and therefore have less pressure on national or international river resources. On the other hand, it can also be problematic, when the production or marketing of food is related to conflicts that are ignored because the food is consumed far away. For resources such as oil or 'lootable' resources such as diamonds, gold or coltan, the actual resource can be traced from its mining, transportation, marketing to its consumption - often in the affluent countries. The socio-economic and political linkages that go hand in hand with the physical linkages are often harder to trace. Market regulation through political participation of people directly affected is needed to shape the physical linkages: be this in the case of the Nile a pastoralist in South Sudan, a high-land farmer in Ethiopia, a city dweller in Khartoum, a peasant farmer in North Egypt, or a high-tech farmer in the US.

On a conceptual level, the linkage approach to conflicts over the use of resources and the environment fills one of the gaps often found in case study approaches or statistical analyses using national data. This gap entails focusing on the content, the 'conflict', and its causes, rather than on how the 'conflict' is related to its context - both on a sub level (e.g. local conflict dynamics) and super level (e.g. global markets). The added value of the linkage approach is not only to understand conflict as being influenced by its context, but to place this relationship at the heart of the analysis. If these links are addressed, the number of management options increases. Water as a physical resource 'trickling down' and sometimes 'spilling over' these different arenas serves to demonstrate some of the questions involved.

22 Extractive Industries and the Environmental Aspects of International Security

Saleem H. Ali

22.1 Introduction: Redefining Security

Soon after the end of World War I, the French oil executive Senator Berenger in a historic dinner speech alongside the distinguished British diplomat Lord Curzon stated that “as oil had been the blood of war, so it would be the blood of peace” (cited: in Yergin, 1991: 183). These words continue to echo in contemporary discourse about the environment and security, yet they are often presented with strong political underpinnings. Among the resource conflict determinists, Michael Klare has been most strident in his writings with books whose titles, such as *Resource Wars* (Klare 2001) or *Blood and Oil* (Klare 2005) reflect the fervour of his argument. Following the tragic events of 11 September 2001, scholars such as Klare have argued that much of America’s national security strategy is focused on securing extractive resources, particularly oil. This resource determinism is presented on the one hand as a critique of US foreign intervention motivated by greed rather than need, while also highlighting the peril of relying on non-renewable resources. However, these writings are often politically charged and rarely offer a balanced critical analysis of the issues.

The aim of this chapter is simply to identify the fault lines among communities that are grappling with extractive industry projects, and how an environmental analysis of the issues can inform discussions of local, national, and regional security. After a critical definition of ‘security’ as perceived in environmental narratives, the relevance of extractive industries to this definition is discussed. Other chapters will address the economic and political aspects of this discourse in more detail as well.

The national security challenges of confronting environmental change were most acutely realized after the Cold War ended. The inclusion of ‘environmental security’ can be traced to the transitional period between Perestroika and the fall of the Iron Curtain,

when US and Russian researchers began to collaborate on environmental issues. In a joint article on ‘oceanic security’ authored by James Broadus of the Woods Hole Marine Policy Center in the United States and Raphael Vartanov of the USSR Academy of Sciences, the term environmental security was defined as follows: “environmental security is the reasonable assurance of protection against threats to national well-being or the common interests of the international community associated with environmental damage” (Broadus/Vartanov 1991).

But approaches to investigating environmental security actually range from the much broader focus on the relationships between environmental change and human security (‘freedom from fear’ and ‘want’) to the somewhat more specific focus on the linkages between environmental stress and violent (deadly) conflict. With respect to the latter approach, which constitutes the largest explicit research stream on environmental security, the debate has centred around whether and why environmental scarcity, abundance, or dependence causes militarized intra-national, international, and transnational conflict (Bächler 1998a; Klare 2001). The resource constraints presented by the ‘survival hexagon’ (Brauch 2002, 2003) often do not explain the emergence of conflict in mineral-rich areas and require a more integrative approach. Such an approach must look at macroeconomic concerns in congruence with micro-level decision-making by corporations, social movements of environmentalists, as well as government planners.

The environmental security discourse has come a long way since its origins in Cold War camaraderie. The field has been approached by natural scientists, social scientists and historians from across the world – empirically and interpretively. While different ideological strains have used the instinctive appeal of ‘security’ to further their cause, the seminal role of environmental factors in determining the fate of human societies (Diamond 2005) remains firmly entrenched.

22.2 Environmental Conflicts in Extractive Industries

The ecological harm caused by fossil fuel emissions, land degradation, and pollution of waterways is given a security dimension by many environmentalists. However, this critique has many underlying value judgments that need to be unravelled about extractive industries. This chapter attempts to provide a framework for analysing the extractive industries with a lens of international security, and clarifying some of the issues that are often conflated in the literature.

The term 'extractive industries' has various connotations, but for our purposes the extractive element suggests a degree of non-renewability at a human timescale. By this measure, the major natural resources that fall within this definition are minerals – solid, liquid, and gaseous. In addition, certain old growth forests are also classified as non-renewable because of the enormous temporal investment and care required for such forests to reach maturity. The issue of non-renewability also comes up often in the context of the use of the material for energy, whereby it is chemically altered, or the infrastructure required to generate the energy that may leave an unalterable impact on the landscape. By this measure, hydroelectric energy stations greater than 50 MW are often defined as 'non-renewable', because of their irreversible impact on the landscape and since often dams larger than this size cannot be restored after removal. This chapter will focus on mineral resources as the 'extractive industries', and also discuss the limitations of defining 'renewability' in this context.

There are primarily seven ways in which the international security aspect of extractive resources should be analysed:

1. *Resource dependence conflict*: The reliance on extractive resources for energy needs leading to national necessity for foreign intervention in case of threats to the resource. This is the argument that Klare and other resource determinists have made and indeed, the US government made during the first Gulf War in 1991. The security narrative in this case is particularly focused on oil and gas resources. It also focuses on not only the areas of extraction but also the transportation routes by which these resources reach demand centres, particularly oil and gas pipelines.
2. *Community conflicts and destabilization*: Environmental conflicts caused by non-renewable resource extraction or pollution in areas of extrac-

tion and transportation with communities leading to regional destabilization. Examples of this kind of security threat have been observed in cases such as the copper mine on the island of Bougainville in Papua New Guinea, which is believed to have contributed greatly to a secessionist movement on the island.

3. *Economic stagnation and security*: Dependence on export of extractive industries in source countries leading to economic stagnation through a loss of diversification in the industrial sector, excessive reliance on imported manufactured goods and an overall increase in the vulnerability of the economy. This effect is often described as the 'Dutch Disease', referring to the impact of oil exports on the Dutch economy during the 1960's. However, as was the case with Holland, this stagnation can be short term and does not always lead to conflict, though it can be a development challenge with potential security implications.
4. *Resource looting and conflict*: The portability or 'lootability' of certain extractive resources leading to a 'resource-capture', which causes internal economic disparities thus instigating or perpetuating intra-national conflicts. This is the most widely studied kind of resource conflict in Africa, and is often referred to as the 'resource curse' by environmentalists (Ross 2001a, 2001b). The causal mechanism by which this may occur could be due to either scarcity (shrinking pie effect) of a commodity leading to violent competition for survival or due to 'rapacious' onslaught over an abundant resource (honey pot or gold rush effect).
5. *Criminal cash flows from minerals*: The use of revenues from extractive industries to fund international terrorist networks due to their ease of smuggling and linkage to criminal cartels. The linkage between diamonds and other precious gems in West Africa and Al-Qaeda has been established by investigative journalists such as Farah (2004). This is perhaps the area that is most directly linked to the current global "war on terror", and of most policy relevance to the United States. However, the scale of these contributions to funding terrorist networks has not been empirically established.
6. *Monopsonistic power and security*: The domination of one firm as the sole purchaser of labour and services is referred to as monopsony (as opposed to monopoly where a firm is the sole seller of products). Extractive industries can have a profound impact on certain remote areas since they

are often the sole source of employment, infrastructure development, and tax contributions. This can often translate into political control that can be perceived as co-optation of the state apparatus.

7. *Mutual dependence and cooperation:* There is a potential for extractive industry projects to lead to collaboration between states and communities either due to need for joint capital investment or the passage of transportation infrastructure such as pipelines through different jurisdictions. However, this has not been empirically studied in much detail. Some interesting cases have emerged recently in this regard such as cooperation between India and Pakistan to allow for a gas pipeline from Iran to pass through Pakistan and reach demand centres in India.

Each of these dimensions of international security deserves attention; however, there is a cross-cutting environmental theme to all these possible causalities that first needs to be addressed. This chapter attempts to present the environmental dimension to this discourse on extractive industries and security, with an aim at finding clear policy prescriptions that can guide communities with extractive resource endowments.

Non-renewable resource extraction has been anathema to environmentalists because extraction of such a resource is, by definition, irreversible and hence leaves an indelible impression on the ecology of a region. However, extracting some non-renewable resources, such as metals, is often defended on the grounds that metals are recyclable and hence even though the extraction from the Earth is non-renewable, the material itself is more worthwhile than a non-recyclable substitute such as a composite plastic. This argument, nevertheless, ignores the fact that metals can also be oxidized and decay into forms that are not economically reusable, and certainly does not apply to energy minerals such as coal and uranium. Furthermore, the energy required for recycling must also be considered in any systematic analysis of impact. Perhaps more research on this issue is needed from an industrial ecology perspective to fully understand the life cycle impact of different materials for a specific use (Ayres/Simonis 1994).

There is also a continuing perception among Cornucopian researchers (Gleditsch 2003) that innovation, spurred by scarcity, will self-correct any potential depletion of the resource.¹ Modern technology has already led to the substitution of copper by fibre optics (produced from sand), and the substitution of iron by

ceramic materials and composites. In some cases materials technology has been advancing very rapidly in response to supply limitations signalled by rising prices for individual minerals. Moreover, the potential for recycling and conservation of less abundant minerals is enormous. The late economist Julian Simon extended this reasoning perhaps too optimistically to declare that even with the finite resources of minerals at our disposal, we can still say that the supply is infinite because we do not know the full potential of reserves and how they can be utilized. He compared the situation to a straight line segment which has a finite length, but which has an infinite number of points contained within it (Simon 1996, 1999).

The question of sustainability has been approached from diametrically different perspectives with reference to the mineral sector. Pro-mining forces tend to frame the issue as one of livelihoods, while anti-mining activists have framed it as an issue of resource depletion. The debate has thus been markedly polarized and reconciling these differences has been a challenge for policymakers and planners. Table 22.1 is an attempt to dissect the arguments on both sides.

The arguments on both sides of this debate are plausible, but often the result of any effort at planning for a mining venture results in positional entrenchment. Given the analysis in table 22.1, it appears that non-renewability of minerals is only an issue vis-à-vis sustainability if we believe that:

1. Keeping the resource in the ground is inherently valuable, and analogous to the preservation of biodiversity. However, since the resource in this case is inanimate and perhaps less consequential to food chains and other biological processes, the argument is often considered less convincing.
2. The environmental damage of the extraction process itself will cause irreversible damage and hence is contrary to any vision of sustainable development. In this case, the non-renewability is a derivative issue and the irreversible environmental impact is the primary issue. Therefore the damage should be compared to renewable resource extraction.

1 For an excellent review of the debate among resource economists about the market mechanisms for dealing with resource depletion concerns see (Auty 1999).

Table 22.1: Divergent Arguments on Sustainability of Mineral Extraction Activities. **Source:** The author.

Cassandran	Cornucopian	Evaluative Notes
<i>Non-renewable resource extraction:</i> Mineral ores cannot be replenished in the earth's surface over human timescales and thus reliance on them is risky and unsustainable. Energy needed to harness abundant minerals such as aluminium must also be considered.	<i>Non-renewable but Recyclable (at least metals):</i> Metals are elements and hence irreducible low entropy products that can be recycled rather than being 'regrown'.	<i>Highly dependent on type of mineral.</i> E.g. aluminium is both very abundant and easily recyclable, whereas nickel is much less abundant and requires complex product disaggregation for recycling. Also, is there intrinsic value to keeping minerals in the ground?
<i>Land Degradation is Irreversible:</i> Common forms of mining and beneficiation effluents scars the landscape in ways that leave it unproductive for future uses.	Economic output per land acreage is high: <i>While open-pit mining can leave permanent landscape scars, much of the use area is underground and productive land used is relatively small.</i>	Underground mining and leaching techniques may reduce the need for large-scale land degradation, though still require reclamation and monitoring after closure to prevent pollution and subsidence risks.
Supply Creating Demand: Corporate marketing is creating 'wants' of consumers. Such 'wants', rather than needs of society, are spurring investment in mining.	Demand Creating Supply: <i>Needs of remote communities and traditional demands of consumers are spurring investment in mining. Few alternative development trajectories for remote communities.</i>	Diamond and gem-stone demand may have been spurred by marketing. Gold demand can easily be met through recycling and bullion reserves, though the subsistence 'needs' of artisan gold miners and 'traditional' users of gold are prescient.
<i>Ephemeral Employment:</i> Mines usually have a life of a few decades and hence employment is not continuous and leads to deceptive economic indicators.	Evanescent but Catalytic: While mining operations may fold, satellite industries which they spawn can continue and perpetuate economic development.	Mining planners need to consider whether a new 'mining town' is viable following closure or a fly-in operation makes more sense. Highly dependent on derivative industries that could potentially evolve.
<i>Negative Impacts Outlast Closure:</i> Large financial investment is required to reclaim land after mining, as well as rebuilding economic and social capital of communities.	<i>Positive Impacts also Outlast Closure:</i> Infrastructure development, service sector jobs, and educated workforce are also a by-product of mining that outlive the life of the mine.	Closure planning must be part of the initial environmental impact assessment before the project commences, in order to ensure long-term viability of land-use.
Sustainability of Natural Capital Guides Development of Economic and Social Capital	Natural Capital is a means of Attaining Economic and Social Sustainability	Both views necessitate the viability of natural capital – whether for ornamental or instrumental purposes.

3. The dependence on the use of mined resources will lead to severe economic and social problems when they are eventually depleted, since there will be a paucity of production opportunities for alternatives.
4. The dependence of remote communities on a resource extraction as a sole means of livelihood will lead to economic stagnation after mine closure, and is thus not sustainable without a plan for subsequent development.

The sector of the mining industry that most closely meets these criteria is gold mining. It is highly disruptive to biogeochemical cycles because of the use of various chemicals in the extraction phase, even at the small-scale level and the level ratio of what is in the

ground to what is on land is unfavourable to arguments supporting mining.

22.3 National Institutions and Extractive Conflicts

Scholarly writings pertaining to reform of the extractive industries have unfortunately reached a point of positional entrenchment that is proverbially generating more heat than light. The World Bank's report: *Treasure or Trouble* (2002) and the reactions to its analysis exemplify this polarization most acutely. The report and the criticism offered by scholars such as Michael Ross (2001) and notable representatives from activist communities such as Friends of the Earth

(2001), miss the larger issue of scale and context in research analyses. The problem lies in the increasing reliance on macroeconomic data as a means of generating causality in cases where impacts and benefits of extractive industries are often highly localized. The World Bank study attempted to bring in a local flavour by including Egypt, China, and India in the analysis to show that despite the lack of importance of macroeconomic indicators, local (or domestic) areas do indeed benefit from extractive industries, thereby improving regional security. While this is an important insight, it is somewhat simplistic to aggregate conclusions about development trajectories.

Unfortunately, the Bank and its critics are both falling into the correlation trap. The country-wide data presented in macroeconomic analyses are only useful in telling us that mining investment is by no means a *sufficient* condition for economic growth, which is certainly a useful insight in some cases. However, the data cannot provide insights about whether resource extraction is a *necessary* condition for growth or lack thereof. Even in cases where there is negative growth, extraction of resources may still be a necessary condition for positive growth because of the effect of intervening variables such as ethnic strife.

What is more troubling about the criticism offered by environmentalists is their lack of alternative options in these cases. Would a cessation of mining in Liberia or Sierra Leone improve their economic plight and improve security? A careful historical analysis would be useful in such cases. Twenty years ago, Sierra Leone was not embroiled in civil war and mining was contributing favourably to the economy. The civil strife may have been exacerbated by the availability of ready cash from mining, but the problem then lies with the management of the resource in a changing socio-political context. What we need to understand is under what circumstances can the mineral sector be corrupted in ways that hamper growth and the diffusion of benefits?

There are two aspects to the resistance: i) normative resistance predicated on environmental impact and related concerns, ii) resistance to garner greater diffusion of economic benefits. While extractive companies should respect the right of communities to not want certain projects in their areas, activists should similarly respect the importance of communities to decide their own economic trajectory. In certain remote areas where communities have, for better or for worse, joined the market economy, mining can indeed be a source of tremendous economic benefits. It is disingenuous to try and hide this reality behind

macroeconomic indicators, just as it is misleading to hide localized impacts of a mismanaged mine behind corporate financial reports.

Rather than casting aspersions of methodological deception on one another, researchers, activists, and the development community need to focus on what communities want and what options are available to them. There are indeed cases where more viable alternatives to a mine may be feasible, but there will also be numerous cases in remote areas where mining will be the only viable option for economic development. The challenge in such regions then is to channel the monopsonistic and monopolistic power of the industry in a productive fashion to maximize benefits. Civil society, as manifest in various non-governmental organizations (NGOs), can certainly provide important guidance and quasi-enforcement to ensure that this power is appropriately wielded and not exploited. However, such constructive engagement is only possible when we move away from positional strategies and focus on the unique needs of each community where extractive enterprises are being considered.

22.4 Planning for Mines in Remote Areas: Considering Monopsony

In much of the public policy literature the concern with firm regulation tends to revolve around the notion of monopoly power. While mining firms in some cases have been accused of monopoly, particularly the diamond mining and processing firm DeBeers, the most significant issue that concerns mining projects in remote areas is not monopoly power but *monopsony* power. While the former refers to a market that is dominated by one *seller*, the latter refers to a market situation where one *buyer* is dominant. In remote areas, mining companies are often the sole source of income for communities and hence have monopsony power over labour.

Extractive industries are a kind of 'windfall development' similar to the establishment of a casino in an impoverished neighbourhood, ushering in a sudden influx of wealth to a community. However, extractive enterprises are a kind of windfall development that is very different from other projects, such as casinos, stadiums or army bases, because of its inherent obsolescence.

Therefore, in order for such a windfall development to be successful in the long run, it must be coupled with some other development strategy, otherwise the result is a proverbial 'mining ghost town' that

is sadly the scourge of many pristine landscapes. The extractive sector can only provide an opportunity for sustainable development if it is viewed as a proximate solution to day-to-day technological necessities, and not an end in itself. Historically, primary resource extraction industries have been considered sacrosanct by many governments and have received numerous subsidies. Clearly this has not provided companies an incentive to diversify and think in the long run about alternative services which they could provide in terms of recycling materials and investing in alternative material science research which employs renewable resources. This move would be congruent with the oil industry, which is now shifting gears to be considered an 'energy service' industry and investing in solar and other renewable forms of energy research.

Clearly these issues need to be addressed at all levels of governance. However, the international level is most salient in this context to prevent the proverbial 'pollution havens phenomenon'. Given the multinational nature of most mining companies, there needs to be some way of standardizing best practices in the mining sector. There should perhaps be a series of ISO (*International Organization for Standardization*) standards for non-renewable resource extraction industries, given their unique and obsolescent nature. Meanwhile regional, national, and local oversight of mining operations is also essential. Just as human rights are nowadays trumping the past primacy of 'sovereignty'. It is also likely that environmental issues will follow a similar path.

Extractive industries are often a 'leading sector' in the area where they exist, and should therefore be used to encourage other businesses to invest in the region. Since mines are usually located in remote parts of the world, it is difficult to get other manufacturing or service businesses in the area. A usual solution that is proposed is to develop a tourism industry (often in its most green incarnation as 'eco-tourism'). This is of course limited to the kind of terrain where the mine is located and is often not feasible.

Perhaps a preferable way of approaching this question is first to study and evaluate the lifestyle of the people before the mining activity, and to see how that 'pre-development' lifestyle could be improved *without* the 'windfall development'. Such an analysis would highlight some of the limiting factors that could be preventing a more sustainable yet inchoate sector from developing. For example, a poor agricultural economy may be deficient in appropriate farming technology to make it develop. Now, once this evaluation has been conducted, the 'windfall developer'

can institute measures to specifically target that sector for improvement through direct financial means or through technology transfer.

22.5 Security and Sustainability: Concluding Thoughts

Sustainability for our purposes is the attribute of a process that can harness a resource while allowing for replenishment of its base capital (natural, economic, and social) to meet future needs. The future needs of a community must be defined in terms of technological forecasting as well as physical resource constraints. Considerations include: social and community market economics. Social implementation of sustainable processes is important but must not overlook the reality that many projects which are socially satisfying can be utterly unsustainable from a physical perspective. Within the spectre of technological innovation, we cannot defy physical constraints. On the other hand, if there is social reluctance to a physically sustainable process, there is greater leverage to change social views through education, training, and economic means. Thus, the social concerns are important, but only after the physical sustainability of the project are fully understood.

So the question still remains: are extractive enterprises compatible with sustainable development and hence congruent with a long-term vision of security? The answer must consist of two parts: First there is no doubt that extractive industries under present technological conditions do have a certain degree of permanent impact on a region. Mineral industries also involve extraction of non-renewable resources. By these measures the answer at one level is No: mining is not sustainable. However, while the landscape may be permanently changed by extractive enterprises in certain ways, that does not necessarily mean that communities cannot thrive if projects are appropriately planned. Extractive enterprises can therefore be a prelude to sustainable development if the community is willing to absorb a certain degree of permanent impact. The key then is to be able to use extractive industries as an entry point towards a more stable industrial or service-based economy that is not inherently obsolescent.

Economic diversification is the operative word for both inter-state and intra-state security. This applies to countries diversifying their energy sources, as well as their industrial investment. Indeed, one of the less compelling aspects of the arguments of resource war

determinists regarding US security interests has been the ongoing diversification of US oil and gas sources. Furthermore, the US gets almost half of its oil from domestic sources, followed by the largest foreign contributors that are collectively its neighbours - Canada and Mexico.

American energy policy is trying to diversify away from dependence on Middle Eastern oil, and thus the argument that the US government is going to war in the region simply over oil sounds less convincing, especially given the high financial and human cost involved. Another interesting rebuttal to the resource war determinist is that dependence can often lead to more cooperation than conflict, as observed with water resource issues where hardly any conflicts over water resources have been documented in recent memory, despite much sabre rattling (Uitto/Wolf 2002). Hence the fact that the Taliban visited Texas and met with gas company executives before 11 September 2001, rather than fuelling conspiracy theories about conflict, could be considered a mark of how resource interests can potentially foster cooperation between two utterly different cultures. The key to a fruitful outcome depends on how governments in extractive countries handle their resource endowments, and what international mechanisms exist to moderate the wealth and woe that they might bring.

Education is a critical issue in many areas where windfall development is to occur and the establishment of schools and other vocational training programmes independent of their utility to the developers is critical. Hence a contingency development plan would be essential, particularly for projects of planned obsolescence, such as mining. Nevertheless, alternative development strategies should be strongly encouraged for any risky 'windfall development'. Such a system will likely require regulatory enforcement as it is a classic externality for the developer.

However, the specifics should remain flexible given the highly diverse nature of alternatives that may exist for various communities. Some examples of successes and failures in this context need to be further studied with the aim of testing various hypotheses regarding the efficacy of extractive industries and their influence on intra-state and inter-state security. These hypotheses are likely to focus on five areas: a) stakeholder engagement: negotiation versus consultation and transparency of the process, b) supply chain management of the mineral resource, c) pollution prevention and risk management systems, d) post-closure remediation and sustainable livelihoods, e) potentially cooperative linkages of projects through mutual de-

pendence. Clearly some of the process issues, stakeholder involvement in decision-making, organizational dynamics and implementation would need to be ironed out in order for such a system to be effective. However, extractive industry projects must not take place in a vacuum, and should be catalysts rather than reactants in the synthesis of development.

23 Energy Security: Conceptualization of the International Energy Agency (IEA)

Klaus-Dietmar Jacoby

23.1 Introduction

The creation of the International Energy Agency (IEA) in 1974 was directly linked to the oil price shock in 1973-1974. At that time, 16 member countries established the IEA as an autonomous body within the framework of the Organisation for Economic Co-operation and Development to implement an international energy programme.

The main aims of the energy cooperation among the now 26 member countries are:

- To maintain and improve systems for coping with oil supply disruptions;
- To promote rational energy policies in a global context through co-operative relations with non-member countries, industry and international organizations;
- To operate a permanent information system on the international oil market;
- To improve the world's energy supply and demand structure by developing alternative energy sources and increasing the efficiency of energy use; and
- To assist in the integration of environmental and energy policies.

Oil crisis management and the information system on the international oil market are the IEA's only short-term policy issues and instruments. Promotion of national energy policies, improvement of the world's energy supply and demand structure and the fostering of environmentally-related energy policies are more related to medium- and long-term tasks.

Both short-term and long-term policies and objectives have changed over time, with liberalization and globalization of markets and a different use of specific energies in sectors such as industry, transportation or electricity generation.

This chapter reviews the history and development of the IEA's energy security programme, from the lead-up to the 1974 Agreement on an International En-

ergy Programme (I.E.P.) signed by all IEA member countries, through subsequent modifications in the response mechanism enabling more flexible *co-ordinated emergency response measures* (CERM), also reviewing the IEA's coordinated actions during the oil supply disruptions of the 1991 Gulf War and in 2005 in response to disruptions caused by Hurricane Katrina. Emergency reserve stocks and demand restraint programmes are also detailed. The chapter then describes how changes in energy markets have led to broadening the scope of the IEA's energy security programme to considerations of security of gas supplies and electricity.

23.2 Evolution of the IEA's Concept of Energy Security

23.2.1 Origins in Security of Oil Supplies for Military Purposes

The origin of the notion of the need for oil stocks to be used for probably goes back to World War I, when Lord Admiral Winston Churchill first became aware of the need to procure fuel (in this case, coal) for his military fleet. In 1917, France experienced a rupture in oil supplies when its army required more petrol than was available, as most supplies were diverted for use in the Russian Revolution and by American submarines. Subsequently, in 1925, France imposed the requirement on its oil industry to reserve stock representing 25 per cent of the declared amount of oil delivered for consumption during the last 12 months, or 91.25 days of domestic consumption. In order to supply fuel for military operations during World War II, countries resorted to compulsory demand restraint programmes such as fuel rationing. As Germany had no indigenous oil production, it succeeded in a type of 'ersatz' [substitute] fuel switching by converting coal into a type of petrol.

23.2.2 Security of Energy Supply: Building up Oil Stocks

After Egypt's blockade of the Suez Canal in the 1950's European politicians became increasingly aware of the necessity to maintain oil reserves. The awareness of the need for governments to take responsibility in safeguarding their nations' access to oil supplies emerged in parallel with OECD countries' growing dependence on oil. From 1960 to the oil crisis of late 1973 was a period of rapid economic growth and burgeoning oil demand. GDP in OECD countries grew by 90 per cent, energy demand by a similar amount and oil demand by 120 per cent as transport demand boomed and oil cut into coal's markets as a furnace fuel. In the world as a whole, the period saw oil demand rise from rather more than 20 mb/d to a level approaching 60 mb/d., of which OECD demand accounted for two-thirds. With most OECD countries without domestic production, and North American oil production on a weak trend, OECD countries became heavily dependent on imports, mostly from OPEC countries, with the Middle East dominating.

By 1968, the six members of the European Economic Community (Belgium, France, Germany, Italy, Luxembourg, and the Netherlands) agreed to maintain a minimum level of crude oil stocks and oil products corresponding to 65 days of domestic consumption. In 1972, this obligation was raised to 90 days.

The oil price shock resulting from the end-1973 crisis had profound damaging effects on economies ending the period of rapid growth. From 1974 and for the rest of the 1970's, OECD countries and the world were stricken by high inflation, trade and payments imbalances, high unemployment and weak business and consumer confidence. Against this background, the U.S. Secretary of State called together the Washington Energy Conference in February 1974 which led to the establishment of the IEA in November 1974.

From its inception, the objectives of the IEA have focused on energy security, extending from responses to short-run oil emergencies and to long-term ameliorative solutions to the broader problems of reducing oil import dependence, promoting energy policy which supports energy efficiency and diversifying fuels. The IEA's initial stockholding obligation as formulated in 1974 was "to maintain emergency reserves sufficient to sustain consumption for at least 60 days with no net oil imports" [Article 2.1 of the Agreement on an International Energy Program (see IEA 1994, Appendix III)]. In 1975-1976, the Governing Board raised the minimum legal obligation from 60 to 90

days by stipulating incremental increases until the 90 days' level was achieved in 1980.

Throughout the 1980's and 1990's, the overall emergency reserve stock level of IEA net importing countries was well above 90 days, peaking at 193 days in 1986. It currently averages 114 days. The IEA used its stocks in 1990-1991 during the Gulf War, when it made 2.5 million barrels per day available to the market and most recently in 2005 to mitigate the disruptions in supply coming from the Gulf of Mexico caused by Hurricanes Katrina and Rita (see 23.5).

23.3 The IEA's Emergency Response Measures

The IEA now has 28 Member countries¹ which represent some 60 per cent of total world oil demand and include all old EU countries as well as two of twelve new EU countries (the Czech Republic and Hungary). Core commitments of the member countries under the I.E.P. Agreement include:

- The maintenance of oil reserves equivalent to at least 90 days of net oil imports;
- A programme of demand restraint measures to reduce national oil consumption by 7 to 10 per cent; and,
- To participate in an oil sharing system in a severe supply disruption using these tools.

In addition, member countries cooperate with the oil industry for advice and operational assistance in emergencies. The committee for the discussion and development of security policies and procedures is the IEA *Standing Group on Emergency Questions* (SEQ), which is comprised of representatives from our member countries, together with a representative of the European Commission as an observer. The SEQ makes recommendations to the IEA Governing Board for consideration and adoption and it is assisted by an Industry Advisory Board, which includes senior representatives of oil companies headquartered in IEA member countries.

1 IEA member countries include: Australia, Austria, Belgium, Canada, the Czech Republic, Denmark, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Japan, the Republic of Korea, Luxembourg, the Netherlands, New Zealand, Norway, Poland, Portugal, Slovak Republic, Spain, Sweden, Switzerland, Turkey, the United Kingdom and the United States. The European Commission takes part in the work of the IEA.

For major international oil disruptions, the IEA founders established a treaty-based system for the physical sharing of oil (Emergency Sharing System) which requires members to build and maintain oil stocks, to plan for a carry out short-term reduction of demand for oil (called demand restraint in IEA terminology), and to gather and transmit emergency oil data (to enable the Agency to make sound emergency decisions) (IEA 1995: 69; 1999).

To reflect the evolution of energy markets since the IEA was established, its underlying I.E.P. Agreement treaty obligations to share oil in an emergency have been reinforced by a system of co-ordinated emergency response measures that can be readily calibrated to the circumstances at hand to permit more flexibility in emergency response, for example, during oil supply disruptions of less than 7 per cent of supply. *Coordinated Emergency Response Measures* (CERM) established a flexible framework for international consultations on co-ordinated stockdraw and other response measures in the event of an actual or potentially significant oil supply disruption. The formal sharing system has not been deployed to-date and CERM-based collective responses reflect the belief that, under normal circumstances, the global oil market is fully capable of determining the most efficient initial physical re-allocation of supplies in any given crisis scenario. Collective action utilizing stocks and other measures provides a strategic safety net to reinforce the market.

The original IEA plan and subsequent mechanisms integrated the following emergency response measures: stockdraw and allocation of oil (i.e. sharing among IEA member countries), demand restraint, fuel switching and surge production. The relative effectiveness of these various measures has changed over the years. With the privatization of oil companies in the 1980's and 1990's, there has been an increasing preference for more stocks to be held by public (i.e. government-controlled) agencies over industry in order to strengthen member countries' response capability. Despite the difficulty in quantifying the results of demand restraint measures apart from market effects, increasing attention has been given to ensuring legislative authorities mandating demand restraint measures to be activated during an emergency; these either reduce the amount of oil actually used by consumers or limit the amount of oil supply available to consumers (IEA *Emergency Management Manual* (EMM) ⁵1994, sect. 4.2). With the gradual shift in electricity generation from coal to oil and from oil to gas or nuclear power, the capability to switch from oil

to other fuels has been diminished. Surge production for IEA net exporting countries remains a possibility, although known oil reserves are diminishing in some of these countries.

While stockdraw remains the main tool, the strength of the programme rests also on the IEA's impressive oil supply information systems and market analysis. A hidden asset is the effect of the market's awareness of the IEA's rapid response capability.

23.3.1 The IEA Coordinated Action in Response to the 1990-1991 Gulf Crisis

When the Iraqi occupation of Kuwait led to the United Nations embargo of all exports of oil from Kuwait and Iraq, resulting in a loss of 4.3 million barrels of oil per day from the market, about two-third of which directly affected IEA countries, at the time of the outbreak of hostilities in the Gulf ('Desert Storm') the IEA activated its Contingency Plan on 17 January 1991 to make available to the market 2.5 million barrels of oil per day. The biggest component of the response was stockdraw.

Figure 23.1: IEA Gulf War Contingency Response Plan.

Source: IEA.

23.4 Evolution of Oil Markets

By the mid-1990's, many changes in the oil market resulted in a renewed focus on assuring supply of oil in case of a disruption for both oil-producing and -consuming countries.

...the market has become more capable of immediate responses to disruptions, much more sophisticated in its operations, and more 'global' in its geographical reach. Spot market transactions ... now account for the bulk of international oil transactions. Price movements now become known almost instantaneously to a large number of market participants, making potential market reactions to supply disruptions and other market affecting events appear almost without delay (IEA 1994: 131).

The market became more global with increased production from non-OPEC producers, and output increased to keep pace with the booming U.S. and Asia Pacific economies. But OPEC's slow reaction in adjusting its production quotas to accommodate the Asian economic crisis of 1998 and U.S. economic downturn of 2000 made oil prices drop.

Emergency plans and procedures of the International Energy Agency and its member countries were reviewed and reshaped in anticipation that possible computer problems related to Y2K could seriously impact on energy security. This coincided with the Asian economic downturn and concomitant drop in oil demand and hence oil prices. Then, just as OPEC and non-OPEC producers had instituted lower production quotas to regain control of oil prices in 2001, the terrorist events of 9/11 raised fears that oil could again be used as a weapon.

23.4.1 The Geo-political Situation in the Late 1990's to the Present and the IEA

Other geopolitical events, along with perceived diminution of the ability of oil producers to compensate for a supply loss by using spare capacity, have acted to create a climate of uncertainty about future supply. In 2002–2003, problems in Venezuela led to a strike at *Petróleos de Venezuela SA* (PDVSA), causing Venezuelan production to plummet. Both social unrest in Nigeria, which affected that country's oil production, and the second war in Iraq in 2003 reinforced possible risks of a significant supply disruption. With spare capacity in oil-producing countries at historical lows and demand from fast-growing economies like China or India increasing, the market must find a new balance. In this context, economies are more vulnerable, as increasingly high oil prices could negatively effect economic growth. Also, because of tighter management of stocks due to technological innovation, even historically smaller supply disruptions could have significant market ramifications. Reminding the world of the existence of the IEA's collective stockpile through well-timed news releases serves to assuage the insecurity.

Until September 2005, there had been no need to draw on IEA's emergency stocks since 1991. But between these two times, the IEA actively monitored geo-political situations developed even quicker procedures for agreeing on and implementing an emergency response. Indeed, as scenarios evolved in the wake of 11 September 2001, followed by the strikes in Venezuela, unrest in Nigeria and war in Iraq, the IEA

Secretariat was carefully assessing the situation on a daily basis and kept in close contact with its member countries, the oil industry and strategic non-member countries. The IEA and its member countries were ready to act in coordination with oil-producing countries, in particular, with OPEC countries, and the markets knew it. For these reasons, the possible risk of a supply disruption was minimized and price spikes and their duration were limited.

The IEA has regularly carried out Emergency Response Exercises, which serve to train staff in administrations and industry in IEA emergency procedures as well as to give the opportunity for an in-depth exchange of views between experts from administrations and the oil industry to review procedures and to introduce, if necessary, new measures to react to market changes (IEA 2001). Since 2002, these exercises have included participants from major oil consuming countries outside the IEA, like China. In 2004, a special Emergency Response Exercise for non-member countries with the participation of delegates from China, India, ASEAN countries, Brazil and new EU member countries was held.

23.5 IEA Response to the Hurricane Katrina Oil Supply Disruption

Following the damage wrought in the Gulf of Mexico coast by Hurricane Katrina during the last week of August 2005, on 2 September 2005 the IEA Executive Director announced that all 26 IEA member countries would take collective action in response to the interrupted oil supplies. The IEA member and candidate countries plus the EU Commission unanimously supported this action to make available to the market 60 million barrels of oil for an initial period of 30 days. This agreement was achieved in less than ten hours from the time that the IEA Secretariat sent its initial assessment of the situation recommending the activation of an emergency response.² The IEA also consulted with major producers and the OPEC President, who also stated OPEC's commitment to make incremental oil available to the market to cope with the supply disruption resulting from the hurricane. This illustrates the flexibility and preparedness of the IEA in handling an international energy crisis.

² This was an impressive record in political decision-making for an international organization, considering the time difference of 16 hours between member countries in the East and West.

During the months leading up to Hurricanes Katrina and Rita in the Gulf of Mexico, the global oil market had been very tight, with historically low spare oil production capacity. Oil prices had been pushed upward in mid-August 2005 by geopolitical issues, including the death of King Fahd in Saudi Arabia, tensions over the Iranian nuclear programme and ethnic unrest in Nigeria, as well as by downstream disruptions caused by fires and accidents at some U.S. refineries. The trend was further exacerbated by U.S. gasoline stocks falling to the low-end of the 5-year range.

By mid September 2005, member countries had pledged to make available to the market some 64 million barrels over the initial period of 30 days, the equivalent of 2.1 mb/d. The majority of member countries opted to reduce emergency stock. 94 per cent of the total volume of the response was to be achieved through the drawdown of either industry or government stocks, 3 per cent by demand restraint and 3 per cent by increased indigenous production. Within the total amount of stocks to be released by member countries, 65 per cent was to be crude oil and 35 per cent oil products.

By end-October of 2005, approximately 54 million barrels had been made accessible to the markets through all actions from IEA member countries related emergency stocks and increased indigenous oil production. This included stock volumes made available by the lowering of stockholding obligations on industry, as well as sales and loans from publicly held emergency stocks.

Figure 23.2: Stock release and increased production, 2005 IEA Collective Action. **Source:** IEA.

Some supplies offered from public stocks were not taken up by the market, largely accounting for the lower total response at the end of October than the volume of supplies initially pledged. This was because 1) American refineries shut in were not able to accept the crude oil offered and 2) shipping capacity for oil products from Europe was limited. While some 39

Table 23.1: Total IEA Response, 2005 IEA Collective Action. **Source:** IEA.

Total Oil (Overall Results in Million Barrels)	
Industry Stocks	22.5
Public Stocks (including 9.9 mb of SPR loans)	28.6
Total Stocks	51.1
Indigenous Production	6.4
Total	57.5 +

million barrels was initially pledged from public emergency reserves, slightly more than 17 million of this has been taken. However, when counted together with the loans from the US Strategic Petroleum Reserve, a total of nearly 29 million barrels were released from member countries public stocks by end October.

Increased indigenous production and the lowering of minimum stockholding requirements put at the disposal of industry an additional 25 million barrels. These amounts in effect allow a potential transfer of incremental oil supply, making previously unavailable volumes accessible to the market.

23.6 Response Potential

On the supply side, stocks are by far the most rapid and effective response measure to meet physical supply shortfalls or the threat of an imminent shortfall. The IEA stocks are for strategic use to avoid negative economic impacts of a severe supply disruption; they are not to be deployed as a means to manage the market.

As at 1 June 2005, total combined government-controlled and industry-held stocks in IEA countries were about 4 billion barrels. The IEA's net importing countries held an amount equivalent to 118 days of the previous year's net imports, but when stocks held by net exporting members are taken into account, stock coverage actually rises to the equivalent of 152 days of net imports, well above the minimum requirement of 90 days. The ready availability of stocks is important when OPEC spare capacity is unsure and commercial stocks are low. In this context the IEA Secretariat sees, with some satisfaction, a trend in member countries to create or increase government-controlled stocks in place of mandatory industry stocks. With the completion of the U.S. effort to fill its *Strategic Petroleum Reserve* (SPR) to its 700 million barrel capacity, the government-controlled reserves held by IEA members are at an all-time high of nearly 1.5 billion barrels. To put this in perspective, IEA govern-

ment-controlled reserves could compensate for a 2 mb/d supply loss for about 700 days, nearly two years. IEA members also hold over 2.5 billion barrels of commercial stocks.

Other response measures on the supply side, such as fuel switching or surge production, would not contribute as much now as in the past. An IEA internal survey (IEA 2001, internal restricted document) showed that only a few countries like the United States, Japan or Italy have a significant potential to switch from gas to oil or vice versa, a result of the trend to replace oil with natural gas in electricity generation. Nevertheless, the IEA is updating this fuel switching survey and will discuss the outcome and implications on short and long term policies. The capacity for surge production as a potential response to a global supply disruption has also diminished.

On the demand side, policies and measures to save oil have a relevant importance, particularly for the transport sector. Member countries are obliged by the IEP to have ready demand restraint programmes which may include light-handed measures to increase public transit usage, car-pooling, eco-driving, telecommuting (working at home) and speed limit reductions as well as more compulsory measures like driving bans and fuel restrictions. The IEA (2005) study, *Saving Oil in a Hurry*, evaluated the potential oil savings by various measures if implemented in all member countries with the conclusion that, *inter alia*:

- Car pooling and driving bans could save more than one million barrels per day.
- Speed limits, free public transit, telecommuting, compressed work week (fewer but longer work-days), driving bans (1 in 10 days) and eco-driving can save more than 500 000 barrels per day.
- Other measures such as reduced speed limits, encouraging use of public transit, telecommuting, compressed work week, driving bans and eco-driving could save more than 500 000 b/d.

23.7 Security of Gas and Electricity Supply

Oil is no longer the only fuel for which there would be serious ramifications if there were a supply disruption. Natural gas (IEA 2004) and electricity (IEA 2005, 2005b) have been added to the list in recent years. Local or regional electricity and gas supply disruptions, in particular in North America and Europe, have become a major concern to consumers, producers and energy administrations in most OECD

member countries. While some of these supply disruptions were caused by normal supply/demand patterns, external market events such as natural catastrophes also contributed to some. In addition, market liberalization was accompanied by poor market regulation, which contributed to making these energy sources vulnerable to geopolitical events. Lack of investment incentives could also contribute to insufficient energy security. With market liberalization, the responsibility for security of supply has to be defined and shared between all players involved, including governments, producers, suppliers, traders, regulators and customers.

In particular, the concept of security of gas supply has broadened beyond country borders. The external dimension of security of supply requires increased attention given the growing import dependency of most IEA member countries (figures 23.4, 23.5). While import dependency is not, in itself, a threat, it requires governments and companies to pursue their efforts to diversify natural gas supply (supply sources and mode of imports: pipeline gas vs. LNG) and transmission routes.

With the liberalization of the natural gas industry, the market is becoming more fragmented due to both the unbundling of activities and the entrance of newcomers into the market. The responsibility for security of supply must thus be defined and shared among all players involved, including governments, producers, suppliers, traders, regulators and customers. Policy makers have the responsibility of creating a framework for security of supply and defining the objectives for security of supply and the responsibilities of each market participant. For some countries, gas storage will be the most economic choice for ensuring security; for others, supply flexibility and diversity is adequate to ensure security.

The IEA (2004) published a comprehensive study on *Security of Gas Supply in Open Markets* and is involved in monitoring gas security in its member countries. It has also started a dialogue with member governments and the gas industry to review the changing concept of security of gas supply in open gas markets and the roles of the different stakeholders. However, it is the belief of the IEA that - once the framework and the role of the different players has been defined - governments should leave market players the choice of instruments and means to provide the required level of security of gas supply.

Electricity is also an increasing concern for supply security, as several shortfalls in recent years in OECD countries all over the world have shown. Similar to

Figure 23.3: Oil import dependence in IEA [Import dependence has been calculated as (net imports)/(total primary energy supply + bunkers)]. **Source:** IEA (2006).

gas, electricity shortfalls have mostly national and regional impacts but no global ones. While there is no urgency to introduce global emergency response policies and measures, there is nevertheless the need to analyse the different types of emergencies and how best to avoid shortfalls or to remedy the situation. The IEA’s analysis of the conditions affecting trans-

missions system reliability points to the effects of market reform, which “has brought unbundling and independent, decentralized decision-making ... fundamentally changing utilization of transmission networks” (IEA 2005b: 38-39). The IEA suggests the following directions to assure security of electricity:

Table 23.2: World Primary Energy Demand in the Reference Scenario (Mtoe). **Source:** IEA (2005a: 82). Permission to reprint was granted by IEA.

	1971	2003	2010	2020	2030	2003–2030*

* Average annual growth rate

Management of system security needs to be transformed to maintain reliable electricity services in this changed environment. Clearly defined responsibilities and authority to act are required. Improved operating practice, with greater emphasis on system-wide preparation, and coordination to support flexible, integrated real-time system management are also needed. Effective real-time system operating requires accurate and timely information and state-of-the-art technology to facilitate effective contingency planning system monitoring, flow management and co-ordinated emergency response (IEA 2005b: 107).

Another IEA study (IEA 2005c) explains that reliability of electricity supply can be 'unbundled' into three parts of a chain: 1) secure fuel supply as input for power generation; 2) adequacy of generation capacity, transmission and distribution markets, and 3) system security in transmission system operation. In this context, the IEA has also published a study on *Saving Electricity in a Hurry* (IEA 2005d) which deals with temporary shortfalls in electricity supplies. Key messages are how to develop a strategy to save electricity quickly and what measures might be appropriate to use.

23.8 Challenges

As the oil market continues to evolve, the IEA and its members recognize the importance of keeping pace with market dynamics. One by-product of the increasingly sophisticated oil market is price volatility. This is an issue of common concern to producers and consumers. The IEA does not believe that strategic oil stocks can be effectively used to address price fluctuations. This would distort market mechanisms and signals, and invite unnecessary confrontation with

producers. The IEA believes emergency oil stocks should be reserved for emergency use. Issues of volatility and other market imperfections should be addressed, *inter alia*, through dialogue and data transparency.

The IEA's *World Energy Outlook 2005* (IEA 2005a) projects that by 2030 the world will be consuming two-thirds more energy than in 2007 (table 23.1). Almost three-quarters of the increase in demand is expected to come from the transport sector and oil is expected to still dominate this sector. Meanwhile, consumption in developing countries and the transition economies is expected to grow much faster than in the OECD. Under one scenario, almost two-thirds of incremental demand for oil between now and 2030 is projected to come from outside the OECD, particularly from Asian economies.

If policies do not change and this scenario becomes a reality, it would have significant implications for the security of supply which cannot be addressed adequately from an insular perspective. The success of the IEA's efforts today to reach out to these emerging consuming countries and to encourage the adoption by these countries of the principles embodied in the IEA's 'Shared Goals'³ can significantly improve global energy security in the coming decades.

The Agency is proactively involved in the wider producer/consumer dialogue at the Ministerial level in the International Energy Forum and at a technical level in the Energy Experts Meeting, as well as at regional and topical workshops and seminars. Also, the Agency has Memoranda of Understanding in place with Russia, China and India and extends its global

reach further through collaboration with regional organizations. The IEA is committed to forging a dialogue and cooperation with regional bodies, thus avoiding duplication of effort and ensuring that topics of specific regional concern are addressed and evaluated from a global perspective.

The span and scope of the Agency's outreach programme reflects the IEA's commitment to improved global energy security and a clear recognition of the increasingly global nature of security of supply issues. As advocates for the collective benefits to be derived

from adherence to the IEA shared goals to which all EU countries subscribe, the IEA Secretariat is confident that with sustained and targeted effort, this wider collaborative effort will bear fruit and global energy security response policies will converge.

23.9 Toward a Sustainable Energy Future

Furthermore, it is now widely understood that the attainment of energy security embraces other policy objectives too (IEA 2001a). Indeed, as far back as 1993, IEA member governments stated their “Shared Goals,” which included a commitment to “seek to create the conditions in which the energy sectors of their economies can make the fullest possible contribution to sustainable economic development and the well-being of their people and of the environment” (see at: <<http://www.iea.org/Textbase/about/sharedgoals.htm>>). To this end, the IEA Energy Ministers adopted the following economic values:

... Undistorted energy prices enable markets to work efficiently. Energy prices should not be held artificially below the costs of supply to promote social or industrial goals. To the extent necessary and practicable, the environmental costs of energy production and use should be reflected in prices.

... Free and open trade and a secure framework for investment contribute to efficient energy markets and energy security. Distortions to energy trade and investment should be avoided.

... Co-operation among all energy market participants helps to improve information and understanding, and encourage the development of efficient, environmentally acceptable and flexible energy systems and markets worldwide. These are needed to help promote the investment, trade and confidence necessary to achieve global energy security and environmental objectives...” (excerpt from IEA Shared Goals)⁵

As we move into an era of “petropolitics”,⁴ energy security concerns have begun once again to take precedence in policy making, as awareness of the far-reaching consequences of energy supply and demand heightens.

24 Scenarios of Energy Demand and Supply until 2100: Implications for Energy Security

Leo Schrattenholzer

24.1 Introduction¹

This chapter combines two discussions in different disciplines: the work on environmentally compatible energy supply in the frame of sustainable development in the scenario community with the security discourse in the social sciences, and the policy debate on energy security. This linkage is not without problems because security as an individual or societal political value has no independent meaning, and is always related to specific individual or societal value systems and their realization (Brauch 2003).² As a social science concept, “security is ambiguous and elastic in its meaning” (Art 1993: 821). Arnold Wolfers (1952, 1962: 150, 1962a) pointed to two sides of the security concept: “Security, in an objective sense, measures the absence of threats to acquired values, in a subjective sense, the absence of fear that such values will be attacked.” From a constructivist perspective security is what ‘actors make of it’.

Since 1990, the erstwhile narrow national and primarily political and military external security concept has been widened to include also economic, social, and environmental dimensions (Buzan/Wæver/de Wilde 1998; Wæver 1995, 2008, 2008a) and deepened to include not only the nation state (‘national security’) but also other referent objects, such as human beings or humankind (‘human security’), the society (‘societal security’), the micro or macro region (‘regional security’), the international or global domain (‘international’ or ‘global security’).

Since the oil crisis of 1973, ‘energy security’, and especially the access to and supply of fossil fuels, has become a key concern of policies of governments and

international organizations (IEA, OECD, NATO, EU) alike. Not surprisingly, there is no consensus on an energy security concept, but in the opinion of this author, the aspect of risk should guide the analysis of energy security. Accordingly, ‘security’ is understood as the ‘absence of risk’ and risk as the ‘probability of an unwanted event’.³ Adopting this view, the seemingly different concepts of *energy supply security* and *energy demand security* are analytically identical. In both cases it is the minimization of risk, just the ‘unwanted events’ are – quite naturally – different, depending on the vantage point: *Energy supply security* focuses on the interest of states dependent on energy imports (chap. 23 by Jacoby), while *energy demand security* reflects the interests of energy exporting states in a stable oil or gas rent (chap. 29 by Selim/Sohar).

In 2005, during an IEA/NEA (OECD) workshop on “Security of energy supply for electricity generation”⁴, Bertel (2005: 4) saw the security of energy supply not as an academic issue but as a prerequisite:

from a decision-making viewpoint, for designing adequate policy measures to ensure security of supply and for monitoring their effectiveness. ... The notion of security of energy supply ... may be defined in a broad sense as the lack of vulnerability of national economies to volatility in volume and price of imported energy. ... Security of energy supply has economic, social, and political dimensions at the same time. Energy system analysts and economists can define the economic aspects, but the social and political dimensions are more difficult to capture. In addition, the analysis of energy system evolution shows that national policies aiming at security of energy supply have different objectives depending on the country context and global situation, and therefore follow different approaches. It is

1 The author gratefully acknowledges the contribution of Hans Günter Brauch to the conceptualization of energy security.

2 “Sicherheit”, in: *Brockhaus Enzyklopädie*, vol. 20 (Mannheim: F.A. Brockhaus, 1993): 227–229.

3 See the Oxford Dictionary at: <<http://physchem.ox.ac.uk/MSDS/glossary>>.

4 See for a documentation of this workshop at <<http://www.nea.fr/html/ndd/security/index.html>>.

generally agreed that insecurity of supply may result not only from physical disruptions, but also from increases in the prices of imported energy products. Physical disruptions may be caused by insufficient production or transport capabilities resulting from natural causes, socio-political conflicts or by abuse of market power on the part of monopolistic or oligopolistic producers. Similarly, a price increase might result from market mechanisms – demand exceeding supply – or from political decisions.

To illustrate how the concept of energy security can also be analysed from the level of the international system, of a political region (e.g. ‘European security’) of the nation state (‘national security’) but also from the perspective of the individual and social groups (‘human security’), US Senator Lugar on 13 March 2006 called for a “new realism” in US national ‘energy security’ pointing to six threats: a) vulnerability of oil supplies to natural disasters (Hurricane Katrina) and terrorist attacks, b) decline in oil and gas supplies, c) use of energy as a weapon by suppliers, d) oil as a means to prevent democratic reforms, e) the threat of climate change, and f) high costs of oil. Senator Lugar called for a shift from a narrow concept of US national energy security focused on oil at affordable prices, instead US “long-term security and prosperity require sufficient, affordable, clean, reliable, and sustainable energy”.⁵

As adopted here, these six threats describe unwanted events from the perspective of consumers. Addressing energy security from a balanced view, the perspective of demand security must be added that would include threats like a) abrupt reductions of oil and gas demand, b) use of ‘sunk costs’ as a weapon against the owners of transportation infrastructures to put pressure on energy prices, and c) energy prices too low to allow for returns on investments (in production and transportation infrastructure, for example). A global approach to increasing energy security would aim at minimizing the joint probabilities of all sides’ unwanted events.

In any case, the actors in such a global energy security management are likely to orient their assessment of the (subjective) probabilities involved in this exercise according to scenarios of future developments. Thus, energy projections have always played a major role in longer-term national security considerations (chap. 32 by Linkohr) but also in short- and me-

dium-term policy decisions of governments and international organizations (IEA, EU).

In the light of this observation, this chapter employs the concept of long-term energy security using quantitative indicators that are derived from existing long-term E3 (energy-economy-environment) scenarios. The aim is to reflect both the access to fossil fuels (‘economic security’) but also the impact of their use on the environment (‘environmental security’) and specifically on anthropogenic climate change. Using terms quoted above, these two criteria reflect ‘the availability of sufficient energy sources at affordable cost’, and we note that we explicitly include external (most importantly environmental and human health-related) cost into our consideration.

This overview will use long-term E3 scenarios from a perspective of energy security and draw conclusions for the strategic design of long-term energy supply strategies. By focusing on the long-term future excludes issues that are an issue for near-term political action, but this omission should not be seen as a failure as these issues are anyway covered elsewhere, as the issue of strategic energy reserves (chap. 23 by Jacoby) or the loss of economic output as a consequence of volatile prices (Awerbuch/Sauter 2006).

From a long-term global perspective, ‘conventional’ interruptions of energy security – such as natural catastrophes or anthropogenic interference – are only random oscillations. Thus, a long-term assessment of energy security does not focus on risks connected with random oscillations themselves but rather on the factors determining the vulnerability of energy systems to these oscillations. Linking this observation with scenarios of global energy demand and supply suggests thinking about the issue in terms of ‘potential security’⁶, of given long-term E3 scenarios rather than just ‘security’. This distinction properly accounts for the difference in temporal scope, and the notion of potential security is related to politically accepted risk connected with scenarios of global development.

One essential point of long-term scenarios – such as those prepared by IIASA and summarized in Schrattenholzer/Miketa/Riahi/Roehrl/Strubegger/Totschnig/Zhu (2004) – is quantification. Accordingly, this chapter uses quantitative information (indicators) to dis-

5 See speech by Senator Lugar on 13 March 2006 at the Brookings Institution on: “U.S. Energy Security – A New Realism”, at: <<http://lugar.senate.gov/energy/press/speech/brookings.html>>.

6 To think of potential security instead of unqualified security does justice to the observation that more factors than those included here will influence the actual energy security in the course of the 21st century. At the same time it acknowledges that long-term security is more abstract than actual and near-term security.

cuss the implications of long-term E3 scenarios for energy security. For reasons of transparency, the process of selecting indicators is described by first giving a comprehensive list of indicators that were used by Schrattenholzer/Miketa/Riahi/Roehrl/Strubegger/Totschnig/Zhu (2004) to characterize E3 scenarios. These indicators include

- Global and world-regional population
- Global and world-regional GDP growth
- Equity
- Primary-energy demand
- Resources-to-production ratios
- Cumulative CO₂ emissions
- Atmospheric CO₂ concentration
- SO₂ emissions
- Global temperature change 1990 to 2100

These items are all connected with IIASA's MESSAGE model⁷. Some of them are model inputs while others are model results. The causal relationships between assumptions and results are described in Schrattenholzer/Miketa/Riahi/Roehrl/Strubegger/Totschnig/Zhu (2004), and in many primary publications. Here is no room for classifying these indicators as assumptions or results. Rather, the scenarios are presented as portraits of future developments without detailed explanations of the logic that led to their formulation, and only the context of those indicators is explained that were selected to best characterize energy security, that is *equity* and *resource-to-production ratios*.

In the author's judgment, these two capture important features of other important indicators included above. Definitions and a discussion of their significance for energy security follow in 24.2. Section 24.3 presents typical scenario results and discusses them from the perspective of energy security, and section 24.4 assesses the implications of energy scenarios on international, regional, national security.

24.2 Defining Two Indicators Properly

Above equity and resource-to-production ratios were presented as the preferred indicators of energy security in long-term E3 (energy-economy-environment) scenarios. It remains to motivate this choice and to give a proper definition of the indicators.

⁷ An overview description of MESSAGE is given in the appendix of Schrattenholzer/Miketa/Riahi/Roehrl/Strubegger/Totschnig/Zhu (2004). A user's guide of an earlier version of MESSAGE is found in Messner/Strubegger (1995). A new user's guide is in preparation.

A *resource-to-production* (R/P) ratio is a hypothetical number measuring, for any given year and any given resource, the amount of the given resource left for consumption ('in the ground'), divided by the annual consumption in that given year.⁸ The R/P ratio is therefore expressed in years and signifies the time until the complete exhaustion of the resource. This time span is informative, but highly hypothetical because it would be quite unrealistic to assume constant future consumption and its sudden end at the same time. In general, low values of this indicator suggest a stress on resources and thus an increased risk of supply disruptions, but the indicative power of this number is also a function of the size of the denominator: A high R/P ratio can thus be the consequence of either large amounts of resources or low consumption in the year in question.

This chapter shall focus on the R/P ratios in the year 2100 for crude oil and natural gas.⁹ It is plausible to interpret higher R/P ratios as higher energy security, no matter whether the high value of this indicator is due to the large size of resources left for global consumption after the year 2100 or due to low levels of consumption in that year. If, for instance, the R/P ratio for crude oil is high due to low consumption in the year 2100, then even low amounts of remaining resources should not be considered as a major threat to energy security.

To illustrate the past behaviour of oil and gas resources, figure 24.1 depicts the development of oil and gas consumption, remaining reserves, and their

⁸ A more commonly used indicator is the reserves-to-production ratio. The difference between the two is based on the distinction between resources and reserves. According to this distinction, reserves are only that part of resources that are known to exist and that can be produced at competitive cost. When talking about a time span reaching almost a century into the future, it appears more appropriate to speak of resources instead of reserves and to think of something like 'ultimately recoverable reserves'.

⁹ We leave coal and uranium out of consideration here because coal resources are so redundant that their R/P is much less relevant than those for crude oil and natural gas. Uranium stands for resources of nuclear energy, but the size of this resource crucially depends on the technology used for its utilization. This touches on the issue of breeder reactors, which is considered outside the scope of this chapter. Let us just remark that in a scenario in which breeder reactors are considered an acceptable option for energy supply, energy security will be enhanced, although nuclear safety may become a bigger issue at the same time.

Figure 24.1: Annual Production and Known Reserves of Crude Oil and Natural Gas (1945-1995). **Source:** Nakicenovic/McDonald/Grübler (1998).

respective reserves-to-production ratios between the years 1945 and 1995. In both cases, the general trend of the reserves-to-production ratios is upwards – the consequence of rising prices and technological progress in exploration and production.

Equity was selected as the second indicator of energy security implied by long-term E3 scenarios on the basis that increased equity provides for a generally more peaceful global environment than an inequitable world. Obviously, the risk of harmful human intervention with energy supply is less of a risk in a more peaceful world. As an indicator of (intra-generational) equity we have chosen the ratio of average GDP per capita in today's developing regions and today's industrialized world regions. In 1990, this ratio was approximately six per cent. For the purposes of this chapter the *equity indicator* of a long-term E3 scenario is defined as the value of the corresponding GDP-per-capita ratio in the year 2100.

For both indicators higher values point to higher long-term potential energy security.

24.3 Typical Results of Long-Term Energy-Economy-Environment Scenarios

This section uses scenarios that were designed and published by the *Intergovernmental Panel on Climate Change* (IPCC). More precisely, all illustrative scenarios used here are included in the *Special Report on Emission Scenarios* (SRES; Nakicenovic/Swart 2000) or in the *Third Assessment Report* (TAR; Metz/Davidson/Swart/Pan 2001). The SRES scenarios were developed to represent the range of driving forces and emissions in the scenario literature so as to reflect cur-

rent understanding and knowledge about underlying uncertainties. The TAR scenarios included here were designed to analyse the consequences of imposing limits on the atmospheric concentration of greenhouse gases on selected SRES scenarios.

A detailed presentation of the IPCC scenarios is beyond the scope of this chapter, but explaining the naming convention used in the IPCC reports gives an important clue to their understanding. All scenario names include a combination of one of two letters ('A' and 'B') and one of two digits ('1' and '2'). These two pairs of identifiers characterize the scenarios along two independent dimensions. 'A' denotes a scenario world that emphasizes economic development more than the environment and 'B' the converse. The identifier '1' refers to a more globalized world whereas '2' refers to a more regionalized world. More will be said below about the characteristics of specific scenarios, but readers are referred to the original publications for more detailed descriptions.

For the assessment of the long-term *energy-economy-environment* (E3) scenarios with respect to their energy security implications, it appears useful to further distinguish the following three scenario groups: a) *sustainable-development scenarios* (24.3.1), b) *mitigation scenarios* (24.3.2); and c) *high-impact scenarios* (table 24.1).

Briefly speaking, *sustainable-development (SD) scenarios* meet a formalized set of criteria presented and discussed below; *mitigation scenarios* are the result of imposing greenhouse gas concentration limits on existing reference scenarios; and c) *high-impact scenarios* feature high environmental impact of energy conversion and use.

Table 24.1: Typology of Long-Term Energy-Economy-Environment Scenarios according to IPCC-SRES. **Source:** Nakicenovic/Swart (2000); Metz/Davidson/Swart/Pan (2001).

Types of scenarios ŷ »family of scenarios	Sustainable development scenarios	Mitigation scenarios	High-impact scenarios

SRES-B2			SRES-B2
SRES-A1	SRES-A1T	A1B-500 A1C-550	SRES-A1B SRES-A1C SRES-A1G
SRES-A2		A2-550	SRES-A2

24.3.1 Sustainable Development Scenarios

24.3.1.1 Definitions

For the purpose of this chapter it suffices to use a definition of sustainable development only to the extent that it applies to long-term E3 scenarios.¹⁰ According to this definition (Klaassen/Miketa/Riahi/Schrattenholzer 2002: 553), sustainable development scenarios are defined by satisfying the following four criteria:

1. *Economic growth*, expressed in terms of GDP per capita, is sustained throughout the whole time horizon of the scenario.
2. *Socio-economic inequity* among world regions (that is, intra-generational equity), expressed as the world-regional differences of GDP (gross domestic product) per capita, is reduced significantly over the 21st century, in the sense that by 2100, the per capita income ratios between all world regions are reduced to ratios close to those prevailing between OECD countries today.
3. *Long-term environmental stress* is mitigated significantly. In particular, carbon emissions at the end of the century are approximately at or below the emissions in the year 2000. Other greenhouse gas emissions may increase, but total radiative forcing, which determines global warming, is on a path to long-term stabilization. Other long-term environmental stress to be mitigated includes impacts on land use, e. g., desertification. Short- to medium-term environmental stress (e. g., acidifica-

tion) may not exceed critical loads that threaten long-term habitat well-being.

4. The *reserves-to-production* (R/P) ratios of exhaustible primary energy carriers do not decrease substantially from today's levels. This criterion reflects the principle of inter-generational equity.

This definition is consistent with the 'Brundtland definition' according to which sustainable development means "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED 1987: 54). At the same time it is also sufficiently quantitative to serve the purpose of classifying long-term energy-economy-environment scenarios. This means that the quantities used for the working definition are either parameters or outputs of the models used for the scenario formulation. The two indicators chosen which characterize long-term energy security in this chapter are also found among those defining sustainable development scenarios.

24.3.1.2 Characteristics of Sustainable Development Scenarios

All three scenarios¹¹ of the *SRES-B1* family (Nakicenovic/Swart 2000) belong to the group of sustainable development scenarios. In these scenarios, sustainability is achieved by assuming *service-oriented prosperity*, while taking into account *equity and environmental concerns* without policies directed at mitigating climate change. Telecommunications and

¹⁰ A precise and comprehensive general definition of sustainable development would not only be beyond the scope of this chapter but also be controversial, because several competing definitions have been proposed by different authors.

¹¹ As the focus of SRES was on greenhouse gas emissions by the energy sector, these three scenarios reflect three different energy systems (for details see: Schrattenholzer/Miketa/Riahi/Roehrl/Strubegger/Totschnig/Zhu (2004) and for the IPCC-SRES see: Nakicenovic/Swart (2000)).

Table 24.2: Selected results and indicators of sustainable-development scenarios. Indicators of long-term energy security are emphasized. **Source:** Schrattenholzer/Miketa/Riahi/Roehrl/Strubegger/Totschnig/Zhu (2004).

Scenario	Equity		Primary Energy Demand, EJ			Natural Gas				Crude Oil			
	1990	2100	1990	2050	2100	1990		2100		1990		2100	
						Cons	R/P	Cons	R/P	Cons	R/P	Cons	R/P
SRES-A1T	0.06	0.64	352	1213	2021	72	58	196	127	139	43	77	178
SRES-B1	0.06	0.59	352	837	755	72	58	215	49	139	43	45	55
SRES-B1G	0.06	0.60	352	911	1157	72	58	244	40	139	43	53	44
SRES-B1T	0.06	0.59	352	819	714	72	58	166	81	139	43	48	54

information technology expand rapidly, giving less developed world regions important opportunities to progress rapidly. Economic production is thus characterized by rapid ‘dematerialization’, and the introduction of clean technologies eventually leads to hydrogen-based economies in all world regions. The *B1 scenarios* describe a rapidly converging world, emphasizing *global solutions* for environmental and social sustainability, including concerted efforts aiming at rapid technology development, technology transfer, dematerialization of the economy, and improving equity (both worldwide and within regions). World population projections are low in all B1 cases. Global GDP is considerably higher than in ‘regionalized’ scenarios in the ‘SRES-2’ families (A2 and B2), the concepts of ‘green’ GDP gaining increasing importance.

The A1T scenario¹², also developed in the IPCC-SRES (Nakicenovic/Swart 2000), portrays a ‘*post-fossil*’ sustainable development future with rapid cost decreases of solar and advanced nuclear technologies¹³ on the supply side, and mini-gas turbines and fuel cells used in energy end-use applications. In contrast to the B1 scenarios, A1T is characterized by very rapid economic growth, and hence, also comparatively high energy demands. A1T assumes medium levels of availability of oil and gas. This, together with the relatively fast turnover of capital, leads to the rapid diffusion of carbon-free and advanced decentralized technologies (e.g., solar PV), particularly in the second half of the century. Selected indicators of these sustainable development scenarios are summarized in the following table 24.2.

¹² ‘T’ here stands for (advanced) technology.

¹³ Advanced nuclear power plants are defined as technologies that produce energy with higher efficiency and increased (‘inherent’) safety compared to today’s nuclear-technology standards. They are therefore assumed to be generally acceptable by the society.

Overall, the two indicators of energy security – *equity* and *resources-to-production ratios of oil and natural gas* at the end of the 21st century – show very favourable values for the sustainable development scenarios. In particular, the equity indicator expresses that the income ratio between the industrialized regions and today’s developing regions drops from a factor of 15 to less than 2, quite plausibly reducing the risk of major threats to security in general and energy security in particular.

As to the reserves-to-production ratios of oil and natural gas, the results summarized in table 24.2 illustrate that high values of this indicator can be achieved in two principal ways, that is, either by high availability or by low consumption. The high availability of natural gas reserves ensures high R/P ratios despite production that will have increased by factors between 3 and 4 in the period from 1990 to 2100. For oil, high R/P values are the result of the year 2100 production levels that have dropped significantly when compared with 1990.

The highest R/P values are found in the A1T scenario. They reflect the assessment, published by Rogner (1996), that resources of conventional and unconventional oil and gas are estimated sufficiently high so that technological progress made within the 21st century could turn these resources into reserves¹⁴.

24.3.2 CO₂ Mitigation Scenarios

24.3.2.1 Definitions

For the CO₂ mitigation scenarios included here, carbon emission constraints equivalent to climate policies that lead to a stabilization of atmospheric CO₂ concentrations at 550 ppmv were defined.¹⁵ Although

¹⁴ See Rogner (1996) for detailed characterizations of these resources.

Table 24.3: Selected results and indicators of CO₂ mitigation scenarios. Indicators of long-term energy security are emphasized. **Source:** Schrattenholzer/Miketa/Riahi/Roehrl/ Strubegger/Totschnig/Zhu (2004).

Scenario	Equity		Primary Energy Demand, EJ			Natural Gas				Crude Oil			
	1990	2100	1990	2050	2100	1990		2100		1990		2100	
						Cons	R/P	Cons	R/P	Cons	R/P	Cons	R/P
A2-550	0.06	0.23	352	959	1571	72	58	254	48	139	43	52	25
B2-550	0.06	0.33	352	881	1227	72	58	332	30	139	43	58	12
A1B-550	0.06	0.63	352	1339	2505	72	58	342	62	139	43	122	80
A1C-550	0.06	0.64	352	1269	2188	72	58	117	37	139	43	59	29

this level was chosen for illustration purposes, it should also be noted that it roughly corresponds to twice the pre-industrial concentration level of 380 ppmv. Therefore, the widely known ‘climate sensitivity’ parameter – quantifying the global temperature increase as a consequence of this doubling – directly corresponds to the value of 550 ppmv. It should also be noted that limiting CO₂ concentrations in this way gives the scenarios flexibility in space and in time, which means that, in principle, mitigation can occur at any time and in any world region depending on where and when it is the cheapest to mitigate.

Since greenhouse gas emission reductions will have significant consequences for sustainable development, the distinction between the scenarios of this group and sustainable-development scenarios may be considered fine, but it appears justified by the fact that the mitigation scenarios often include distinctly non-sustainable features. This observation suggests that sustainable development is a more general goal than climate mitigation.

24.3.2.2 Brief Characterization of CO₂ Mitigation Scenarios

For the purposes of the analysis, the quantification of CO₂ concentration constraints was the only difference between the mitigation scenario and the corresponding reference scenario.¹⁶ Although it would have been arguably plausible to also make different assumptions about technological development in a mitigation scenario, this option was not chosen so as to

study the effect of emission constraints under *ceteris paribus* conditions. Selected indicators of the CO₂ mitigation scenarios (with a constraint on atmospheric CO₂ concentrations at levels of 550 ppmv in 2100) are summarized in table 24.3.

With respect to the indicators of long-term energy security, we see here that the A2-550 and B2-550 scenarios show a comparatively poor performance with respect to equity. This, however, has nothing to do with the imposed concentration limits. Rather, it simply mirrors the indicators of the corresponding reference scenarios and the general design feature, mentioned above, that the ‘SRES-2’ family features less globalization and less economic growth than the scenarios in the ‘SRES-1’ family. The reserves-to-production ratios for natural gas could be considered satisfactory. For oil, the values of this indicator appear less comforting, particularly in the B2-550 scenario. However, as the A1B-550 scenario shows, long-term energy security can be high also in a scenario that does not belong to the group of sustainable development scenarios.¹⁷

24.3.3 High-Impact Scenarios

This group comprises all scenarios that cannot be categorized in the other two groups. It is also the biggest group of scenarios included here. In contrast to sustainable-development and CO₂ mitigation scenarios, which have distinctive normative elements, the high-impact scenarios are, in general, more descriptive than prescriptive (that is, normative). Many of them can be considered as ‘*dynamics as usual*’ scenarios. In other words, no new major global efforts to

15 The Third Assessment Report of the IPCC (Metz/Davidson/Swart/Pan, 2001) also reports scenarios with concentration limits of 450, 650, and 750 ppmv respectively.

16 Accordingly, the name of the mitigation scenario is the name of the corresponding reference scenario, extended by a suffix identifying the concentration limit included.

17 See Schrattenholzer/Miketa/Riahi/Roehrl/Strubegger/Totschnig/Zhu (2004) for a more detailed discussion of the difference between greenhouse gas abatement and sustainable-development scenarios.

achieve climate stabilization or sustainable development are assumed. As a technical characterization, it can be said that scenarios in this group are often used to quantify baselines relative to which the difference – expressed in terms of cost and benefits – between increased efforts and reference policies is quantified. As a result of this categorization, scenarios in this group feature the highest greenhouse gas emissions.

24.3.3.1 Brief Characterization of High-impact Scenarios

The SRES-A1 family contributes three scenarios to this group. Like the sustainable development scenario of this family (A1T, see the characterization above), the high-impact scenarios are characterized by *very* rapid economic growth¹⁸, combined with low population growth (according to Lutz/Sanderson/Scherbov 1996: 361 and Lutz/Sanderson/Scherbov 1997: 803). World-regional average incomes per capita converge to the extent that ‘poor’ countries virtually disappear. The A1 world exhibits much higher energy demands, a consequence of assumed lower energy prices. Also, the higher incomes assumed for A1 encourage comfortable and convenient (often energy-intensive) lifestyles.

The SRES-A2 scenario foresees future developments toward a very heterogeneous (regionalized) world, characterized by high population growth in the developing regions, self-reliance of world regions in terms of resources, and less emphasis on economic, social, and cultural interactions between world regions. Eventually, the world ‘consolidates’ into a series of economic trade blocks. Compared to the other scenarios in this high-impact group, A2 is characterized by relatively slow capital stock turnover, slower technological change, and a more slowly narrowing income gap between today’s industrialized and developing countries. High-income but resource-poor regions shift toward advanced post-fossil technologies, while low-income resource-rich regions generally rely on traditional fossil technologies. This leads to steadily increasing levels of GHG emissions, with CO₂ emissions approaching 28 GtC in 2100. For comparison, global GHG emissions in the year 1990 were approximately 6 GtC.

The SRES-B2 scenario world is one of high concern for environmental and social sustainability. In contrast to the sustainable development in the B1 scenario family however, inter-national institutions decline in importance, with a shift toward local and regional decision-making structures and institutions, which favours local and regional pollution control. In the B2 world, most of the world’s economic growth takes place in today’s developing countries but leads only to a moderate convergence in productivity and income levels over world regions. In terms of population, technological change and energy use, B2 is clearly a *dynamics-as-usual* scenario. Population follows historical trends (including recent faster-than-expected-earlier fertility declines) toward a completion of the demographic transition within the next century (UN 1998). Between 1990 and 2100, global primary-energy demands increase by a factor of four, mainly due to demand increases in today’s developing regions. However, contributions to supply increase significantly for some energy carriers, in particular wind power generation and solar photovoltaic, but also for gas combined-cycle power plants, integrated gasification combined-cycle (IGCC), solar thermal power plants, and advanced nuclear power plants.¹⁹ Global GHG emissions in B2 increase approximately along a straight line with CO₂ emissions reaching 14 GtC by 2100. Selected indicators of these high-impact scenarios are summarized in table 24.4.

From the inclusive definition of high-impact scenarios one might expect that indicators might cover a wide range of values. As far as the unfavourable side (the low end) of the indicators is concerned, however, we do not find any values that are lower than those we have already seen in the other two groups of scenarios described above. On the favourable side (the high end), we find R/P ratios (for oil in SRES-A2 and for natural gas in SRES-A1G) that are higher than any of the according values above, but they appear in a range where their magnitude is anyway beyond critical values for energy security.

24.4 General Conclusions and Policy Implications

Looking at these results from the perspective of energy security it should be noted that typical long-term

18 In the A1 scenarios, the global economy is projected to grow at an average annual rate of 3 per cent to 2100, which corresponds to a replication, in today’s developing countries, of the post-World War II growth of Japan and South Korea.

19 The same safety features of nuclear technologies as in the sustainable development scenarios are assumed here.

Table 24.4: Selected results and indicators of high-impact scenarios. Indicators of long-term energy security are emphasized. **Source:** Schrattenholzer/Miketa/Riahi/Roehrl/Strubegger/Totschnig/Zhu (2004).

Scenario	Equity		Primary Energy Demand, EJ			Natural Gas				Crude Oil

E3 scenarios are built with a positive attitude in the sense that catastrophic scenarios are left out of consideration. This may lack the spirit of risk analysis, but we think that it is justified on several grounds. First, analytically, scenarios featuring catastrophes would be too trivial to produce interesting or non-expected results. Secondly, when looking at the future as an opportunity for constructive planning, it appears obvious to focus on catastrophe-free global developments.

Drawing policy conclusions based on long-term analyses must be different from those based on an analysis of immediate consequences of policy action aimed at immediate effects. The simple reason is that aiming at a situation occurring decades away in the future requires the following of a decision *style* rather than simply implementing decisions on one or the other project. Accordingly, we propose to think of ‘potential security’ of long-term E3 (*energy-economy-environment*) scenarios rather than of an actual degree of security in a given situation, which would anyway be difficult to predict for any given future point in time.

As indicators of such a potential energy security we have proposed (1) resource-to-production ratios, in the year 2100, of crude oil and natural gas, and (2) an indicator of equity. These indicators were chosen from a larger set of indicators that were, in many reports, designed to characterize driving forces and results of long-term E3 scenarios. It should not come as a surprise that the indicators chosen for the quantification of an energy security potential coincide with two of four criteria proposed in an IIASA paper (Klaassen/Miketa/Riahi/Schrattenholzer 2002: 553) to define sustainable-development E3 scenarios. We can therefore note immediately that, accordingly, pursuing long-term energy security pursues sustainable development at the same time. In other words, a truly sustainable energy supply system minimizes the risk of

a dangerous exhaustion of energy resources and thus contributes in a major way to energy security.

The general policy conclusion therefore is that a decision-making style that favours sustainable development overlaps considerably with one that aims at energy security in an isolated way. In more concrete terms, drawing conclusions from the importance of equity for long-term energy security suggests that policies aiming at a more equitable world will increase the energy security potential while contributing to sustainable development at the same time. The results of the long-term E3 scenarios summarized here suggest that the converse is not necessarily true, that is, equity – and, thereby, energy security – can thrive in a world that need not be on a sustainable development E3 path. The SRES-A1C scenario, which scores high on the ‘equity’ indicator but low on environmental sustainability, can serve as an example for this combination.

It must be noted that of course, equity is a normative input to the formulation of scenarios, and not a result. Its use as an indicator (of long-term energy security and sustainable development alike) could therefore be regarded to have some flavour of a truism. While this observation may limit the usefulness of this indicator as policy guidance, it was judged that nonetheless, it is useful also to policymakers to include equity as an important characterization of sustainable-development scenarios, which, as it is argued, suggests high long-term energy security.

The policy implications from analysing the second indicator of long-term energy security – resources-to-production (R/P) ratios of oil and natural gas – appear less trivial. The policy recommendations based on the analysis of scenarios with high R/P ratios (implying high potential long-term energy security) refers to the well-known dual character of technology as a problem and its solution at the same time. Taking the

SRES-A1T scenario - which was considered one of the most attractive sustainable development scenarios and therefore discussed in detail in Schrattenholzer/Miketa/Riahi/Roehrl/Strubegger/Totschnig/Zhu (2004) - as an illustration, we can see how technological progress, driven by a global dedication to environmentally compatible E3 systems, results in a sustainable-development E3 scenario that needs no further policy constraints for its realization. Using a well-known metaphor, A1T could be seen as a sustainable-development scenario that is mostly realized by the 'carrots' of successful technology policy without having to resort to the 'sticks' of stringent environmental legislation. The same general conclusion thus holds for pursuing long-term energy security.

25 Projections of Fossil Energy Reserves and Supply until 2050 (2100): Implications for Longer-term Energy Supply Security

Werner Zittel and Joerg Schindler

25.1 Introduction

Conditions of the world's oil supply have entered into a new phase: increasing demand pressure, worries about the security of supply in important oil producing countries, speculative factors, but particularly, clear indications that limitations on the supply side have caused unexpected and high price increases. This chapter argues that the world oil production is nearing its peak. Since crude oil is presently the most important primary energy source, this will have great implications on the availability of energy sources in the coming decades. The situation with natural gas is not much better and thus natural gas is no substitute for a declining oil supply. Based on these analyses (Schindler/Zittel 2000; Zittel/Schindler 2005) *fossil fuel supply scenarios* for the coming decades are sketched (Schindler/Zittel 2006). According to these scenarios the availability of fossil fuels is reaching its limit and an overall decline is highly probable.

Energy supply is not primarily a regional or political question which can be analysed as 'access to resources', rather the finiteness of fossil resources will unfold in the coming decades. A possible solution is an intensive use of renewable energy sources which could grow much faster than generally assumed. This will also be outlined in a rough scenario. But even in the best case this will not be sufficient to compensate for the fossil gap. This is true for the next few decades but potentially less problematic later on. The world is entering a transition phase from a fossil energy world to a post-fossil - renewable - future. But it is unlikely that this transition will be easy or smooth.

After peak oil and peak gas the supply of oil and gas will be physically constrained and will decrease over time. In a very basic sense the supply of vital energy sources is not secured anymore. As a consequence the competition for the remaining resources will intensify. Will this competition then follow other rules than is done today? Today the distribution and

use of oil and gas is determined by market forces, i.e. the ability and willingness to pay.

Will the distribution after peak be determined to a significant degree by military force and is it conceivable that this will 'work'? The 'success' of the military option is very doubtful for a number of reasons. One consequence would be the further growth of terrorism which would further decrease the supply (as can be seen in Iraq). Another consequence would be the repercussions on energy markets which are not predictable and might lead to severe economic disruptions endangering free trade. A final question may be appropriate: Would the supply and distribution of oil from the Middle East be different if the USA were not engaged militarily in the region?

The chapter analyses the empirical evidence of the imminent peak oil production and the subsequent declining supply (25.2), reviews the probable future natural gas supply (25.3), and discusses the future supply potential of coal, nuclear and renewable energy technologies (25.4). Then a scenario is offered for the future most probable energy supply (25.5) that is not intended to provide exact numbers, but to sketch the major trends and challenges arising over the next decades (25.6).

25.2 Oil Supply

25.2.1 General Pattern of Oil Production

The different phases of oil production can be described as follows: In the early phase of the search for oil, the easily accessible oil fields are found and developed. With increasing experience new oil fields are detected more systematically. This leads to a boom where ever more new fields are developed, initially in the primary regions, later on all over the world. Those regions which are more difficult to access are explored and developed only when sufficient new oil

cannot be found anymore in the easily accessible regions. As oil prospecting is linked to production, in general shortly after the discovery of new fields their development will begin. With increasing production the pressure of an oilfield diminishes and the water levels rise, and after some time the production rate begins declining. This trend can be controlled to a certain extent and the decline in production can be delayed or reduced: by injecting gas or water into the reservoir in order to increase the pressure, by heating the oil, or by injecting chemicals in order to reduce the viscosity of the oil.

In every oil province the big fields will be developed first and only afterwards the smaller ones. Once the first big fields of a region have passed their production peak, an increasing number of new and generally smaller fields must be developed to compensate the decline of the production base. Then it becomes increasingly difficult to sustain the rate of production growth. A race begins which can be described as follows: More and more large oilfields show declining production rates. The resulting gap must be filled by a larger number of smaller fields which reach their peak much faster and then contribute to the overall production decline. Thus, the region's production profile resulting from the aggregation of the production profiles of the individual fields becomes more and more 'skewed', the aggregate decline of the producing fields becomes steeper and steeper. This decline must be compensated for by a faster connection of more and more ever smaller fields.

The production pattern of an oil province over time can be characterized as follows: To increase the oil supply will become more and more difficult, the growth rate will decline and costs will rise until a point is reached where the industry is unable to bring into production a sufficient number of new fields fast enough. Then, production will stagnate temporarily and eventually start to decline. This pattern can be observed in many oil provinces. Sometimes this general pattern was not followed: either because the timely development of a 'favourable' region was not possible for political reasons, or because of huge surplus capacities so that production was held back for a longer time period. But the more existing spare capacities are reduced, the closer the production profile will follow the described pattern.

In the history of oil production, for more than 150 years, some fundamental trends can be identified (Campbell/Laherrere 1995; Deffeyes 2001; Campbell/Liesenborghs/Schindler/Zittel 2002):

- The world's largest oilfields were all discovered more than 50 years ago.
- Since the 1960's annual oil discoveries had a declining tendency.
- Since 1980 annual consumption has exceeded new annual discoveries.
- Until now more than 42,000 oilfields have been found, but the 400 largest (1 per cent) contain more than 75 per cent of all oil ever discovered.
- The historical maximum of oil discoveries reaches after some time a maximum of oil production ('peak').

How near is the peak? How steep is the decline after the peak? These are crucial remaining questions for the discussion of major oil producing regions of the world.

25.2.2 Countries outside OPEC and the Former Soviet Union (FSU)

Globally the development of different oil regions occurred at different times and at varying speeds. Now, production regions in different development stages can be identified and the above patterns can be exemplified by empirically validating the concept. Nearly all major movements in the oil markets over the last eight years can be explained well with this pattern, while other attempts to explain the changing situation over the last years had to refer to 'unexpected market changes', 'speculation', 'unforeseen growth of consumption', etc.

Total production of the countries outside of the *Former Soviet Union (FSU)* and *Organization of Petroleum Exporting Countries (OPEC)* increased until the year 2000, but since then total production has been declining. A detailed analysis of the individual countries within this group shows that most of them have already reached their production peaks, and that only a very limited number of countries will still be able to expand production, particularly Brazil and Angola.

Responsible for the stagnation of oil production in this group of countries was the peaking of oil production in the North Sea, which occurred in 2000 (in 1999 in Great Britain, in 2001 in Norway).¹ Outside the OPEC and Former Soviet Union (FSU) countries, onshore oil production had reached a plateau much earlier, and has been declining since the mid-1990's.

1 Werner Zittel: "Analysis of UK Oil Production", February 2001, at: <www.peakoil.net> and <www.energiekrise.de>.

Figure 25.1: Oil production of countries/regions outside OPEC and FSU (Denmark, UK, Canada, Norway, Alaska, USA, Mexico, Brazil, Argentina). Estimates for 2005 based on government statistics for January–November, analysis and projection by LBST. **Source:** IHS (2003); BP St. Rev. (2005).

This decline could be balanced by the fast development of offshore fields which now account for almost 50 per cent of the production of all countries in this group. The North Sea alone has a share of almost 40 per cent of the total offshore production within this group. The peaking of the North Sea was decisive because the following production decline could not be overcompensated anymore by a timely connection of new fields in the remaining regions – it was only possible to hold the plateau for a few years.²

Crucial for the further development was the production peak of Cantarell in Mexico, the world’s biggest offshore field. This field, discovered in 1978, still contributes more than half of the Mexican oil production. It reached a plateau for some years and started to decline in 2005. Also the quality of the oil produced in Mexico has degraded steadily. Today, the share of light oil has halved since 1997.

The example of Indonesia is of particular interest, the only OPEC member which is included in this group of countries, because in March 2004 for the first time more oil was imported in this country. Oil production in regions having passed their peak can be forecasted with some certainty for the next 10 years.

If it is assumed that the remaining regions with growth potential (Angola, Brazil, Gulf of Mexico) will considerably expand their production by 2015 (based on optimistic forecasts of companies operating in these regions), but total oil production of these countries will decline by 10–15 Mb/day by 2015.

As the production of conventional oil is declining, these countries (figure 25.1) will supply additional amounts only from non-conventional sources. Non-conventional oil sands in Canada and heavy oil in Venezuela will contribute 3–4 Mb/day in 2015, provided that the already announced expansion plans will be realized without any further delay.

25.2.3 Former Soviet Union (FSU)

Oil production in the Former Soviet Union peaked at a production rate of more than 12 Mb/day at the end of the eighties. Soon afterwards production collapsed by almost 50 per cent within 5 years. The production peak at the end of the eighties had been forecasted by western geologists based on the depletion patterns of the largest oilfields (Masters/Root/Attanasi 1990). However, the following production collapse during the economic breakdown was much steeper than expected. After the liberalization of the oil market, Russian companies were able to stop this decline and to

2 This analysis is based on the database PEPS from IHS-Energy, edition 2003.

increase production levels again – at double-digit rates between 2000 and 2001 – with the help of international cooperation and investments. However, this fast recovery has now come to an end as the easily accessible fields have been developed and the financial and technological backlog is widely closed. The strong growth rates of Russian production in recent years have contributed by compensating for the inescapable production decline in other regions of the world. But the growth of Russian production is now coming to an end.

The two other important oil regions of the Former Soviet Union are Azerbaijan and Kazakhstan. Azerbaijan is the oldest industrial oil region of the world. Its highest production rates were reached in the 1960's. Now an expansion of production can only be expected offshore. Here the field complex Azeri-Chirag-Guneshli must be mentioned. Once fully developed, this field will probably reach its maximum by 2008 or 2009, with a production rate of 1 Mb/day. Soon thereafter the production rate will decline very fast to negligible amounts within 10 to 15 years. But the total production of this region will increase by a smaller amount as 150.000 bbl/day are already produced from Azeri-Chirag-Guneshli today, and as the production from other fields will drop noticeably in coming years.³ For several years Kazakhstan was considered as a potential counterbalance to Saudi Arabia. But these hopes were exaggerated. They were nurtured by speculations of the US Environment Information Agency (EIA) which expected oil and gas reserves around the Caspian Sea amounting up to 300 Gb of oil equivalent. But only about 45 Gb of oil are likely, about half of this amount is located in already developed fields. Azerbaijan and Kazakhstan will at best be able to increase their production rate by 2015 – from 1.6 to 3.0 Mb/day – but more seems unrealistic.

According to this assessment, the whole region may be able to increase its production in the coming years, but the very big expansion expected by some experts will not occur. A total production increase of 2–3 Mb/day is probably already on the high side.

25.2.4 OPEC Member Countries

The expected production decline in the above group of countries is partly offset by a possible expansion in Russia and in the Caspian Sea. But there still remains a gap of 5–10 Mb/day which must be closed to keep world oil production constant until 2015. Only the OPEC member countries may fill this gap. If the world oil consumption grows further, these additional amounts must also come from OPEC. According to conventional wisdom this will easily be possible for OPEC. But a production growth of 5–10 Mb/day within ten years constitutes a problem. Particularly as it is widely accepted that, apart from Iraq which cannot be considered to be a reliable oil producer for the time being, only Saudi Arabia will be able to increase its oil production significantly. This would require an expansion of at least 50 per cent of the Saudi Arabian oil production within very few years. This is a very ambitious goal, even for a country with an abundance of oil.

Moreover, in recent years the suspicion has grown that conditions for oil production in Saudi Arabia are not as favourable anymore and are getting more difficult. For the future production potential of Saudi Arabia, Ghawar, the world's biggest oilfield, plays a key role. This field was discovered in 1948 and has now been producing oil for more than 50 years. Meanwhile, more water is pumped into the field than oil is extracted, and it is possible that the production rate will decline in the near future. It is certain that Ghawar cannot contribute to an expansion of the Saudi Arabian production.⁴

Based on a comprehensive in-depth analysis of technical papers in the public domain addressing the problems of oil production in Saudi Arabia, and on a great number of interviews with engineers working on site, and also a visit of the oil fields in Saudi Arabia, Matthew Simmons (2004), an American investment banker (Simmons 2004), launched a debate whether Saudi Arabia will be able to increase its production significantly. If one applies the same criteria which are common practice in Western companies, then Saudi Aramco's allegation for proven reserves should be reduced by 50 per cent.⁵

3 AIOC (abbreviation) needs to increase investment in Azeri-Chirag-Guneshli oilfields. Alexander's Oil & Gas Connections, Company News: Central Asia, 28 August 2002.

4 For details see in: ASPO Newsletter, No. 40, April 2004; at: <www.peakoil.ie>.

5 Sadad al-Husseini, Saudi Aramco: "At the current depletion rate of 3 billion bbl/y, which represents 2.3 per cent of the remaining 130 billion bbl of proven developed reserves ..." quoted in: Aleklett (2004).

Table 25.1: Remaining proven oil reserves for 'ME Five', according to major estimates. **Sources:** [1] O&GJ, 19 December 2005 (for 1 January 2006); [2] BP, June 2005 (until end of 2004); [3] ASPO Newsletter, 62 (February 2006); [4] Bakhtiari (February 2006).

Country	Oil & Gas Journal [1]	BP Statistical Review [2]	Colin Campbell [3]	Bakhtiari [4]
Iran	132.5	132.5	69.0	35-45
Iraq	115.0	115.0	61.0	80 - 100
Kuwait	101.5	99.0	54.0	45 - 55
Saudi Arabia	264.3	262.7	159.0	120 - 140
UAE	97.7	97.8	44.0	40 - 50
TOTAL:	711.0	707.0	387.0	320 - 390

The problem of assessing the realistic reserves of the Middle Eastern (ME) oil producing countries is reflected in table 25.1. While O&GJ and BP mainly rely on published 'official' figures (which are often inflated), Campbell and Bakhtiari are based on detailed evidence (see: *ASPO Newsletter*, 63, March 2006). Bakhtiari is from Tehran and is one of the most reliable experts on ME oil reserves.

The analyses of Simmons and others argue that Saudi Arabia's potential to increase production will soon reach its limits. Also the potential of other ME countries is smaller than commonly assumed. The world is nearing the moment of truth.

25.2.5 World Oil Production Is Approaching Its Peak

The IEA (2005d) has published its latest scenario in '*World Energy Outlook 2005*'. In this scenario world oil production is projected to rise to 120 Mb/day by 2030. This is quite implausible as already today most world regions have either reached or passed their production peak. Once more and more regions shift from growing to declining production, it is getting increasingly difficult for the fewer remaining countries to compensate for this decline, let alone to add to total production. During the last 50 years the world has managed to increase global production per year from 5 Gb, by 25 Gb, to about 30 Gb. In half of this period it is assumed to be possible to increase yearly production by another 15 Gb! This is incredible due to the irreversible decline in major producing regions and a rate of new discoveries falling behind the production rate by a factor of about five. Given the remaining production potentials it is more likely that global oil production will never be able to exceed the 30 Gb level significantly, and only for a few years.

The German federal agency for earth sciences and raw materials (Bundesanstalt für Geowissenschaften

und Rohstoffe 2003; 104) has criticized the scenarios of the IEA and concluded: "The forecasts of EIA and IEA assume a continuous growth in oil consumption, without assessing sufficiently the real supply of oil and the production potential." In order to illustrate the possible availability of crude oil in coming decades two oil supply scenarios are defined:

- The 'high fossil' scenario is based on the ASPO production profile with a peak before 2010 and a moderate decline rate of 2–3 per cent per year.⁶
- The 'low fossil' scenario is based on the fears that future global decline rates will be higher than in the old mature oil regions (e.g. decline rates in Alaska and the UK are 5 to 10 per cent vs. 3 per cent in the 'lower 48' states of the USA). Accordingly, after peak in 2008 and plateau until 2010, a decline rate of 5 per cent per year is assumed between 2010–2020, of 3 per cent between 2020–2040, of 2 per cent until 2050, and of 1 per cent thereafter.

25.3 Natural Gas

Presently the world consumes two thirds as much gas as it does oil. But the substitution of declining oil supplies by natural gas would result in a drastic increase of gas consumption. Natural gas reserves and production rates can be analysed similar to oil. This leads to an estimate of possible future gas production rates and the probable timing of the peak gas supply. The main conclusion of this analysis is that the world's natural gas supply might peak about 20 years from now. If the production is increased at a faster rate, or future discoveries and stated 'proved' reserves are smaller than assumed in this analysis, the peak might

6 C. Campbell (2005) in: Association for the Study of Peak Oil, see at: <www.peakoil.ie>.

come earlier. If production is increased at a slower rate, then a few years would be saved until the inevitable start of decline.

This global 'top-down' analysis is somewhat theoretical because - unlike oil - natural gas is supplied and consumed in regional markets. Only 7 per cent of the total natural gas supply is globally traded in form of LNG. Production in these regional markets is determined by differing and specific supply conditions which are not correlated. Individual regional markets are better described with 'bottom-up' analyses of producing fields, ranking of fields by size, and their status of depletion. A full analysis must be included in the evaluation and interpretation of regional creaming curves of past discoveries (time series of the success ratio of exploration drillings). These analyses were published elsewhere (Schmidt/Weindorf/Wurster/Zereta/Zittel 2005).

At present, North America is the largest regional market with an annual volume of about 780 billion m³, amounting to almost one third of the world market. This market has already experienced its production maximum in the early 1970's, followed by a second smaller peak in 2001. But also in Europe, the second largest gas market, further expansion of consumption is getting more and more difficult as aggregate domestic supplies already have passed their peak. For example, UK gas production started to decline in 2001.

25.3.1 'Top-down' Scenario of the Global Availability of Natural Gas

Annual discoveries peaked around 1970 and are slightly declining since then (IHS 2005). In contrast, annual consumption is still rising and has already exceeded annual discoveries for several years (IHS 2005). Extrapolating the declining rate of new discoveries results in the assumption that a total of about 12,000 Tcf (~ 325,000 billion m³) might be discovered until 2100. Proven gas reserves are comparable in size to proven oil reserves (~ 160 Gtoe), but the already produced share is smaller (one third for gas against half for oil). Therefore the global production peak can be expected to happen later than for oil. A rough 'top-down' approach suggests that gas production will peak around 2025.

A bell-shaped production profile which fits the historical production pattern until 2004 and assumes the estimated total of 12,000 Tcf, results in a smoothly diminishing annual production growth rate which currently is at 2.5 per cent, and is projected to be at 1.9

per cent in 2010. If future growth rates are larger, the expected production peak would happen sooner, and vice versa. This extrapolation assumes that about 75 per cent of world gas reserves have already been discovered (compared to 90 per cent for oil). Future reserve reassessments and upward revisions of (older) already producing gas fields will only marginally influence this pattern, as they usually do not result in changes of the production profile of these fields (Laherrere 2006).

This 'top-down' analysis does not take into account the different quality of the gas fields. Especially it does not reflect the 'stranded gas' situated far away of existing transport infrastructures, or for low quality gas with a high content of CO₂ or SO₂. Stranded gas is presently not used for economic reasons. However, this could change with increasing gas prices. But this would also imply much higher costs for the development of these fields and for the conditioning of the produced gas, especially in case of liquefaction or upgrading into other liquid hydrocarbon fuels. The conditioning, transport, and upgrading of this gas would consume between 20-50 per cent of its energy content, depending on whether the gas is liquefied or transformed into synthetic crude oil, ammonia, methanol or hydrogen. This conditioning would reduce available gas reserves accordingly.

These additional problems and the lead times for the construction of the necessary infrastructure make it probable that the calculated production rate in this scenario provides an upper (optimistic) limit for the gas extraction curve shown in figure 25.2. Probably the peak will be sooner followed by a plateau lasting several years.

Natural gas liquefies at temperatures of below -160° C. At ambient conditions it is gaseous and can be transported best in pipelines. Therefore pipelines are the backbone of the established gas markets which have developed over time, connecting the major consumers with their supply regions. This regionalization is the main difference to crude oil. Oil can be transported very easily, which helps to equalize regional imbalances. The importance of the pipeline infrastructure leading to separate regional markets makes it questionable whether the above sketched 'top-down' approach provides the basis for a meaningful interpretation. Probably this scenario will never be realized. Regional supply scenarios are more important as they reflect regional supply problems. Though liquefaction is possible and will be expanded in the future, a much higher effort is necessary regarding energy, materials, investments, and lead times.

Figure 25.2: Annual gas production 1920-2004 and extrapolation based on a bell-shaped profile and an estimated ultimate recovery of 12,000 Tcf. Currently 3,000 Tcf have been consumed and proven reserves are at 6,300 Tcf. **Source:** History: IHS Energy (2005); projection: LBST (Schindler/Zittel 2006).

Below, the most important regional markets are sketched. North America and Europe together produce about 45 per cent and consume about 55 per cent of the world's gas. In both markets the supply situation has dramatically deteriorated during the last few years, coming as a complete surprise for economically oriented gas market analysts. The analysis of these regional markets provides a better understanding of possible future supply restrictions than the optimistic 'top-down' approach sketched above.

25.3.2 'Bottom-up' Scenario of the Global Availability of Natural Gas

25.3.2.1 North America

In North America natural gas has been used almost as long as oil. The natural gas market grew in parallel with oil production. Production and consumer regions are distributed all over North America. Natural gas production peaked in the US in 1972, and rapidly declined thereafter. But more wells were drilled in mature and new areas, with a doubling of active wells from 200,000 in 1985 to more than 405,000 in 2005, thus reversing the decline after 1985. But, since the mid 1990's this second production increase came to a halt, only the imports from Canada still grew. In 2001

the production in North America passed its peak and entered the decline phase.⁷ The declining domestic oil and gas production in combination with limited import capacities (new LNG terminals are planned but have long lead times to construct) probably will increase future supply problems. For many market observers and politicians an energy crisis looms over the horizon, with grave consequences for North American energy markets, the whole economy, and for other regions as well.

25.3.2.2 The United Kingdom

As newly developed fields cannot compensate for the decline of the base production, the UK gas production is in decline since 2001, and has already dropped by 20 per cent. Since new field developments are rare, the future production profile can be estimated with a high level of confidence. Until 2010 the total production will be 50 per cent below the level of 2000, and until 2015 another 30–50 per cent below the level of 2010, depending on the success of finding new fields. Very soon the gas supply of the UK will depend on imported natural gas. A large expansion of import ca-

⁷ US Department of Energy, Energy Information Agency, see statistics; at: <www.eia.doe.gov>.

Figure 25.3: Gas production forecast for Russia. **Source:** Laherrere (2003); LBST estimate (2004).

capacities must be provided with new LNG terminals. The oil and gas supply of the UK should be seen as a warning which demonstrates how soon the days of surplus production of oil and gas with their corresponding high export revenues can be followed by steadily rising imports.

25.3.2.3 Europe

Europe has passed its gas production peak. Even a 50 per cent increase of the Norwegian gas production cannot stop the overall decline. Europe is in need of rapidly rising imports from Russia, North Africa, or other parts of the world. According to this analysis, gas imports must rise at an annual rate of 5 per cent until 2020, just to keep the supply base flat. Future demand growth would require even higher rates. Even this zero growth scenario requires the construction and operation of about 4–5 new pipelines with a net import capacity of about 30 billion m³/year until 2020.

25.3.2.4 Russia

The required additional amounts of gas cannot come from Russia as the three largest fields (Urengoy, Yamburg and Medvezhye) – containing about one third of the discovered gas – are already in decline.⁸ It is very

questionable whether Russian gas production can still be expanded for a longer time period, based on a field by field analysis of Russian gas production since 1960 and a forecast until 2020.⁹ This forecast is based on already known but not yet developed fields and supposes a hypothetical time schedule for their development (figure 25.3).

The analysis leads to the conclusion that probably an annual production increase of 1 per cent can still be realized in the next 10 to 15 years. However, this requires a timely development of new fields. These fields are situated further north (Barents Sea, Kara Sea) or further east; their development will be much more time consuming and much more expensive than the development of the already producing fields. It is uncertain how much of this gas will be available for export to Europe, as Russian domestic consumption is expected to rise and East Asian countries (China, Korea, Japan) as well as North America will compete for imports.

25.3.2.5 Global Analysis

Performing such an analysis for all gas producing countries leads to the conclusion that probably worldwide gas production will peak when Russian gas pro-

⁸ Analysis of field production profiles by Jean Laherrere. The data are taken from Petroleum Exploration and Production Statistics (PEPS) from IHS – Energy, 2004.

⁹ Own analysis extrapolating the historical production data from IHS-Energy and adapting total production volume to the field size as provided in: IHS-Energy: *The World's Gas Potential 1995* (Campbell/Laherrere 1995).

Figure 25.4: Worldwide Gas production According to LBST Scenario Calculations. **Source:** IHS Energy (2005); BP Statistical Review of Energy (2005); Projection: LBST (2005).

duction peaks. Though some world regions will still expand their production beyond 2020 (e.g. Qatar and possibly Iran), the decline in North America and Russia probably cannot be compensated. A probable scenario for the global gas production until 2030 is shown in the figure. The graph shows the production volume of each major region (figure 25.4).

For the formulation of global energy scenarios two alternative global gas production scenarios are used:

- The first is the future gas production according to the Association for the Study of Peak Oil. It exhibits a production plateau between 2015 and 2040 at 3,000 Mtoe ($\approx 3,400$ billion m^3 or 35 per cent above the 2004 level).
- A second 'low fossil' scenario assumes that this peak production plateau can only be sustained for ten years until 2025, and will then be followed by a decline of 3 per cent per year.

25.4 Fossil Scenarios

The aggregation of the production histories and scenario projections for the different fossil and nuclear energy sources is shown in Figure 25.5. This view of how the supply situation may probably develop in the

next decades is biased to the high side. Oil production is assumed according to ASPO projections, gas production is taken from ASPO with a production plateau between 2015 and 2040 exhibiting a 35 per cent higher production level than today. Coal projections assume a bell-shaped profile based on the more probable R/P-ratio of 180 years and on the 'upper limit' 370 years. Even within this 'upper limit' scenario, a further growth of world energy supply comes to a halt as soon as gas production cannot rise any more. A further decline is unavoidable in the following decades.

The production of nuclear energy cannot reverse this trend. Projections for nuclear energy show the energy production from existing reactors and their phasing out after 40 years on average. For this figure, the conversion from nuclear electricity to primary energy is based on 33 per cent efficiency. However, more appropriately, nuclear should be treated as primary electricity, then being directly comparable to renewably produced electricity later on. The low share of only a few per cent and the resource base makes nuclear energy already irrelevant for the global energy supply situation, irrespective of whether its share is kept or not. Yet from a financial view it is very relevant whether budgets are directed to the nuclear industry or to other energy sources.

Figure 25.5: ‘High fossil’ scenarios of future production of fossil and nuclear fuels based on peak oil before 2010 and a decline after peak of about 2-3 per cent per year and a gas peak around 2040. **Source:** for oil and gas: Campbell/ASPO (2005); coal and nuclear scenario: LBST (Schindler/Zittel 2006).

In order to better understand the upper and lower boundaries of the possible future development, a ‘low fossil’ scenario is also formulated. Such a scenario is presented in figure 25.6. Oil starts to decline with 5 per cent annually between 2010 and 2020 and by 3 per cent until 2040, then declines with 2 per cent until 2050, and with 1 per cent thereafter. The plateau of world gas production is expected to end in 2025 (and not by 2040 as in the ‘high fossil’ scenario) with an annual decline rate of 5 per cent in the following ten years, and with 3 per cent thereafter. The growth of coal production is assumed to be smaller than in the ‘high fossil’ scenario, with a plateau at 3,600 Mtoe (not 4,600 Mtoe as before) lasting from 2020 to 2050 and followed by an annual decline of 1 per cent. In this ‘low fossil’ scenario the paramount importance of peak oil is demonstrated. Once oil peaks and then declines with 5 per cent per year, no other energy source will be able to stop the aggregate decline of supplies, even for a few years. This scenario is not unlikely.

The ‘high fossil’ scenario is regarded as being positive from an economist’s point of view but is certainly regarded as negative from an ecologist’s point of view. Even with fossil fuel consumption peaking around 2010, these high emission levels might remain constant for thirty years before they begin to decline. And the worst scenario with respect to greenhouse gas emissions (with an assumed R/P-ratio for coal of 370 years) maintains this emission level until the end of this century.

But both scenarios are not as bad as the “business as usual” scenarios calculated by the Intergovernmental Panel on Climate Change (IPCC). The

IPCC scenarios are not based on a corresponding available resource base. In contrast, the above described ‘low fossil’ scenario (Figure 25.6) would even support a climate protection policy as total carbon dioxide emission could drop by about 30 per cent until 2050 and by about 55 per cent until 2100.

The scenarios sketched here contradict the IEA scenarios as published in the “world energy outlook” (IEA 2005d). The basic difference is that the IEA scenarios (and most other scenarios) are demand driven, while the present scenario attempts to describe the upper limit of the evolution of the supply in the best case. The demand then has to adapt to the possible supply, while the IEA scenarios balance the calculated demand by fossil fuels, not accounting for their limited reserve base. As a consequence, the future role of renewable energy is highly underestimated by the IEA, seeing no need for their enforced market penetration. Only the role foreseen for nuclear energy in this scenario – at least over the next 25 years – does not deviate much from the view of the International Energy Agency.

25.5 Renewable Energy Scenario

Renewable scenarios can be built in various ways by extrapolating past trends and incorporating expected future changes. The International Energy Agency builds its scenarios primarily by using economic considerations in which no drastic price changes for fossil and renewable fuels are assumed. Therefore it is no surprise that no incentives for a rising contribution from renewables are foreseen. The IEA does not narrowly interpret its scenarios as forecasts, but still they tend to interpret them as more or less likely, and in any case as an upper boundary, for possible future developments.

In contrast, the following scenarios are calculated by extrapolating observed past growth trends and then limiting the further growth by taking into account the estimated total supply potential for the different technologies. These are in effect market penetration scenarios, but they do not represent a forecast, rather they describe what would be possible under most favourable market conditions (while still starting from the empirical data describing the past development). No assumptions are made regarding actual future market conditions. The resulting scenarios therefore show the technical limitations of possible future developments not regarding economic limitations.

Figure 25.6: 'Low fossil' scenario of future production of fossil and nuclear fuels. Assuming oil peaking in 2010 and decline rates of 5 per cent per year. **Source:** for oil, gas, coal, and nuclear scenario: LBST (Schindler/Zittel 2006).

The main purpose of these scenarios is not so much to show how global energy demand might be supplied in 2100, but to sketch the major characteristics of the transition period between today's fossil fuel based energy economy and a possible future based on renewable energies. These scenarios are modelled with logistic functions which grow exponentially in the beginning, and then approach the ultimate potential attributed to these sources with continually decreasing growth rates. The assumptions for the calculation of these potentials are based on available literature sources (as specified below) and own calculations. For the scenario calculations a figure close to the minimum value of the respective potential was always used.

The calculation of this so called 'technical' potential was based on the following studies:

- **Geothermal Energy:** According to common practice the potential for electricity production was calculated by multiplying the number of the active volcanoes within the specified region with a scaling factor (Bjornsson/Fridleifsson/Helgason/Jonatansson/Mariusson/Palmason/Stefansson/Thorsteinsson 1998; Stefansson 2005).
- **Hydropower:** the results are based on a literature survey (Bjornsson/Fridleifsson/Helgason/Jona-

tansson/Mariusson/Palmason/Stefansson/Thorsteinsson 1998; WEC 2001).

- **Photovoltaics:** The Potential was calculated by multiplying the forecasted number of inhabitants and the gross domestic product with a specific factor which takes care of available roof areas and solar radiation. The link between population and gross domestic product was used to estimate the available roof area in the year 2100. This methodology is described in detail in reference (Schmidt/Weindorf/Wurster/Zerta/Zittel 2005) and Quaschnig (2000). Therefore, the basic assumption is that PV modules are only roof and façade mounted. Obviously, this underestimates the full PV-potential.
- **Biomass:** Biomass is the most discussed renewable resource as the potential varies by a factor of ten, depending on the assumptions regarding arable land area and fertilizer use. The results are based on a literature survey and on own calculations (Hoogwijk 2004; Kaltschmitt/Hartmann 2001).
- **Wind Energy:** The results are based on literature survey and own calculations (EWEA/ Greenpeace 2004; Elliot/Wendell/Gower 1991; Kruska/Ichiro/Ohbayashe/Takase/Tetsunari, Evans/Herbergs/Lehmann/Mallon/Peter/Sekine/Suzuki/Assmann 2003).
- **Solarthermal Power Plants:** For North Africa and Middle East countries the results of the Mediterra-

Figure 25.7: Possible market penetration of renewable energy sources. **Sources:** LBST (Schindler/Zittel 2006).

nean study (DLR) were used. These results were adapted to other regions (Klaiss/Staiss 1992; Trieb 2005; Leitner 2005; see chap. 28 by Trieb/Kre-witt/May).

It is impossible to accurately forecast how much of this potential will be used in the future. This depends on many aspects which are not of a technical nature. Most important will be their acceptance by the public, given increasing environmental and supply problems. Society must decide on the value of both environmental aspects, and of producing and using energy. To partly account for such decisions, the scenario calculations were based on the minimum values of the estimates of the technical potential, which by definition do include environmental restrictions as they are obvious today but do not include additional restrictions from lacking public acceptance.

The renewable energy scenario is shown in figure 25.7. It represents the aggregation of possible market share potentials for each technology in each world region. In general and in the long run plenty renewable energy will become available. The capacity increase of renewable energies might eventually reach its maximum around 2060. Primary renewable sources will supply most energy as electricity, and not as fuel or heat. This analysis focuses on the next 20 to 30 years which are the critical period. The accurate size of the

renewable potential does not influence the growth rates during the next 20 to 30 years; therefore it is of minor importance in the present context.

25.6 Transition towards Sustainability

The world is entering a crucial transition period: from nearly total reliance on fossil energies to a sustainable energy future based on renewable energy sources. The world will experience the peaking first of oil and later also of natural gas. The resulting energy supply gap cannot be filled by a rising share of nuclear energy, and can only partly be filled by an increased use of coal. But (without CO₂ sequestration) this would increase carbon dioxide emissions to unacceptable levels. The limits to growth will become apparent and this will probably happen rather soon. Renewable energies will have to fill the gap. They have a much bigger potential than the established institutions are willing to attribute to them. But even when renewables are fully used, the transition remains a difficult task. In the coming decades the build-up of renewable energy capacities will – even in the best case – be slower than the decline of fossil energy supply. Only in the later decades of this century will it be possible to reach again today's consumption levels.

The arrival of peak oil will lead to rising and eventually permanently higher energy prices. However, this is by no means a catastrophe. High energy prices will initially hurt an economy like ours which is presently not adapted to such an environment. Yet, higher energy prices must be seen as a necessary precondition for the transition to a sustainable energy future. In the longer run, high energy prices are not the problem but the first step towards a solution.

One important aspect is the efficient use of energy. In our present system with low energy prices, efficiency is not really attractive, and the economic rewards are weak. This will certainly change with higher prices, and also the social valuation of efficient energy use will increase. This is the case of private virtue versus public responsibility.

Declining oil and natural gas supplies for stationary applications (like electric power generation and the provision of heat) can relatively easily be substituted by energy efficiency measures and by strongly rising contributions from renewable energy sources. Probably there will be plenty of renewable electricity available but not enough fuels for transport. A serious deficit of fuels will develop over time, which can only partly be compensated by improved efficiency along the whole transport chain.

Various options for producing alternative fuels exist: Hydrogen produced from electricity, hydrogen or synthetic liquid fuels produced from biomass, hydrogen or synthetic liquid fuels produced from remaining coal instead of using it for power generation. But whatever option is chosen eventually, fundamental changes in lifestyles and in the whole economy will be caused by limited supplies and higher energy prices.

The transport intensity will have to be reduced without endangering mobility and also the energy intensity of the production and use of goods. Less available energy and higher fuel costs will increase transport resistance. There will be a stronger preference for activities in the neighbourhood, and there will be a penalty on longer distances as a consequence of higher relative prices caused by limited supplies. This will eventually change land use patterns, suburbia in many cases will not work anymore, and perhaps there will be a revival of the inner cities in the US. The dominance of the private car will recede, and the perception of what properties an attractive car should have will also change. Other modes of transport will gain importance and social acceptance. But until now all incentives are still pointing in the wrong direction.

Our industrialized economies rely on growth. Once growth rates are shrinking this is seen as a symp-

tom of crisis, no growth is a disaster. So nobody is prepared for a future with continually declining fossil energy supplies. This scenario is not on the radar of public awareness. Rising energy prices will change the perception and only then society will look for sustainable pathways into the future. The most important task will be to adapt our way of life, our economies, and our political and social systems to this situation. There are no ready solutions. A comprehensive public debate has not yet started. The outcome is open.

25.7 Conclusions

Peak oil is imminent and will cause an energy supply gap which cannot be filled by any other energy source. This is even more so since fuels for transport will have to be produced from other primary energy sources incurring high energy losses. Renewable energy sources will most likely not grow fast enough in the first two to three decades after peak oil to compensate the supply gap.

Putting all aspects together, one can expect that peak oil will be an inflection point leading to structural changes which will enforce changes in the lifestyle of industrialized countries – irrespective of the fact whether we like it or not. The quality of the life after peak oil will depend on the timely recognition of the challenges ahead, and on the appropriate actions taken by society.

In order to secure energy supply, it will be necessary to use energy in all sectors much more efficiently than today, and to promote the rapid transition towards renewable energies. The view of the authors is that the attempt to secure future energy supplies by military force will cause more problems than it solves.

26 Technical and Economic Potentials of Biomass until 2050: Regional Relevance for Energy Security

André P.C. Faaij

26.1 Introduction

Rapidly developing international bio energy trade may develop over time into a 'commodity market' which can secure supply and demand in a sustainable way; sustainability being a key factor for long-term security. It is clear that on a global scale and over the longer term, large potential biomass production capacity can be found in developing countries and regions such as Latin America, Sub-Saharan Africa, and Eastern Europe. If indeed the global bio-energy market is to develop to a size of 400 EJ over this century (which is well possible given the findings of recent global potential assessments), the value of that market at US \$ 4/GJ (considering pre-treated biomass such as pellets) amounts to some US \$ 1,600 billion per year.

This creates important future opportunities for such regions, given the expected increased role of bio energy within the world's energy supply. Consequently, this poses the fundamental question of how these potential major producers and exporters of bio energy can benefit from the growing global demand for bio energy in a sustainable way, i.e. that bio energy exports can contribute to rural development, benefit local communities, and can be an integral part of overall development schemes, including the existing agricultural and forestry sectors.

In this chapter bio-energy market developments, resource potentials, and links between developing bio-energy markets, trade and socio-economic development, and how sustainable bio-energy production could be realized are explored. Drivers, barriers, and future potentials for international bio-energy markets are discussed and socio-economic implications for possible exporting countries are identified. By doing so, several key opportunities and issues for the developing international bio-energy markets and their possible impacts are raised that should be taken into account by policymakers, market parties, international stakeholders, and other key stakeholders.

Summarizing; although international bio-energy trade and markets are developing very rapidly, and the future looks bright given market demand and potential supplies, also barriers occur that can disturb or at least slow down a sound development of such markets. Also, there are important concerns about competition for land that may conflict with food production, water resources, and biodiversity protection. Although biomass production may well provide a crucial strategy to enhance sustainable land-use management, negative developments should be avoided, e.g. by clear standards and best practice guidelines for (the design of) biomass production systems and their integration in agricultural areas.

Global energy demand is growing rapidly. The total current commercial energy use amounts to some 440 EJ (BP Statistical Review 2006). About 88 per cent of this demand is covered by fossil fuels. Energy demand is expected to at least double or perhaps triple during this century (Faaij/Wagener/Junginger/Best/Bradley/Fritsche/Grassi/Hektor/Heinimö/Klokk/Kwant/Ling/Ranta/Risnes/Peksa/Rosillo-Calle/Ryckmanns/Utria/Walter/Woods 2005).

At the same time, concentrations of greenhouse gases (GHG) in the atmosphere are rising rapidly, with fossil fuel bound CO₂ emissions being the most important contributor. In order to stabilize related global warming and climate change impacts, GHG emissions must be reduced drastically to less than half the global emission levels of 1990. In addition, security of energy supply is a global issue. Supplies of conventional oil and gas reserves are increasingly concentrated in politically unstable regions, and increasing the diversity in energy supplies is important for many nations to secure a reliable and constant supply of energy.

In this context, biomass use for energy can play a pivotal role. Biomass use for energy, when produced in a sustainable manner, can drastically reduce GHG emissions compared to fossil fuels. Most countries

have various biomass resources available or could develop a resource potential, making biomass a more evenly spread energy supply option across the globe. It is a versatile energy source, which can be used for producing power, heat, liquid and gaseous fuels, and also serves as carbon neutral feedstock for materials and chemicals.

International biomass markets have rapidly developed over the past years. International trade in biofuels (such as ethanol) as well as solids (e.g. pellets) and vegetal oils may develop over time into a new 'commodity market' which can secure energy supply and demand in a sustainable way; sustainability being a key factor for long-term security. Recent studies indicate that the technical and economic potentials of biomass resources and biomass production could be large, in the order or magnitude of 1/3 of the global future energy demand during this century.

If such potentials would indeed be developed it creates important future opportunities for producing regions. Consequently, this poses the fundamental question of how these potential major producers and exporters of bio energy can benefit from the growing global demand for bio energy in a sustainable way, i.e. that bio-energy exports can contribute to rural development, benefit local communities, and can be an integral part of overall development schemes, including the existing agricultural and forestry sectors. Although international bio-energy trade and markets are developing very rapidly, and the future looks bright given market demand and potential supplies, barriers occur that can disturb or at least slow down a sound development of such markets. Also, there are important concerns about competition for land that may conflict with food production, water resources, and biodiversity protection. Although biomass production may well provide a crucial strategy to enhance sustainable land-use management, negative developments should be avoided, e.g. by clear standards and best practice guidelines for (the design of) biomass production systems and their integration in agricultural areas. Those are important concerns.

Linking to the key theme of this book, large supplies of biomass and biofuels to the world's energy markets may have a profound effect on the diversity of energy supply in the world. This is in particular the case when biomass would be used for production of transport fuels (currently the key growth market for biomass use) because this provides an alternative for mineral oil.

In this chapter the bio-energy market developments, resource potentials and links between develop-

ing bio-energy markets, trade and socio-economic development, and how sustainable bio-energy production could be realized, are explored. Drivers, barriers, and future potentials for international bio-energy markets are discussed and implications for possible exporting countries are identified, including the impacts on energy supply, security, and stability. By doing so, several key opportunities and issues for the developing international bio-energy markets and their possible impacts are raised that should be taken into account by policymakers, market parties, international and other key stakeholders.

26.2 Developments in Global Bio-energy Use

Over the past decades, the modern use of biomass has increased rapidly in many parts of the world. In the light of the Kyoto greenhouse gas (GHG) reduction targets, many countries have ambitious targets for further biomass utilization. Also the recent increase of the oil price has strongly fuelled the interest in bio energy. For example, at an oil price of over sixty dollars per barrel, it is a very attractive option to drive on bioethanol derived from sugar cane instead of fossil fuel-based transportation fuels. At present, biofuels are seen as a key diversification strategy to reduce the dependency on mineral oil, thus as a way to improve energy supply security.

However, especially in developed countries domestic biomass potentials are often used to a high degree, though in some countries still untapped potentials remain. In the longer term, the pressure on available biomass resources will increase. Also, biomass produced in developed countries can generally be associated with higher production costs.

Ambitions and expectations for biomass use for energy are high in many countries, for the EU and also on a global basis, given a variety of policy objectives and long-term energy scenarios. A reliable supply and demand of bio energy is vital to develop stable market activities. Given the expectations for a high bio energy demand on a global scale and in many nations, the pressure on available biomass resources will increase. Without the development of biomass resources (e.g. through energy crops and better use of agro-forestry residues) and a well functioning biomass market to assure a reliable and lasting supply, those ambitions may not be met. The development of truly international markets for bio energy may become an essential driver to develop bio energy potentials,

which are currently underutilized in many regions of the world. This is true for both residues and for dedicated biomass production (through energy crops or multifunctional systems such as agro-forestry).

The fact that biomass potentials are underutilized is true both for available residues as well as possibilities for dedicated biomass energy plantations or multifunctional systems such as agro-forestry. On the other hand, many developing countries have a large technical potential for agricultural and forest residues and dedicated biomass production, e.g. ethanol from sugar cane, wood or other crops. Given the lower costs for land and labour in many developing countries, biomass production costs are much lower, and thus offer an opportunity to export bio energy.

The possibilities to export biomass derived commodities to the world's energy markets can provide a stable and reliable demand for rural communities in many (developing) countries, thus creating an important incentive and market access that is much needed in many areas in the world. For many rural communities in developing countries such a situation would offer good opportunities for socio-economic development.

Sustainable biomass production may also contribute to the sustainable management of natural resources. Importing countries on the other hand may be able to fulfil cost-effectively their GHG emission reduction targets and diversify their fuel mix. The future vision for global bio energy trade is that it develops over time into a real 'commodity market' which will secure supply and demand in a sustainable way; sustainability being a key factor for long-term security. It is clear that on a global scale and over the longer term, large potential biomass production capacity can be found in developing countries and regions such as Latin America, Sub-Saharan Africa, and Eastern Europe. This creates important future opportunities for such regions, given the expected increased role of bio energy within the world's energy supply. Such developments could give access to an open world energy market. Consequently, this poses the fundamental question of how these potential major producers and exporters of bio energy can benefit from the growing global demand for bio energy in a sustainable way, i.e. that bio-energy exports can contribute to rural development, benefit local communities, and can be an integral part of overall development schemes, including the existing agricultural and forestry sectors.

26.2.1 Current Use of Biomass

Over the past decades, the modern use of biomass has increased rapidly in many parts of the world. In the light of the Kyoto greenhouse gases (GHG) reduction targets, many countries have ambitious targets for further biomass utilization. Also the recent increase of the oil price has strongly fuelled the interest in bio energy. For example, at an oil price of over sixty dollars per barrel, it is a very attractive option to drive on bioethanol derived from sugar cane instead of fossil fuel-based transportation fuels. At present, biofuels are seen as a key diversification strategy to reduce the dependency on mineral oil, thus as a way to improve energy supply security.

Current energy supplies in the world are dominated by fossil fuels (some 80 per cent of the total use of over 400 EJ per year). Nevertheless, about 10–15 per cent (or 45 ± 10 EJ) of this demand is covered by biomass resources, making biomass by far the most important renewable energy source used to date. On average, in the industrialized countries biomass contributes some 9–13 per cent to the total energy supplies, but in developing countries the proportion is as high as a fifth to one third. In quite a number of countries biomass covers even over 50 to 90 per cent of the total energy demand. A considerable part of this biomass use is however non-commercial and used for cooking and space heating, generally by the poorer part of the population. This also explains why the contribution of biomass to the energy supply is not exactly known; non-commercial use is poorly mapped. In addition, some traditional use is not sustainable because it may deprive local soils of needed nutrients, cause indoor and outdoor pollution, and result in poor health. It may also contribute to GHG emissions and affect ecosystems if biomass is taken for energy without replanting and other conservation management. Part of this use is commercial though, i.e. the household wood in industrialized countries and charcoal and firewood in urban and industrial areas in developing countries, but there are almost no data on the size of those markets. An estimated 9 ± 6 EJ is covered by this category.

26.2.2 Growth of Modern Bio Energy

Modern bio energy (commercial energy production from biomass for industry, power generation or transport fuels) makes a lower, but still very significant contribution (some 7 EJ/yr in 2000), and this share is growing. Biomass combustion is responsible for over

90 per cent of the current production of secondary energy carriers from biomass. Combustion for domestic use (heating, cooking), waste incineration, use of process residues in industries and state-of-art furnace and boiler designs for efficient power generation all play their role in specific contexts and markets.

The liquid biofuels most widely used for transport today are ethanol and biodiesel. Ethanol is currently produced from sugar or starch crops, while biodiesel is produced from vegetable oils or animal fats. The growth in the use of biofuels has been facilitated by their ability to be used as blends with conventional fuels in existing vehicles, where ethanol is blended with gasoline and biodiesel is blended with conventional diesel fuel.

Ethanol currently accounts for more than 90 per cent of total bio-fuel production. About one-quarter of world ethanol production goes into alcoholic beverages or is used for industrial purposes (as a solvent, disinfectant, or chemical feedstock); the rest becomes fuel for motor vehicles. Most of the world's biodiesel is used for transportation fuel. Global ethanol production has more than doubled since 2000, while production of biodiesel, starting from a much smaller base, has expanded nearly threefold. In contrast, oil production has increased by only 7 per cent since 2000. (In absolute terms, however, world petroleum production increased by about 360 million litres per year from 2000-2005, compared to some 19 million litres for ethanol. In 2005, ethanol comprised about 1.2 per cent of the world's gasoline supply, by volume. The total production of biofuels currently (2006) equals about 1.5 EJ as transport fuel (Hunt/Easterly/Faaij/Flavin/Freimuth/Fritsche/Laser/Lynd/Moreira/Pacca/Sawin/Sorkin/Stair/Szwarc/ Trindade 2007).

26.2.3 Market Developments

Especially due to high prices for fossil fuels (especially oil, but also natural gas, and to a lesser extent coal) the competitiveness of biomass use has strongly increased. In addition, the development of CO₂ markets (emission trading), as well as ongoing learning and subsequent cost reductions for biomass and bio-energy systems, have strengthened the economic drivers for increasing biomass use, production, and trade. Biomass and bio energy are a key option in energy policies. Security of supply, an alternative for mineral oil, and reduced carbon emissions, are key reasons. Targets and expectations for bio energy in many national policies and long-term energy scenario's are am-

bitious, reaching 20-30 per cent of total energy demand in various countries, as well as worldwide.

However, without the development of sufficient biomass resources (e.g. through energy crops) and a well functioning biomass market that can assure a reliable and lasting supply, those ambitions may not be met. A lack of availability of good quality (and competitive) biomass resources has proven to be a show-stopper for many market initiatives in the past. On the other hand, various countries have considerable experience with building biomass markets and linking available resources with market demand. Examples are found in Brazil, Sweden, Finland, Canada, the Netherlands et al. International trade of biomass resources has become part of the portfolio of market parties, and volumes traded worldwide increase at a very rapid pace with an estimated doubling of volumes in several markets over the past few years. The fact that markets are growing means that more and more resources are becoming available from regions where biomass use was low or absent so far, and supply risks for biomass users have reduced due to more diverse and reliable supplies.

26.3 Biomass Resource Potentials: Long-term Outlook

Various biomass resource categories can be considered: residues from forestry and agriculture, various organic waste streams and, most important, the possibilities for active biomass production on various land categories (e.g. grass production on pasture land, wood plantations and sugar cane on arable land, and low productivity forestation schemes for marginal and degraded lands).

Active biomass production requires land. The potential for energy crops therefore largely depends on land availability, considering that worldwide a growing demand for food has to be met, combined with nature protection, sustainable management of soils and water reserves, and a variety of other sustainability criteria. Given that a major part of the future biomass resource availability for energy and

materials depend on these (intertwined, uncertain, and partially policy dependent) factors, it is not possible to present the future biomass potential in one simple figure. Table 26.1 provides a synthesis of a range of analyses that have assessed the longer term potential of biomass resource availability on a global scale. Also, a number of uncertainties are highlighted that can affect biomass resource availability.

Table 26.1: Overview of the global potential bio-energy supply in the long term for a number of categories, and the main pre-conditions and assumptions that determine these potentials. **Sources:** Compiled by the author based on: Hoogwijk/Faaij/van den Broek/Berndes/Gielen/ Turkenburg (2003); Berndes/Hoogwijk/van den Broek (2003); Smeets/Faaij/Lewandowski/ Turkenburg (2007); Hoogwijk/Faaij/Eick-hout/de Vries/Turkenburg (2005).

Biomass category	Main assumptions and remarks	Potential bio-energy supply up to 2050.
Energy farming on current agricultural land	Potential land surplus: 0-4 Gha (more average: 1-2 Gha). A large surplus requires structural adaptation of intensive agricultural production systems. When this is not feasible, the bio-energy potential could be reduced to zero as well. On average higher yields are likely because of better soil quality: 8-12 dry tonne/ha*yr is assumed. (*)	0 – 700 EJ (more average development: 100 – 300 EJ)
Biomass production on marginal lands	On a global scale a maximum land surface of 1.7 Gha could be involved. Low productivity of 2-5 dry tonne/ha*yr. (*) The supply could be low or zero due to poor economics or competition with food production.	(0) 60 – 150 EJ
Residues from agriculture	Estimates from various studies. Potential depends on yield/product ratios and the total agricultural land area as well as type of production system: Extensive production systems require re-use of residues for maintaining soil fertility. Intensive systems allow for higher utilization rates of residues.	Approx. 15 – 70 EJ
Forest residues	The (sustainable) energy potential of the world's forests is unclear. Part is natural forest (reserves). Range is based on literature data. Low value: figure for sustainable forest management. High value: technical potential. Figures include processing residues.	30 - 150 EJ
Dung	Use of dried dung. Low estimate based on global current use. High estimate: technical potential. Utilization (collection) for longer term is uncertain.	5 – 55 EJ
Organic wastes	Estimate on basis of literature values. Strongly dependent on economic development, consumption and the use of biomaterials. Figures include the organic fraction of MSW and waste wood. Higher values possible by more intensive use of biomaterials.	5 – 50 EJ
Total	Most pessimistic scenario: no land available for energy farming; only utilization of residues. Most optimistic scenario: intensive agriculture concentrated on the better quality soils. (between brackets: more average potential in a world aiming for large-scale utilization of bio energy)	40 – 1100 EJ (250 - 500 EJ)

(*) Heating value: 19 GJ/tonne dry matter.

Issues that require further research and especially more regional demonstrations and experience with biomass production are:

1. *Competition for Water Resources:* Although the analyses mentioned above generally exclude irrigation for biomass production, in some countries this could lead to further enhancement of an already stressed water situation. But there are also countries where such impacts are less likely to occur. More region specific knowledge is needed to what extent competing

demand for water resources is a constraint for biomass production (Berndes 2002).

2. *Availability of Fertilizers and Pest Control:* Better agricultural management and higher productivities imply availability of fertilizers and pest control methods. Its use needs to be within sound limits. Sound agricultural methods (agro-forestry, precision farming, biological pest control, etc.) exist that can achieve major increases in productivity with neutral or even positive environmental impacts. Such practices must how-

ever be secured by sufficient knowledge, funds, and human capacity and knowledge.

3. *Land-Use Planning Taking Biodiversity and Soil Quality into Account*: Further intensification of agriculture and large-scale production of biomass energy crops may affect biodiversity compared to current land-use. Biodiversity standards are to be interconnected with biomass production still when changes in land-use are considered. Perennial crops (which are the preferred category of crops for energy production) have a (much) better ecological profile than annual crops, and benefits with respect to biodiversity can be achieved when perennial crops are displaced. However, insights in how biodiversity effects can be optimized (and improved compared to current land-use) when sound landscape planning is introduced are limited. Also here, more regional efforts, experience, and specific solutions are needed.

4. *The Use and Conversion of Pasture Land Connected to More Intensive Methods of Cattle Raising*: A key land category in making more efficient use of land used for food production are the world's grasslands used now for grazing. The analyses that were discussed here show that much land can be released when production of meat and dairy products is done in more intensive (partly landless in closed stables) schemes. Grasslands could then be used for production of energy grasses or partly converted to woodlands. The impacts of such changes should be closely evaluated.

5. *Socio-Economic Impacts*: Large-scale production of modern biofuels, partly for the export market, could provide a major opportunity of many rural regions around the world to generate major economic activity, income, and employment. Given the size of the global market for transport fuels, the benefits that can be achieved by reducing oil imports and possibly net exports of bio energy are vast. Nevertheless, it is not a given that those benefits end up with the rural population and farmers that need those benefits most.

6. *Macro-economic Impacts of Changes in Land-use Patterns*: Although the analyses discussed indicate that both the world's food demand and additional biomass production *can* (under relevant preconditions) be achieved, more intensive land-use and additional land-use for biomass production may lead to macro-economic effects on land and food prices. Although this is not necessarily a bad mechanism (it could be vital for farmers to enable investment in current production methods), the possible implications on macro-economic level are poorly understood. More

analyses are needed that can highlight with what speed of implementation and change undesired economic effects can be avoided.

In theory, energy farming on current agricultural (arable and pasture) land could, with projected technological progress, contribute over 800 EJ, without jeopardizing the future world's food supply. Latin America, Sub-Saharan Africa, Eastern Europe, and Oceania clearly are promising regions. These analyses also show that a significant part of the technical potential (around 200 EJ in 2050) for biomass production may be developed at low production costs in the range of US\$ 2/GJ (Hoogwijk 2004; Rogner/Cabrera/Faaij/Giroux/Hall/Kagramanian/Lefevre/Moreira/Notstaller/Odell/Taylor 2000) assuming this land is used for perennial crops. Another 100 EJ of biomass could be produced with lower productivity and higher costs at marginal and degraded lands. Regenerating such lands requires more upfront investment, but competition with other land-use is less of an issue, and other benefits (such as soil restoration, improved retention functions) may be obtained, which could partly compensate biomass production costs (Smeets/Faaij/Lewandowski 2005).

Organic wastes and residues could possibly supply another 40–170 EJ, with uncertain contributions from forest residues and potentially a very significant role for organic waste, especially when biomaterials are used on a larger scale. This is a very important potential resource category once 2nd generation bio-fuel conversion technology becomes available. It should be noted though that parts of this potential are used for production of power and heat as well. In total, the bio-energy potential could be over 400 EJ (per year) during this century. This is comparable to the total *current* global energy use of about 430 EJ.

Key to the introduction of biomass production on the suggested orders of magnitude is the rationalization of agriculture, especially in developing countries. There is room for considerably higher land-use efficiencies that can more than compensate for the growing demand for food.

Major transitions are however required to exploit this bio-energy potential. Especially improving agricultural efficiency in developing countries (i.e. increasing crop yields per hectare) is a key factor. It is still uncertain to what extent and how fast such transitions can be realized in different regions. In developing countries (e.g. Sub-Saharan Africa) very large improvements can be made in agricultural productivity, given the current agricultural methods deployed (often subsistence farming), but better and more efficient agri-

cultural methods will not be implemented without investments and proper capacity building and infrastructure improvements. Such schemes, in which the introduction of bio energy can play a pivotal role, can create more income for rural regions by additional bio-energy production. Financial resources generated could then accelerate investments in conventional agriculture and infrastructure, and also lead to improved management of agricultural land. Finally, technological developments, market development, and high prices for fossil fuels can dramatically improve competitiveness and efficiency of bio energy. Increased competitiveness is logically a driver to develop the production potentials of bio energy. This will be discussed below.

26.4 Markets for Bio Energy

Absolutely crucial for the success of bio-energy systems is their economic performance. Biomass is a competitive alternative in many situations, but this is generally observed where cheap or even negative costs of biomass residues or wastes are available (Junginger/Faaij/Koopmans/van den Broek/Hulscher 2001). In order to make large-scale bio-energy use (especially from dedicated biomass crops) competitive with fossil fuels, the conversion technologies, biomass production, as well as the total bio-energy systems, require further development and optimization. Table 26.2 gives a global overview of the main short and longer term markets for biomass energy use.

26.4.1 Heat, Power, and Fuels from Biomass: Key Markets

With biomass prices of about 2 US\$/GJ, state of the art of combustion technology at a scale of 40 - 60 MWe can result in costs of electricity (COE) of around US\$ct 5-6/kWh produced. Co-combustion, particularly at efficient coal-fired power plants, can obtain similar or lower cost figures, largely depending on the feedstock costs. When BIG/CC technology becomes available commercially, COE could drop further to about 3-4 US\$ct/kWh, especially due to higher electrical efficiencies. For larger scales (i.e. over 100 MWe) cultivated biomass will be able to compete fully with fossil fuels in many situations. The benefits of lower specific capital costs and increased efficiency certainly outweigh the increase in costs and energy use for transport for considerable distances

once a reasonably well developed infrastructure is in place.

Decentralized power (and heat) production is generally more expensive, but better suited for off-grid applications. The costs that could ultimately be obtained with e.g. gasifier/diesel systems are still unclear, and depend strongly on what emissions and fuel quality are considered acceptable. Combined Heat and Power generation is generally attractive when heat is required with high load factors.

As discussed, production of heat and electricity dominate current bio-energy use. At present, the main growth markets for bio energy are the European Union, Central and Eastern Europe, and South East Asia (Thailand, Malaysia, Indonesia), especially with respect to efficient power generation from biomass wastes and residues. Two key industrial sectors for application of state-of-the-art biomass combustion (and potentially gasification) technology for power generation are the paper and pulp sector, and cane-based sugar industry worldwide.

Table 26.2 gives a broad overview of the perspectives for various markets combined with main biomass resources on short and longer term (Faaij 2006). Key points are:

- In traditional bio-energy use, heat for cooking and space heating are crucial. It is not expected that the traditional use of biomass will diminish in the coming decades, since traditional biomass use is often interlinked with poverty and underdevelopment, which prove difficult problems to solve. Nevertheless, modernizing bio-energy use for the poorer part of populations is an essential component of sustainable development schemes in many countries. This creates opportunities and major markets, for example for improved stoves, production of high quality fuels for cooking (e.g. bio-fuel based on such as ethanol and *fischer-tropsch* liquids) with considerable efficiency and health advantages. Furthermore, biogas, e.g. produced with digesters on the village level, prove very effective in various countries (such as China and India) in solving waste treatment problems and supplying high quality energy carriers (clean gas and power when used in gas engines) along with hygienic bio-fertilizers (Karthi and Larson, 2000).
- For commercial heat production reliable technology (e.g. gasification, advanced stoves, etc.) is commercially available for many applications (industrial, district, and domestic heating), but profitability of power generation (or CHP) seems better in most current markets. Especially for specific

Table 26.2: Generic overview of performance projections for different options and biomass markets on shorter (~5) and longer (>~20) years. **Source:** Based on data in Faaij (2006).

Biomass feedstock category	Heat		Electricity		Transport fuels	
	Short term: roughly stabilizing market	Longer term	Short term: strong growth market world-wide	Longer term: growth may stabilize due to competition of alternative options	Short term: growing market, but dependent on policies and financial support.	Longer term: potential key market for (cultivated) biomass.
Organic wastes (i.e. MSW etc.)	Undesirable for domestic purposes (emissions); industrial use attractive; in general competitive.	Especially attractive in industrial setting and CHP. (advanced combustion and gasification for fuel gas)	<3–5 US\$ct for state-of-the-art waste incineration and co-combustion. Economics strongly affected by tipping fees and emission standards.	Similar range; improvements in efficiency and environmental performance, in particular through IG/CC technology at large scale.	N.A.	In particular possible via gasification routes
Residues: • Forestry • Agriculture	Major market in developing countries (<1-5 US\$/kWhth); stabilizing market in industrialized countries.	Especially attractive in industrial setting and CHP. Advanced heating systems (domestic) possible but not on global scale	4-12 US\$ct kWh (see below; major variable is supply costs of biomass); lower costs also in CHP operation and industrial setting depending on heat demand.	2-8 US\$ct kWh (see below; major variable is supply costs of biomass)	N.A.; only for surpluses of food crops	See below (where?).
Energy crops: • oil seeds • sugar/starch • sugar cane • perennials	N.A.	Unlikely market due to high costs feedstock for lower value energy carrier; possible niches for pellet or charcoal production in specific contexts	6-15 US\$ct kWh High costs for small scale power generation with high quality feedstock (wood) lower costs for large scale (i.e. >100 MWth) state-of-the-art combustion (wood, grasses) and co-combustion.	3-9 US\$ct kWh Low costs especially possible with advanced co-firing schemes and BIG/CC technology over 100-200 MWe.	8-25 US\$/GJ; lower figures for ethanol from sugar cane; higher for biodiesel (RME) and sugar and starch crops in Europe and North America.	5-10 US\$/GJ; low costs obtainable with lignocellulosic biomass (<2 US\$/GJ) advanced hydrolysis techniques and large-scale gasification (i.e. <1000 MWth) for MeOH/H ₂ /FT, as well as improved sugar cane production and subsequent ethanol production in optimized distilleries.

industrial applications, heat production from biomass seems most attractive.

- Power generation from biomass by advanced combustion technology and co-firing schemes is a

growth market worldwide. Mature, efficient, and reliable technology is available to turn biomass into power. In various markets the average scale of biomass combustion schemes rapidly increases due to improved availability of biomass resources and the economic advantages of economies of scale of conversion technology. It is also in this field that competitive performance compared to fossil fuels is possible where lower cost residues are available. This is in particular true for co-firing schemes, where investment costs can be minimal. Specific (national) policies (such as carbon taxes, renewable energy support, e.g. by direct investment subsidies or feed-in tariffs) accelerate this development. Gasification technology (integrated with gas turbines/combined cycles) offers even better perspectives for power generation from biomass in the medium term and can make power generation from energy crops competitive in many areas in the world once this technology has been proven on the commercial scale. Gasification (in particular larger-scale Circulating fluidized bed (CFB) concepts) also offers excellent possibilities for co-firing schemes.

26.4.2 Production of Liquid and Gaseous Fuels from Biomass

For costs of various fuels that can be produced from biomass, a distinction is made between performance levels on the short and on the longer term. Generally speaking, the economy of 'traditional' fuels like Rapeseed MethylEster and ethanol from starch and sugar crops in moderate climate zones is poor and unlikely to reach competitive price levels even in the longer term. Also, the environmental impacts of growing annual crops are not as good as perennials because per unit of product considerable higher inputs of fertilizers and agrochemicals are needed. In addition, annual crops on average need better quality land than perennials to achieve good productivities. Perennial crops can also be grown on marginal lands, thereby achieving potential other key benefits such as soil quality improvement.

A key exception under 'conventional' biofuels is the production of ethanol from sugar cane in tropical regions where good soils are available, which proves currently a competitive system in the Brazilian context and some other countries. For countries where sugar cane production is feasible, commercially available technology allows for production of relatively low cost ethanol. The Brazilian experience shows that eth-

anol production competitive with gasoline is possible at current oil prices (Rosillo-Calle 1998; Goldemberg/Teixeira Coelho/Nastari/Lucon 2004). Ethanol production capacity based on sugar cane is increasing in some African, several Latin American, and Asian (most notably India and China) countries. Furthermore, better use of cane residues (e.g. for power generation or use via hydrolysis processes) can further improve the performance of cane-based ethanol production.

But it is production of methanol (and DiMethyl-Ester (DME)), hydrogen, Fischer-Tropsch liquids, and ethanol produced from ligno-cellulosic biomass that offer much better perspectives and competitive fuel prices in the longer term (e.g. between 2010-2020). Partly, this is because of the inherent lower feedstock prices and versatility of producing ligno-cellulose biomass under varying circumstances. Furthermore, the (advanced) gasification and hydrolysis technologies under development have the inherent improvement potential for efficient and competitive production of fuels (sometimes combined with co-production of electricity).

An important point is also that when the use of such 'advanced' biofuels (especially hydrogen and methanol) in advanced hybrid or Fuel Cell Vehicles (FCVs) is considered, the overall chain ('tree-to-tyre') efficiency can drastically improve compared to current biodiesel or maize or cereal derived ethanol powered internal combustion engine vehicles; the effective number of kilometres that can be driven per hectare of energy crops could go up with a factor of 5 (from a typical current 20,000 km/ha for a middle class vehicle run with RapeseedMethylEster (RME) up to over 100,000 km/ha for advanced ethanol in an advanced hybrid or FCV (Faaij/Hamelinck 2002). Note though, that the exception to this performance is sugar cane-based ethanol production; in Brazil the better plantations yield some 8,000 litre ethanol/ha*yr, or some 70,000 km/yr for a middle class vehicle. In the future, those figures can improve further due to better cane varieties, crop management, and efficiency improvement in the ethanol production facilities (Damen 2001).

Furthermore, FCVs (and to a somewhat lesser extent advanced hybrids) offer the additional and important benefits of zero or near zero emission of compounds like NO_x, CO, hydrocarbons, and small dust particulates, which are to a large extent responsible for poor air quality in most of the world's urban zones.

In Europe, policy targets create a major push for biofuels and large-scale demonstration, e.g. Fischer-Tropsch liquid production via gasification of biomass is likely in the foreseeable future (e.g. before 2010) (EC 2001). Various European countries have shown interest in moving in this direction, and serious demonstration activities are being undertaken in Germany and Sweden. Crucial for the economic feasibility of such schemes is their application on a large-scale (i.e. over 1000 MW_{th}). Related development and investment risks (also concerning a secure supply of biomass) are therefore considerable. Ethanol production from lignocellulose biomass offers similar perspectives, as well as technological and development challenges. RD&D efforts in developing advanced ethanol production technology (including hydrolysis techniques) are significant and various demonstration projects are being carried out (Sweden, USA) that may pave the way to large-scale commercial use of this technology before 2020 or so.

Inherent to the advanced conversion concepts, it is relatively easy to capture (and subsequently store) a significant part of the CO₂ produced during conversion at relatively low additional costs. This is possible for ethanol production (where partially pure CO₂ is produced), and in particular for gasification concepts. Production of syngas (both for power generation and for fuels) in general allows for CO₂ removal prior to further conversion. For Fischer-Tropsch (FT) production about half of the carbon in the original feedstock (coal, biomass) can be captured prior to the conversion of syngas to FT-fuels. This possibility allows for carbon neutral fuel production when mixtures of fossil fuels and biomass are used, and negative emissions when biomass is the dominant or sole feedstock. Flexible new conversion capacity will allow for multiple feedstock and multiple output facilities, which can simultaneously achieve low, zero or even negative carbon emissions. Such flexibility may prove to be essential in a complex transition phase of shifting from large-scale fossil fuel use to a major share of renewables and in particular biomass. The possibility of achieving negative carbon emissions may prove a crucial 'back-stop' technology when climate change develops at a more rapid pace than so far considered, and very rapid emission reductions are aimed at.

26.5 Biomass in the Total World Energy Supply

What contribution can biomass make to the future global energy (and material) demand? A wide diversity of projections of the potential future energy demand and supply exist. Typically, scenarios are used to depict uncertainties in future developments and possible development pathways. *Descriptive* scenarios, such as the *Special Report on Emission Scenarios* (SRES) developed in the context of the *Intergovernmental Panel on Climate Change* (IPPC), give insight in possible pathways to reach a certain future image. This set of 40 scenarios was developed to simulate long-term (up to 2100) GHG emissions. Typical dynamical driving forces are changes in population, economy, technology, and society. All these, in various forms, influence energy and materials demand and supply. The SRES scenarios are based on four storylines that describe how the world could develop over time. Differences between the scenarios concern the economic, demographic and technological development, and the orientation towards economic, social and ecological values. The storylines denoted with A1 and A2 are considered societies with a strong focus towards economic development. In contrast, the B1 and B2 storylines are more focused on welfare issues, and are ecologically orientated. While the A1 and B1 storylines are globally oriented, with a strong focus towards trade and global markets, the A2 and B2 storylines are more regionally oriented.

Figure 26.1 depicts the total energy demand for secondary energy carriers (such as transport fuels, electricity, gas, etc.) in four distinct years of the four scenarios. The various scenarios show large differences in demand and energy mix, as a result of variations in population dynamics, and economic and technological development. Total *primary* (so the presumed mix of fossil fuels, renewables, and nuclear) energy demand in 2050 varies from about 800 EJ up to 1400 EJ.

As discussed in 26.3, the total primary biomass supplies in 2050 could amount to 200–400 EJ. Increased availability of primary biomass is simulated in figure 26.2, showing a gradual development as well as possible ranges in future supplies. Assuming conversion to transport fuels with an expected average conversion efficiency of 65 per cent, this would result in 130–260 EJ fuel. This is more up to double the current demand and a similar range as the expected demand in the discussed SRES scenarios. Conversion to power with an assumed average efficiency of 50 per

Figure 26.1: Projections for global final energy demand for the four IPCC scenarios and energy models as used in Fig. 2.2. (A1, A2, B1, B2). **Source:** Based on IPCC (2000).

Figure 26.2: Geographical potential of woody biomass energy crops as assessed for the four SRES scenarios over time, as well as the simulated total primary energy consumption. **Source:** Based on Hoogwijk/Faaij/Eickhout/de Vries/Turkenburg (2005).

cent logically results in 100–200 EJ, also a similar range as the expected future demand. Additional future demand for (new) biomaterials such as bioplas-

tics could add up to 50 EJ (Sark/Patel/Faaij 2006) halfway this century.

26.6 Market Development and International Trade

Bio-fuel and biomass trade flows are modest compared to total bio-energy production but are growing rapidly. Trade takes place between neighbouring regions or countries, but increasingly trading is occurring over long distances. Examples are the export of ethanol from Brazil to Japan, the EU, and the USA, palm kernel shells from Malaysia to the Netherlands, wood pellets from Canada to Sweden, etc. This is happening despite the bulky and lower calorific value of most biomass raw material.

Biomass-derived transportation fuels currently represent a modest 1.5 EJ (about 1 per cent) of transport fuel use worldwide (largely covered by ethanol production from sugar and starch crops). But it is especially in this field that global interest is growing in Europe, Brazil, North America, and Asia (Japan, China and India). Four main drivers explain this growing interest:

1. The transport sector is particularly difficult to tackle in terms of GHG emission reductions; biomass is the only option for supplying (liquid) carbon neutral hydrocarbons.
2. The strategic importance of reducing the dependency on oil, imported from a declining number of exporting countries that experience political instability, is growing, as is concern that global conventional oil production may peak sooner than previously expected; transport fuels are by far the most important product produced from mineral oil (chap. 25 by Zittel/Schindler).
3. Technological developments offer clear perspectives of competitive and efficient production of biofuels from biomass, most notably ethanol via hydrolysis and fermentation techniques, and fuels such as Fischer-Tropsch, methanol, DME, and hydrogen via gasification. Sugar cane-based ethanol production in tropical regions already provides a competitive alternative, and ethanol production from this source is growing rapidly.
4. In addition, in the medium term (e.g. after 2015), biomass use for transport fuels may prove to become a more effective way to reduce GHG emissions using biomass rather than power generation. This can be explained by the partly observed and partly expected reduction in carbon intensity of power generation due to large-scale penetration of wind energy, increased use of highly efficient natural gas-fired combined cycles, and deployment of

CO₂ capture and storage (in particular at coal-fired power stations).

Biofuels from tropical regions (ethanol from sugar cane and palm oil) are considerably cheaper than biofuels from agricultural crops in temperate zones, providing strong incentives for trade. Trade barriers do not allow for large-scale supplies to e.g. Europe or the United States at present, and it is uncertain to what extent key demand centres will import biofuels in the future. This is a major variable in where and with what resources and technologies biofuels will be produced in the coming decades.

The possibilities to export biomass-derived commodities to the world's energy markets can provide a stable and reliable demand for rural regions in many (developing) countries, thus creating an important incentive and market access that is much needed in many areas in the world. For many rural communities in developing countries such a situation would offer good opportunities for socio-economic development. Sustainable biomass production may also contribute to the sustainable management of natural resources. Importing countries on the other hand may be able to fulfil cost-effectively their GHG emission reduction targets and diversify their fuel mix.

Given that several world regions have inherent advantages for producing biomass and biofuels (including lignocellulose resources) in terms of land availability and production costs, they may gradually develop into net and structural exporters of biomass and biofuels. International transport of biomass (or energy carriers from biomass) is feasible from both an energy and cost point of view. Especially for 2nd generation biofuels, where lignocellulose biomass is the feedstock and large-scale, capital intensive conversion capacity is required to obtain sound economics, import of densified or pre-treated lignocellulosic biomass from various world regions may be preferred. This is a comparable situation to current oil refineries in major ports which use oil supplies from around the globe. Such systems are in fact current practice: large paper and pulp complexes import wood from all over the world. Of course, when feedstock such as wood are considered, trade-offs should be weighed between producing the bio-fuel where the feedstock is harvested (and then exporting the liquid fuel), versus importing just the (processed) feedstock (and then converting it into biofuels in the country where the end products are to be consumed). Studies on intercontinental biofuels trade, and even of bulk transport of e.g. pellets, have found that maritime transport of these commodities could be economically feasible, as

it does not appear that dramatic energy losses would be incurred. For example, exporting forest residues some 1,500 kilometres from the Baltic region to the Netherlands – including inland transport and transfer, and using smaller-size vessels – results in an overall energy use of 5 per cent of the energy content of the biomass transported. And exporting (cultivated) wood some 10,000 kilometres from Latin America to Europe – accounting for inland transport and transfer, and using large-size vessels – uses about 10 per cent of the energy content of the biomass (Hamelinck/Suurs/Faaij 2005).

26.7 Closing Remarks

Biomass is one of the renewable energy sources capable of making a large contribution to the world's future energy supply. Biomass is a versatile energy source that can be used for production of heat, power, transport fuels, as well as biomaterials and, when used efficiently, make a large contribution to reducing net GHG emissions. Biomass is the most important renewable energy option at present and is expected to maintain that position during this century. At present, the state-of-the-art combined heat and power generation (CHP), co-firing and various combustion concepts provide reliable, efficient, and clean conversion routes for converting solid biomass to power and heat. Biofuel production is growing at a very rapid pace.

Although the future role of bio energy will depend on its competitiveness with fossil fuels and on agricultural policies worldwide, it seems realistic to expect that the current contribution of bio energy of 40–55 EJ per year will increase considerably. A range from 200 to 400 EJ may be observed looking well into this century, making biomass a more important energy supply option than mineral oil today; large enough to supply 1/3 of the world's total energy needs during this century.

Development of global bio-energy markets provides major opportunities, and links international bio-energy trade with rural development on a global scale. If indeed the global bio-energy market is to develop to a size of 300 EJ over this century (which is well possible given the findings of recent global potential assessments) the value of that market at 4–8 US\$/GJ (considering pre-treated biomass such as pellets up to liquid fuels as ethanol or synfuels) amounts some 1.2–2.4 trillion US\$ per year. Not all biomass will be traded on the international markets logically, but such

an indicative estimate makes clear what the economic importance of this market can become for rural regions worldwide, as are the employment implications.

On top of residues and use of marginal lands, the largest contribution of the biomass resources can be produced on good quality agricultural and pasture lands without jeopardizing the world's food supply, forests, and biodiversity. The key precondition is that agricultural land-use efficiency is increased, especially in developing regions. Improvement potentials of agriculture and livestock are substantial, but exploiting such potentials is a challenge.

Considering that about one third of the mentioned 300 EJ could be covered by residues and wastes, one quarter by regeneration of degraded and marginal lands, and the remaining from current agricultural and pasture lands, almost 1,000 million hectares worldwide may be involved in biomass production, divided over some 400 million hectares of arable and pasture land and a larger surface of marginal and degraded land. This is some 7 per cent of the global land surface and less than a fifth of the land currently in use for agricultural production.

There are rapid developments in bio-fuel markets; increasing production capacity, increasing international trade flows, increased competition with conventional agriculture (rising prices observed for e.g. sugar and maize), and strong international debate about the sustainability of biofuels production. Biomass and biofuels are developing into a globalized energy source with advantages (opportunities for exporters, more stability on the market; increased availability of biomass and more secure investments in conversion capacity and bio-fuel supplies) and concerns (competing land claims, involvement of farmers).

Biomass trading and the potential revenues for biomass produces could provide a key lever for rural development and enhanced agricultural production methods given the market size for biomass and biofuels. However, safeguards (for example well established certification schemes) need to be installed internationally to secure sustainable production of biomass and biofuels. In the period before 2020, substantial experience should be obtained with both sustainable biomass production under different conditions, as well as deploying effective and credible certification procedures.

Especially promising are the production of electricity via advanced conversion concepts (i.e. gasification and state-of-the-art combustion and co-firing) and modern biomass derived fuels like methanol, hydrogen, and ethanol from lignocellulosic biomass.

Sugar cane-based ethanol production already provides a competitive biofuel production system in tropical regions and further improvements are possible. Both hydrolysis based ethanol production and production of synfuels via advanced gasification from biomass of around 2 Euro/GJ can deliver high quality fuels in a competitive with oil prices down to 40 US\$/barrel. Net energy yields for unit of land surface are high and GHG emission reductions can be achieved over 90 per cent. Flexible energy systems, in which biomass and fossil fuels can be used in combination, could be the backbone for a low risk, low cost, and low carbon emission energy supply system for large-scale supply of fuels and power, and providing a framework for the evolution of large-scale biomass raw material supply systems. The gasification route offers special possibilities to combine this with low cost CO₂ capture (and storage), resulting in concepts that are both flexible with respect to primary fuel input as well as product mix, and with the possibility of achieving zero or even negative carbon emissions.

However, a number of questions are still open and should be elaborated in the future, while building experiences with the growing bio-energy markets over time. Below, several important issues are listed:

26.7.1 Domestic Production vs. Import/Export

Because biomass use is in particular favoured because of its desired impact on lowering GHG emissions, resources and chains should be favoured (and perhaps certified) that maximize GHG mitigation. This implies minimization of energy inputs, but also optimizing the use of biomass, e.g. including comparison between indigenous uses versus export.

While many developing countries have a low energy consumption compared to developed countries, their energy demand is increasing rapidly. Should biomass for energy be utilized locally or for export; should market forces have the last say? For example, Brazil is planning to increase ethanol production drastically over the next 8 years, and to start up biodiesel production from soybeans, palm oil, etc. Only a fraction will be exported, the rest will be used domestically. A similar situation can occur in developed countries, e.g. in Finland which currently exports large volumes of pellets to the EU, which could also be utilized domestically. The main driver being the different national incentives paid to pellets. In general, it would be more rationale to use the biomass primarily locally, and only the (certificated) excess should be exported. However, it should be borne in mind that interna-

tional competition will force domestic producers to be more competitive (Schlamadinger/Woess/Byrne/Green/Cowie/Faaij/Fijan/Gustavsson/Hatton/Hedding/Kwant/Pingoud/Ringer/Robertson/Solberg 2005).

In addition, biodiesel production in Western Europe, and ethanol in the EU-25, the USA and Canada has been increasing rapidly over the last few years. Even though these biofuels are often far more expensive (e.g. factor 2–3 compared to Brazilian ethanol), and the energy balance may be questionable. This is due to a combination of other factors e.g. fuel security, and employment in the agricultural sector. Therefore, these biofuels are currently subsidized or enjoy fiscal advantages (e.g. tax exemptions) in many countries.

26.7.2 Solving Sustainability Issues: International Classification and Certification of Biomass

Certification of biomass may be one way to prevent negative environmental and social side-effects. By setting up minimum social and ecological standards, and tracing biomass from production to end-use, the sustainability of biomass can be ensured. In an exploratory study it has been shown that such social and environmental standards do not necessarily result in high additional costs (Smeets/Faaij/Lewandowski 2005).

However, when implementing a certification scheme for sustainable bio energy, several other issues have to be dealt with. Firstly, criteria and indicators need to be designed/adopted according to the requirements of a region. Also, the compliance with the criteria has to be controllable in practice, without incurring high additional costs. Secondly, avoidance of leakage effects (leakage can be defined as activity-induced changes in land use that occur outside the area in which the activity takes place). The net effect is that carbon benefits gained in one place are partially lost in (leak away) in another location. Leakage in the context of biomass trade could stand for an unwanted shift of activities from the area of biomass production to another area where it leads to negative effects on the environment.

It should be investigated whether an independent international certification body for sustainable biomass is feasible. This should be done by a consortium of all stakeholders in the biomass for energy production chain. Probably a gradual development of such a certification scheme is most feasible with gradual learning and expansion over time. Any certification scheme should on the one hand be thorough,

comprehensive and reliable, but also not become a barrier to markets in itself.

26.7.3 Setting up Technical Biomass Standards

By setting up an internationally accepted quality standard for specific biomass streams (e.g. the biofuel standards of the *Comité Européen de Normalisation* (CEN)), biomass end users may have a higher confidence in using different biomass streams. Task 40 may possibly contribute on this, e.g. by collecting information on technical specifications required by consumers and conveying them to potential suppliers. Furthermore, classification of organic matter streams as specific biomass fuel may aid WTO classification as EGS (Environmental Goods and Services).

26.7.4 Lowering of Trade Barriers

Biofuels could help industrialized countries to promote reduction of carbon emissions but, in some cases – as is the case of ethanol exporting to the US and EU – exporting countries face trade barriers. Most of these barriers are established based on technical reasons, but the aim is pretty much to protect local producers that have production costs much higher than developing countries. The solution pointed by some analysts is to liberalize environmental goods and services (EGS), and to include biofuels as EGS. Building up structural international statistics (volumes and prices) on bio-energy trade are desired, this is not done so far.

26.7.5 Building up Long-term Sustainable International Bio-energy Trade

As described above, different issues can hamper the development and growth of international biomass trade flows. It has also been shown that further growth is needed to develop working markets and the related industries. To achieve both growing markets and long-term sustainable biomass trade, a pragmatic approach is needed. It is recommended to focus first on routes with low barriers. A compromise should be found between developing certification efforts, and ensuring sustainability of bio energy, and developing the market. While not all biomass types may fulfil the entire set of sustainability criteria initially, the emphasis should be on the continuous improvement of sustainability. For such an approach, public information dissemination and support is crucial.

The main targets and spin-offs of bio-trade should lead to a stable and reliable demand for rural communities, provide a source of additional income and an increase in employment for exporting countries, contribute to the sustainable management of natural resources, fulfil cost-effectively GHG emission reduction targets, and diversify their fuel mix. Sustainability may best be addressed by a sound certification framework. A gradual process in an international setting seems best to develop this, keeping in mind that a certification process should not become a barrier in itself.

For stakeholders involved, such as utilities, producers, and suppliers of biomass for energy, it is important to have a clear understanding of the pros and cons of biomass energy. For example, investment in infrastructure and conversion facilities requires risk minimization of supply disruptions, in terms of volume quality, as well as price. More important even, the long-term future of large-scale international bio-trade must rely on environmentally sustainable production of biomass for energy. This requires the development of criteria, project guidelines and a certification system, supported by international bodies. This is particularly relevant for markets that are highly dependent on consumer opinions, as is presently the case in Western Europe. It is even more important for developing countries and rural regions to be aware of the opportunities as well as limitations for modern bio energy in an international setting, and to get involved in debate and collaboration for achieving sustainable development where it is most needed.

26.7.6 Biomass, Biofuels, Biomass Markets, and Energy Security

Based on the insights in global biomass resource potentials, techno-economic perspectives for production of 2nd generation biofuels and the rapid market growth for bio energy, including international trading, it is evident that biomass may be able to play a crucial role in enhancing diversity of energy supplies and energy security, as well as reducing greenhouse gas emissions and supporting rural development.

In particular, developing regions in Sub-Saharan Africa, Latin America as a whole, and Eastern Europe are capable of producing large amounts of bio energy next to meeting (growing) food demand while protecting forests and biodiversity. Those regions are also able to supply biomass resources that, combined with advanced technologies in the supply chain and for final conversion to especially transport fuels, can com-

pete fully with main fossil fuel-based alternatives, most notably mineral oil. Assuming that biomass resource potentials are developed in a sustainable way, the right infrastructure is put in place, and that markets and international trading are well developed, biomass and biofuels can be produced in a large number of countries, including export capabilities. In terms of energy security, this promises an improvement compared to currently concentrated mineral oil supplies in the world. We may see a number of 10–20 countries in the world develop into major biomass and biofuel exporters. Brazil already has such a position in the world market, and is likely to stay a leader in this respect. However, Eastern Europe (Ukraine, Russia), the SDAC region (with countries like Mozambique, Zambia, Zimbabwe, and Malawi), Central Africa and other parts of Latin America (Argentina, Central America, Colombia, and Cuba) are potential large exporters. Also other countries and regions have very significant biomass potentials (including North America, the EU, and parts of Asia), but their internal energy markets are so large that it is unlikely that they will develop into bio-energy exporters. We may therefore see a completely new number of players in the global energy market, while at the same time dependency on especially oil imports can diminish.

The information discussed in this chapter also showed that a gradual and sustainable development is necessary to develop the biomass resource base and infrastructure over time. Securing sustainability, e.g. by means of well established and credible certification schemes, is essential to avoid conflicts with food production and sustainable development.

27 Solar Energy on a Global Scale: Its Impact on Security

David Faiman

27.1 Introduction¹

In developed societies, fossil fuel has become all but indispensable for electricity generation, for transportation, and for a variety of heating purposes (both industrial and domestic). However, with the dwindling world fuel supplies, the danger of an international race to gain control of what little remains serves to emphasize the close connection that exists between energy and security, and the precarious position in which any hope of world peace accordingly finds itself.

In order to try and probe a possible way out of this dangerous situation it is important to realize the increasing role that electricity has assumed starting from about the beginning of the 20th century and the way in which it tends to dominate our lives today. It is this dominance that leads one to realize that a solution to the problem of how to generate low-cost electricity from renewable energy could essentially decouple the security issue from that of energy.

The necessary ingredients for such a de-coupling, not necessarily in the order in which they will be developed, are:

- A world-wide, low-loss (possibly superconducting) electrical transmission grid;
- A network of renewable energy power plants to feed it (solar, wind, tidal, hydro, etc. according to geographic availability);
- Efficient storage methods to ensure the dispatchability of electricity from renewable energy plants,

particularly in the lead-up period to a world-wide grid;

- Hydrogen-‘burning’ engines for ground and air transportation (fuelled by hydrogen that is locally produced by the electrolysis of water, using electricity generated from renewable energies).

If every country in the world had access to sufficient grid power, both to serve its electricity needs and to generate its own hydrogen fuel, it would be freed from many of the political considerations that today constrain its economic development. There would also be a natural changeover from the use of primary fuel to lower-cost electricity for a great many industrial purposes.

Naturally the key factors for such a reorganization of the world’s energy sector must be the availability of renewable energy in sufficient quantities, and the possibility of using it to generate electric power at low cost – where ‘low’ essentially means, at lower cost than has hitherto been possible with fossil fuel.

This chapter will discuss the potential for concentrator photovoltaic technology to play a major role in effecting such a solution to the energy problem. This is a technology that has recently been proposed for the large-scale generation of solar electricity at low cost (Raviv/Rosenstreich 2003, 2004, 2004a), if introduced into a number of key areas in the world.

27.2 The Magnitude of the Problem

In order to help us appreciate the magnitude of the problem, figure 27.1 shows the rate at which the world generation of electricity has been increasing in the past 10 years. The year 2003 is the latest for which data are presently available (IEA 2003). The increase is seen to be linear, with a slope of 395 TWh per year. To maintain this rate of increasing demand, the world will have to construct additional new power plants *each year*, with a combined power rating of approximately 80 GW, which will add to our fuel burden an

1 Research funded in part by the Israel Ministry of National Infrastructures. The author is indebted to his colleagues in the IEA Task 8 Photovoltaic Specialist Group *Very Large Scale Photovoltaic Solar Power Plants* for critical discussion of the assumptions made herein, and to Dov Raviv and Roy Rosenstreich for ‘lighting the fire’ and stimulating discussion. The author is indebted to Ms. Shoshana Dann for editorial assistance.

Figure 27.1: World electricity production during the years 1994-2003. Growth rate = 395 TWh per year. **Source:** IEA (2003).

extra 88 M tonnes (590 M barrels) of oil equivalent per year - each year.

Now figure 27.1 also indicates that the current annual world production of electricity is in excess of 15,000 TWh. Compared to this figure, an increase of 395 TWh per year may seem small. However, if the latter could be generated by renewable energies it could stabilize, at its present level, the annual demand for fossil fuel for electricity generation. Of course, ambitious as even this programme would be, it does not represent the world's *entire* energy needs: only the electrical part, which represents approximately one third of the total world fossil fuel consumption. But let us start by looking into what would be involved in trying to stabilize just the electrical part of the present world energy demand, by using solar energy to off-set the annual incremental requirements. This kind of approach has recently been applied in a study of the southwest states of the USA (Faiman/Raviv/Rosenstreich 2007), where high solar radiation levels, the availability of large areas of desert land, and relatively

high electricity tariffs combine to render such a goal feasible and highly cost-effective.

The biggest problem for solar is that, compared to fossil fuel, it is an *extremely dilute* form of energy. This can be appreciated by realizing that it requires *almost a year* for 1 m² of the (relatively sun-rich) deserts to intercept from the Sun the energy equivalent of 1 barrel of oil. And the world is currently consuming energy at a rate in excess of 200M barrels of oil equivalent *per day*. This means that we would need to collect solar energy over an area of 365 x 2,000M m² (assuming a nominal 10 per cent conversion efficiency) to generate this much usable solar energy. Are the world's deserts large enough to accommodate 730,000 km² of solar collectors? Since the Sahara alone is more than 10 times this area, and it is not the only desert, the answer is clearly in the affirmative. However, because an appropriate low-loss transmission method has not yet been developed for transporting electricity over global distances, it would be premature to think of the Sahara desert as an electric-

Table 27.1: World electricity generation statistics on a regional basis and linear projections to the year 2012. [*Generation for Eastern Europe and the Former Soviet Union fell steeply during the years 1990-1998. The linear fit for this region is therefore based on the past 5 years of data only]. **Source:** IEA (2003).

Region	Production in 2003 [TWh]	Percentage of World Production	Rate of Increase [TWh y ⁻¹]	Goodness of fit (R ²)	Projection to 2012 [TWh]
North America	4668.11	29.4	84.15	0.960	5425
Asia	4365.61	27.5	167.67	0.976	5875
Western Europe	2973.66	18.8	57.82	0.991	3494
Eastern Europe*	1668.18	10.5	36.67	0.992	1998
South America	723.74	4.6	20.97	0.944	912
Middle East	506.19	3.2	23.04	0.997	714
Africa	471.06	3.0	13.90	0.987	596
Oceania	370.95	2.3	13.59	0.999	493
Central America	104.92	0.7	4.02	0.992	141

ity source for the entire world. Instead, we have first to address smaller regions.

But what of the regional scale: Could solar energy reasonably be employed on a continental or even state-wide scale? Clearly the answer becomes more site-specific the smaller the scale that is considered, because it depends upon local population densities, land availability, and of course the quality of sunlight. Table 27.1 shows a break-down of figure 27.1 into its regional components. The regions are listed in descending order according to their present annual electricity production. The table gives for each geographic region of the world: the electricity generation figures for the year 2003 (IEA 2003); the rate of increase, based on a linear fit to the last 10 years of data; and the projected electricity requirements in the year 2012, based on a continuation of these linear fits. The projection for Eastern Europe, including the former Soviet Union, is based on the past 5 years of data only, due to the sharp fall in electricity production that occurred there during the years 1990-1998.

The reason that table 27.1 projects electricity generation to the year 2012 is that, as will be explained below, this is the *earliest* that a full-scale implementation of a solar alternative could realistically commence, and hence the last year that fossil fuel requirements for electricity production need continue to rise.

In a number of cases (North America, Asia, and South America) curvilinear least-squares-fits would match the data slightly better than the linear fits in table 27.1, but they are of no intrinsic significance as one can not predict the future. What is important is to realize that any such extrapolations, linear or otherwise, over such a lengthy period of time can not be

anything more than indicative as to *what we might expect* under a so-called 'business as usual' scenario. However, such extrapolations are useful for our present purpose, because they enable us to estimate the amount of land area that would be needed for a solar energy alternative, and the extent to which that land may or may not be available.

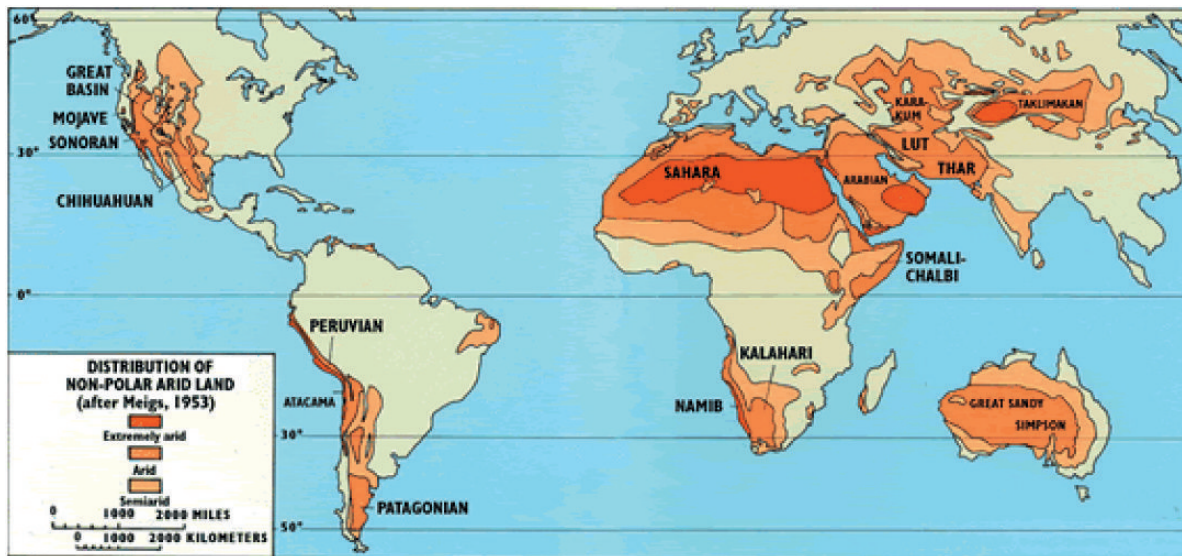

As regards the question of land availability, we see that the largest electricity requirements presently come from North America. Fortunately, the south-western part of this continent is amply endowed with desert areas in which large solar plants could be located. For example, the 300,000 km² Sonoran desert (Fig. 27.2) could, in principle, generate about 10 times the projected 2040 electricity requirements for this continent, as will be explained in the next section.

Similarly, the 1.3M km² Gobi desert and the 200,000 km² Thar deserts should be ample for providing Asia's future electricity needs. Western Europe could also be served by part of the Sahara desert. Eastern Europe could receive solar electricity from the 350,000 m² Kara-Kum desert and from the Gobi.

South America could employ the 670,000 km² Patagonian desert and the 140,000 km² Atacama desert. Of course the Middle East, being more or less entirely desert, has no lack of space for providing its future electricity needs. Africa has the Sahara in the North and the Kalahari and Namib deserts in the southwest, the latter two comprising more than 1 M km² of potential solar collection area.

Finally, although small on the world scale of consumption, the great Australian deserts could provide all of Australia's future electricity needs. As for the remainder of Oceania and also of Central America, al-

Figure 27.2: Distribution of the world's deserts. **Source:** U.S. Geological Survey; at: <<http://geology.com/records/sahara-desert-map.gif>>.

though deserts are not available, it is not impossible that cost-effective local solar energy solutions might be available on a country by country basis. However, because their energy needs are minuscule on a world scale, their fuel requirements are correspondingly modest. We shall therefore not deal with them further in this chapter. We turn now to the question of the type of solar technology that is appropriate for our task.

27.3 Photovoltaics – The Concentrator Variety

One might imagine spreading something like 730,000 km² of photovoltaic (PV) panels over the Sahara and feeding the resultant electric power into a future world electricity grid. In fact, the PV Task 8 Specialist Group, established by the International Energy Agency, recently performed a study of the feasibility of employing very large scale photovoltaic (VLS-PV) power generation systems in the deserts of the world (Kurokawa 2003). Such plants would typically be of the order of 1 GW in power production capability, and occupy some 10 km² of desert apiece. The study found that VLS-PV plants are already technically feasible, but that their cost is high compared to conventional power plants, mainly due to the need to use large amounts of PV material.

However, the IEA study also considered an approach known as *Concentrator Photovoltaics* (CPV). This method collects the solar energy over large, low-

cost, areas of glass mirrors, and concentrates it onto relatively small amounts of PV material for conversion to electricity. In this manner, a saving by typically a factor of 1000 can be effected in the amount of expensive PV material that is required. Thus, the world's present-day energy consumption rate of 200M barrels per day would still require 730,000 km² of mirrors in order to collect the sunshine, but only 730 km² of PV material for converting it to electricity.

Figure 27.3 shows a large parabolic dish reflector built for research purposes at Sede Boqer, Israel. Its capture area consists of more than 400 m² of silvered glass mirrors. In a European-funded project known as *HiConPV*, this dish was used to test a specially fabricated CPV cell module at a solar concentration 1000 times more intense than natural sunlight (1000X). A module of such solar cells, with dimension 65 cm x 65 cm, if illuminated by a 400 m² dish, could generate 120 kW of electric power under peak sunny conditions, or about 250,000 kWh of electrical energy per year.

An alternative CPV technology employs fresnel lenses, instead of mirrors, for concentrating sunlight. Figure 27.4 shows a prototype lens-based CPV collector under test in Phoenix, AZ, USA. This collector has a gross area of 225 m². Its 5760 plastic lenses concentrate sunlight by a factor 260X, focusing it onto an array of silicon CPV cells. This collector can produce about 25 kW under peak sunny conditions, or about 50,000 kWh of electrical energy per year.

Ten-thousand of the mirror dishes, or forty-thousand of the lens-type collectors could be packed into

Figure 27.3: CPV cell module exposed at 1000X at the 400 m² *PETAL* solar dish test facility in Sede Boqer, Israel. **Source:** Photo by David Faiman.

a 10 km² field and would generate an annual amount of electricity comparable to that of a conventional large modern power plant.

The two particularly promising characteristics of CPV compared to standard PV technology are its ability to reduce the amount of PV material per generated watt, as we have seen, by typically a factor of 1000; and the concomitant reduction in cost of the entire power-generating system - to levels that can compete with fossil-fuelled systems. In particular, it has been estimated that on the scale of GWs per year, large fields of CPV collectors could cost as little as \$850/kW installed (Raviv/Rosenstreich 2003, 2004, 2004a).

27.4 Storage Requirements for CPV

Storage is a problem for all power-generating systems *no matter what their energy source*. For example, coal-fired and oil-fired power plants can not be turned on and off at will, in order to provide energy only when needed. As a result, many utility companies resort to offering low-cost electricity at off-peak demand times in order to enable them to try and maximize the revenue from the fuel they are constantly forced to burn. However, provided that their peak generating capacity does not fall short of peak demands, such plants never have a problem of providing power when it is needed. Nevertheless, their fuel efficiency is low and in situations where storage can be provided (e.g. via water pumping), night-time electricity can be sold during the following day, and fuel efficiency increases accordingly.

Figure 27.4: A large pre-commercial CPV system under test in Phoenix, AZ, USA, consists of 5760 plastic fresnel lenses, which each focus sunlight onto one of a similar number of individual 1 cm x 1 cm silicon CPV cells. **Source:** Photo by David Faiman.

Now, renewable energy plants, particularly of the solar or wind variety, also have a storage problem, but one that is of a qualitatively different nature. Here, the variability of the energy source turns the plants on and off at random times of the day. This is an unacceptable situation for an economy that requires power to be available at all times. Therefore, in the case of solar, some form of storage is an absolute necessity. This problem can be approached in three stages.

At the first stage, solar generating capacity is so small that the electricity grid is capable of accepting all power if and when it is generated. Here, the word 'small' means that the peak solar output would never exceed the difference between demand and what the fossil-fuelled plants can generate. This would never be the situation if fossil plants were sized to exceed maximum demand levels. However, because of ever rising demands for electricity, utility companies constantly have to face situations in which additional power plants need to be constructed. In this connection, one of the great attractions of the 30 MW solar-thermal plants that were constructed in California during the 1980's, was their modularity and comparatively low cost compared to the giant 1000 MW plants that were

the available fossil alternatives. Thus, solar was able to fill the gap between rising electricity needs and available fossil-fuelled capacity, in a more cost-effective manner than would have been the case by adding an additional very large fossil plant. Of course, there was still the problem of what to do during cloudy periods (because the solar-thermal plants required direct sunlight). This problem was solved by employing gas-fired backup - i.e. small amounts of fossil fuel.

In the case of our proposed CPV plants, the first stage would employ battery storage, or perhaps small gas-burning generators. In the case of batteries, they would be charged at night (using fossil-generated power from the grid) and used during the day to fill in the cloud-cover gaps between successive sunny spells. The precise sizing of the batteries and the strategy for buying and selling fossil-generated energy for charging them would be a matter for optimization to specific local conditions. However, it has been suggested (Raviv/Rosenstreich 2003, 2004, 2004a) as a starting rule-of-thumb, that for each 3 GWp of solar generating capacity, batteries with 1 GW of 6 h storage capacity should be included.

Stage 2 of the storage problem is reached when the fraction of solar-generated electricity is no longer small compared to a given utility's overall mix of power inputs. This problem will require further research for the creation of optimal power usage strategies from the various types of grid input plants (fossil, solar, wind, etc. – and storage). It will also require new technological developments in various potential forms of storage.

Stage 3 is reached when there is a world-wide grid. At that stage, the global storage problem will be solved by the fact that the sun always shines somewhere. However, there may still remain some local storage requirements, and these will be handled by the various technologies that will have been developed at stage 2.

The bottom line of this storage discussion is that the world does not need to await the development of a complete solution to the storage and transmission problem before embarking upon the construction of very large solar power plants. Provided the latter can be built in a cost-effective manner and their use can lead to a significant reduction in the demand for fuel then such a programme should go ahead.

27.5 Land Requirements for CPV

There is one restrictive characteristic of CPV, compared to standard PV, and that is its need for direct sunshine. Conventional flat PV panels generate power in direct proportion to the amount of light they receive, irrespective of whether it is bright sunshine or the diffuse light from cloudy skies. This means that even on dull, cloudy days they produce some power. In contrast, CPV collectors, because they concentrate sunlight, need to be able to see the sun. This kind of technology is therefore mostly suitable for desert regions. But of course, since a solar solution, of any kind, will require large areas of available land, desert wastelands are in any case the most suitable locations. This is the reason why, in our search for a global solar solution, we have focused on countries that have substantial desert areas available for the CPV plants, and of their proximity to countries that do not. For example, Europe does not have deserts, but it is relatively close to the Sahara. Hence, via links between Morocco and Spain, or between Libya and Sicily, the European electricity grid could be fed from CPV stations located in the Sahara. On the other hand, much of Oceania is relatively far removed from the Australian deserts. Consequently, a CPV solution for those coun-

tries would need to await the further development of low-loss transmission cables.

Regarding the amount of land area that would actually be required for the erection of large CPV plants, a study of the seven southwest states of the USA concluded that, depending upon the intensity of sunlight available at the site, it would take from 4.85 km² (California) to 5.90 km² (Utah) of land to generate each 1 TWh of electricity per year (Faiman/Raviv/Rosenstreich 2007). Therefore, if we take 5 km² per TWh y⁻¹ as a rough guide, we see that in order to generate the 395 TWh per year at which world demand is increasing, we would need to cover approximately 1975 km² of additional desert each year. The operation of such an increasing quantity of CPV plants would enable the world's fossil fuel consumption for electricity-producing purposes to level off at its present value (or at whatever value it would have reached by the time the first set of CPV plants become operative).

Table 27.2 shows a region-by-region examination of the amount of land that will be required for enabling solar energy to halt the present annual growth in fossil fuel consumption. The table also identifies the name and the size of the closest desert terrain. The land requirement calculations are based upon a nominal 5 km² per 1 TWh y⁻¹.

27.6 Economic Assumptions for CPV Construction

In the following section we shall study the electricity needs of a number of single countries, from each of the regions in table 27.2. We shall then calculate the rate at which VLS-PV plants would need to be built in order to stop that country's annual fuel requirements from increasing. Equally important, we shall use the Raviv Model (Raviv/Rosenstreich 2003, 2004, 2004a) to calculate the expected costs and economic benefits associated with taking such a step. We therefore first review the economic assumptions of the Raviv Model that will be common to all of our examples. Since they have been discussed at length elsewhere (Faiman/Raviv/Rosenstreich 2007), there is no need to do more than to list them here.

- It is assumed that it would take 4 years to set up a collector manufacturing facility with an annual throughput of 1 GWp. The cost of this production line was calculated to be US\$630M. If a decision to implement such a programme were to be taken in 2007, then construction of the manufacturing facility would occupy the years 2008–2011.

Table 27.2: Estimated area of desert land required for enabling each geographical region to freeze its fossil fuel requirements at the anticipated 2012 level, by the annual construction of VLS-PV plants of the CPV type starting in the year 2012. [*Eastern Europe includes Russia and the former Soviet Union states, and is listed as being problematic owing to its comparative large distance from the nearest deserts.] **Source:** <www.geosource.ac.uk/worldguide/guide_deserts.html> after Chambers Book of Facts (2003).

Region	Annual increase in power generation [TWh y ⁻¹]	Solar land requirement [km ² y ⁻¹]	Nearest desert	Size of desert [km ²]
North America	84.15	421	Sonoran	311,000
Asia	167.7	838	Gobi Thar	1,295,000 453,000
Western Europe	57.82	289	Sahara	9,065,000
Eastern Europe*	36.67	183	problematic	
South America	20.97	105	Atacama	140,000
Middle East	23.04	115	Arabian	1,700,000
Africa	13.90	70	Sahara Kalahari	9,065,000 582,000
Oceania	13.59	68	Great Victoria	647,000
Central America	4.02	20	Chihuahuan	453,000

- Also to be established during the same 4 year period would be a storage battery manufacturing facility with an annual throughput of 333 kW. The batteries should have an effective storage capacity of 6 hours. The cost of the battery manufacturing facility was estimated to be US \$ 100M.
- It is assumed that the production cost of each 1 GWp VLS-PV plant (including 333 kW of battery storage) will be US \$ 1.133M. This cost includes components, manufacturing, delivery to site, plant construction and checkout. Manufacture and construction of the first plant would occur in the year 2012. This would accordingly be the last year that the state in question would have increased its fossil fuel consumption for electricity production: From 2013 onwards, all additional electricity needs would be provided by solar energy.
- A further US \$ 220M is included for research and development (R&D) costs. In principle, this is a one-time item that affects only the first manufacturing facility. However, since we do not know where that will be, we shall add this cost to the total cost required for setting up such a facility at each of the sites under discussion.
- In addition to the preceding large cost items, we also include general and administrative (G&A) costs of 5% of electricity sales up to a ceiling of US \$ 100 M per year.
- We assume that operation and maintenance (O&M) costs will amount to 0.5 US¢/kWh.
- We assume an annual interest rate of 5 per cent in constant dollars (i.e. above inflation).

27.6.1 Electricity Tariff

In our previous CPV studies, we made various assumptions about the tariff at which the electricity will be sold. In the case of our study for Israel (Faiman/Raviv/Rosenstreich 2007a) we assumed a tariff of 9 US¢/kWh, corresponding to the prevailing cost of electricity in that country. In our more general sensitivity study (Faiman/Raviv/Rosenstreich 2005) we assumed 10 US¢/kWh. In our study of the seven southwestern states of the USA (Faiman/Raviv/Rosenstreich 2007) we used the average tariffs prevailing in each of those states. In all of those cases (except for Utah) we found that VLS-PV systems in their CPV variety turned out to exhibit ‘sustainability’ in three distinct ways.

First, was the fact that mounting annual electricity revenues cause the initial capital investment plus interest to be paid back well within the lifetime of the first (and therefore oldest) VLS-PV plant. Second, after the initial investment is paid off, the electricity tariff can be lowered to a level that enables the continued annual plant construction, but without the need for any further external capital investment (so-called *Type-2 sustainability*). Third, assuming a 30-year effective lifetime for each VLS-PV plant, it becomes necessary to construct two plants per year from year 35 onwards. It

Figure 27.5: Electricity production in Mexico during the years 1994-2003. Growth rate = 8.2 TWh per year. Source: IEA (2003).

turns out, however, that this can also be done without the need for additional external capital investment, if only a slight adjustment is made to the type 2 sustainability tariff (except for the case of Utah). This ability of VLS-PV plants of the CPV variety to cover the costs of plant renewal was termed *Type-3 sustainability*.

For our present study, we shall turn the question around. Instead of assuming that the solar-generated electricity will be sold at some prevailing tariff we shall ask: What is the minimum price for which the electricity can be sold that will just permit Type-3 sustainability? That is to say, we shall calculate the minimum tariff, for each country considered below, that would enable the full investment plus interest to be paid off by the time VLS-PV plant No. 1 is 30 years old, and permit the subsequent construction of 2 new plants per year entirely from electricity revenues.

27.7 Some Specific Examples

27.7.1 Mexico

We have chosen Mexico as our example for North America because, on the one hand, the cases of seven of the states of the USA have been discussed in detail elsewhere. Secondly, unlike Canada, Mexico has its own desert, the Chihuahuan, in which the VLS-PV plants can be located. Let us first address the size of the VLS-PV plants needed for this country. Figure 27.5 shows the rate at which electricity production in Mexico has been rising during the past 10 years (IEA 2003).

One sees that Mexico's electricity needs are rising at a rate of 8.2 TWh per year. In order to generate this much electricity per year from solar energy, it would be necessary to construct VLS-PV plants at the rate of 4.1 GWp per year, each such plant requiring approximately 41 km² out of the 453,000 km² of the Chihuahuan desert.

Figure 27.6: Electricity production in Chile during the years 1994-2003. Growth rate = 2.5 TWh per year. **Source:** IEA (2003).

Regarding cost, a tariff of 6.13 US¢/kWh would be the minimum that would enable Type-3 sustainability for such plants. Such a starting tariff would permit the entire investment plus interest to be paid off in year 34 (i.e. the final year in the life of VLS-PV plant No. 1). From then onward, the electricity tariff could be lowered to 4.37 US¢/kWh for continued Type-3 sustainability.

With such a low starting tariff, the required credit line would reach a maximum value of US \$ 25.36B, in year 20. However, by employing a higher starting tariff, the credit line would be paid off sooner and it would not reach such a large maximum value. For example, for a starting tariff of 10 US¢/kWh, a credit line maximum of only US \$ 13.44B would be reached in year 12 and fully paid off by year 21. The tariff could then be lowered to 3.99 US¢/kWh for Type-2 sustainability and then raised in year 35 to 4.37 US¢/kWh for Type-3 sustainability.

27.7.2 Chile

From North America we move south to Chile. Although this country is not the largest electricity producer in South America it has the advantage, for our purposes, of being located close to the Atacama desert. So let us again first address the size of the VLS-PV plants needed for this country. Figure 27.6 shows the rate at which electricity production in Chile has been rising during the past 10 years (IEA 2003).

One sees that Chile's electricity needs are rising at a rate of 2.5 TWh per year. In order to generate this much electricity per year from solar energy, it would be necessary to construct VLS-PV plants at the rate of 1.25 GWp per year, each such plant requiring approximately 12.5 km² out of the 140,000 km² of the Atacama desert.

Regarding cost, a tariff of 6.84 US¢/kWh would be the minimum that would enable type-3 sustainability for such plants. Such a starting tariff would permit the entire investment plus interest to be paid off in

Figure 27.7: Electricity production in Spain during the years 1994-2003. Growth rate = 10.6 TWh per year. **Source:** IEA (2003).

year 34 (i.e. the final year in the life of VLS-PV plant No.1). From then onward, the electricity tariff could be lowered to 4.42 US¢/kWh for continued Type-3 sustainability.

With such a low starting tariff, the required credit line would reach a maximum value of US \$ 13.75B, in year 18. However, by employing a higher starting tariff, the credit line would be paid off sooner and it would not reach such a large maximum value. For example, for a starting tariff of 10 US¢/kWh, a credit line maximum of only US \$ 8.59B would be reached in year 13 and fully paid off by year 21. The tariff could then be lowered to 4.07 US¢/kWh for Type-2 sustainability and then raised in year 35 to 4.42 US¢/kWh for Type-3 sustainability.

27.7.3 Spain

For our European example we have chosen Spain because of its close proximity, via the Strait of Gibraltar,

to the Sahara, where it is assumed European VLS-PV plants would be sited. It is also an example of a state with special feed-in tariffs to promote the use of alternative energies. Again, we first address the size of the VLS-PV plants needed for this country. Figure 27.7 shows the rate at which electricity production in Spain has been rising during the past 10 years (IEA 2003).

One sees that Spain's electricity needs are rising at a rate of 10.6 TWh per year. In order to generate this much electricity per year from solar energy, it would be necessary to construct VLS-PV plants at the rate of 5.3 GWp per year, each such plant requiring approximately 53 km² out of the 9.065M km² of the Sahara desert.

Regarding cost, a tariff of 6.01 US¢/kWh would be the minimum that would enable Type-3 sustainability for such plants. Such a starting tariff would permit the entire investment plus interest to be paid off in year 34 (i.e. the final year in the life of VLS-PV plant No.1). From then onward, the electricity tariff could

Figure 27.8: Electricity production in South Africa during the years 1994-2003. Growth rate = 4.0 TWh per year. **Source:** IEA (2003).

be lowered to 4.31 US¢/kWh for continued Type-3 sustainability.

With such a low starting tariff, the required credit line would reach a maximum value of US\$66.31B, in year 20. However, by employing a higher starting tariff, the credit line would be paid off sooner and it would not reach such a large maximum value. For example, for a starting tariff of 10 US¢/kWh, a credit line maximum of only US\$34.29B would be reached in year 12 and fully paid off by year 20. The tariff could then be lowered to 4.11 US¢/kWh for Type-2 sustainability and then raised in year 35 to 4.31 US¢/kWh for Type-3 sustainability.

It should be mentioned that at the present time, solar entrepreneurs in Spain enjoy an artificially high feed-in tariff, equivalent to approximately 50 US¢/kWh, in order to promote the use of solar energy. If such high tariffs will still be available for the coming 30-40 years then VLS-PV plants of the kind discussed here will return their initial investment in record time. For example, with a starting tariff of 50 US¢/kWh, a

credit line maximum of only US\$11.98B would be reached in year 6, and fully paid off by year 8. The tariff could then be lowered to 14.92 US¢/kWh for Type-2 sustainability and then lowered yet again in year 35 to 4.31 US¢/kWh for Type-3 sustainability.

27.7.4 South Africa

From Spain we move south to the largest producer of electricity in the African continent, South Africa. Again, we first address the size of the VLS-PV plants needed for this country. Figure 27.8 shows the rate at which electricity production in South Africa has been rising during the past 10 years (IEA 2003). One sees that South Africa's electricity needs are rising at a rate of 4.0 TWh per year. In order to generate so much electricity per year from solar energy, it would be necessary to construct VLS-PV plants at the rate of 2.0 GWp per year, each such plant requiring approximately 20 km² out of the 582,000 km² of the Kalahari desert.

Figure 27.9: Electricity production in Saudi Arabia during the years 1994-2003. Growth rate = 5.7 TWh per year. **Source:** IEA (2003).

Regarding cost, a tariff of 6.13 US¢/kWh would be the minimum that would enable Type-3 sustainability for such plants. Such a starting tariff would permit the entire investment plus interest to be paid off in year 34 (i.e. the final year in the life of VLS-PV plant No. 1). From then onward, the electricity tariff could be lowered to 4.37 US¢/kWh for continued Type-3 sustainability.

With such a low starting tariff, the required credit line would reach a maximum value of US \$ 25.36B, in year 20. However, by employing a higher starting tariff, the credit line would be paid off sooner and it would not reach such a large maximum value. For example, for a starting tariff of 10 US¢/kWh, a credit line maximum of only US \$ 13.44B would be reached in year 12 and fully paid off by year 21. The tariff could then be lowered to 3.99 US¢/kWh for Type-2 sustainability and then, in year 35, raised to 4.37 US¢/kWh for Type-3 sustainability.

27.7.5 Saudi Arabia.

We now move north to the largest producer of electricity in the Middle East, Saudi Arabia. Again, we first address the size of the VLS-PV plants needed for this country. Figure 27.9 shows the rate at which electricity production in Saudi Arabia has been rising during the past 10 years (IEA 2003).

One sees that Saudi Arabia's electricity needs are rising at a rate of 5.7 TWh per year. In order to generate this much electricity per year from solar energy, it would be necessary to construct VLS-PV plants at the rate of 2.85 GWp per year, each such plant requiring approximately 28.5 km² out of the 1.700M km² of the Arabian desert.

Regarding cost, a tariff of 6.08 US¢/kWh would be the minimum that would enable Type-3 sustainability for such plants. Such a starting tariff would permit the entire investment plus interest to be paid off in year 34 (i.e. the final year in the life of VLS-PV plant

Figure 27.10: Electricity production in India during the years 1994-2003. Growth rate = 23.4 TWh per year. **Source:** IEA (2003).

No. 1). From then onward, the electricity tariff could be lowered to 4.34 US¢/kWh for continued Type-3 sustainability.

With such a low starting tariff, the required credit line would reach a maximum value of US \$ 35.93B, in year 20. However, by employing a higher starting tariff, the credit line would be paid off sooner and it would not reach such a large maximum value. For example, for a starting tariff of 10 US¢/kWh, a credit line maximum of only US \$ 18.85B would be reached in year 12 and fully paid off by year 21. The tariff could then be lowered to 3.94 US¢/kWh for Type-2 sustainability and then raised in year 35 to 4.34 US¢/kWh for Type-3 sustainability.

27.7.6 India

Of the countries exhibiting a linear rise in their electricity production, the slope of India's exceeds all others by far. It is therefore appropriate to consider this state as our example from the Asian continent. Again,

we first address the size of the VLS-PV plants needed for this country. Figure 27.10 shows the rate at which electricity production in India has been rising during the past 10 years (IEA 2003)

One sees that India's electricity needs are rising at a rate of 23.4 TWh per year. In order to generate this much electricity per year from solar energy, it would be necessary to construct VLS-PV plants at the rate of 11.7 GWp per year, each such plant requiring approximately 117 km² out of the 453,000 km² of the Thar desert.

Regarding cost, a tariff of 5.97 US¢/kWh would be the minimum that would enable Type-3 sustainability for such plants. Such a starting tariff would permit the entire investment plus interest to be paid off in year 34 (i.e. the final year in the life of VLS-PV plant No. 1). From then onward, the electricity tariff could be lowered to 4.30 US¢/kWh for continued Type-3 sustainability.

With such a low starting tariff, the required credit line would reach a maximum value of US \$ 144.98B, in

Figure 27.11: Electricity production in Australia during the years 1994-2003. Growth rate = 6.6 TWh per year. **Source:** IEA (2003).

year 20. However, by employing a higher starting tariff, the credit line would be paid off sooner and it would not reach such a large maximum value. For example, for a starting tariff of 10 US¢/kWh, a credit line maximum of only US \$ 74.37B would be reached in year 12 and fully paid off by year 20. The tariff could then be lowered to 4.07 US¢/kWh for Type-2 sustainability and then raised in year 35 to 4.30 US¢/kWh for Type-3 sustainability.

27.7.7 Australia

For our last example, we examine the case of Australia, by far the largest electricity producer in Oceania. Again, we first address the size of the VLS-PV plants needed for this country. Figure 27.11 shows the rate at which electricity production in Australia has been rising during the past 10 years (IEA 2003).

One sees that Australia's electricity needs are rising at a rate of 6.6 TWh per year. In order to generate this much electricity per year from solar energy, it

would be necessary to construct VLS-PV plants at the rate of 3.3 GWp per year, each such plant requiring approximately 33 km² out of the 647,000 km² of the Great Victoria desert.

Regarding cost, a tariff of 6.06 US¢/kWh would be the minimum that would enable Type-3 sustainability for such plants. Such a starting tariff would permit the entire investment plus interest to be paid off in year 34 (i.e. the final year in the life of VLS-PV plant No. 1). From then onward, the electricity tariff could be lowered to 4.33 US¢/kWh for continued Type-3 sustainability.

With such a low starting tariff, the required credit line would reach a maximum value of US \$ 41.53B, in year 20. However, by employing a higher starting tariff, the credit line would be paid off sooner and it would not reach such a large maximum value. For example, for a starting tariff of 10 US¢/kWh, a credit line maximum of only US \$ 21.70B would be reached in year 12 and fully paid off by year 20. The tariff could then be lowered to 4.14 US¢/kWh for Type-2

sustainability and then again in year 35 to 4.33 US¢/kWh for Type-3 sustainability.

27.8 Conclusions

In this chapter we have taken a sample of the world's larger electricity producers, one from each geographical region, and shown that it would be both technically and economically feasible for them to freeze their fossil fuel consumption at the 2012 level by embarking upon a massive construction programme of CPV solar power plants. Specifically, a decision would need to be taken in 2007 that would enable a plant manufacturing facility to be constructed during the 4-year period 2008–2011, and the first CPV plant to be constructed and connected to the grid in 2012. The level of investment needed is of the order of tens of billions of US\$, however, the capital investment is shown to be *fully recoverable* from electricity revenues within the expected lifetime of the power plants. Furthermore, because of the so-called 'triple sustainability' of CPV power plants, this kind of technical solution would stabilize the country's fuel requirements for an indefinitely long period of time. That is to say, a government which decides to adopt this kind of solution, solves the problem of power plant construction forever, and would use fossil fuel at a constant annual rate instead of an ever-increasing rate.

The example of Spain was particularly instructive because there we were able to see the striking effect of introducing high feed-in tariffs. In particular, the amount of capital investment needed is very much lower, and the infrastructure is paid off very much faster. This fact indicates that a relatively short-term public loan could enable CPV infrastructure to be installed relatively rapidly - i.e. in less than 10 years.

These single-state examples could be extended to most of the world. For this purpose, it would require approximately 1,000 km² of desert each year in order to enable CPV plants to generate the 395 TWh per year by which the world's present electricity production is rising. However, by stabilizing the electrical part of the world's fossil fuel requirements to a constant level, the amount of remaining fuel would last very much longer and the concomitant decrease in uncertainty would surely help promote security.

But there are several problems that must not be forgotten. First, a number of major electricity consumers are located relatively far from available deserts. Such is the case, for example, of the eastern European states. A CPV solution for them will require signifi-

cant technological advances in the development of low-loss transmission lines. At present the lowest loss method of transmitting power over distances of hundreds of kilometres is to employ high voltage DC cables. However, using solar to extend the length of time that fossil fuel will last will provide more time for developing alternative forms of low-loss transmission, such as high-temperature superconducting methods.

Storage is another technology area for which the additional time bought by the implementation of large-scale CPV plants will promote development. Storage is needed, not so much for night-time power generation (for which abundant fossil-fuelled capacity already exists) but rather for ensuring dispatchability during periods of cloud cover. For any given location, storage must be sized so that *available* night-time fossil-fuelled generating capacity can fully charge it in one night with sufficient energy to overcome a completely cloudy following day.

As for the non-electrical requirements of fossil fuel, we have seen that the estimated O&M cost of CPV electricity is of the order of 0.5 US¢/kWh. This is, effectively, the true generating cost of solar electricity after the CPV plants have paid themselves off. At such a low price, it would become cost-effective to generate hydrogen via the electrolysis of water and to use it as transportation fuel. Similarly, truly low-cost solar-generated electricity would enable this commodity to replace fossil fuel for a great many of today's processes for which the burning of fuel is more cost-effective than using electricity.

Naturally, this is a bootstrapping process. Using solar to freeze the fossil requirements for electricity production would already promote security by enabling the remaining fossil fuel reserves to last longer. However, using low-cost solar electricity to generate transportation fuel and also to replace other direct uses of fossil fuel would enable the latter to last even longer. This would obviously promote security still further. Furthermore, the development of low-loss transmission and efficient storage would enable other renewables, such as wind and wave power, to make their respective contributions, along side of solar, to a world electricity grid - and hence to greater security. But a start has to be made somewhere, *and very soon*. In this chapter we have argued that a suitable starting point could be concentrator photovoltaics in that the technology is ready and it would substantially reduce the dependence of electric power on fossil fuel.

28 Solar Energy as a Key for Power and Water in the Middle East and North Africa

Franz Trieb, Wolfram Krewitt and Nadine May

28.1 Introduction

This chapter argues that a strategy for energy and water security¹ in the Southern European Union, the Middle East, and North Africa (MENA) can be based on a combination of rational use of energy, renewable energy sources, and international cooperation. A well balanced mix of renewable and fossil energy sources is a prerequisite not only for environmental stability, but also for economic development, in fact being the least cost option for energy and water in the medium-term future. Renewables require no long-term subsidies like nuclear or fossil energies, but they need start-up investments that must be provided now by sound energy policies based on a Trans-Mediterranean partnership for energy, water, and development (Nitsch/Staiß 1997; Brauch 1997c, 1997d, 2000a, 2001a, 2006a).

The perspectives given here are the result of a study about the Mediterranean region that had the scope of evaluating the technical, economic, and environmental feasibility of a sustainable electricity supply system based on renewable sources, and give policy-makers a data basis for acting accordingly within their specific environment. As the MENA region is very heterogeneous, the scope was not to propose specific policies or strategies, but give local decision-makers a basis for acting according to their specific needs and frame conditions.

The authors are well aware of the present activities, policies, and problems in the MENA region. The perspective given here cannot be interpreted as prognostic. A scenario like the one presented here is a consistent pathway to the future leading to a certain goal,

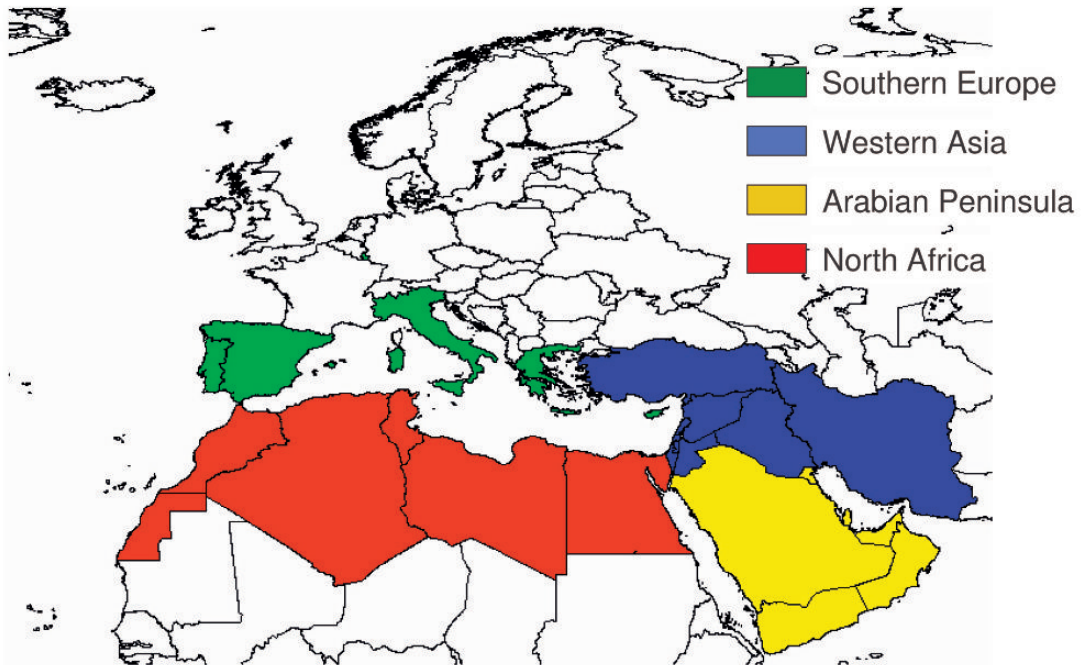

e.g. sustainability. There may be many variations of that scenario or different scenarios leading to the same or to other goals. Their achievement will in any case require effort, political will, and technical skills. The scenario presented here will not happen spontaneously, but it shows a viable path to the future for those who want to take that route.

The Middle East and North Africa (MENA) is a major focus of global interest, holding more than 60 per cent of the world's mineral oil reserves, showing high growth rates of population and economy, and at the same time facing serious hazards like the depletion of freshwater resources and desertification through climate change (IEA 2005). Countries like Morocco or Jordan that have no mineral resources are heavily burdened by any energy cost escalation, while others like Iran or the United Arab Emirates are feeling an increasing conflict between selling fuel to the world market and burning it for their domestic needs. The economic development of the North Western hemisphere – mainly Europe and USA – in the past centuries was flashed by the fossil energy resources of the MENA region, but now that this region also claims its share for economic development, the international pressure on those resources grows higher, and many MENA countries may be deprived of their means of economic development just when they are starting it. Separatism and fundamentalism are blooming, both in the Arab world and in the West, and terrorism is affecting both sides. Territorial conflicts on energy and water have been a regional reality, and they may soon break out on a large scale.

This situation is something of a paradox, because neither land, nor energy, nor water is scarce in this region. There is plenty of water in the Mediterranean Sea, the Red Sea and the Persian Gulf, plenty of unused desert land in most MENA countries, and – with a solar energy equivalent of 1 to 2 barrels of oil per year on every square metre – more solar energy than mankind will ever need. However, the knowledge is

1 Here, the term security refers primarily to security of supply. However, a sustainable form of supply is envisaged. This implies avoiding a number of environmental, economic, and societal risks, and leads to a more comprehensive effect on societal security in this region.

Figure 28.1: Countries of the EU-MENA region analysed within the MED-CSP Study **Source:** MED-CSP (2005) that is co-authored by these authors.

lacking on how to exploit these treasures. Civilizations have disappeared due to a lack of knowledge, while those having key information (and using it) have survived. Then there is a need for cooperation. Today, there is a strong trend for solving conflicts by force, driven by the illusion of military strength and national autonomy. However, in contrast to solving conflicts by cooperation, solving conflicts by force never creates added value but usually leads to the destruction of means, making everybody poorer and sharpening scarcity.

This chapter addresses the following questions:

1. Can renewable energy sources cope with the growing energy demand of the Middle East and North Africa?
2. Are renewable energy sources too expensive for this region?
3. Is there a solution for the problem of water scarcity in the MENA region?
4. Is a trans-national EUMENA partnership for renewable energy a viable option for development?

28.2 Perspectives of Energy and Water in the Euro-Mediterranean until 2050

This chapter focuses on the electricity and water supply of Southern Europe (Portugal, Spain, Italy, Greece, Cyprus, and Malta), North Africa (Morocco, Algeria, Tunisia, Libya, and Egypt), Western Asia (Turkey, Iran, Iraq, Jordan, Israel, Lebanon, Syria) and the Arabian Peninsula (Saudi Arabia, Yemen, Oman, United Arab Emirates, Kuwait, Qatar, Bahrain) (figure 28.1)

In these countries the growth of population (Brauch/Selim/Liotta 2003: 972) and of the economy will significantly increase the water and energy demand (MED-CSP 2005). By 2050, the MENA countries may reach a similar electricity demand as Europe (3500 TWh/y). Although this scenario assumes efficiency gains and moderate population growth or even population declining in some countries, electricity demand is projected to almost triple from 1500 TWh/y in 2005 to 4100 TWh/y in 2050 (figure 28.2). Electricity demand has already tripled during the past 20 years.

Water demand of the MENA countries will rise from 300 billion cubic metres per year in 2005 to over 500 billion m³/y by 2050 (figure 28.3). In most countries agriculture has stagnated or declined, while the

Figure 28.2: Gross electricity consumption of countries analysed. **Source:** MED-CSP 2005 that is co-authored by these authors.

domestic and industrial sector has strongly grown. In many MENA countries and in some Southern European regions, natural water resources have already been exploited beyond their sustainable yield by an overshoot of 40–50 billion m³/y, which is almost equivalent to the volume of the Nile River.

This excessive use of freshwater resources is only possible for a transient time. Overexploitation of groundwater resources must be reduced in the mid term and avoided afterwards, but additional demand must also be satisfied. This will require efficient water management and environmentally compatible technologies for seawater desalination based on a sustainable and affordable energy source.

Fossil or nuclear fuels cannot cope with any of these criteria due to being heavily subsidized, and suffering unsolved problems like nuclear waste disposal and proliferation of plutonium. Fossil fuels have caused international conflicts and contribute to climate change. Oil, gas, and uranium have multiplied in cost during the past few years, and a backward trend is not visible. In some oil exporting countries there is an increasing competition between exports and internal consumption. Building the future MENA water supply system on those resources by using those energy carriers for desalination would be highly risky.

Energy and water supply can therefore not rely on fossil fuel resources alone.

28.3 Renewable Energy Sources are Plentiful

The central thesis of this chapter is that the renewable energy sources in the analysed region can cope with the growing demand of the developing economies. Wind, geothermal power from hot dry rocks, hydropower, and biomass electricity potentials are each in the order of about 400 TWh/y. Those resources are more or less locally concentrated and not available everywhere, but can be distributed through the electricity grid. The by far biggest resource in the MENA region is solar irradiance, with a potential that is several times larger than the total world electricity demand.

Wind power is a strongly fluctuating energy source that cannot be delivered on demand (table 28.1). However, distributed wind parks partially compensate each other's fluctuations and show a relatively smooth transition of their total output. Depending on the different situation in each country, up to 15 per cent of the installed wind capacity can be considered as se-

Figure 28.3: Water demand projection in the MENA countries in the MED-CSP scenario. Water demand already exceeds the sustainable resources of fresh water today, with an alarmingly increasing deficit. **Source:** MED-CSP (2005).

cured. Photovoltaic electricity is also strongly fluctuating and only available during daytime. There is no contribution to secured power, but a good correlation with the usual daytime power demand peak of most countries. PV is specially suited for distributed power supply, but also very large-scale PV systems are an option for the future. Geothermal power can be delivered on demand as base, intermediate or peaking power using the earth as a natural storage system. It can thus compensate the fluctuations from wind and PV.

Biomass can deliver power on demand as it is easily storable. However, biomass is scarce in the MENA region and subject to seasonal fluctuations. As a strategic guideline, biomass can be supplied in times when wind and PV power is low in order to compensate those sources, and shut down when wind and PV power is available to save the scarce biomass resources. The situation is similar for hydropower from dams, which can be delivered on demand but is scarce in the MENA and subject to strong seasonal fluctuations. If used only when PV and wind power are low, it acts like a complement and as a storage system for those resources.

Concentrating solar thermal power stations² can deliver power on demand, making use of their ther-

mal storage capability and hybrid operation with fuels. They are an ideal link between the fossil system and other renewables. As the largest natural resource, they will provide the core of electricity, taking over base and peaking load duties from fossil plants. Oil and gas fired power plants are most widely used. They will subsequently close the gap between the load and renewable power during peaking times. Thus, average fossil fuel consumption and carbon emissions will be reduced faster than their installed capacity. Only few MENA countries use coal fired power plants. Coal constitutes a feasible, problematic supplement to power generation in the MENA that is exclusively based on imports and contributes to global warming. Domestic sources like renewables, oil, and gas will be the preferable option in most MENA countries.

Power technologies based on hydrocarbons will increasingly be charged with extra costs of carbon sequestration, as their effect on climate change is very dangerous. If they decide for a power supply based mainly on fossil fuels, most MENA countries will

2 Steam or gas turbines operated with high temperature solar heat from concentrating solar thermal collectors and by fuel as backup. Thermal energy storage avoids the need for storing solar electricity during daytime.

Figure 28.4: Maps of renewable energy yields of different sources in the EU-MENA (darker colours indicate higher potentials per unit area; on the colour code see: MED-CSP (2005).

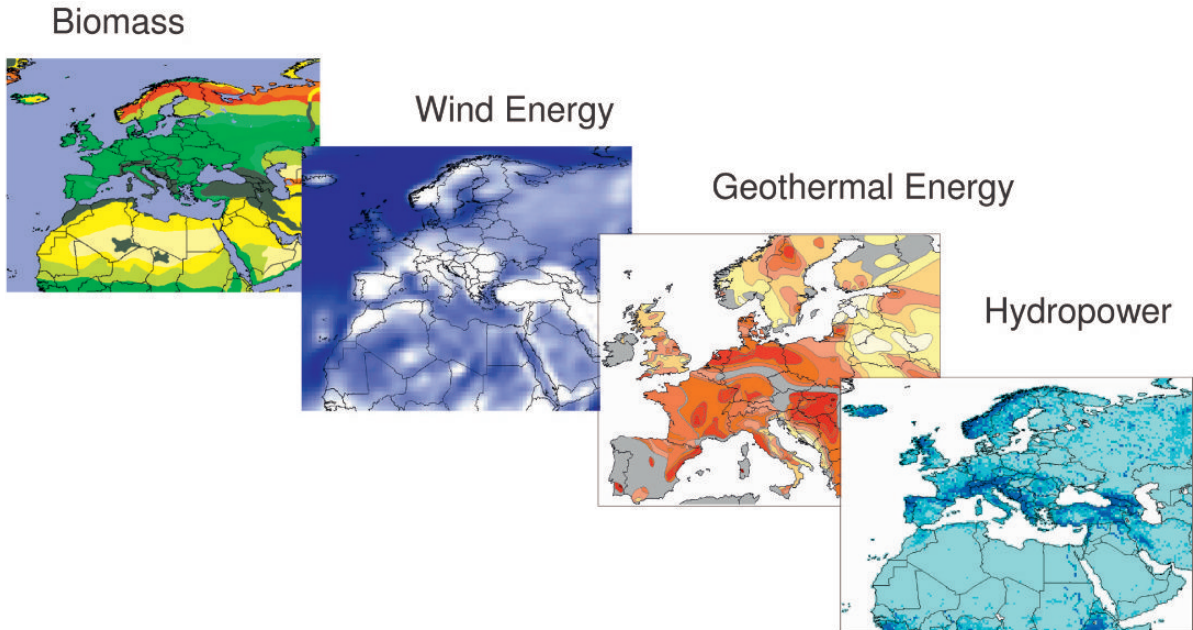

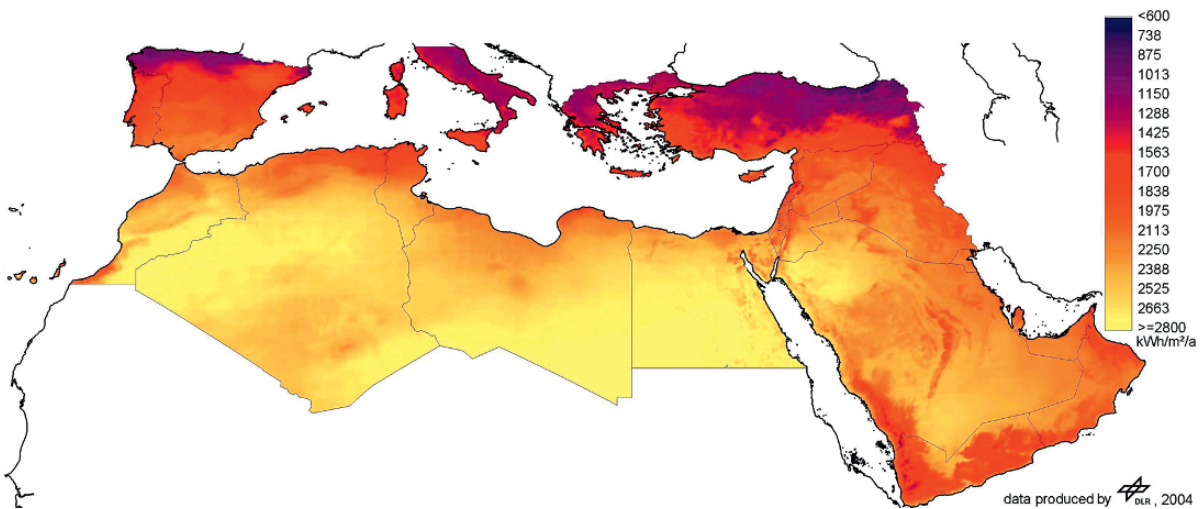

Figure 28.5: Annual Direct Solar Irradiance in the Southern EU-MENA Region. The primary energy received by each square meter of land equals 1–2 barrels of oil per year.

soon face a situation where they must decide either to overload their economy by subsidies to afford CO₂ sequestration or to overload the global environment and thus accelerate desertification.

Nuclear plants are a fading technology with unsolved problems of nuclear waste disposal and high environmental and political risks. In the early 21st century only 5 per cent of world energy demand is supplied by nuclear energy. The global uranium resources will not last longer than 50 years and are becoming more expensive. Breeder technology could expand

those resources but would lead to a dangerous proliferation of plutonium and increase nuclear waste by an order of magnitude. Despite massive subsidies of several billion US\$ per year, nuclear power had in 2005 a global share of the power plant market place of less than 1 per cent.

In spite of R&D expenditures of more than a billion US\$ per year spent by OECD countries for several decades and scheduled also for the future, electricity from nuclear fusion is not expected to be available before 2050, and the outcome of this costly

Table 28.1: Some characteristics of contemporary power technologies. **Source:** The authors.

Technology	Unit Capacity	Capacity Credit	Capacity Factor	Resource	Applications	Comment
Wind Power	1 kW – 5 MW	0 – 30 %	15 – 50 %	kinetic energy of the wind	electricity	fluctuating, supply defined by resource
Photovoltaic	1 W – 5 MW	0 %	15 – 25 %	direct and diffuse irradiance on a fixed surface tilted with latitude angle	electricity	fluctuating, supply defined by resource
Biomass	1 kW – 25 MW	50 - 90 %	40 – 60 %	biogas from the decomposition of organic residues, solid residues and wood	electricity and heat	seasonal fluctuations but good storability, power on demand
Geothermal (Hot Dry Rock)	25 – 50 MW	90 %	40 – 90 %	heat of hot dry rocks in several 1000 meters depth	electricity and heat	no fluctuations, power on demand
Hydropower	1 kW – 1000 MW	50 - 90 %	10 – 90 %	kinetic energy and pressure of water streams	electricity	seasonal fluctuation, good storability in dams, used also as pump storage for other sources
Solar Chimney	100 – 200 MW	10 to 70 % depending on storage	20 to 70 %	Direct and diffuse irradiance on a horizontal plane	electricity	seasonal fluctuations, good storability, base load power
Concentrating Solar Thermal Power	10 kW – 200 MW	0 to 90 % depending on storage and hybridization	20 to 90 %	Direct irradiance on a surface tracking the sun	electricity and heat	fluctuations are compensated by thermal storage and fuel, power on demand
Gas Turbine	0.5 – 100 MW	90 %	10 – 90 %	natural gas, fuel oil	electricity and heat	power on demand
Steam Cycle	5 – 500 MW	90 %	40 – 90 %	coal, lignite, fuel oil, natural gas	electricity and heat	power on demand
Nuclear Power	>500 MW	90 %	90 %	uranium / breeder	electricity and heat	base load power

effort is yet unknown. Obviously, neither of these nuclear power technologies can contribute to the reduction of greenhouse gas emissions or to sustainable development needed within the next 50 years.

28.4 A Scenario for Energy and Water Security

By the year 2050, wind, hydropower, biomass, geothermal energy, and photovoltaic systems could generate 200–300 TWh/y each and thus contribute considerably to meet the increasing electricity demand of the EU-MENA region. With the potentials of over

Figure 28.6: Share of different technologies for electricity generation in the year 2000. **Source:** MED-CSP (2005).**Electricity Mix 2000**

400 TWh/y for each technology, this permits future growth. Wave and tidal power will also have minor contributions. The largest renewable energy contribution will come from solar thermal power with over 2200 TWh/y. This represents less than 1 per cent of the concentrating solar power resource potential of this region, but over 50 per cent of the region's electricity demand expected for 2050.

Each EUMENA country has its own specific natural sources of energy and water, and different demand patterns with a different mix of renewable and fossil energies for a sustainable supply system. The MED-CSP scenario shows how resources and demand with regard to technical, economic, ecologic, and social constraints of each country can be matched in a sustainable way. Renewable energies will initially need public support but will steadily grow within niche markets and become cheaper due to learning and economies of scale. In the medium term, electricity from renewables will be cheaper than electricity from fossil fuels, even if the societal external costs of fossil fuel consumption are excluded. Therefore, renewable energies are the only way for a long-term stabilization of energy costs on a low price level.

At present, many MENA countries have high electricity growth rates that may lead to similar levels of consumption as in Europe by 2050. However, business-as-usual strategies for energy and water would

lead to a depletion of fossil fuel and natural water resources within a few years, to unaffordable costs of energy and water and to social conflicts. Economic development would be increasingly burdened by subsidies and conflicts. The possible impacts from climate change may make desertification irreversible and further increase the loss of arable land and floods. Due to progressing water shortage, self-sufficiency in cereals will decline and imports will increase significantly in the MENA region by 2030 (FAO 2003; Brauch 2003b). Only renewable energies can lead to affordable and secure energy and water. This will not require long-term subsidies but only initial investments as part of a concerted effort by all EUMENA countries to put the new renewable energy technologies in place.

Comparing figures 28.6 and 28.7 it becomes obvious that the growing electricity demand in the MENA region can only be satisfied in a sustainable way with renewables. By the year 2050, the electricity consumption of many MENA countries, like Egypt and Turkey, will by far exceed the consumption of present EU countries, like Italy. Many oil exporting countries, like Iran, Iraq and Saudi Arabia, will follow this trend that may result in an increasing competition between domestic consumption and the export of that precious commodity.

Figure 28.7: Total electricity consumption and share of different technologies for electricity generation in the analysed countries in the year 2050 according to the MED-CSP scenario. **Source:** MED-CSP (2005).

Figure 28.8: Annual electricity demand and generation within the countries analysed in the MED-CSP scenario. **Source:** MED-CSP (2005).

Comparing figure 28.8 (electricity generation) with figure 28.9 (installed capacity) reveals that the installed concentrating solar power capacity by 2050 may be as large as that of wind, PV, biomass and geothermal plants combined, but due to their built-in so-

lar thermal storage capability, CSP plants deliver twice as much electricity per year as the other resources.

For each country, the installed capacity of the power park was calculated in a way that the national peak load is always covered with an additional mini-

Figure 28.9: Installed power capacity and peak load within the analysed countries in the MED-CSP scenario. **Source:** MED-CSP (2005).

minimum reserve of 25 per cent of secured capacity. While PV and wind power are resource driven, the other renewable energy technologies can be applied in a demand driven manner, providing peak load, intermediate load and base load capacity on demand and serving as backup capacity for the fluctuating resources. As wind and PV electricity only contribute a minor share for the secured capacity, the total installed capacity increases subsequently in relation to the peak load.

Renewable energies will compete with fossil fuels. The cost of electricity from fossil fuel fired plants was calculated on the basis of the average annual full load hours of each country's power park, and according to the relation of oil/gas and coal plants installed. The electricity cost of new natural gas fired combined cycle power plants is displayed in those figures as well as the cost of steam-coal plants. The cost of fuel oil steam cycles is usually higher than the cost of gas fired combined cycles or coal plants, and is not displayed here (figure 28.9).

In Europe, the electricity cost of most renewable energies will decline below the cost of fuel driven plants between 2010 and 2020. Most renewable power plants will then produce electricity at a lower cost than new, fuel driven plants, especially after CO₂ sequestration is introduced in 2020. But even in the MENA countries, where CO₂ sequestration is not expected to become applicable within the analysed time

span, most renewable power plants will produce cheaper electricity than new fuel fired plants after 2020.

Once electricity costs between 3 and 6 cents/kWh will be achieved by renewable energy sources in the long term they will become a motor for economic development between 2025 and 2050. Thus, the relatively high initial costs of renewables may only be a temporary initial barrier that can be overcome by technology development, and by appropriate policies and financing schemes. Besides environmental concerns, the main reason to change to renewable energies is the high cost level expected for electricity generated from fossil fuels, which in the medium term will reach between 5 and 10 cent/kWh. This and the additional high volatility of fuel prices will be strong driving forces for the market expansion of renewables (figure 28.10).

Although climate change and environmental concerns are very good reasons for shifting to renewable energy sources, the main reason is the security of supply and future energy costs. Most economies in the MENA region will be unable to develop properly with the increasing costs of fossil fuels. These countries will also be severely affected by climate change and desertification (Kepner/Rubio/Mouat/Pedrazzini 2006; Brauch 2002, 2006). Thus, both economic and ecological considerations lead to a solar energy economy in the EUMENA region.

Figure 28.10: Example of electricity costs and learning in the MED-CSP scenario. **Source:** MED-CSP (2005).

The transient support for renewables must be considered as a public investment for a better and cheaper supply system, compared with the long term, steadily increasing subsidies that are required for fossil and nuclear power.

The specific carbon dioxide emissions of the national power park of each country were calculated on the basis of specific average values that have been obtained from life cycle analysis of each technology. For the future fuel-based power generation in Europe, an increasing share of CO₂ sequestration was considered. At present, the total carbon emissions of electricity generation of all countries analysed in the study amount to approximately 770 million tons per year. Instead of rising to 2,000 million tons of CO₂ emissions per year that would be expected for the year 2050 in a business as usual case, the scenario achieves a reduction of emissions of 40 per cent to 475 million tons within that time span. Thus, 28 billion tons of carbon dioxide are avoided until 2050, which is equal to the present total annual emissions worldwide (figure 28.11). Fossil power systems show emissions that are one or two orders of magnitude higher than those of renewables. CO₂ sequestration will require extra energy and thus will lead to higher emissions, which must additionally be disposed of, entering a kind of vicious circle. In contrast to that, renewable electricity will in the long term provide carbon avoidance without additional cost.

Contrary to prevailing views, the mitigation of greenhouse gases in the power sector based on renewable energies must not necessarily be financed with

subsidies. Rather, renewables constitute the most economic solution for future energy security. They require initial investments to launch and to continue the learning curves of renewable energy technologies and to become competitive with fossil fuels. The sooner this development starts; the sooner subsidies for the power sector may be cut. The fastest way is shifting present subsidies from the fossil and nuclear power sector to renewables. If this is not possible due to social constraints, renewable energy feed-in tariffs guaranteed by law are the best solution. As they reduce investment risks, they reduce the required equity interest rates and thus, the cost of market introduction. E.g. within the German Renewable Energy Act, a usual project rate of return of only 6–7 per cent is accepted, while conventional power investments require 9–15 per cent.

MENA countries will benefit from renewables by reducing their energy subsidies, especially those importing fuels, like Jordan and Morocco. They will be able to foster their national economies through a low cost, secure energy supply. Oil and gas exporting countries will be relieved from burning their major export product, and in the long run they may also export solar electricity. A strong renewable energy industry in the MENA region will lead to highly qualified jobs and reduce the present brain drain.

The water supply situation in the MENA region is very critical. In some places the groundwater level falls 6 metres per year. Large cities like the capital of Yemen Sana'a may come to a point where their water supply runs dry and their groundwater resources may

Figure 28.11: CO₂ emissions of electricity generation in million tons per year for all countries for the MED-CSP scenario and emissions that would occur in a business as usual case (BAU). **Source:** MED-CSP (2005) to which the authors contributed.

be exhausted within 10 years. A solution could be using large amounts of energy for seawater desalination. However, a strategy based on fossil or nuclear energy would not lead to an affordable and secure water supply system. Again, renewables and especially solar thermal power may become a key tool to reduce the conflict potential associated with energy and water scarcity.

The scenario offers a possible path towards a sustainable energy supply system in the EU-MENA region. This path is affordable, technically feasible, and desirable from the perspective of protecting the global environment. There are no serious counterarguments against such a development, except a widespread underestimation of the potentials of renewable energy sources and the interest of some lobbies to keep their subsidies in the future. However, the global environment and society cannot afford any longer obsolete, dangerous and costly energy supply schemes of the past. Fossil and nuclear power technologies were useful in pushing the technological and economic development in developed countries, but they - and the environment - would be overburdened to do the same for the rest of the world. Their increasing scarcity and cost will become an economic burden, and a cause for future resource conflicts (Klare 2001, 2001a), if no alternatives are built up in time. These alternatives are available and must be used now with appropriate political, technological, and financial efforts. Waiting for

the pressure to grow will deprive most national economies of their economic and political means to react properly to the global challenges this century will face.

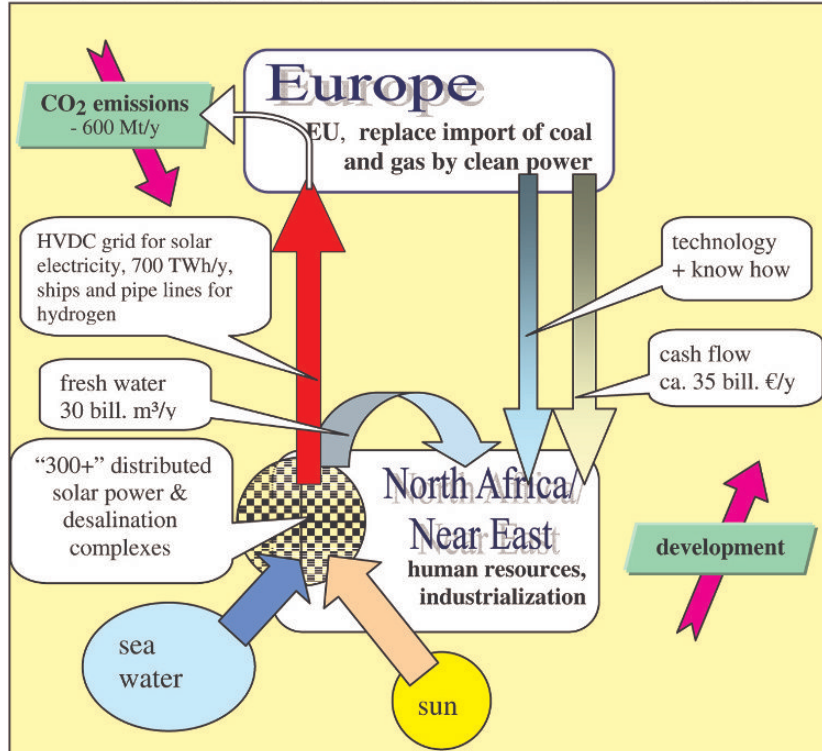

28.5 Trans-Mediterranean Renewable Energy Cooperation

Under the auspices of HRH Prince El Hassan bin Talal of Jordan and of the Club of Rome, and in the framework of the Arab Thought Forum in Amman, in 2003, a group of scientists, engineers, economists, and other professionals presented an initiative for a Trans-Mediterranean Renewable Energy Cooperation (TREC), with the goal to solve the scarcity of affordable and environmentally compatible energy and water resources of Europe, the Middle East, and North Africa (EUMENA) in a cooperative way (Kabariti/Moeller/Knies 2003).

It was suggested that the MENA countries could exploit their superior solar and wind energy potentials and generate clean electricity as a competitive industrial product for export to the European market. The developmental circuit, the flow of technology, know-how, and capital from the EU to the MENA countries, and the reverse flow of clean power and eventually hydrogen from the MENA region to Europe is illustrated in figure 28.12. Electricity generation from

Figure 28.12: A new circuit of development: CO₂ reduction in Europe fosters development for North Africa and the Middle East. **Source:** Earlier version (Kabariti/Moeller/Knies 2003); updated version with numbers for EU25 based on the CSP studies (2004-2006). Trans- Mediterranean Renewable Energy Cooperation

Features of TREC

- hundreds of distributed solar power & desalination plants, with 10-400 MWel
- Wind & solar power, and hydrogen for export from MENA to Europe, and for local demand
- interconnecting HVDC grid
- water desalination for MENA in cogeneration
- component production in MENA
- industrial & socioeconomic development in MENA
- faster climate stabilisation
- create jobs in MENA instead of CO₂ in Europe

Power of 700 TWh/y is about 17 % of EU annual electricity consumption, and also about the power generated from imported coal in the EU. Such a capacity could be installed within about 30 years

solar radiation and wind energy requires larger manufacturing efforts and installations than the extracting of crude oil or natural gas requires. Thus, widespread technological development and industrial activities will create many jobs at different levels of skills and qualification.

As a 'by-product' of solar power plant expansion in MENA and solar power export to Europe, large amounts of sea water could be desalinated by solar power and also by cogeneration of solar heat and power to overcome the expected shortages of fresh water in the MENA countries (Brauch 2006a, 2006b). Additional fresh water for drinking, industry, and eventually for irrigation purposes constitutes an indispensable precondition for further development. Thus, the proposed TREC project would expand the perspectives for human and socio-economic development in the MENA countries. According to a technology assessment (TA) the combination of concentrating solar thermal power stations (CSP) and high voltage direct current transmission lines (HVDC) is the most appropriate technical and economic solution for such a con-

cept. The environmental impacts of such a large-scale infrastructure would be acceptable, and large amounts of carbon emissions could be avoided at competitive costs (May 2005).

In January 2005, a study project called TRANS-CSP commissioned by the German Federal Ministry for the Environment, Nature Conservation and Nuclear Safety (BMU) was launched by the German Aerospace Centre (DLR) and several partners from the Mediterranean region to assess the feasibility of a high voltage interconnection of Northern Africa and Central Europe with the purpose of exporting solar electricity from the Sahara to Europe.

The reasons for choosing HVDC transmission instead of the usual AC (Alternate Current) transmission lines for such a long distance transmission scheme are lower losses of HVDC of less than 4 per cent per 1,000 km of distance, the compact installation of the power lines with only 120 m width for 10,000 MW of transfer capacity, and the capability of crossing the Mediterranean Sea. With over 70,000 MW of installed capacity, HVDC technology is well

Figure 28.13: Three samples of high voltage direct current (HVDC) interconnections between Europe, the Middle East, and North Africa (EUMENA) analysed for potential environmental impacts and costs. **Source:** TRANS-CSP (2006) to which the authors contributed.

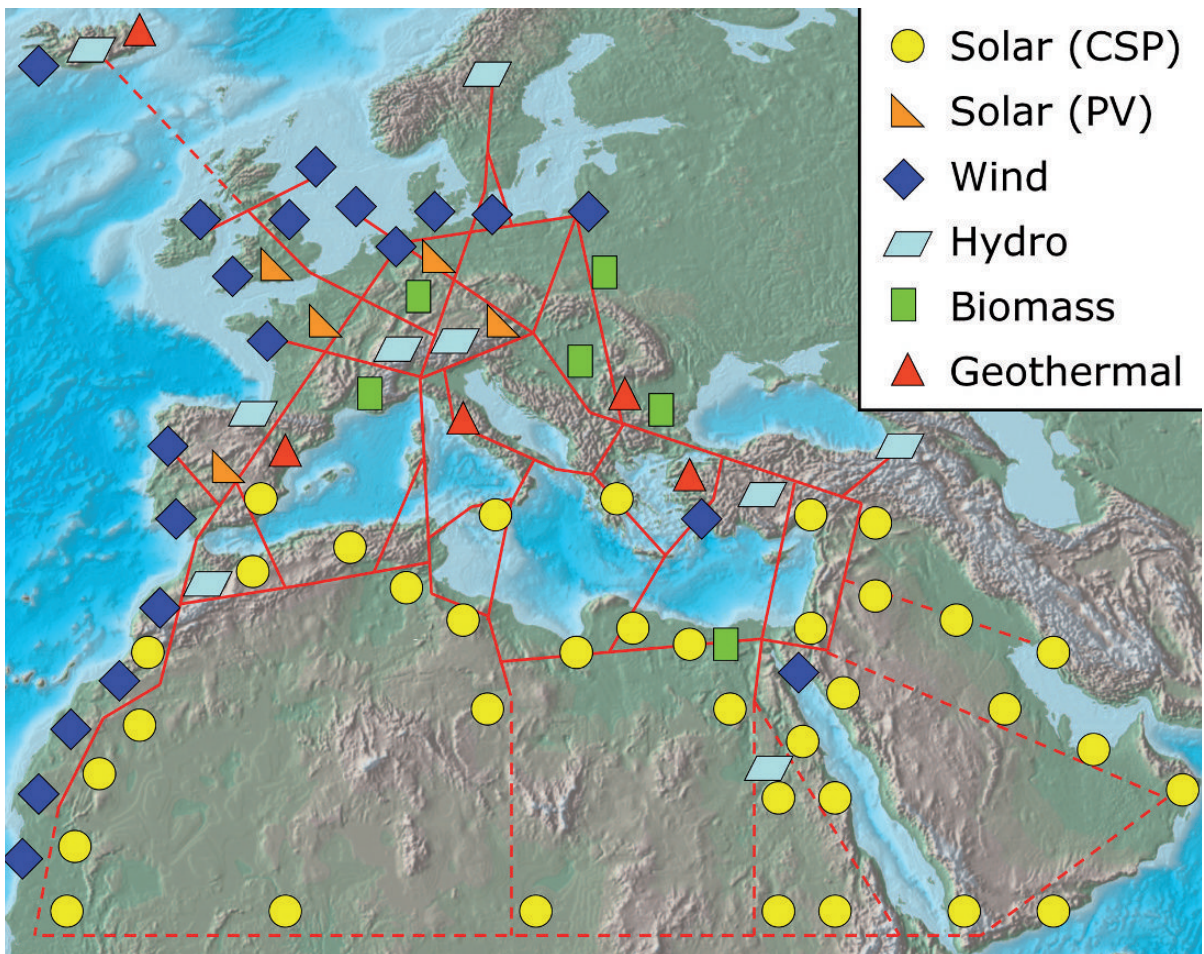

established in many projects globally. In the near future, many power lines will close the power grid around the Mediterranean Sea. The transfer capacity of the conventional electricity grid is limited to 1,000 MW. This would not allow considerable exports of solar power to Europe.

Three exemplary HVDC lines were assessed, interconnecting three sites of very high solar electricity yield in the Western, Central, and Eastern Sahara with three European centres of high electricity demand, each transferring 5 GW of power. In the final stage, a grid of 20 such power lines would allow the export of 700 TWh/y of solar electricity per year, which is equivalent to the present annual electricity consumption of Germany and Belgium or 15 per cent of the consumption of the 30 European countries analysed in the study (TRANS-CSP 2006).

There are three good reasons for choosing concentrating solar power technology for generating renewable export electricity. *First*, CSP plants are capa-

ble of delivering electricity steadily around the clock and around the year with firm capacity, which would enable them to deliver base load power like conventional nuclear or fossil fuel fired power stations. This is crucial to achieve a reasonable amortization of the HVDC infrastructure. *Secondly*, only solar energy resources are so vast that they will be able to cope both with the rapidly increasing regional electricity demand in the MENA region and at the same time with the European need for clean power, while the other renewable resources are more limited and will rather be used to supply a reasonable part of regional needs. *Thirdly*, CSP plants can be used for the co-generation of electricity and heat for the thermal distillation of brackish water and sea water, and thus help to solve the increasing scarcity of fresh water in the MENA region with a by-product from power generation or using directly solar electricity for desalination via membrane technologies.

Figure 28.14: Vision of a future Trans-Mediterranean HVDC electricity grid interconnecting sites of high renewable electricity potentials in Europe and beyond. **Source:** Trieb and Mueller-Steinhagen (2007).

The scarcity of freshwater resources has made food self-sufficiency impossible. Water scarcity may lead to social instability of a growing population in the MENA region. Efficient power generation and fresh water is vital. The need for seawater desalination leads to higher energy demand and to an unavoidable additional burden for national economies. There is no sustainable solution for water security based on fossil or nuclear energy, and moreover, there is a growing conflict between domestic consumption and export of fossil fuels.

Cost traps in the energy sector originating from fluctuating fuel prices are serious enough, but the traps originating from a future fresh water deficit will be even worse, because water is indispensable even at the lowest economic level of development. With a water deficit equivalent to the Nile expected in the short term, the North African states face a challenge never experienced before in their history. To solve this se-

vere societal problem, they will require large amounts of low cost energy for desalination and, of course, an enhanced water infrastructure and optimal water management.

Solar power and desalination plants will not only tackle the problems related to a sustainable energy supply at a low cost, but also those related to clean water and to the conservation of productive soils. In the world's arid regions, such plants could become the nucleus of a totally new social paradigm: the conservation and recuperation of land endangered by desertification, comparable to the conservation and recuperation of flooded land in the Netherlands. Providing power, water, shadow and foreign exchange from the export of green power and revived agriculture, such plants can provide all that is needed to effectively combat desertification, and to regain land for human settlement and agriculture that otherwise would be lost to the desert.

Figure 28.15: A scenario^{a)} of the power sector in 30 European countries aiming at economic and ecological sustainability using a balanced mix of national and imported renewable electricity sources. **Source:** TRANS-CSP (2006) to which the authors contributed.

a) TRANS-CSP covers: Iceland, Norway, Sweden, Finland, Denmark, Ireland, United Kingdom, Portugal, Spain, France, Belgium, Netherlands, Luxembourg, Germany, Austria, Switzerland, Italy, Poland, Czech Republic, Hungary, Slovakia, Slovenia, Croatia, Bosnia-Herzegovina, Serbia-Montenegro, Macedonia, Greece, Romania, Bulgaria, Turkey.

Arable land resources in the MENA region and globally are disappearing at a speed of several hectares per minute. Concentrating solar multi-purpose plants in the margins of the desert could generate solar electricity for domestic use and export, fresh water from seawater desalination, and in addition provide shade for agriculture and other human activities. Such plants could turn waste land into arable land and create labour opportunities in the agriculture and food sector. Tourism and other industries could follow. Desertification could be stopped. Other decentralized renewable energy sources could also come into use in those newly developed regions, like e.g. photovoltaics, solar thermal collectors, wind energy, and biomass.

Solar energy and salt water are unlimited resources if used in a way compatible with environmental and socio-economic constraints. The economic figures of most renewable energies indicate clearly that within a manageable time span they will become much more cost effective than fossil fuels. Renewable energies are the least cost option for energy and water security in the MENA region. With increasing electricity intensity in a developing world, their importance will steadily

grow, being only limited by demand, and not by resources.

In the coming decades, the European electricity grid will subsequently be transformed, on one side by applying more decentralized supply structures in the medium- and low-voltage level, interconnected by information networks and operated like 'virtual' single power plants. These structures will include PV and wind power systems, micro-hydropower, fuel cells, and micro-gas turbines, but also consumers and storage facilities for load management. A grid of 'electricity highways' will be established on a high-voltage level, with a large long-distance transfer capacity and low transfer losses (figure 28.14). Both centralized and decentralized grid structures will provide high security, redundancy and diversity of power supply, and good economic performance through high competition. It will activate the best sites for renewable electricity generation, both in the centralized and decentralized level, and cope both with the energy demand of decentralized consumers as well as that of growing megacities in the MENA region while the urban centres in Southern Europe will shrink.

This option is more than a long-term vision. It should be given serious consideration in the present

planning of new power, because investment cycles in the power sector extend to 30–40 years. Present strategies and scenarios for the European electricity sector consider solar electricity imports as a major element of an environmentally and economically compatible, sustainable electricity supply in the medium- and long-term future (figure 28.15). A well balanced mix of national resources and import energies will provide energy security even for a region like Central Europe that has only scarce domestic fossil and nuclear energy resources.

28.6 Conclusions

Renewable energies can relieve Europe and the quickly growing economies of the Middle East and North Africa (MENA) from increasing subsidies for their energy and water sector, and from overloading their environment and natural resources. A strategy for energy sustainability must include three components: a) the rational use of energy, b) renewable energies, and c) a Trans-Mediterranean Partnership for Energy and Development. The challenges of the 21st century must be tackled in a joint EUMENA effort rather than lost through separatism and wishful thinking of national energy autonomy.

The studies presented here show that the EUMENA region has the technical means and the natural resources to achieve sustainable supply of power and water in the Mediterranean region and Europe. However, technology will not solve problems by itself. Political decisions and a cooperative policy framework are needed to implement this vision. The task of this chapter was to show that this option exists. Policies must be developed and implemented.

A good starting point can be the example of the renewable energy feed-in laws in Germany, Spain, and many other European countries. They provide the necessary revenues for renewable power in form of a long-term power purchase agreement guaranteed by law. This gives enough security to investors and helps to reduce equity interest rates, thus reducing the cost of market introduction. E.g. in Germany equity interest rates in the frame of the feed-in law are usually 6–7 per cent, while in the conventional power sector, due to the higher risk, 9–15 per cent are demanded by investors. Thus, a feed-in law is the most cost effective way to introduce renewables. As the tariffs are paid by all electricity consumers, the individual financial load is almost negligible, but future benefits by cost reduction are great.

Secondly, a EUMENA free trade area for renewables could be helpful to extend the achievements of the European renewable power sector also abroad, and could even help to initiate a more comprehensive free trade area in this region. At least in the renewable energy sector, it has become clear that the cooperation between European and MENA countries will be beneficial for both regions.

29 Energy Security in the Arab World

Mohammad Selim and Abdullah Sahar

29.1 Introduction: The Concept of Energy Security

Since the age of the Industrial Revolution, it has been widely acknowledged that energy is a major sector of modern economies. However, it took the world almost two and half centuries to acknowledge that the supply of energy is a major element in the conceptualization of national security, and to devise the concept of energy security. The concept was mainly developed in mid-1970 as the flow of cheap oil to the West from the Arab world was disrupted during and after the October War of 1973.

This concept came to refer to the quest of Western powers to secure the uninterrupted flow of oil from foreign suppliers, and the attempt to rationalize its use and diversify energy sources (Fried/Trezise 1993; Downs 2000). The literature on energy and energy security was characterized by the dominance of the oil dimension. Energy was viewed as equivalent to oil. This was mainly an outcome of the emphasis in the West on the question of the continued access to foreign oil. At a later stage, the concept of energy security was expanded into four directions, (i) to comprise all sources of energy, including oil, coal, nuclear, solar, and hydro energy so as to establish the 'optimum' mix of energy sources which best suits a nation's needs, and most importantly the continuous access to that mix; (ii) to refer to the threats to national security resulting from energy including supply shortages; (iii) to deal with the strategies needed to establish an energy regime which does not pose a threat to the quality of the environment, and reduces the negative environmental consequences of energy production and consumption; and (iv) to assess the impact of the quest to secure sources of energy on the flare-up of conflicts, and the impact of conflicts on securing sources of energy. The main questions to be asked in this domain are: to what degree are energy problems causes of certain conflicts, and what is the probability

of occurrence of energy problems as a result of conflicts?¹

This chapter deals with these issues in the context of the Arab world. The concept of the Arab world refers to the 22 members states of the *League of Arab States* (LAS). These are Mauritania, Morocco, Algeria, Tunisia, Libya, Sudan, Egypt, Lebanon, Syria, Jordan, Palestine, Iraq, Saudi Arabia, Oman, Kuwait, Bahrain, Qatar, Oman, Yemen, Somalia, Djibouti, and the Comoros Islands. The last three states will not be included as they are mostly at the periphery of the Arab regional system.

The main emphasis of this chapter will be the extent to which the concept of energy security has been integrated into the Arab conceptualization of security, the main substantive issues being debated in the Arab world on the question of energy security, the main energy-related threats to Arab security, the main strategies pursued by the Arab countries to achieve energy security, and the interlinkages between energy and conflicts in the Arab world. To what extent have energy issues led to conflicts in the Arab world, and have conflicts influenced energy questions? What are the implications of these linkages for the energy security in the Arab world?

1 The US *Nuclear Energy Institute* in Washington defined energy security as: "the ability to manage the economics, supply, and environmental consequences of energy sources or produce electricity. A diverse mixture of energy sources enables our nation to balance cost, availability, and environmental impacts to our best advantage." See at: <www.nei.org/doc.asp?catnum=4&catid=123>. Jabeen (2006) also established the Energy Security Index (ESI) which comprised three dimensions: dependency, certainty, and affordability.

29.2 Arab Conceptualizations of Energy Security

The Arab discourse on issues related to energy security has been traditionally restricted to the intellectual elites, and experts, governmental and non-governmental, perhaps with the exception of the question of nuclear energy which has been a subject of public debate in a number of Arab countries. Further, most conceptualizations of energy scrutiny have mainly dealt with the state level of analysis rather than the level of the pan-Arab regional system. It is only recently that the second level has been seriously considered in Arab conceptualizations of energy security.

Arab conceptualizations of energy security passed through two main stages. The first stage extended from the second half of the twentieth century. The question of energy was viewed from a dominantly technical perspective. The emphasis was on securing world markets for Arab oil exports, comparing the economics of various sources of energy, oil, natural gas, coal, solar, hydro, and nuclear energy. The literature was heavily dominated by references to oil as the main energy source. Other sources were viewed as residual. The main exception was Egypt's emphasis on hydroelectric power as a main source of energy, which led to the establishment of the 'High Dam' in Aswan in the 1960's. After the October War of 1973, Egypt moved in earnest in the direction of building an ambitious nuclear programme, with a view to generating electricity, and there was a genuine debate in Egypt over the merits and demerits of such a programme (Selim 1982; Mustafa 1985). However, the Egyptian programme was abruptly ended in 1986 and the debate subsided. Further, Arab states established a regional organization, the Organization for Arab Petroleum Exporting Countries (OAPEC) to coordinate their oil policies. However, it rarely exercised a significant success in achieving its objective.

By the beginning of this century, the discourse on energy was expanded to include other dimensions such as rationalizing the use of energy, diversifying global partners in marketing and producing oil and other energy sources, emphasizing upon pan-Arab regional cooperation in the area of energy security, the consideration of other sources of energy such as nuclear energy, and linking energy with environmental issues. The last two dimensions deserve special attention. In 2006, Egypt and the Gulf Cooperation Council States (GCC) began to advocate a nuclear option for generating electricity. This came in the context of the global debate on the Iranian nuclear pro-

gramme and the revelations that Iran has succeeded in building an elaborate programme for uranium enrichment. After twenty years of the abandonment of the nuclear energy option, Egypt reintroduced the question of nuclear energy, claiming that its traditional energy sources were fast declining. It began to reactivate the old plans to build a nuclear reactor on the northern coast near Al-Dab'a, to find out that the area had been sold to real estate developers and that another location must be found. Surprisingly, the Gulf Cooperation Council (GCC) states followed suite as the 27th summit of the GCC held in 2007 resolved to embark on a GCC nuclear programme, and these states approached the International Atomic Energy Agency (IAEA) to help in developing such programmes. Until that time, the GCC states used to criticize Iran for embarking on a nuclear programme as it has plenty of oil resources. As Arab countries joined the Kyoto Protocol, they became mindful of the environmental consequences of energy (especially of oil) production and consumption which led to an assessment of the impact of the Protocol on the continued access to global markets in the light of the necessity to reduce carbon dioxide emissions. This trend in the Arab discourse on security began in 2003 with the convening of a conference in Abu Dhabi on 'Energy and Environment'. The main themes discussed were: a) the impact of energy on the environment, b) the social and economic impacts of energy policies, and c) developing sustainable energy sources. The main issues for discussion were the implications of energy-related policies on the environment, fossil fuels for economic development and security, energy policies and their implications for sustainable development, socio-economic aspects of energy policies, promoting participation in developing sustainable energy policies in the Arab countries, environmental management systems as tools for energy management, and compliance with energy-related environmental standards in the Arab countries. The Conference also issued *the Abu Dhabi Declaration*, which recommended developing a new strategy which deals with the environmental consequences of energy production and consumption. Further, the *Council of Arab Ministers Responsible for the Environment* (CAMRE) issued an "Action Plan on Environment and Energy for Arab Countries" in 2004. For the first time, this Action Plan addressed the question of energy in the larger framework of the environment. The Abu Dhabi Declaration and the following Action Plan represent a noticeable shift in the Arab discourse on energy in the

direction of linking the issues of energy and the environment (Al-Lababidi 2003).

However, the question of energy security in the Arab world has not been integrated into the overall conceptualization of national security. The concept of 'energy security' (*Amn Al-Taka*) is not directly employed in the Arab discourse on energy and security. If one reviews the publications of Arab energy analysts, and the proceedings of Arab institutions majoring on energy questions, such as OAPEC, one hardly finds direct references to the concept with few exceptions.² There are no significant public debates on energy questions with the exception of the Egyptian debate in the 1950's on building the High Dam in Aswan to generate hydropower, and the debate in the 1980's on the use of nuclear power to generate electricity. This can be partially attributed to two factors, oil and electricity surpluses in Arab countries, and the dominance of the Arab security agenda by hard security issues. A brief review of these factors may be in order:

According to the 2002 statistics of OAPEC, Arab oil reserves were almost 650 billion barrels which represented 57 per cent of world oil reserves, and Arab oil production was 20.2 billion barrels a day which represented 28 per cent of world oil production. Arab

natural gas reserves are almost 40.7 billion cubic meters representing almost 26 per cent of global reserves. Electricity production was 492,538 gigawatt hours (GWh) and the consumption was 317,223 GWh. This means that the Arabs are producing oil and consuming electricity below their potential or actual capacity, which has provided the Arabs with a sense of energy security.³ Most Arab countries are either oil exporting or self-sufficient in oil production. Arab countries in the Gulf, Libya, and Algeria export huge quantities of oil. Other countries, such as Egypt, Syria, and Sudan either export small quantities or are self-sufficient. As a result, the sense of oil security is dominant in these countries, despite the long-term threats.

The Arab security agenda is also dominated by hard security issues related to territorial claims and foreign occupation, existential threats resulting from regional power disequilibrium and Israel's possession of nuclear weapons. The dominance of hard security issues has kept Arab strategic communities engaged in these issues to the detriment of the incorporation of soft security issues, such as energy, into the overall conceptualization of national security. However, that does not mean that the concept does not exist as the Arab literature just referred to is laden with references to the prospects of an energy crisis and the long-term threats to energy supplies in Arab countries.

2 In 2004 the *Organization for Petroleum Exporting Countries* (OPEC) held a seminar in Vienna on 'Petroleum in an Interdependent World' where the concept of energy security was clearly on the agenda of the conference. In 2004, the OAPEC held two conferences: "The 11th Co-ordination Meeting for Environmental Experts in OAPEC Member States," and "The 4th Meeting of Working Group on Possible Cooperation in Natural Gas Investment." Also in 2004, the *Emirates Center for Strategic Studies* in Dubai held its 10th Annual Energy Conference on the "Oil and gas sector in the Gulf." In these three conferences the concept of energy security was not discussed. For a review of the conferences see the: *OAPEC Monthly Bulletin*, 30, 10 (October 2004). In 2005, the *Bahrain Center for Studies and Research* issued a book entitled *International Energy Security and Cooperation* which contained the proceedings of a joint conference held in Shanghai in collaboration with the Shanghai Institute for International Studies. This is one of the few books in the Arab world which employed the concept of energy security. The main emphasis of the book was on Sino-Arab cooperation in the field of energy (Bahrain Center for Studies and Research 2005) Further, the April 2006 issue of *Al-Siyassa Al-Dawliya* [International Politics], a quarterly journal published by *al-Abram* (Cairo), was devoted to the theme of "energy security and the future of international relations". Thirteen papers were published in that issue, however, none of them provided a definition of energy security.

29.3 Energy-related Threats in the Arab World

The fact that there are oil and electricity surpluses in Arab countries should not conceal the reality that there are a number of short-term and long-term threats to energy security in the Arab world. Arab population growth rate is almost twice as high as the average world population growth, which resulted in an Arab energy consumption increase of about 1-1.5 per cent per year above the global average. The Arab energy demand is higher than the average global demand, which implies that these surpluses may be temporary and may not last for more than a quarter century. As almost one third of the Arabs have no access to electricity and as governments must supply them with electricity, the energy demand will grow even more. The quality of electricity supply to another one third of the population is below standards, with supply cuts, low and intermittent voltage, and other prob-

3 See: *OAPEC Monthly Bulletin*, 30, 10 (October 2004), and 30, 11 (November 2004).

lems that disrupt electricity services (Al-Khatib 2000). Further, the electricity sector in most Arab countries experiences major difficulties due to price subsidies and inadequate revenue collection, which reduces the efficiency of this sector.

In this respect, a number of security threats have been articulated by Arab intellectuals and energy experts. It is interesting to note that these threats have not been reflected in the Arab official discourse on energy which implies the existence of a gap between actual and perceived threats. Further, most of these threats have been articulated at the state and pan-Arab levels as awareness of the interconnectedness among Arab states in the area of energy security has been growing since the beginning of the 21st century.

The first main energy-related threat is the emergence of new oil producers in the global markets. The Caspian Sea and Central Asian oil suppliers have begun to extract and export huge quantities of oil directly to Western markets through Turkey.⁴ In 2006, Arab countries supplied almost 38 per cent of the world oil demand. But the Caucasian and Central Asian states have recently entered the market as serious contenders. There are two main views on the threat posed by these new producers.

The first argues that the new producers do not pose a real threat to Arab oil as the Arabs possess almost two thirds of proven world oil reserves and that “the Caspian current oil estimates cannot match the awesome size of proven reserves found in the Middle East” (Hussain 2002), and that “the vast oil space in the Arabian Gulf will become in the near future the only oil choice upon which the industrial world will depend.” It was also argued that Arab oil represented 42 per cent of global oil consumption, and this percentage will increase to 50 per cent in 2008, and that China is increasingly depending on the Arabian Gulf oil (Al-Gehany 2002). The maximum capacity of the Caspian Sea oil is 3–4 billion barrels a day, which is the production of one Arabian Gulf state (Al-Shalaby 1999). Sheikh Yamani, the former Saudi Minister of Oil, also subscribed to this estimation when he argued that “the future is bright for oil reserves in the Gulf area. Presently non-Arab oil producers are rapidly depleting their oil reserves by producing large volumes, while Arab oil producers are producing much less” (Yamani 1999).

Advocates of the contending viewpoint argue that “it will not be too long before these new Caspian pro-

ducers emerge as competitors of the OPEC countries in international oil markets” (Ehtishami 1999). It seems that the new competitors do not pose an immediate threat to Arab oil exporters. However, if this potential threat is assessed in conjunction with other threats, such as Western strategies to reduce the reliance on Arab oil, its impact will be felt.

The second main energy-related threat is Arab over-dependence on oil. Oil is a non-renewable source of energy and it is estimated that Arab oil reserves will be exhausted within eight or nine decades. Other sources of energy are either not available or not utilized. The Arab world is quite poor as far as coal and hydropower are concerned. With the exception of Egypt’s reliance on the Aswan High Dam to generate electricity, hydropower is hardly utilized in Arab countries. Solar energy, with which the Arab world is endowed, is also hardly exploited as its use has some technical and financial dimensions especially if used in household activities. Further, with the exception of Algeria, which has a small nuclear reactor to generate electricity, nuclear energy is hardly known in the Arab world. Egypt has two small nuclear reactors to generate radioisotopes with no capacity to generate electricity. During the 1970’s and 1980’s, Egypt developed an ambitious programme to build eight nuclear reactors with a capacity of 600 megawatt each. In 1986, the programme was disbanded as a result of American persuasion.

The third main energy-related security threat is the overdependence on foreign markets in the utilization of oil. Oil production policies are externally oriented and connected with the world oil market. This means that Arab oil revenues depend to a large extent on the oil prices which are determined in the global market rather than by the Arabs. The problem is further complicated by the overdependence of Arab economies on oil exports, especially in the Gulf countries oil revenues represent around 20 per cent of Arab gross domestic product (GDP). This percentage increases in the case of the Gulf Cooperation Council states to almost 30 per cent. Oil exports represent almost 75 per cent of the total exports of all Arab countries, and almost 92 per cent of total exports of the Arab countries in the Arabian Gulf. These high percentages imply a high dependence on a commodity whose price fluctuates quite often with wide implications for Arab economies. As oil prices fluctuate, Arab development policies suffer. The fall of oil prices in 1998 led to the decline of Arab income from oil exports in 1998 to almost one third of its level in 1980 in real terms. As a result, the Arab economies grew only 2.5 per cent per

4 In July 2006, the Baku-Ceyhan Pipeline was officially inaugurated and became operational.

year during the period 1980–1999 compared with a 5 per cent growth for other developing countries. This had drastically weakened Arab economies which depend on oil exports and the economies of other countries which also suffered as these countries felt the impact of that fall in the form of a corresponding fall in economic aid and remittances of expatriates (Al-Khatib 2000). This trend has been exacerbated by the decline of the demand of Western countries for oil during the 1990's. For the first time, there was a decoupling between economic growth and oil consumption and demand. The share of oil in the energy consumption of these countries declined from 54 to 45 per cent, and the share of natural gas increased from 17 to 37 per cent. The Asian financial crisis in 1997 has led to a decline in the Asian demand for Arab oil and resulted in a drastic decline of oil prices (Al-Shalaby 1999). Do increasing oil prices and a resulting surplus of 'petrodollars' boost Arab security? Not necessarily. Oil revenues were used to build modern infrastructures in Arab oil-exporting countries, and to provide social services to the population such as education, housing, and health. It has contributed to a significant rise in the standards of living in the Arab oil-exporting countries. The *Human Development Report* of 2006 by the United Nations Development Program (UNDP) classified Qatar, the Emirates, Bahrain, and Kuwait among the high human development category, while other Arab oil producing countries led the medium human development category. Oil revenues have also contributed to the establishment of Arab development agencies and funds, such as the Arab Fund, the Islamic Development Bank, and the development funds of Kuwait, Saudi Arabia, and the United Arab Emirates. These agencies have contributed significantly to the development not only of Arab countries but also of other developing countries.

But oil revenues have also reinforced the power of the state compared with the society as the former emerged as the only distributor of benefits and as a result the authoritarian grip of the state was solidified and state-society relations took the form of "no taxation and no representation", which means that the state, which relies on foreign sources for most of its income, will not impose local taxes, will provide services and finances in return for the absence of any representative bodies and the acceptance of the authoritarian state.⁵ In turn, this had led to extravagant and sometimes corrupt patterns of expenditures. These social expenditures have created a 'relaxed consumer society' in Arab oil-exporting countries, a society which despises manual labour, and overdependence

on foreign labour, and mostly oriented towards consumerism (Khatib 1999). A sizeable portion of the oil revenues was also used to purchase arms. In fact, since the 1973 oil boom, the military expenditures of the Arab oil-exporting countries, defined by the percentage of military expenditures from total GDP, remained the highest in the world for many years, reaching sometimes a threshold of 25 per cent. Weapons were bought on a turnkey basis and did not contribute to an indigenous military industrialization. The military industry in these countries remains weak and totally dependent on foreign sources. Thus, after three decades of the 1973 oil boom, the Arab oil-exporting countries are in a more vulnerable position than they were before. The regional balance of power has dramatically shifted in favour of non-Arab powers in the region, despite the surplus petrodollars.

The fourth main energy-related security threat is the decline of global demand for oil. Whereas oil represented 44.5 per cent of global energy supply in 1990, it represented 42.4 per cent of that supply in 2000. The global trend is towards increasing the use of renewable sources of energy such as wind, water, and solar energy (Abdullah 2002). This is because of the problems resulting from overdependence on oil, which results in carbon dioxide emissions leading to global warming. In fact, according to the Kyoto Protocol, developed member states are obliged to reduce these emissions until 2008–2012 compared to 1990 by five per cent. Flavin and Lensen (1990) expect that a shift to solar energy will be the cornerstone of a new global energy regime in the near future. Further, developed economies have achieved great progress in increasing energy efficiency, which has reduced the energy/economic growth coefficient, which means that economic growth is achieved with declining energy consumption. This threat is further complicated by (i) the rise of new oil producers in Central Asia and the Caucasus; (ii) Western strategies to diversify sources of oil importation and develop non-oil sources; and (iii) the Kyoto Protocol to which we will refer later.

The fifth main energy-related threat is the inefficiency in energy utilization in Arab countries. Such efficiency is measured by the GDP in \$ per kg of energy consumption. Whereas this measure has improved for industrial countries during the 1980–1996 period by

5 In fact, the concept of the 'rentier state' was developed to reflect this situation. The rentier state is the one which relies heavily on foreign sources of income to distribute to its society, which in turn makes the society dependent on the state (Luciani 1995).

22 per cent, and worsened for developing countries by 8 per cent, it has worsened more seriously in Arab countries by 23 per cent, reflecting the inefficiency of Arab policies on energy consumption. Energy is over-consumed for non-productive purposes, and energy supply is subsidized by the state, which results in extravagant patterns of energy consumption. There are also problems of inadequate revenue collection in most developing countries, which means that the revenues collected are usually less than the cost of energy production. Any policies to rectify this situation will most likely deprive more people from access to electricity, given the low per capita income in most Arab countries.

The sixth main threat to Arab energy security are the environmental consequences of energy production and consumption in the Arab world. Gas emissions have harmful environmental consequences. The Kyoto Protocol was devised to reduce global carbon dioxide emissions resulting from burning fossil fuels (oil, gas, and coal). It stipulates that by 2010, emissions from greenhouse gases should be reduced by five per cent below the level of 1990, which means reducing the use of oil (a major source of carbon dioxide emissions as a source of energy). Consequently, when fully implemented, the Kyoto Protocol will have a far-reaching long-term impact on the future of the Arab oil market. A major trend is towards natural gas, which is considered as the cleanest fossil fuel. Arabs are also increasingly converting to natural gas, but Arab reserves of natural gas are almost 53,123 billion cubic metres which is almost 28 per cent of the global reserves, which will put the Arabs in a disadvantageous situation in the future. Oil and natural gas represent the two main sources of Arab energy consumption (57 and 39 per cent respectively). Despite its major positive impacts, shifting from oil to natural gas will imply higher financial burdens for Arab economies (Al-Lababidi 1999). The Arabs must reduce carbon dioxide gas emissions for a healthier environment, but in doing so they incur a heavy financial burden by shifting to an energy source where they do not have an absolute relative advantage. Further, their key strategic commodity, oil, loses its attractiveness. The Kyoto Protocol also requires oil-producing member states to limit the pollution associated with the production of oil and oil products, which means that the oil producing countries will have to incur more costs and this increases the cost of production and subsequently of the commodity itself in the global markets.

Finally, one may refer to some other potential long-term threats to Arab energy security which could

emanate from inside and outside the region. The first is the threat of terrorist attacks on Arab oilfields. This is actually happening in Iraq after the Anglo-American invasion in 2003. On average, there are eight attacks a month, mostly pipeline bombings which kept Iraqi oil production 27 per cent below its pre-invasion level. There was also a failed attack on Saudi oilfields in February 2006. The last attack led to an increase of about 4 per cent of the price of the barrel of light crude. Osama bin Laden, the leader of Al-Qaeda, has persuaded his followers in December 2004 to attack oilfields in order to “stop the greatest theft of (Arab) oil in history” (Jenkins 2006). However, with the exception of the Iraqi case, such a threat to Arab oilfields is not eminent unless the region is engulfed in an all-out regional war which brings into the equation sectarian rifts.⁶ The second threat could result from a potential Sino-American rivalry over access to Arab oil. In 1993, China turned into a net oil importer, and as a result of the growing industrialization of the country, demand for oil has been galloping. China has been pursuing an active policy of securing oil from the Arabian Gulf states and Sudan through long-term partnerships. In pursuing that policy, China is keen to assure the US that this is not a zero-sum game and that it is not out to eliminate the American share. However, the US has expressed concern over the new Chinese policy for two reasons. The first is the US concern about the rise of China and the high military expenditure of that country. Repeatedly American policymakers have argued that China is ‘a strategic competitor’. The second source of American concern is that China is ready to provide its Arab oil exporting partners with arms, and some of them, such as Sudan, are considered as ‘rogue states’. If the Sino-American rivalry should escalate in the future, Arab oil may be

6 As the Iranian nuclear crisis mounts in the Arabian Gulf region, the possibility of such attacks also increased. During the World Energy Forum in Doha in April 2006, Hany Hussain, the Executive Director of the Kuwaiti National Oil Company, warned of the increased likelihood of terrorist attacks on the oilfields in the Gulf region. However, Abdel-Hussain Mirza, the President of the National Corporation for Oil and Gas of Bahrain, assured during the same conference that oilfields in the Gulf are secure and will not be influenced by any terrorist attacks. See: *Al-Qabas* (Kuwait), 26 April 2006. However, in February 2007, an attack on the world’s biggest oil-processing facility, located in Abqaiq, Saudi Arabia, was narrowly foiled. Although the attack was foiled, it sent global oil prices soaring. The USA has offered to help the Saudis in protecting their oilfields against future attacks (*Bahrain Tribune*, 23 December 2006).

one of the main targets of both sides. The US could cut off oil supplies to China, especially as it controls the supply routes to China. This explains the motives of China to diversify its partners and to import oil from Russia and Kazakhstan through routes uncontrolled by the US.

29.4 Arab Strategies to Deal with Energy-Related Threats

The Arab ability to deal with these threats was constrained by the dominant sense of energy security in the Arab world. No meaningful attempts were made to create less oil-dependent economies by diversifying the sources of energy. It is only in 2006 that the question of nuclear energy has been put on the Arab security agenda. However, this was mainly an attempt to match the Iranian nuclear success rather than a reflection of a genuine consideration of the nuclear option. Few believe that the Arab countries could actually embark on a nuclear programme to diversify the sources of energy.

The bulk of Arab strategies are mainly oriented towards diversifying global oil markets, and improving the efficiency of the oil sector and promoting the natural gas option. Most Arab investments in the oil sector are directed towards the exploration and field maintenance, and building refineries and petrochemical industries. Not only Western powers have been trying to reduce the dependence on Arab oil to avoid a replay of the 1973 oil embargo scenario, but the Arabs have also tried to reduce the overdependence on Western customers. There has been a noticeable shift in Arab oil strategy to diversity partners by building long-term relationships with Asian customers such as China, India, and South Korea. Today, the Arabs export 60 per cent of their total oil exports to Asian markets compared with 16 per cent to Western Europe, 15 per cent to North America, and 2 per cent to Africa (Al-Lababidi 1999). The Gulf Cooperation Council (GCC) states have been developing strategic partnerships in building oil refineries in East Asia and granting Asian companies oil concessions. It is expected that the Arabian Gulf oil-exporting countries will account for 11.7 million b/d, which will represent 66 per cent of total Asian oil demand by 2010 (Abdelwahab 2001).

Most Arab states have developed the refining industry to enable them to keep up with international requirements for clean fuel products and to improve the value added of refined oil. Conversion processes

top the technology options available because they can convert heavy residues left from direct refining into light, high-value products, give a refinery the flexibility to refine heavy crude, and allow producing countries to utilize poor quality oils which are difficult to export. Conversion processes for primary distillation residues also form an important part of Arab strategies to strengthen their ability to achieve oil price stability in world markets. Price instability stems from a shortage of refinery capacity, which has been exacerbated by the suspension of refinery building in some industrial countries. This has had a serious impact on the bottlenecks in world markets, as refineries in major consumption centres were unable to meet the growing demand for gasoline.⁷

Further, many Arab states have pursued a strategy to improve the quality of the environment resulting from oil by producing unleaded gasoline. Qatar began producing it in 1984, Tunisia in 1992, Egypt in 1996, Kuwait and Syria in 1997, Algeria in 1998, Bahrain in July 2000, and Saudi Arabia in January 2001. Moreover, most Arab states are cutting the sulphur in their diesel from 1 per cent in weight to 0.05 per cent in conformity with local laws and circumstances and oil refinery capacities. This requires installing new hydrocracking units in refineries. The target of 0.05 per cent sulphur content or less in diesel has already been achieved in Qatar and Oman, and most Arab countries are implementing projects to achieve that target.

At the regional level, the countries of the Arab Orient and the GCC states have devised strategies of integration in the energy sector. Egypt, Jordan, Lebanon, and Syria have already begun connecting their electricity grids and are building natural gas pipelines that connect these countries to supply them and Turkey with Egyptian surplus natural gas. The GCC states have also approved a plan in 1997 to connect their electricity grids. (Badawi 2002). In 2001 these states formed "The Electricity Grid Authority of the GCC states" based in El-Dammam, Saudi Arabia to supervise the linking of their electricity grids (*Al-Siyassa*, (Kuwait) 8 May 2007). The gas networks, through which Algerian gas is exported to Europe, also connects with Tunisia and Morocco.

At the international level, a main emphasis is to reduce reliance on Western markets and to diversify oil-importing partners by going east. This is mainly the strategy pursued by some GCC states. It evolves around creating partnerships with Japan, China, South Korea, and India through which Arab countries

7 See in: *OAPEC Monthly Bulletin*, April 2004.

would secure oil importers. Sometimes this takes the form of joint ventures, as with China, South Korea, and India. China seems to be the main long-term reliable partner upon whom most Arab countries are counting to secure oil partnership (Ahmed 2005; Guang 2005; Strecker 2000). But China as the main Asian customer is apprehensive about Arab oil because its maritime transport lines are controlled by other oil-hungry powers, and thus China is increasingly moving towards Russian and Central Asian oil-fields, oil from which is transported through more secure land routes.

Arab energy analysts have recommended certain strategies to boost energy security such as rationalizing energy consumption, developing new and renewable energy sources, improving the quality of local industries so as to reduce the 'domestic elasticity' of energy consumption, and building inter-Arab networks for the exchange of electricity in emergency cases (Abdullah 1992; Omar 2004). Arab governments are partially pursuing these strategies. The main trend is to reduce, if not eliminate, state subsidies for electricity consumption which mostly hurts the underprivileged classes in Arab countries and those who need access to electricity. Recently, the electricity grids of Egypt, Jordan, and Syria were connected so as to exchange energy in cases of emergency. Also Egypt has built a trans-Arab Mashreq pipeline to sell natural gas to Jordan, Lebanon, Syria, Israel, and possibly also Turkey. The natural gas pipeline became operational in 2003. The main objective is to secure continued access in this part of the world to energy supplies.

29.5 Energy and Conflicts in the Arab World

Energy issues were the source of many conflicts in the Arab world. Since the Anglo-German rivalry to control oil resources in Iraq in the late 19th century, great powers have been competing for dominance in the Arab Orient. During the Cold War, Western powers tried to prevent the Soviet Union from approaching the oil wells in the Arabian Gulf, and as a result they established a permanent military presence in the region. The dramatic increase in oil prices during the 1970's led to a military build-up in the Arabian Gulf states. These states possessed the capability to buy huge quantities of arms, which made the region an 'arms bazaar' (Sampson 1977). Some Western powers thus 'recycled' the surplus petrodollars into their economies. According to Lesser (2004) the name of

the game was 'Arms for Oil'. Control of Arab oil in the Gulf was also one of the main motives of the Iraqi invasion of Kuwait in 1990. The American campaign to end the Iraqi occupation of Kuwait as soon as possible was motivated by the quest to prevent a change-oriented power in the region from controlling a large percentage of oil production in the region. Likewise, the Anglo-American military invasion and occupation of Iraq in 2003 was motivated by the desire of the US to control Iraqi oil, the second largest reserve in the world, thus solidifying its single super power status and controlling the flow of oil to China, its future strategic competitor (Noshab 2003). However, it is also argued that oil was not the major motive of the invasion and that the USA could have controlled Iraqi oil by lifting the sanctions on Iraq without invading it (Al-Hajji 2004).

Conflicts have partially shaped the energy landscape in the Arab world. The Arabs have used oil supplies during the 20th century to achieve political gains. This was done during the Arab-Israeli war of 1973 when Arab oil producers stopped supplying pro-Israel countries with oil in order to persuade them to adopt a more balanced stance. This caused the US to threaten an occupation of Arab oil wells and to persuade the Arabs to lift the oil embargo as quickly as possible.

The Arab oil embargo policy triggered the establishment of the International Energy Agency (IEA), whose basic objective was to reduce dependence on Arab oil and finding alternative energy sources. The discovery of oilfields in other regions has also reduced Arab share of world oil production to almost 28 per cent. As a result, it became difficult for the Arabs to resort to the 1973 strategy of an oil embargo as Arab oil could be partially replaced by an increase in the production from other sources (Al-Shalaby 1999). When Mahathir bin Mohammad, the then Prime Minister of Malaysia, suggested during the summit of the Organization of the Islamic conference held in Kuala Lumpur in 2003 to use oil wells to curtail an eminent Anglo-American invasion of Iraq, the Arab member states ignored his suggestion. Most Arab analysts believe that the best strategy is to protect the Arab share in the global oil market and use the revenues to promote development and reinforce the Arab deterrent capability (Abdullah 2002).

During the final years of the first Iran-Iraq War (1980-1988) the two countries attacked the oil facilities of each other, including tankers exporting oil to world markets, which has led to the American intervention to protect tankers of third parties by re-flag-

ging them. These linkages between energy and conflicts in the Arab world call for a re-conceptualization of energy and security questions by integrating them into an overall energy security concept along with other dimensions such as the environment, climate change, and others.

The energy sector has also been one of the favourite targets of American sanctions against some Arab countries, such as Libya and Iraq. American companies were banned from investing in the oilfields of these countries, which led to a drastic deterioration of the quality of the oil extraction technology. Although the policy of sanctions has hurt the Libyan and Iraqi economies, it did not achieve its objectives as the change in the Iraqi and Libyan policies was an outcome of the invasion of Iraq in 2003 rather than the oil-related sanctions (Lesser 2004).

29.6 Conclusion: Towards a Securitization of Energy in the Arab World:

Problems emanating from energy-related questions pose threats to Arab security. An Arab energy analyst concluded that “the future of energy in the Arab world must be a source of anxiety to decision makers,” and went on to argue that “the present energy and electricity situation in the Arab world is not sustainable” (Al-Khatib 2000). However, because of present oil, natural gas, and electricity surpluses in the Arab world, which are not evenly distributed among the Arabs and among the population of the same Arab country, Arab strategists and consumers have not developed a sense of an imminent energy crisis which could pose an immediate security threat, except in countries with limited oil reserves.

Given the short-term and long-term threats, the Arabs need to develop an ‘Arab energy security’ concept which should be integrated into the overall conceptualization of security. Such a concept would include elements of the use the available energy and diversifying energy sources, and partners, and building new strategic relations with oil customers.

The first element in the Arab energy security concept is to increase the efficiency of oil and natural gas utilization. Other sources of energy should be seriously considered. For example, it was found that installing 2 million wind turbines along the west coast of the Arabian Gulf in 60 rows separated by 11 m, where each blade length is of 10 m and efficiency 35 per cent, would produce 556,660 MW, which is the

current total energy capacity of the GCC states (Al-nasser 2006). The same observation may be generalized to solar and nuclear energy in the Arab world.

More emphasis on local oil conversion and petrochemical industries to increase the added value of oil, and pan-Arab regional integration in the field of connecting the electricity grids and transporting natural gas have helped Arab countries during the last few years to boost energy security. Another major element of the suggested energy security concept is to find the optimal energy price subsidization policy which will increase the efficiency of the energy sector, and at the same time provide energy and electricity to those presently deprived of them.

A more refined strategy to secure international partnerships is also needed. This strategy should proceed in two directions. The first is to rectify the unbalanced trade relationships between Arab oil-exporting countries and their Western customers which are based on the formula of ‘Oil for Dollars’, and/or ‘Oil for Arms’, in the direction of a more equitable relationships based on partnerships in the extracting, processing, and trading oil, and more importantly, indigenizing technology in Arab countries. What is needed is a strategy through which the producers and the consumers benefit. The second direction is to cement East and South Asian partnerships, by establishing long-term relationships with them and making sure that China will be engaged in the long run in producing and commercializing Arab oil.

Finally, not all Arab countries are oil rich. Some of them, such as Morocco, Tunisia, and Jordan are net importers of oil and gas. The oil reserves of others, mainly Egypt, are about to run out in or two decades. These countries need to develop alternative energy sources, such as wind, solar, and nuclear energy. These countries need to explore the option of nuclear energy for industrial purposes. In fact, after the Egyptians disbanded their nuclear programme in 1986, they are now debating the wisdom of the decision in light of the increase of the oil prices and Egypt’s limited oil reserves (Ahmed 2006).

30 Turkey: Energy Security and Central Asia: The Politics and Economics of the So-called Great Game

Gareth M. Winrow

30.1 Introduction

Buzan (1991) and his colleagues (Buzan/Waever/de Wilde 1998) widened the concept of security to include political, economic, societal, and environmental dimensions as well as a military component. The term 'energy security' became increasingly employed after the oil price rises in the 1970's, the 1991 and 2003 Iraq wars, and the increase in oil prices in 2005. Energy security may be placed within the context of the economic dimension of security, but energy security may also accommodate other components of security. This is evident in the so-called 'Great Game' concerning Central Asia and the transportation of crude oil and natural gas to outside markets.¹

Turkey is a key player in this Great Game. Political and economic issues and energy security concerns are perceived to be closely intertwined. Because of an over-dependence on Russian natural gas, Turkish officials may look to Central Asia to diversify their natural gas suppliers. In the future, crude oil from Azerbaijan and Kazakhstan may also be imported. The authorities in Ankara are also stressing the strategic value of Turkey as part of a transportation corridor to deliver gas and oil from Central Asia and Russia, and possibly from the Middle East and North Africa, to markets in Europe.

30.2 What is Meant by 'Energy Security'?

According to Deese (1979–1980: 140), energy security is "a condition in which a nation perceives a high probability that it will have adequate energy supplies ... at affordable prices." Energy security interacts with three components of broader security concerns: so-

cial, cultural and political; economic; and military. Energy is essential to improve the quality of peoples' lives, boost industrial development, and fuel the military machine of a state. Influenced by the oil crises of the 1970's, Deese (1979–1980: 144–145) and others such as Maull (1989: 511–512) focused on how to reduce a state's vulnerability to the possible disruption of energy supply. Their proposals were in line with the recommendations of the International Energy Agency (IEA) (35.3). They also suggested diplomatic or military actions to ensure a guaranteed energy supply.

In his discussion of 'environmental scarcities', Homer-Dixon (1994: 8, 18–19) noted that there have been conflicts between states over limited non-renewable resources such as oil and minerals because these resources can power factories and maintain armies. Buzan, Waever, and de Wilde (1998: 74–75) observed that environmental scarcity involved energy problems such as the depletion of natural resources, shortages, and uneven distribution. While the issue of the scarcity of energy supplies has tended to be placed on the environmental agenda, questions pertaining to the access and security of energy supplies have largely remained on the economic agenda, although both issues have potential serious societal, political, and military consequences.

The wider concept of 'economic security' has been challenged. Cable (1995: 305–306) suggested that the concept had lost much of its relevance in the international economic system of the 1990's where uncertainty and risk were part and parcel of this system. Nonetheless, he also argued that threats to economic security from disrupted supplies could become a major public policy issue, especially where there was a high degree of dependence on a small number of suppliers, and when the impact of a disruption was 'strategic' – i.e. affected defence interests (Cable 1995: 313).

1 Azerbaijan is here included although geographically it is strictly speaking a Caucasian or Caspian state.

Buzan, Waever and de Wilde (1998: 22–25 and 95–106) argued that economic security should only apply in those cases where there was an “existential economic threat”, when the import of crucial resources from outside suppliers was threatened and this endangered the survival of the importing state. In these cases the issue was securitized by the government of the importing state, and emergency measures could be taken. In most cases in international economic relations, though, issues were politicized – i.e. became a part of public policy – rather than securitized by governments, and the survival of a state was not in question.

Buzan and his colleagues attempted to define economic security (and energy security) more narrowly by stressing the significance of state survival and existential threats. However, they also acknowledged that how an issue was presented by officials and perceived by the public was important. In practice, therefore, a supposed real existential threat depicted by the ruling authorities may not actually exist (Buzan/Waever/de Wilde 1998: 24–25). Hence, the boundaries between the so-called securitization and politicization of issues, and the level and nature of threats, are not clear.

This chapter will focus on the security of energy supply. The vulnerability of Turkey to the possible manipulation of supplies by Russia will be discussed. This vulnerability could have serious strategic, economic, societal, and political costs, although the survival of the Turkish state is not in question. Turkey could diversify its sources of energy supply and import oil and gas from Central Asia. This application of the term “energy security” is in line with IEA usage.

30.3 Energy Security and the IEA

The IEA was established in 1974 to ensure that the major industrialized countries would not be vulnerable to a future major disruption of oil supplies. The International Energy Programme (IEP) adopted by the IEA in 1974 set up emergency response mechanisms. Members were required to hold oil stocks, restrain demand, switch to other fuels, increase domestic production, and share available oil in the event of a major supply disruption. Coordinating energy policies and increasing efficiency in energy use were later agreed. These were outlined in the shared goals adopted by the IEA in June 1993. The IEA had broadened its agenda and no longer focused solely on oil. Emphasis was given to the need to develop open mar-

kets, and cooperation between energy producers and energy consumers was encouraged. More attention was given to environmental concerns. Closer coordination with non-members of the IEA was recommended – Turkey is a member of the IEA, but Russia and the Central Asian states are not members.²

According to the IEA, energy security includes not only the security of energy supplies, but also the rational management of the world’s energy resources and the protection of the environment. IEA officials are eager to promote an international cooperative approach to the issue of energy security. However, while adhering to these goals individual IEA members may still be vulnerable to energy supply difficulties. Moreover, the IEA itself is still sensitive to the concern for energy supplies, especially in the wake of developments in the Gulf since 1990. Significantly, in September 2005 IEA members released oil as an emergency response to Hurricane Katrina, which had devastated oil production in the United States (US).

Energy transit is an important issue for energy security. Piped crude oil or natural gas may not reach its intended destination because of sabotage or due to transit states illegally tapping into the pipelines to satisfy their own energy needs. Natural gas pipelines are fully dedicated transport infrastructures that are particularly vulnerable to transit risk (Luciani 2004: 13). In contrast to crude oil, natural gas may not be delivered by road or rail, and high costs until recently limited the amount of gas which could be liquefied and transported by tanker. Significantly, Russia has refused to ratify the Energy Charter Treaty which provides for legal safeguards for energy transit. This is mainly because of disagreements over transit tariffs and transit rights through third countries. Ratification by Moscow would open up access to the Gazprom-controlled Russian pipeline system for Central Asian natural gas producers hoping to export their energy to Europe (Roberts 2004: 12).

30.4 Turkey’s Energy Needs and Energy Policy

Officials in Ankara are aiming to reform Turkey’s energy sector through privatization, liberalization, and restructuring to create an effective regulatory framework for a favourable market environment. Eager to

2 See “International Energy Agency: An Overview”, at: <<http://www.iea.org/Textbase/about/index.htm>>, 4 March 2005, pp. 3–7 of 8.

join the EU, Turkish policy-makers are seeking to integrate Turkey with European energy markets and align with the EU's energy *acquis* (Isik 2004: 1). Hence, an Electricity Market Law and a Gas Market Law were enacted in Turkey in 2001, followed by a Petroleum Market Law in 2003. An Energy Market Regulatory Authority was established in 2001 to handle secondary legislation, and, in particular, licensing and tariff regulations. These reforms were in line with the IEA's recommendations concerning the rational management of energy resources and the creation of free and open markets.

Turkey's future energy needs are difficult to predict given uncertainties over future economic growth, internal political developments, and questions over EU membership. With stand-by assistance packages worth US\$ 26.6 billion offered by the International Monetary Fund (IMF), the Turkish economy recovered after financial crises in 2000 and 2001. Turkey's real gross domestic product (GDP) grew by 8.9 per cent in 2004. However, the substantial black economy remains to be tackled, agriculture must be modernized, much more foreign direct investment is required, and a sizable debt and a growing current account deficit still need to be properly addressed.

According to the State Institute of Statistics in 2004 electricity consumption in Turkey increased 6.6 per cent year-on-year to 149.6 billion kilowatt hours (kWh).³ In 2004 the Ministry of Energy and Natural Resources (MENR) and other public institutions completed a study which forecast future electricity consumption in Turkey. Figures were projected based on a low demand growth, a high demand growth, and a main scenario that assumed a 6.4 per cent average GDP growth rate (table 30.1).

Table 30.1: Electricity Demand Scenarios by MENR (kWh). **Source:** Isik (2004: 4).

	Main Scenario	Low demand growth scenario	High demand growth scenario
2005	163	159	168
2010	242	217	246
2020	499	407	571

3 See the figures produced by the State Institute of Statistics of Turkey at: <<http://www.die.gov.tr/english/SONIST/ENERJI/e230305.xls>> and at: <<http://www.die.gov.tr/english/SONIST/ENERJI/060404.htm>>, 21 September 2005.

Turkey's Energy Minister Hilmi Güler announced in February 2005 that substantial investment would be required to ensure a generating capacity of 54,000 megawatts (MW) by 2020 to enable Turkey to consume 499 billion kWh.⁴ Three years earlier Hilmi's predecessor, Zeki Cakan, had warned that there could be an energy shortage in Turkey in 2006 unless more funds were invested in the power sector.⁵ However, the figures used by Cakan were inaccurate, due to poor planning and problems with corruption. Fears of an energy shortage have been renewed. Without new investments the Electricity Transmission Company of Turkey (TEA) has warned that in 2010 it would only be able to supply 197 billion kWh (Isik 2004: 6). Güler has emphasized the need to use more local and renewable sources of energy and begin to use nuclear energy after 2012 to avoid a looming energy crunch.⁶

Natural gas is becoming more important as a source of electricity generation in Turkey. According to the State Institute of Statistics, in 2003 natural gas accounted for 44.8 per cent of electricity generation, ahead of hydropower with 21.5 per cent, lignite with 17.95 per cent, and fuel oil with 5.46 per cent.⁷ In 2002 about 67 per cent of natural gas utilized in Turkey was for power generation: a figure three times higher than the European average (Isik 2004: 7).

In the 1989–2002 period Turkey's demand for natural gas grew by 14 per cent per year on average (Isik 2004: 7). In 2004 Turkey imported 22.2 billion cubic metres (bcm) of gas, of which 14.3 bcm originated from Russia.⁸ More gas will be imported as a

8 Figures produced by the Petroleum Pipeline Corporation of Turkey (BOTAS) at: <http://www.botas.gov.tr/eng/naturalgas/ng_trade.asp>, 7 March 2005.

national gas grid takes shape. Domestic gas production is very limited and has been declining. According to the Petroleum Pipeline Corporation of Turkey (BOTAS), Turkey's demand for gas will increase to 38.5 bcm in 2010, 41.1 bcm in 2015, and 43.2 bcm in 2020, with much of this covered by Russian natural gas imports (table 30.2). These figures are open to dispute. BOTAS itself has regularly revised its estimates. However, BOTAS has clearly over-contracted and for the immediate future Turkey will import more gas than is necessary. For 2010 BOTAS has contracted to receive 51.1 bcm to meet an energy demand of just 38.5 bcm. Moreover, this gas is expensive and under take-or-pay obligations Turkey will have to make hefty compensation payments if it chooses not to import agreed upon amounts. The problem is compounded by the fact that Turkey does not have proper gas storage facilities. The influence of the so-called 'Russian lobby' in Turkey accounts for the size of the Russian natural gas imports. Large Turkish construction companies with extensive investments in Russia have been employed to build pipelines and power stations which will make use of natural gas from Russia. Nevertheless, it appears that Turkey will need to find new sources of gas after 2010. The 6 bcm/y with the Russian Federation (with Gazexport) ends in 2011 and may not be renewed. The liquefied natural gas (LNG) contract with Algeria expires in 2014.

Although not as important for electricity generation as natural gas, crude oil is also an invaluable source of energy for the Turkish economy. In 2003 Turkey consumed 29.5 million tonnes (mt) of oil. In the same year local production of crude only amounted to 2.4 mt.⁹ According to the US Energy Information Administration, if the economy grows on average by 3.4 per cent per year, Turkey will need to consume up to 45 mt by 2010 and 60 mt by 2020.¹⁰

Complaining about the high costs of natural gas imports from Russia and Iran, in addition to the over-reliance on natural gas for electricity generation, in April 2003 Güler called for a revision in Turkey's energy policy in order to exploit cheaper and local forms of energy such as lignite, geothermal, and

hydropower. The Energy Minister observed that importing substantial amounts of natural gas to avoid the penalties in take-or-pay obligations had resulted in geothermal and hydropower stations in Turkey lying idle.¹¹ In May 2005 a bill passed through parliament which called for the increased use of wind, and solar energy, and geothermal and hydropower.

In practice it would take several years for Turkey to develop other sources of energy. Much of Turkey's lignite is of quite poor quality. There are more possibilities with regard to hydropower. Turkey has significant reserves and is currently using only 35 per cent of its hydropower potential.¹² The MENR's interest in developing nuclear energy may also encounter future problems. In July 2000 the Turkish government was forced to abandon a US\$ 4 billion project to build a nuclear plant at Akkuyu on the Mediterranean

coast because of financial difficulties and opposition from environmental protest groups. It seems likely, therefore, that Turkey will remain highly dependent on imports of crude oil and natural gas for the foreseeable future. This raises the question of the danger of an over-dependence on Russia, thereby threatening Turkey's energy security.

30.5 The 'Great Game'

Much attention has been given over whether the competition in post-Soviet Central Asia between governments and energy companies for political influence, prestige, and control of oil and gas transportation routes is a new 'Great Game'. The original Great Game involved rivalry between Russia and Britain in Central Asia at the end of the nineteenth century. Critiques of the new Great Game have questioned the scale of energy reserves in Central Asia, with the high costs and difficulties to extract and transport this crude oil and natural gas (Jaffe/Manning 1998–1999: 114–118). It has been argued that the so-called Great Game is not a game as it involves cooperation as well as competition between governments and companies over oil and gas concessions and this is a normal feature of the international economic system (Edwards 2003: 91–95). In non-zero sum games, though, there is cooperation between players in addition to competition. The interests of business lobbies, as seen in Turkey, may not always coincide with those of their home governments. Different games may thus be played at different levels within and between states. The stakes for Turkey with close economic and political interests in Central Asia may be quite considerable. Caspian energy reserves are potential useful alternative sources of energy for the Turkish economy. However, Ankara must also contend with the strategic concerns of Moscow in Central Asia.

The size of energy reserves in Central Asia has indeed been exaggerated. In December 1995 the American Petroleum Institute stated that the Caspian region contained two-thirds (659 billion barrels) of the world's known reserves of oil (Karasac 2002: 15). More recent assessments indicate that the region contains proven oil reserves of from 17 to 44 billion barrels (the higher figure comparable to US reserves) and additional potential reserves of 186 billion barrels. The proven oil reserves of Azerbaijan and Kazakhstan are 7 to 12.5 billion barrels and 9 to 29 billion barrels respectively. The region also has proven gas

reserves of 6,580 bcm (comparable to Saudi Arabia) and another possible 9,302 bcm. Azerbaijan, Kazakhstan, Turkmenistan, and Uzbekistan have proven gas reserves of 851 bcm, 1,843 bcm, 2,014 bcm, and 1,877 bcm respectively (US Energy Information Administration 2005: 1). Moreover, much of the northern Caspian Sea appears to contain significant energy reserves and remains largely unexplored.

With the unravelling of the Soviet Union, and encouraged by the US administration and at first by the leaders of the newly independent Turkic states, officials in Ankara were eager to cultivate close political, military, and economic ties with Central Asia to boost Turkey's prestige and demonstrate that Turkey remained a strategically important state in the post-Cold War era. However, the Turkic states, seeking to diversify their relations, were not willing to bind themselves exclusively to a Turkish-led Commonwealth. Nevertheless, there are still close cultural, political, and economic links between Turkey and post-Soviet Central Asia. In this context, energy issues must also be considered. Recent governments in Ankara have underlined the importance of Turkey as a transit state on an east-west transportation corridor for the delivery of Central Asian crude oil and natural gas to Europe. Some of this energy may in future be consumed on the Turkish market to satisfy Turkey's growing energy needs and avoid an over-dependence on Russian energy imports.

The Baku-Tbilisi-Ceyhan main export pipeline, which will deliver crude oil from Azerbaijan and probably Kazakhstan to the Turkish Mediterranean coast, was initially principally a political project backed by US administrations to ensure that Turkey's influence in the Caspian region would be boosted at the expense of Russia and Iran. Rising oil prices made this project more economically feasible, although doubts remain over when and if the pipeline will operate at full capacity. Natural gas from the Azerbaijani Shah Deniz gas field in the Caspian Sea is planned to be delivered to Turkey along a Baku-Erzurum pipeline from 2007 onwards, although it will be much more difficult to transport natural gas from Kazakhstan, Turkmenistan, and Uzbekistan to Turkey, given the shortage of pipeline connections and Russia's interest in maintaining its substantial stake in the Turkish gas market.

The Great Game also involves legal and environmental issues. The failure to define the legal status of the Caspian Sea and apportion the sea among all the littoral states into national sectors had prevented the construction of an oil pipeline connecting the Kazakh

port of Aktau with Baku. This pipeline could have hooked up with the Baku-Tbilisi-Ceyhan link. The draft provisions of a possible Caspian Convention forbid the laying of subsea pipelines across the Caspian on environmental grounds. With the continued increase in the number of tankers navigating the hazardous Bosphorus Straits, the Turkish government has also cited environmental arguments to press the case for the Baku-Tbilisi-Ceyhan pipeline.

In January 2002 Russian President Vladimir Putin had announced plans for the formation of a Eurasian Alliance of Gas Producers with the governments of Kazakhstan, Turkmenistan, and Uzbekistan. This would have guaranteed the long-term Russian purchase of Central Asian natural gas for its domestic market and would thereby have enabled Moscow to continue to export significant amounts of Russian natural gas to hard currency markets in Europe (Hill/Fee 2002: 16). The EU opposed the establishment of this gas cartel, which ran contrary to the plans of Brussels to promote a liberalized gas market beyond the EU's borders, and which clashed with the provisions of the Energy Charter Treaty with regard to the freedom of transit. Moscow has more recently concluded separate long-term cooperation agreements with Kazakhstan, Turkmenistan, and Uzbekistan to ensure that Central Asian gas will be transported to the Russian market for the foreseeable future.

30.6 Turkey, the Great Game and Energy Security

The Turkish Petroleum Refineries Corporation (TÜPRAS) will import in 2005 4.5 to 5 mt of crude oil from Russia, 5.5 to 6 mt from Iran, 3.5 mt from Saudi Arabia, 4 to 4.5 mt from Libya, and, if security arrangements allow, 3 mt from Iraq.¹³ As previously noted, Turkey may consume up to 45 mt by 2010. Officials in Ankara plan to purchase 15 to 20 mt/y of crude from the Baku-Tbilisi-Ceyhan pipeline if and when the 50 mt/y pipeline operates at full capacity.¹⁴ First oil is expected to be transported along the pipeline in November 2005.

The oil fields in the Caspian Sea off the Azerbaijani coast, which will feed the pipeline, will not reach

peak production of 50–60 mt/y until 2010. But ExxonMobil and Devon Energy, with shares of 8 per cent and 6.5 per cent in the consortium developing the fields, have made alternative arrangements to transport their share of the oil production by rail to the Georgian port of Batumi until at least 2010. Probably up to 20 mt/y of crude from Kazakhstan's Kashagan oil field will eventually be carried to Ceyhan, but production at Kashagan is not expected to commence until 2008. Azerbaijan and Kazakhstan were expected to conclude an intergovernmental agreement in late 2005. A fleet of barges will require commissioning to transport Kashagan crude across the Caspian Sea. Talk of resurrecting plans to construct a subsea pipeline across the Caspian Sea would require the unlikely support of other littoral states. In the meantime, Russian officials have expressed an interest in supporting an alternative Bosphorus by-pass line connecting the Turkish Black Sea port of Samsun with Ceyhan, which could deliver 55 mt/y. Turkey could thus increase its imports of Russian crude in the longer term, although, presumably, officials in Ankara would ensure that Turkey does not become over-dependent on Russian oil.

Transit security problems for the Baku-Tbilisi-Ceyhan pipeline must be considered. Kurdish insurgents escalated their guerrilla campaign against the Turkish authorities in 2005 and may attempt to strike at aboveground oil pumping stations in Turkey. Pipeline routes connecting Azerbaijan and Turkey need to traverse the volatile Caucasus where conflicts over Abkhazia, South Ossetia, and Nagorno-Karabakh remain unresolved. In January 2003, US and Georgian officials created a special military unit to guard the Baku-Tbilisi-Ceyhan pipeline. An agreement has been signed with Northrop Grumman Corporation to provide aerial surveillance over the pipeline route (US Energy Information Administration 2004: 2). The pipe runs through the Akhaltsikhe-Vale sector of Javakhetia in southern Georgia where there is a mixed Armenian and Georgian population. It thus avoids the parts of Javakhetia that are predominantly populated by an impoverished Armenian minority, which is a group traditionally hostile to Turkey. The minority could target the pipeline, especially after the Russian military base at Akhalkalaki closes in 2007–2008. The base provides a major source of employment for the Armenians.

In February 2005, the Deputy Permanent Undersecretary in the MENR, Salih Pasoglu, remarked that if Moscow decided to sever its gas connections, Turkey "would be devastated".¹⁵ Until at least 2011 –

13 "TÜPRAS eyes Gains in Free Market", in: *Turkish Daily News* (14 December 2004): 6

14 See Baku-Tbilisi-Ceyhan COPL Project Directorate, at: <<http://www.btc.com.tr/eng/project.html>>, 21 September 2005.

when the contract with Gazexport expires – Turkey will remain highly dependent on Russian natural gas imports. This gas comes at a high cost and with onerous take-or-pay obligations. Energy officials in Ankara are seeking to reduce this dependence in the foreseeable future and handle the problem of over-contracting by re-selling and re-exporting some Russian natural gas to the European market. Gazprom may consider this if it is awarded contracts to distribute natural gas within Turkey. Re-sales and re-exports would need the construction of gas pipelines to connect Turkey and Europe as a part of an east-west energy transportation corridor.

After the contracts with Gazexport and Algeria expire, BOTAS could look for new suppliers in Central Asia to meet Turkey's gas requirements. Imports of natural gas from Iran and LNG from Nigeria are expensive. Turkey is contracted to receive 6.6 bcm from Azerbaijan's Shah Deniz gas field by 2010. From 2008 onwards up to 0.737 bcm of this natural gas may be re-exported to Greece. A 3 to 11 bcm/y gas pipeline connecting Turkey and Greece is planned to be completed by 2006, and this may be extended to Italy to carry initially 8 bcm by 2008. Negotiations are also under way for the construction of a 20 to 30 bcm/y gas pipeline to Austria via Turkey, Bulgaria, Romania, and Hungary. This network would lead to the realization of an east-west transportation corridor to carry Azerbaijani natural gas to Europe via Turkey. Turkish energy officials could perhaps import more Shah Deniz gas after 2011 when the second phase of production at the gas field would have commenced. The Baku-Erzurum pipeline will have a 16 bcm/y capacity.

In May 1999 Turkey and Turkmenistan concluded a 30-year agreement for the supply of 16 bcm/y to the Turkish market. Deliveries were supposed to begin in 2002. But the \$ 2.7 billion Trans-Caspian natural gas pipeline has not been built because of the legal disputes over the Caspian Sea and disagreements between energy companies and Turkmen President Saparmurad Niyazov over commercial terms. Presumably because the sale and purchase agreement has not been cancelled, Turkmenistan is still referred to in the natural gas supply and demand scenarios of BOTAS. However, it seems highly unlikely that Turkey will consume Turkmen natural gas in the foreseeable future, as Niyazov has turned his attention to

other markets. In April 2003 Turkmenistan and Russia concluded a 25-year gas agreement. If price disputes are resolved, from 70 to 80 bcm/y of Turkmen natural gas will be delivered to the Russian market from 2009. Turkmenistan also has gas supply deals with Ukraine and Iran, and is contemplating exporting natural gas to Pakistan and India. Instead of natural gas, Turkmenistan has instead delivered electricity to Turkey via Iran since December 2003. In 2004, 463 million kWh were exported to Turkey from Turkmenistan.¹⁶ However, this was only a small fraction of the electricity that Turkey consumed.

There are also no prospects in the immediate or medium-term for natural gas from Kazakhstan or Uzbekistan to reach Turkish consumers. Currently Kazakh gas is channelled to the Russian market and this will continue after agreements were signed in 2002 and 2003. Negotiations are ongoing over the possible construction of a pipeline that could result in 8 to 10 bcm of Kazakh gas being delivered to western China in 2008, with this amount rising to 30 bcm by 2020.¹⁷ Uzbekistan produces around 50 bcm/y, but most of this is either consumed locally or exported to Russia and Central Asian neighbours. Uzbekistan and Russia have agreed to strategic cooperation in the gas sector for the 2003–2012 period. Like Kazakhstan, Uzbekistan is hooked up to the Central Asia-Centre gas pipeline which connects to the Russian pipeline system. There is no proper network in place at present which would enable Kazakh and Uzbek gas to reach markets in Turkey and Europe, while avoiding the Russian pipeline system.

30.7 Conclusion

The term energy security is employed in this chapter to refer to issues related to energy supply – i.e. the security of energy transit and the problem of over-dependence on one supplier for a key form of energy. Officials in Ankara are seeking to extricate themselves from a situation where an over-dependence on Russian natural gas imports until at least 2011 has arisen. This over-dependence does not threaten the survival of the Turkish state. Nevertheless, in the near term Ankara has left itself exposed to possible economic or political blackmail. Because of this energy

15 “Rusya dogalgazi keserse mahvoluruz” [“If Russia cuts its Natural Gas we are devastated”], in: *Radikal* (27 February 2005): 15.

16 “Turkmenistan has increased the Export of Electricity to Iran and Turkey 2.2 times”, in: *TASS*, Ashgabat (19 January 2005).

dependence on Russia, Turkish governments in the foreseeable future may enjoy less freedom of manoeuvre in their conduct of foreign policy.

With the exception of hydropower, there is little immediate prospect for Turkey to exploit more local and renewable forms of energy. Ankara may thus import crude oil from Azerbaijan and Kazakhstan. However, natural gas is likely to remain an important resource for electricity generation. More natural gas from Azerbaijan, therefore, may be consumed. In the meantime, some Russian natural gas may be off-loaded in Europe through re-sales and re-exports to avoid immediate problems of over-contracting. Later possible re-sales and re-exports of Russian natural gas would encourage the diversification of Turkey's natural gas imports. In the longer term Turkish energy officials may hope to import natural gas from other Central Asian suppliers if pipeline networks are developed that avoid the Russian pipeline system. The

construction of pipeline connections westward to Europe would result in the realization of the east-west gas transportation corridor. This corridor could enhance the energy security of EU member states, especially if in the future natural gas from Iran and possibly Iraq, Syria and Egypt, as well as from Azerbaijan, could be conveyed along this corridor via Turkey.

The so-called new Great Game with reference to energy issues is not perceived by Turkish officials as a normal interaction within the global economic system, which may be amenable to an international cooperative approach. From Ankara's perspective - and also Moscow's - major economic, political, and strategic issues are closely interlinked. Turkey has been a key player in the Great Game since the 1990's and will remain so, given its sensitivities to developments in the neighbouring volatile Caucasus and the wider Caspian region, and its interests in importing energy from this area.

31 Towards a Sustainable Energy System for Africa: An African Perspective on Energy Security

Nogoye Thiam

31.1 Introduction

Energy is vital to economic, social and environmental development. Secure and affordable access to energy makes it possible to fulfil basic needs, i.e. access to drinking water, health care and to information and communication technologies, electricity for houses and schools, intensive agricultural production and conservation of agricultural products. A sustainable energy system is needed for speeding up the economic and social development process and to ensure food security.

Sub-Saharan African countries are mainly characterized by an extreme lack of energy, which is due to a very limited use of modern energy and a system based on unsustainable supply sources. In 2003, Africa only used 5.7 per cent of the world's energy, whereas its total population represents 14 per cent of the world population (figure 31.1). As a consequence, the level of energy consumption per inhabitant is very low. For instance, in 2003, Senegal and Cameroon have respective consumption levels of 287 and 429 kg of oil equivalent per capita. In developed countries, this consumption reaches, e.g. 7,843 kg of oil equivalent per capita in the US and 4,519 of oil equivalent in France.¹

In Africa, the energy system is characterized by a dual structure which highly depends on oil imports on the one hand and on biomass (figures 31.2, 31.3) products on the other. Those two characteristics clearly show that the energy system is highly vulnerable, which is also reflected by the rate of independence of the energy sector. This rate, which still remains very low in Africa, corresponds to the ratio between the energy produced at the national level and the total availability of primary energy per year. But there is some improvement if biomass energy² is included.

This dependence on oil imports and biomass availability involves several aspects of financial, economic, technical and environmental insecurity. Financial and economic insecurity results from the explosion of oil price and its impact on the trade balance. On the other hand, technical insecurity is related to the high dependence of several sectors of activity (industries, transport) on oil products.³

3 Energy security can have different definitions depending if a country produces or imports oil. For oil exporting countries, energy security means being able to maintain a position as an energy supplier for the long-term, working with stable and low-risk clients, and guaranteeing elevated petroleum prices. This chapter focuses on importing countries that are currently suffering from political, economic, technical, and environmental instability – all of which concern the supply and consumption of petroleum. Political insecurity is linked to physical location of petroleum reserves. According to Jean-Marie Chevalier (2006) “more than 80 per cent of petroleum and natural gas resources are located in politically turbulent or fragile countries: Latin America, West Africa, North Africa/Maghreb, the Middle East, Central Asia, and Russia.” Economic and financial insecurity arise following increased petroleum prices. Such increases hurt countries by disrupting commercial equilibrium and economic flow. Jamal Saghir (2006) notes that these increases will cause oil importing sub-Saharan countries to lose any modicum of economic stability they may enjoy. Following an oil price increase, countries' GDPs already fell more than 3 per cent; poverty rates have also increased 4–6 per cent. Technical insecurity is best defined in terms of insufficiently diversified technology. The vast majority of equipment/machinery in sub-Saharan Africa is dependent on petroleum products. This applies for both the electricity and transportation sectors. The potential outcome of accidents related to production, supplying, or spilling of petroleum has grave implications for such sectors. To mitigate these concerns, many countries have started to experiment with hybrid cars. Since 2003, nearly 35 per cent of cars sold in Brazil are *Fuel Flexible Vehicles* (FFV). The FFVs operate on a fuel mixture comprised of 85 per cent of ethanol. Environmental insecurity is linked to an increase of atmospheric greenhouse gases due to the production and consumption of petroleum products.

2 The energy independence of Senegal was 4.3 per cent in 2004, it reached 42.8 per cent if biomass is included.

Figure 31.1: 1973 and 2003 Regional Shares of Total Final Energy Consumption. **Source:** IEA (International Energy Agency); at: <<http://www.iea.org/statist/index.htm>>.

Figure 31.2: Africa's Share of Total Primary Energy Supply in 2003. **Source:** IEA (2006b); at: <<http://www.iea.org/statist/index.htm>>.

As for *environmental insecurity*, it results from the accumulation of *greenhouse gases* (GHG) in the atmosphere that are responsible for global warming. It is also related to the gap between the pressure on forests for energy purposes and the reforestation process, especially in the Sahel countries. It has become urgent for African governments to find alternative and sustainable energy supply and consumption strategies to deal with this insecure situation. According to several international experts, poverty reduction, food security and the realization of the *Millennium Development Goals* (MDGs) requires a safe supply of modern energy at affordable prices.

This chapter highlights the duality of the energy supply system, based on local biomass and oil product imports (31.2). The second part discusses the need for a more sustainable energy system in order to ensure

economic development and poverty reduction (31.3). This will require a certain willingness of national authorities to implement adequate energy policies based on the sustainable promotion of local renewable resources and consumers' practices change for more rational use of energy. Regional and international cooperation will also be needed in order to mobilize funds and relevant expertise for a large-scale exploitation of the continent's resources.

31.2 Dual and Vulnerable Energy System

The energy system in Sub-Saharan African countries is characterized by two main energy sources: biomass and imported oil products. The biomass represents

Figure 31.3: Energy consumption profiles for Mali and Senegal in 2004. **Source:** Produced by this author based on annual reports by the National Ministries of Energy in Mali and Senegal.

Consumption levels per energy type in Mali

Consumption levels per energy type in Senegal

60 per cent of the total energy consumption, with average rates varying between 40 per cent in Senegal and 80 per cent in countries like Mali, Niger and Burkina Faso. The use of oil products depends on the country's economic structure (53.4 per cent in Senegal and 11 per cent in Mali; figure 31.3).

31.2.1 Oil Dependence

In some countries, available oil resources have led to conflict, corruption and social instability and therefore become a source of social and economic insecurity, but in some countries without any oil deposits the constant price increase for oil products on international markets it has become a real source of insecurity. The purchase of oil products for non-producing countries like Senegal involves major transfers of foreign currency, what negatively affects the trade balance. For landlocked countries, like Mali or Burkina Faso, the situation is even more complicated due to the additional costs for its transportation from sea-ports to the final destination. Thus in some countries, the energy cost often represents over 30 per cent of the total electricity costs. In Mali electricity is most expensive due to the cost of combustibles (33.6 per cent of total electricity cost); the delays in the operation of Manantali⁴ hydroelectric dam have further added the cost of electricity (Thiam 2003: 342, 2006; see chap. 51 by Kipping).

Senegal is facing similar economic problems. The rising oil prices caused a 12.7 per cent increase in oil

import costs, from 247 billion CFA (2003) to 278 billion CFA (2004).⁵ But the volume increased only 4 per cent, from 1693 tons (2003) to 1761 tons (2004). Oil imports represented 20 per cent of the country's total imports and absorbed 40 per cent of the income from exports. The imported oil is used for transportation (75 per cent) and electricity production. The electricity sector exclusively relied on thermal power until 2002 when the Manantali dam became operational that supplies 13 per cent of the electricity demand.

The recent crises in the international oil market had damaging impacts on the transport and electricity sectors. This has been exacerbated by the suppression of state subsidies for the oil sector.⁶ In Senegal, the fuel used by the *Senegal Electricity* (SENELEC) company rose from 75,536 F CFA per ton in January 2004 to 135,000 F CFA in 2005, or a 71 per cent increase⁷. This has resulted in severe supply problems for vehicle fuel and in power cuts. The state supported the most affected sectors to avoid a shortage of vehicle fuel and a collapse of the electricity production. The government established a stabilization fund to minimize fuel prices fluctuations and subsidized SENELEC to avoid bankruptcy, as the real fuel cost is not fully reflected in the electricity costs. The rise in electricity prices was limited to 10 per cent instead of 15 per cent as had been suggested by the National Commission regulating the electricity sector (*Commission de Régulation*

4 Senegal, Mali and Mauritania launched the Manantali hydroelectric project through the Senegal River Organization (*Organisation pour la Mise en Valeur du Fleuve Sénégal* or OMVS). It provides electricity for all three countries (52 per cent of its generation for Mali, 33 per cent for Senegal and 15 per cent for Mauritania). The building process was delayed and the power plant became operational in 2002.

5 This chapter uses an exchange rate of 500–520 CFA francs for 1.00 US\$. The Franc CFA is the currency of the *West African Economic and Monetary Union* (WAEMU) that comprises 8 West African countries: Benin, Burkina Faso, Guinea Bissau, Côte d'Ivoire, Mali, Niger, Senegal and Togo.

6 Subsidies only remain for LPG (liquefied petroleum gas) products due to limitations of forest resource exploitation.

7 From 157 US\$ in January 2004 to 270 US\$ in 2005 (exchange rate 1 US\$ = 500 F CFA).

du Secteur de l'Electricité).⁸ This decision resulted from a consultation and a review of the costs. The measures of the state have two weaknesses:

1. The increased support for the energy sector resulted in a reduction of public spending for health and education.
2. This can impede the evolution of alternative energy sources for electricity and transport.

The funds used to subsidize oil prices and to support this fragile system could have been used more efficiently for instance for technological research and for renewable energy. The dependence on oil had limited environmental impacts in Senegal due to the low levels of CO₂ emissions (3.73 Mt of CO₂ in 2003, or 0.36 t of CO₂ per capita).⁹

31.2.2 Dependence on Biomass

In Africa, 49 per cent of the consumed energy is traditional biomass (figure 31.2). This ratio can reach 60 per cent if the North African countries are excluded: This can pose a real threat for the environment. A reasonable use of biomass is safe, as it is a renewable energy, but the use in Sub-Saharan Africa leads to deforestation, soil salinization, erosion and desertification.

The increasing wood demand impedes the natural reconstruction process of forests, as the rapid population growth requires increasing amounts of combustibles. The improper use and overexploitation of forests contributes to rapid forest destruction. Apart from their environmental benefits, forests can be a highly useful and sustainable source of ligneous and non-ligneous resources and generate employment. Forests also play an important role in maintaining biological diversity, absorbing carbon dioxide and supplying wood for essential needs (fuel, clothing, cooking, buildings etc.).

Forests regenerate more slowly in the Sahel countries¹⁰ and thus overexploitation of natural resources

leads to a gradual disappearance of ligneous resources. In Mali where wood is the main source of energy, 4,800,000 ha of forests are lost, 6,000,000 tons are used every year and the annual CO₂ emissions amount to 8,304,000 tons (Mali 2005). In Senegal the situation is similar: 300,000 tons of wood are used every year what corresponds to a loss of 45,000 ha of forest (PERACOD 2005). But several programmes were developed to increase ligneous resources in those countries, including a Regional Programme funded by the World Bank that evaluated policies on 'traditional' energy (*Regional Programme for The Traditional Energy Sector - RPTES*) aiming at a rational use of the biomass. In several countries afforestation and reforestation campaigns were launched.

The dependence on wood has also caused health impacts, especially for children and women. The burning of biomass produces toxic gases (e.g. carbon monoxide), which causes serious respiratory problems that frequently lead to the death of babies. A study in Gambia on 5,000 children under 5 years showed that those children who are carried in their mother's back during cooking were 6 times more at risk to develop acute respiratory diseases (World Bank 1996).

31.3 Toward a Sustainable Energy System

The oil crises of the 1970's have triggered scientific and technical efforts for a more sustainable energy system. The recent oil price increases highlighted that oil resources are limited and can become a source of economic, social and political tension in many countries. For these reasons countries like France launched nuclear programmes, but uranium resources are also not inexhaustible. The issues of nuclear waste management and the accidents in Three Mile Island (USA, 1979) and in Chernobyl (Ukraine, 1986) led to a reduction of nuclear programmes in many countries and to a total rejection, e.g. in Germany.

In Brazil, the need to reduce the vulnerability due to fluctuating oil prices stimulated the development of biofuels, and already in the 1970's, many vehicles used ethanol (sugar cane alcohol). In other developing countries, especially in Sub-Sahara Africa, strategies were adopted to rationalize energy usage, accelerate oil prospecting and promote renewable energies. But all these initiatives produced limited results, due to a lack of dynamism in the elaboration and implementation process. However, the frequent oil crises

8 A review by the *Commission de Régulation du Secteur de l'Electricité* (CRSE) showed a 17.75 billion CFA deficit for the *Société Sénégalaise d'Electricité* (SENELEC) due to the increased cost of combustibles. This amounts to a 15 per cent increase in electricity costs.

9 In Africa the CO₂ emission rate is very low compared with other countries (global average was 3.99 for 2003), North America: 19.47, Europe: 8.61 and Africa: 0.9 (IEA 2005e).

10 In West Africa the biomass density in the southern coast countries varies between 3 and 5 m³/ha and it does not exceed 1 m³/ha in Sahel countries.

Figure 31.4: Map of oil and gas fields and pipelines in West Africa: **Source:** U.S. Department of Energy; at: <<http://www.eia.doe.gov/emeu/cabs/archives/africa/wafrica.pdf>>.

and the instability in the Middle East have shown that oil is not the most reliable energy source and that all countries should become less vulnerable to oil price fluctuations and diversify their energy sources or at least sources of supply. This requires to secure the supply and to improve the demand side management.

31.3.1 Supply Side Management

Strategies for increasing the energy supply should focus on diversifying energy sources and on facilitating a transition towards alternative energy sources.

31.3.1.1 Towards a Diversification of Sources of Energy Supply

The geopolitical uncertainties in the Arab-Persian Gulf have encouraged major oil importing nations, such as the U.S., to increasingly tap African oil resources. Despite huge oil potentials, Africa has been underexplored¹¹ compared with the rest of the world; Africa has now become a new area for big oil prospecting companies in search of new oil fields and reserves.

The Gulf of Guinea is being promoted as the most promising African region for offshore production.¹² Although this technique is more expensive compared with on-shore production, it is generally preferred because the oil is produced away from human settlements, and safe from social tensions what contributes to reducing hazards and making exploitation projects more promising.

But, making Africa an alternative source for oil supplies requires political and social stability, including an environment in these oil producing countries fostering good governance. Oil has often been a source of tensions, and the distribution of oil subsidies has caused conflicts among different stakeholders. In many cases, 'petrodollars' have not contributed to development programmes in the exporting nations or helped to effectively reduce poverty. They have contributed to maintaining a class of rich people in

11 Senegal has 7 oil wells for 10,000 km² compared to the global average of 85 wells for 10,000 km².

12 Many conferences were held to demonstrate the oil production opportunities in this African region.

Box 31.1: West African Gas Pipeline (WAGP). **Source:** Based on this author's research.

The *West African Gas Pipeline* (WAGP) is an important cross-country project with an estimated cost of US\$ 600 million. It is 567 km long and starts in Alagbado (a suburb of Lagos), and connects the cities of Cotonou (Bénin), Lomé (Togo), Tema, Takoradi and Effasu (Ghana). The project will be developed on a BOO basis (built, own and operate) on behalf of the *West Africa Gas Pipeline Company*

Figure 31.5: West African Gas Pipeline (WAGP). **Source:** U.S. Department of Energy, Energy Information Administration; at: <<http://www.eia.doe.gov/emeu/cabs/wagp.html>>. This map is in the public domain.

(WAPCo), owned by an investment consortium including these six companies: (1) *Nigerian National Petroleum Corporation* (NNPC): 25 per cent; (2) Chevron Nigeria Ltd: 36.3 per cent; (3) Shell Nigeria: 18 per cent; (4) Volta River Authority of Ghana: 16 per cent; (5) *Société Béninoise de Gaz, S.A* (SBG): 2 per cent; and (6) *Société Togolaise de Gaz, S.A.* (STG): 2 per cent.

After an energy cooperation treaty for the exploitation of the gas pipeline was signed in January 2003 at the 26th ECOWAS Summit in Dakar, a joint authority was created to supervise the implementation of the project and to develop the fiscal framework of its management. It was agreed that 85 per cent of the gas production would be used by power plants and 15 per cent by local industries. WAPCO managers assume that gas supplies from different sites in Nigeria may last for 200 years. The project's expected benefits can be measured by the:

1. Shared valorization of energy resources to ensure sustainable energy supply and reduce exploitation costs;
2. Diversification of supply sources for Africa, which contributes to reducing dependence on importations from Middle East countries;
3. Availability of a less polluting and more affordable energy (i.e. less greenhouse gas emissions)
4. Speeding up of regional integration and promoting economic and social growth in different nations.

power, thus widening the gap between social classes and becoming a source of conflict. In other cases, oil producing nations have experienced the economic scheme, commonly referred to as the 'Dutch syndrome', marked by a lack of economic diversification and a total dependency on oil revenues.¹³ Eventually, in both cases, oil revenues are used to set up corrupt regimes, to impede the democratization process and to widen the gap between the rich and the poor. All these factors of social instability can deter attempts to seek alternative sources of energy supply in these countries.

However, with a significant progress towards good governance and accountability in the management of the oil revenues, African oil could contribute to strategies to diversify energy sources for both industrialized and Sub-Saharan African countries. This has

been re-enforced by the identification of oil reserves in Angola, Equatorial Guinea and Mauritania and the exploitation of new oil fields, what raised Africa's oil production by 40 per cent between 1990 and 2004, when the barrels produced increased from 7 to 10 million/day. A further increase of 50 per cent is expected by 2010 (Chevalier 2005). If soundly managed, these new reserves could become a real manna for African nations. For other sectors, such as electricity or other industries, a transition towards alternative energy sources – especially renewable ones – must be encouraged in order to reduce oil dependency.

31.3.1.2 Towards Diversification of Energy Sources

Moving towards a more sustainable energy system requires more energy diversification to reduce the dependency on a single non-renewable energy source. Natural gas is a good alternative for several uses, although it is also non-renewable. As a fossil fuel, gas is cleaner than oil, and produces less *greenhouse gas* (GHG) emissions. Large gas reserves are assumed for Sub-Saharan Africa. All African nations would benefit, what could help their successful energetic transition through effective cooperation in valorizing this re-

¹³ For Equatorial Guinea, the oil revenues account for around 90 per cent of national exports, for 86 per cent of national GDP, and 61 per cent of national income. For Nigeria the figures are: 95 per cent of exports, 40 per cent of GDP and 83 per cent of national income, and for Angola: 90 per cent of exports, 45 per cent of GDP and 90 per cent of national income (Gary/Kall 2003).

Box 31.2: Biofuel: Mali's experience with pourghere. **Source:** This author's research.

Mali, just like India and Madagascar, intends to turn pourghere oil into a real substitute energy source for gasoil and gasoline. The prices of these products are constantly increasing and promoting *pourghere* would enable communities to carry out income generating activities in a poverty reduction context. This was already tested by the colonial government in 1942. But the project was stopped due to the lack of positive results. Biofuel promotion activities were launched again in the 1980's. In 1989, a sugar cane plantation was valorized on 5,000 hectares in order to supply two industrial units in the *Complexe Sucrier du Kala Supérieur* (SUKALA.SA) for the production of 2,100,000 litres of alcohol. But gasoline prices dropped in the meantime, which made the sugar cane project not competitive. But over the last few years, Mali has been suffering from fluctuations in oil prices. Oil prices rose from 210 CFA in 1994 to 510 CFA in 2005, which means that they have more than doubled in ten years. The Malian Government's new energy policy highlighted the importance of developing the biofuel sub-sector, primarily pourghere production, for various uses (electric production, transportation, mechanization of farming equipment etc, in order to reduce the reliance on oil imports. A *National Programme for the Valorization of Pourghere* (PNVEP) was launched, with a total cost of CFA 708,000,000 (in US\$ 1.36 to 1.56 million) in order to:

1. supply rural areas with power using, 50 KWA power generators fuelled with pourghere oil;
2. process and use pourghere oil to fuel 20 4x4 vehicles of 10 to 20 HP CV for public transportation,
3. increase the nation's production of pourghere seeds, through the development of adequate lands in the rural areas.

The area covered by the programme include regions of Kayes, Koulikoro, Sikasso and Ségou in Mali. The *Pro-*

gramme National de Valorisation Énergétique de la Plante Pourghère (PNVEP) therefore helped to supply power to Keleya, a village of 3,000 inhabitants located 100 km from Bamako thanks to a pourghere oil generator. The oil consumption of the first generator of the power station was 3.7 litres/hour. The power supply project, which costs CFA 46,835,500 F has made it possible to run a public electricity network, supply electricity to community and administrative buildings as well as to about 20 subscribers.

The PNVEP Manager talked about the economic and environmental advantages his programme might yield in the long term. According to him, "as the production cost for 1 litre of pourghere oil will be between 170 and 250 CFA, compared to CFA 510 for diesel, which is twice less expensive, this is very competitive and, in the longer run, may yield interesting returns, more specifically for the nation's power electricity bill."

Now, pourghere, which was traditionally used as a medical plant, to make local soap and hedge, will soon supply Mali with energy and provide national income. This plant, which is very resilient to drought effects, can be grown almost anywhere across Mali, but more specifically in the Sikasso, Koulikoro, Ségou and Kayes regions.

However this sector is not sufficiently exploited despite the huge potentials it can represent for Malians. The current area of land developed for pourghere production is largely insignificant, with a production of about 50,000 tons, i.e. the equivalent of 12,500,000 litres of pourghere oil. In addition to the PNVEP Programme, several workshops and conferences were organized in Mali to sensitize, inform and encourage experience sharing among participants on the use of pourghere as an alternative source of energy to diesel and gasoline. The major objective is to promote that plant as a tool to challenge the energy poverty in Africa.

source. Therefore, several African countries launched the West Africa gas pipeline, which is at the centre of the NEPAD energy initiatives. In their action plans the exploitation of the large gas potentials has been included (see box 31.1, figure 31.5).¹⁴

Setting up a sustainable energy system also implies working towards energetic independence by increasingly using local and renewable energy resources. These must be at the core of most national strategies to develop the energy sector. Awareness-raising actions and campaigns to promote their larger scale use would be useful in the dissemination process. Simi-

larly, fiscal incentives and subsidies should be granted for renewable energy technologies in order to significantly increase their share in the energy supply. Several West African nations have established tax exemptions on solar energy equipments as a strategy to promote solar energy. Mali, for instance intends to promote a wider use of renewable energy technologies and equipments in order to increase their share in the nation's electric power production from less than 1 per cent in 2004 to 6 per cent in 2010 and 10 per cent by 2015 (Mali 2006). A huge campaign was launched in order to promote a plant called *pourghere* (scientific name: *Jatropha curcas*) to produce biofuel as a substitute for gas, oil and gasoline (see box 31.2).

14 Africa's share of global gas production increased from 0.8 per cent in 1973 to 5.5 per cent in 2004, while gas production increased globally respectively from 1,226 BCM (*Billion Cubic Metres*) to 2,794 BCM from 1973 to 2004. Africa hosts 7.3 per cent of the world's gas reserves (*La Tribune* (Paris), 6 April 2006)

Figure 31.6: Map of Mali. SOURCE: The University of Texas at Austin, Perry-Castañeda Library Map Collection; at: <http://www.lib.utexas.edu/maps/africa/mali_rel94.jpg>. The map is in the public domain.

Regional and international cooperation may also help boost the development of the renewable energy sector. This sector requires heavy investments and a lot of expertise and will surely benefit from harnessed regional efforts and human/financial resources when they are put together to exploit the existing large potentials. Above all, the estimated potential of hydro-power is 280 GW, and only 5 per cent of that potential is currently being exploited. However, the *West African Power Pool* (WAPP) project (see box 31.3 below), which intends to create a large regional power market with interconnections, represents a good initiative

for using a renewable local resource, as well as a good energy diversification strategy.

However, building regional infrastructure projects requires the adoption of relevant legal, institutional, and governing frameworks in order to attract private investments. This also implies the creation of new multi-state institutions in charge of organizing, operating and regulating such infrastructure. Finally, African nations may benefit from the advantages of the *Clean Development Mechanisms* (CDM) of the Kyoto Protocol as part of the *UN Convention on Climate Change* (UNFCCC). CDM projects, which allow in-

Box 31.3: The West African Power Pool (WAPP). **Source:** This author's research.

The *West African Power Pool* (WAPP) is a far looking project that was initiated by the ECOWAS Ministers of Energy. It fits into the NEPAD priorities in terms of regional infrastructure development. The WAPP's objective is to connect all power networks of ECOWAS countries to exploit the large hydroelectric potentials of this region and to create a real regional power market that would be attractive for investors to permit huge savings, in addition to encouraging cooperation permitting under-supplied and over-supplied countries to share their energy resources.

Regional cooperation in the electricity sector among West African nations started in the 1970's when the first interconnections were established between Togo and Ghana in 1972, and Togo and Benin in 1973, allowing Ghana to export electricity to its neighbours using the water resources of the Akosombo Lake. In 1983, the Ghana-Côte d'Ivoire connection was completed, then the Cote d'Ivoire-Burkina Faso links were established in 2000, before Benin was linked to Nigeria in 2003, what was the first achievement of the short term NEPAD energy plan. The Nigeria - Benin link is highly important for West Africa as it permits to interconnect the electricity networks of six countries: Nigeria, Benin, Togo, Ghana, Côte d'Ivoire and Burkina Faso, representing a crucial breakthrough of the ECOWAS WAPP project, with its two main branches A and B (see map below).

The A branch includes all these countries plus Niger, where many electricity networks are interconnected supplying energy across borders. With such interconnections, 2/3 of the electricity supplied by the *Communauté Electrique du Bénin* (CEB) - a two-states authority created to manage power supply between Benin and Togo - are imported from Ghana and Cote d'Ivoire (before this country experienced political turmoil). As the electricity companies of Benin (SBEE) and Togo (CEET) do not have enough power production capacity they highly depend on

electricity imports. This increases the advantages of interconnecting this region.

In the branch B area that includes other ECOWAS countries (Gambia, Guinea, Guinea Bissau, Liberia, Mali, Senegal and Sierra Leone), there are very few connections among electricity networks; thus it would be more cost-efficient to achieve a complete networking in this region. Once all national electricity networks are linked, an integrated electricity market and exchange within ECOWAS countries will be possible based on comparative advantages in terms of available energy resources. Such a market would help overcome existing constraints such as the size of the market or heavy fuel charges in some oil importing nations especially in Burkina Faso, Mali, and Niger. Such constraints make privatizations unattractive.

While WAPP's main motivation is to exploit the large hydro-electric potential of the continent. To supply their power station, all the interconnected countries may benefit from the wide range of energy supply sources, such as gas from Cote d'Ivoire and Nigeria, or Nigerian oil, in a context of energetic diversification as a way to secure their energy supply.

Similarly to the WAPP experience, other sub-regional groupings have organized themselves to set up energy pools across Africa. The *Pool d'Electricité de l'Afrique Centrale* (PEAC), an integrating project intended to interconnect all Central African member countries of the *Communauté Economique des Etats de l'Afrique Centrale* (CEEAC) is one of them. Among them are the *South African Power Pool* (SAPP) in Southern Africa, the *Comité Maghrébin d'Electricité* (COMELEC) in Northern Africa, and the *East African Power Pool* (EAPP) in Eastern Africa. The objective is to create a tool for sub-regional integration and solidarity that provides the possibility for countries to put their energy resources together in order to foster harmonious economic and social development in the region.

dustrial countries and their companies to fund development projects in developing countries thus reducing GHG emissions, provide funding opportunities for introducing clean and efficient technologies and contribute to popularizing renewable energy potentials.

31.3.2 Demand Side Management

Developing a successful alternative energy policy (through good diversification of resources) while securing continuous energy supplies would be a huge achievement, but it is not enough to set up a sustainable energy system. All energy sources are not inexhaustible. Even renewable energies, when used irrationally, may end up causing serious disruptions, for instance, vegetation losses as the result of heavy pressure on biomass resources.

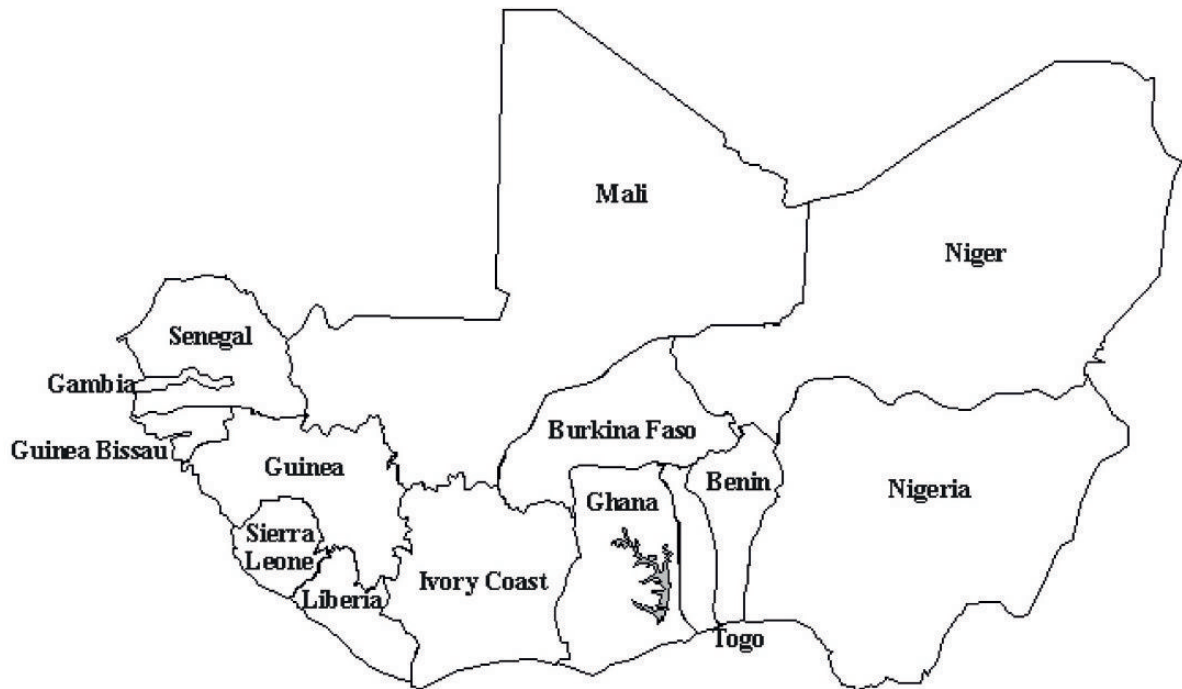

A demand management strategy could help setting up a sustainable energy system and anticipate insecurity risks. This strategy, together with an efficient energy system, would be sounder for the environment, as it helps to save more CO₂ emissions than the diversification strategy. Cutting down energy consumption will require to focus on the implications of the current technologies in this region using oil or biomass, the major energy sources in Sub-Saharan Africa.

31.3.2.1 Actions to Manage the Oil Demand

The fact that the transportation sector alone concentrates the largest quantity of oil used¹⁵ in the majority

¹⁵ For instance 80 per cent of the oil imported in Senegal goes to the transport sector (SIE 2005).

Figure 31.7: Map of ECOWAS countries. **Source:** University of Purdue, West Africa Power Pool Development Group, ECOWAS; at:<<http://www.purdue.edu/dp/energy/images/ECOWAS.gif>>. The map is in the public domain.

of *Sub-Saharan African* (SSA) countries suggests that there's need for an increased focus on that sector where the risks associated with the dependency on oil are the most serious. Optimizing transport systems through improved infrastructure combined with modernization of the vehicle fleet may help move towards more energetic efficiency and significant savings.

Most countries have old vehicle fleets with highly energy-consuming technologies, whereas the new generation of cars use less energy and are less polluting. Thus, any action on car import policies (car age requirement) and use considerations (collective vs. individual) would help to reduce energy costs. The Government of Senegal banned importing vehicles of over 5 years and trucks over 10 years of age. This initiative has contributed to reduce pollution, and should be repeated in other countries. Besides reducing the energy demand in the transportation sector, the efficiency of other industry sectors should be enhanced, as population growth and modern life styles (TVs, computers, large houses, electric appliances) will increase energy demand. This could be achieved by energy efficiency improvements.

Promoting new consumer practices to buy the most energy-efficient items will also help save energy. Therefore several branding/labelling¹⁶ programmes are developed in Europe and elsewhere to help con-

sumers identify the most energy-saving equipment. Some countries even prohibit importing bad quality equipments.

Technical losses during transmission or distribution due to the obsolete equipment in the electricity sector also are quite significant in a lot of countries in Africa. In Senegal, for example, they were estimated at 21.2 per cent from energy production in 2005. Unfortunately, the most electricity generation is done by thermal power plant. Thus, to achieve a substantial reduction of these losses and then saving energy, massive investment in the sector is required to renovate the equipment.

31.3.2.2 Actions to Manage Biomass Demand

Biomass is the most used energy source in sub-Saharan Africa (SSA). According to the Programme for the Promotion of Domestic and Alternative Energies in Sahel countries that belongs to the *Interstate Committee for Drought Management in Sahel countries* (CILSS¹⁷), the current levels of biomass dependency vary between 70 and 80 per cent, and this trend will

16 See: Energy Star, an U.S. energy label of the U.S. *Environment Protection Agency* (EPA), and similar energy labelling programmes in the European Community refer to energy-efficient office equipments.

remain for the next 20 years. Thus a focus on biomass demand and supply issues is needed and a development of best practices and consistent policies, to maintain the biomass chain in an economically viable and ecologically sustainable way.

On biomass supply a sustainable resource management through forest development plans is needed by setting up a system of firewood production quotas and by rotating exploitation areas. Based on experience of other Sahel countries, Senegal replicated this biomass resources management system. Since a new forestry code was established in 1998, biomass production has been regulated, and biomass resources are now exploited in two regions only (Kolda and Tambacounda).¹⁸ In order to secure a sustainable supply system, cost-effective charcoal production techniques require attention and a minimum investment. The Casamance mushroom variety with a higher yield¹⁹ has been very successful in most SSA countries, particularly in Senegal.²⁰ For reducing biomass demand, actions promoting improved stoves have relieved consumers by significantly reducing firewood and charcoal consumption with a specific cooking style. This has reduced the pressure on forestry resources (table 31.1).

Public authorities should launch campaigns to promote and support alternative products including butane, kerosene and other biomass by-products such as typha or rice husk that are crucial for local households' cooking styles. Senegal's policy to promote Liq-

uified Petroleum Gas (LPG) as a replacement for charcoal, reducing the consumption of biomass from 60 per cent in 1994 to at least 40 per cent in 2004 (SIE 2005), has been successful and should be replicated to counter deforestation.

31.4 Conclusion

Modern energy is essential for human development, economic growth, health care, and education, and is crucial for poverty reduction and achieving food security. Thus, an energy system based on a sustainable, affordable and environmentally sound modern energy supply is a key requirement for most *Millennium Development Goals* (MDGs) and *Poverty Reduction Strategies* (PRSP).²¹ But most SSA countries lack enough modern energy capacity in their energy balance, where traditional energies (60 per cent on average) prevail. The small 'modern' energy component strongly relies on oil imports. Such dual energy systems involve economic, financial, and environmental insecurity as well as health issues.²² This trend must urgently be reversed in SSA countries and new conditions for a transition towards sustainable energy sources must be set up. Action plans and concrete measures for supply and demand must be set up to establish sustainable energy supply, production and consumption practices.

On the supply side this requires securing the supply system and diversifying supply sources. This will lead to several actions including the creation of national fossil energy²³ stocks for several months, the development of oil prospecting, and reducing the national expenditure for transport of hydrocarbon products to geographically landlocked importing coun-

17 CILSS (*Comité permanent Inter Etats de Lutte Contre la Sécheresse au SAHEL*) was set up on 12 September 1973 as an intergovernmental organization of 9 Sahel countries including Burkina Faso, Cape-Verde, Gambia, Guinea-Bissau, Mali, Mauritania, Niger, Senegal and Chad. The current CILSS mandate is to "ensure food security and the fight against drought and desertification, in order to achieve a new ecological balance" in the Sahel region.

18 Every year a by-law is issued to regulate forestry activity campaigns. Since the year 2000, Government allows charcoal production only in the regions of Kolda and Tambacounda (in Senegal).

19 This is confirmed by a comparative study conducted in Tanzania on two types of mushrooms used in 9 villages. The study considered 5 types of fireboxes including the Casamance type. The Casamance type proved more efficient, with outputs of 31 per cent (Source IDRC site: *International Development Research Center*; at: <http://www.idrc.ca/>).

20 In the latest issue of the guidelines for the energy sector development policy, the Government of Senegal (2003) decided to introduce and widespread the use of the Casamance mushroom.

21 *Highly Indebted Poor Countries* (HIPC) initiated a participatory process to develop *Poverty Reduction Strategy Papers* (PRSPs) based on a redistributive growth and meeting the basic needs of the poorest communities. The Paper provides a reference framework for country poverty reduction strategies.

tries. Achieving an enhanced energy security requires the implementation of policies to promote and disseminate the use of natural gas and renewable energies. So far, the development of renewables in Africa is constrained by the high costs for importing equipment and the lack of information on the latest technologies used to generate electricity. Thus, all countries should combine their efforts on research and training on setting up an industry to produce the needed equipments. Industrial units operating with solar energy would be a good alternative to using fossil energy, as Africa has a huge solar energy potential. The biofuel production experiences are already initiated in some countries in the region, both experimental or pilot projects, and at present several international seminars have been held to explore the possibilities for developing biofuels on a larger scale in Africa. The objectives of these seminars are mainly to explore the potential and challenges to the dissemination of priority biofuels technologies in Africa and also to promote sharing of experiences and lessons from countries in Africa, Brazil and other regions. Therefore, analyzing the balance between the need for new energy resources and the trade-offs and risks of biofuels requires a lot of attention. Thus, countries should more focus on domestic energy demands over exports; meeting needs in relation to both energy availability and rural development; creating inventories of biofuel technologies; considering the environmental impacts of such technologies; undertaking feasibility studies on potential competition between food and energy crops.

On wood fuel supply, countries should develop efficient decentralization policies to give rural commu-

nities a greater responsibility for the sustainable management of their biomass resources.

On the demand side relevant frameworks must be developed creating conditions for technology transfer and capacity building for an efficient use of various energy sources. Vast energy efficiency programmes in the building sector combined with audits of some industrial branches could help manage energy consumption. An energy policy based on market prices for energy consumption and relevant and targeted subsidies will save energy costs²⁴ Increased efficiency of electricity systems, through rehabilitation of electricity networks will induce savings on power distribution and transportation amounting to over 20 per cent of power production in the majority of SSA countries. Also much electricity is lost in the networks.

The pace of transition to more sustainable energy sources will largely depend on the willingness and capacity of national, regional and international authorities, private actors, NGOs and consumers. Consumers should therefore adopt new energy consumption behaviours that would guarantee more efficiency and reduce energy use. For that purpose, they must give priority to energy saving vehicles and equipment and use collective transportation systems.

National authorities should create attractive legal and governing frameworks to mobilize required funds in order to promote more energy-efficient technologies and renewables.²⁵ International institutions, NGOs and private actors should also provide the required technical and financial support for a better exploitation of the continent's energy potentials. Thus, the development of regional infrastructure – such as the WAPP project and the gas pipeline will prove profitable for all countries.

22 According to a recent publication on cooking with wood, dung, coal and other solid fuels on open fires or simple stoves is a daily reality for more than half of the world's population. This leads to high levels of indoor air pollution, a major risk factor for pneumonia among children and chronic respiratory disease among adults. Globally, pneumonia remains the single most important child killer and is responsible for two million deaths a year. Every year, the killer in the kitchen is responsible for 1.5 million deaths. Sub-Saharan Africa and South East Asia are particularly affected, with 396,000 and 483,000 annual deaths, respectively. Indoor air pollution also disproportionately affects women and children. In 2002, cooking with solid fuels was responsible for nearly 800,000 deaths among children and more than 500,000 deaths among women (WHO 2006).

23 In this respect, Mali (2006) intends to increase their storing capacity to 150,000 in 2015 and 231,000 in 2025.

24 According to J.P. Thomas and Sokona (1997), wealthier social classes benefit much more from global energy subsidies. Such funding can actually cause them to increase their energy consumption. As a result, this can and often does cause energy shortages. The poorest are forced to rely on traditional energy sources that are less expensive. All targeted subsidies (e.g., kerosene) generally require energy suppliers to ration a portion of the subsidized energy. Therefore, suppliers prefer to direct their stocks to those clients that offer the greatest profit potential (e.g., the transport sector for kerosene stocks).

25 For example, Mali introduced an action plan for renewable energy promotion in 2004 in order to reach the objective of 15 per cent renewable energy by 2020.

32 Energy Security: Economic, Environmental, and Societal Opportunity for the North – Potential of Renewables to Avoid Conflicts?

Rolf Linkohr

32.1 Introduction

Bluntly put, Europe's oil comes from the Gulf and gas comes from Russia. In order to secure its energy supply Europe maintains best relations with Moscow, irrespective of what the Russians do in Chechnya, and American soldiers look after the Gulf. The US has offered military protection to the Saudi royal family in return for the free flow of relatively cheap oil. In other words, our oil and gas is dirty if not bloody. This reflects public opinion in Europe.

If the Europeans could replace oil and gas with renewables, Europe would not only become independent from energy imports, but could also withdraw from possible conflicts. Bloody energy could be replaced with clean and environmentally friendly energy sources. By planting wind power and solar power stations in North Africa we would not only use the enormous potential of wind and sun in neighbouring countries, we would also strengthen the ties between them and us, and give these still poor countries a chance to develop their future on the basis of new technologies. Their revenue would be based on solar electricity or hydrogen. A new partnership would develop, and promote wealth and social security (Nitsch/Staiß 1997; Brauch 1990, 1997a, 1997c, 1997e, 2000, 2001a, 2006). Such scenarios are as old as European energy debates. They are simple and radical. This is a benign vision in a cruel world governed by money and greed, and should therefore mobilize the noblest persons on both sides of the Mediterranean.

How realistic is this vision? Is oil by definition bloody as gas is dirty? And if yes, are renewables an answer? And last but not least, are they a realistic concept? This chapter will discuss this vision and contrast it with alternatives. Europe and her neighbours are taken as an example for future North-South energy re-

lations, but these arguments can also be applied elsewhere.

32.2 Growing Energy Consumption

The strife on essential resources, from petroleum to water, will be a growing source of conflict among nations unless the world establishes a system of resource conservation and collaboration. The wars of the future may be fought over diminishing supplies of our most precious natural resources, particularly oil and gas, two needed and coveted commodities.

World energy consumption grew by 4.3% in 2004, the largest annual increase in global energy consumption and the highest percentage growth since 1984. Energy demand in China was up 15.1 per cent, and in India 7.2 per cent. Global oil demand grew by 3.4 per cent, gas demand by 3.3 per cent. Without the United States where gas demand grew slower due to a mild winter, gas was up 4.3 per cent.

Although the growth in the world's energy consumption in 2005 may be lower due to a decline in global economic growth, this trend is severe. Possibly previous assumptions on the growth of global energy consumption were too conservative. In its *World Energy Outlook 2004*, the International Energy Agency (IEA 2004a) assumed an annual growth rate of 1.7% between 2002 and 2030, a figure far surpassed by the statistical data of 2004. The powerhouse of the world seems to be the Asian countries, and probably their needs for energy will also determine Europe's future energy policy.

Certainly, the projections of energy demand and supply are subject to a wide range of uncertainties, including global economic growth, population growth, resource availability, technological developments, as well as government energy and environmental policies. But past experience suggests that energy de-

mand, particularly for oil and gas, will grow. The transport sector will be the main driver for increased oil consumption and we may expect an increase in daily oil demand from 80 million barrels (mb) in 2005 to about 120 mb in 2030. Oil demand will grow faster in developing countries, but Europe also needs more oil. EU-25 imports today nearly 60 per cent of its oil, and these imports are projected to rise until 2030 to nearly 90 per cent.

32.3 Dominant Role of the United States

In the US, oil imports rose to more than 50 % of total consumption in history. China and India are competing to secure access to oil resources for their huge economies. As with Japan, they must import their gas and oil from the same sources as the Americans and the Europeans. The problem of supply is further exacerbated by the fact that in Europe, as in the United States, domestic oil and gas production is declining.

In May 2001, US Vice-President Richard Cheney submitted a report on the *National Energy Policy* (NEP) to President George W. Bush. According to this report, domestic oil field production will decline from about 8.5 million barrels per day (mbd) in 2002 to 7.0 mbd in 2020, while consumption will jump from 19.5 mbd to 25.5 mbd. Imports or other sources of petroleum, such as natural gas liquids, will have to rise from 11 mbd to 18.5 mbd. Most recommendations are aimed at procuring this 9 (1.5 +7.5) mbd increment, or the equivalent of the total oil consumed by India and China.

One third of the recommendations in the Cheney report cover ways to get access to petroleum sources abroad, in Kazakhstan, Azerbaijan, and other Caspian Sea states. In May 2005, the oil pipeline linking Baku (Azerbaijan) with the Turkish port of Ceyhan was opened (Winrow, chap. 30). The US lobbied for this pipeline which prevents the Russians from using energy as a political weapon.

Of the world's major oil-producing areas, the Persian Gulf is most likely to experience conflict during this century. Possessing nearly two thirds of global petroleum supplies, the Gulf will remain the focus of intense worldwide competition as energy demand rises in the decades ahead. Many geologists assume that future discoveries will add to the region's net supply. The reserves are located close to the surface, thus they are easiest to find and to develop. Gulf oil is relatively cheap, and the profits are high. Although new

discoveries are expected in the North Atlantic or in Siberia, the Gulf area alone can provide the vast amount of hydrocarbons that will be needed to satisfy rising demand in the 21st century.

American leaders have persistently argued that the US must be able to employ military power if needed to ensure the continued flow of oil from the Persian Gulf to the markets in the West. "America's vital interests in [the Gulf] are long-standing," General Anthony C. Zinni, then commander in chief of the US Central Command (CENTCOM), told Congress in 1999. "With over 65 % of the world's oil reserves located within the Gulf states," the United States and its allies "must have free access to the region's resources."¹

US policy on the protection of Persian Gulf oil is unambiguous. When a threat arises the US will use whatever means necessary to ensure the continued flow of oil. This principle, known as the Carter Doctrine, was first articulated by Jimmy Carter in January 1980, after the Soviet invasion of Afghanistan and the fall of the Shah of Iran. It has remained part of US policy ever since. In accordance with this principle, the US used force in 1987 and 1988 to protect Kuwaiti oil tankers from Iranian missile and gunboat attacks, and in 1991 to drive Iraqi forces out of Kuwait.

Although the official US interpretation has been that oil had nothing to do with the March 2003 US-led invasion of Iraq: "The only interest the United States has in the region is furthering the cause of peace and stability, not in [Iraq's] ability to generate oil," White House spokesperson Ari Fleischer said in late 2002. But a closer look at the administration's war planning reveals a different picture. In a January 2003 briefing by an unnamed "senior Defense official", presumably Deputy Defense Secretary Paul Wolfowitz, on US plans for protecting Iraqi oil fields in the event of war, the Pentagon leadership revealed that Gen. Tommy Franks and his staff "have crafted strategies that will allow us to secure and protect those fields as rapidly as possible in order to preserve those prior to destruction" (Klare 2004).

Iraq is a major oil supplier with proven reserves of 112.5 billion (bn) barrels, more than any other country except Saudi Arabia, and it may possess another 200 bn barrels in undeveloped fields. Iraq could become a leading oil supplier in future decades if a stable government is in place. It could replace Saudi Arabia if

1 General Anthony C. Zinni, Prepared statement before the US Senate Committee on Armed Services, Washington, DC, 13 April 1999.

this country should turn against the US due to its close ties to Israel and Washington's anti-Islamic bias.

Probably the only way to guarantee the continued energy flow is to guard the oilfields and pipelines with soldiers. Given its strategic and economic importance, securing American dominance in the Gulf will continue to govern US strategy in the first decades of the 21st century. The outcome of such a policy is uncertain. Saudi Arabia is not only the land of oil but also of Osama Bin Laden. From its fundamentalist milieu, the world's most wanted terrorist recruited many followers in the late 1990's and obtained much financial support. A major challenge for US policy is to persuade Saudi Arabia to increase its oil deliveries and eradicate its fundamentalist opposition. Such a strategy requires a will to transform Saudi Arabia into a modern state, an objective that may be light years away from actual politics.

32.4 Is Diversification an Answer?

One answer to the great dependence on the Gulf area has been diversification. Central Asia offers new opportunities, as well as West Africa. According to available data, the Caspian Sea basin, consisting of Azerbaijan, Georgia, Kazakhstan, Kyrgyzstan, Turkmenistan, Tajikistan, Uzbekistan, and the adjacent parts of Iran and Russia, have proven reserves of 17 to 33 bn barrels of oil, and possible reserves of 233 bn barrels. These amounts constitute the second largest untapped reserves after the Persian Gulf area.

But the Caspian Sea basin is landlocked. Oil and gas pipelines have to be built and secured. The authoritarian regimes that predominate in the former Soviet republics are riddled with corruption and reluctant to adopt the legal or tax reforms needed to attract Western investment. The Caspian Sea basin is an oil and gas rich area, driven by numerous disputes and internal divisions, surrounded by strong neighbours who are all waiting for their chance. Oil has only exacerbated existing problems. The most significant source of conflict is the territorial dispute over the ownership of development rights in the Caspian Sea (chap. 55 by Raketl). Therefore to ensure the safety of energy deliveries may require similar military commitments the US has long made to its principal energy supplier in the Gulf.

Another oil supplier is West Africa. These states' share of global oil production might rise from 10 to 25 per cent by 2020. But as in the Caspian Sea region, hopes to obtain additional oil from West Africa could

be hampered by ethnic violence and political unrest. The US might be tempted to respond to these challenges by deploying troops. But such behaviour could generate images of colonialism. At present, the US administration prefers financial and military assistance, mainly to Angola and Nigeria. Both countries stepped up their military expenditure as a percentage of their GNP to become respected regional powers.

Latin America is another important oil and gas producer. A large part of US oil and gas imports come from Mexico, Colombia, and Venezuela. Venezuela owns large amounts of conventional oil and immense reserves of so-called heavy oil or repulsion, a sludge-like material that can be converted to conventional oil through a costly refinery process. At prices above 25 \$ per barrel repulsion becomes competitive. According to the official estimates, the proven reserves of repulsion equal the oil reserves in the Persian Gulf. The American hemisphere will therefore play an important role in the US energy policy. In Mexico and Venezuela the constitutions ban foreign investments in the oil and gas sector. Venezuela's president Hugo Chávez is regarded as a new *enfant terrible* by the G.W. Bush administration.

These areas are not the only conflict-prone regions. Possible conflicts may arise in the South China Sea, where large oil and gas deposits are assumed. The possession of the Spratly Islands would guarantee access to underground resources within a 200 miles distance, but also control the movement of ships crossing the sea. This area may witness large-scale warfare, because all factors associated with resource conflict are concentrated here (quoted from Klare 2004).

It seems to be the curse of oil that it is mainly found in areas of political unrest. Particularly the Persian Gulf, the Caspian Sea, and the South China Sea harbour all ingredients of conflict. But so far the big powers, mainly the US, prevented internal or border conflicts from becoming open wars. But this requires enormous military and political efforts, and alliances with corrupt and undemocratic countries are another price to be paid. Oil is not an ally of democracy.

There are examples in history where oil triggered a war or where the pursuit of oil changed the course of a war. Mostly forgotten is the *Gran Chaco War*, South America's bloodiest twentieth century war. The *Gran Chaco* is a largely uninhabited region in Paraguay, Bolivia, and Argentina where oil was discovered in 1928. A war broke out between Bolivia and Paraguay in 1932 which ended with a victory for Paraguay. There were 100,000 dead and Paraguay held 300,000

prisoners. Bolivia lost a large part of the disputed area to Paraguay. The oil that had inflamed the imaginations of pre-war nationalist agitators never materialized. Bolivia's oil and gas resources are located far away from this disputed area. The oil speculators were mistaken, and both nations paid an enormous price for the mad ambitions of their leaders. The reason for this war was not oil but an old territorial conflict. The territory belonged *de jure* to Bolivia but *de facto* to Paraguay because the few settlers, mainly Mennonite communities from the US and Argentinean land developers and cattle companies, were brought in by the Paraguayan government, whereas Bolivia did not exploit the meagre resources. Oil speculation triggered the war but did not cause it.

A war nearly broke out when Mohammed Mossadeq, an enemy of the Anglo-Iranian Oil Company and a former president of the parliamentary oil committee, was elected Prime Minister of Iran in 1951. The nationalization of this oil company was signed by Reza Shah. But this caused a severe conflict with the British Prime Minister Winston Churchill who was ready to intervene with force. The Americans held him back, but after a political flirt with the Soviets the Americans were convinced that Mossadeq had to be removed, either legally or by force. In 1953 the Shah deposed him with full British and American support. A war broke out when British, French, and Israeli troops occupied the Suez Canal Zone and Sinai in 1956 after Gamal Abdel Nasr nationalized the Canal. Due to American pressure and after an oil boycott by Saudi Arabia, the three powers withdrew and the Suez Canal remained in Egyptian hands.

Oil was a strategic objective in both World Wars but was not a cause of conflicts. All post-World War II conflicts had other causes than oil. They were mainly ethnic conflicts, wars of liberation, or border conflicts. Oil or other resources had only a side-effect. But wars over oil or water resources may become distinctive features of the future global security environment.

So far, OPEC countries still managed to contribute to the security of supply by developing significant spare capacity. During the Gulf Crisis (1990–1991), 4.3 mb/day of crude oil exports were lost as a result of Iraq's invasion of Kuwait. OPEC producers were able to make up this loss within weeks through the use of available spare production capacity.

Therefore the conflict over oil need not necessarily lead to a military engagement. But it is part of that dangerous mixture of economy and armament. A study on: *Southern African Millennium Ecosystem*

Assessment (at: <<http://www.millenniumassessment.org/en/SGA.Safma.aspx>>) indicates that big environmental problems may result in large violent conflicts. A hundred years ago, Kenya was covered by big forests, but in 2005 only 1.7% of the country's surface is still covered by trees. Since the 1960's Kenya's population doubled, but still 75% live on agriculture. They clear the remaining forests in order to have enough wood for cooking and heating. Hence the countryside erodes, water becomes scarce, and dryness expands (see chap. 68 by Ejigu). If it rains, no forest and no brush retains the water, and the last fertile soil is washed away. Craving hunger is the result and many people starve to death. The few remaining fields are a cause of conflict; mostly tribal conflicts, e.g. in 2005 at Turbi in Northern Kenya where 77 people, among them 22 schoolchildren, were slaughtered with machetes by a rival tribe.²

So far major wars could be avoided. One reason is our growing interdependence. We do not only depend on resources, we depend on each other, on technology, or on a stable financial and political environment. The Gulf States are probably more dependent on us than we are on them. Harold Macmillan, a former British prime minister, once made a celebrated observation that the thing he feared most was events. Although it is impossible to predict what will happen in the future, something unforeseen may happen in the Near East, in the Gulf States, or in Saudi Arabia. The situation may be as critical as in Iran under the Shah's regime or under the present authoritarian government. Energy could be a major element in such a conflict, a weapon against the West or an opportune income to strengthen a fundamentalist Islamic state. How oil can become an instrument in foreign policy can be learned from Hugo Chávez who deliberately builds his initiatives in Latin America on a preferential rate for oil. Cheap oil for political concessions has become another shade of oil policy.

One may imagine an insurrection in Saudi Arabia and Pakistan leading to an alliance between two fundamentalist countries, one oil rich and the other in possession of nuclear weapons. Although this nightmare is not probable, it is not unrealistic either. Was Khomeini's revolution probable? The question remains whether a different energy policy could influence positively our politically unstable world. And if so, how this brave new energy era may look like.

2 See information reported in: *Africa Research Bulletin: Political, Social and Cultural Series* 42 (1–31 July 2005): 16271–16306.

32.5 Global Energy Outlook

Energy is the key to solving all problems, from water to population. Already billions of people live without reliable access to clean water for drinking and agriculture. As populations continue to grow and the depletion of existing aquifers worsens, vast new sources of clean water are needed. Our planet has huge water resources, but most are salty, and often thousands of kilometres away from demand. The problem can be solved with energy: desalinate the water and pump it over vast distances. But without cheap energy there is no answer.

Without fresh water, how are we going to provide the food for our burgeoning worldwide population? Without cheap energy, how are we going to produce the fertilizer, till the soil, harvest the crops, process them, package them, and deliver them to the markets? In short, energy is the single most important factor that impacts on the prosperity of any society.

The figures illustrate the magnitude of our problem. In 2004, we consumed on average 220 million barrels of oil per day and the world ran on about 14.5 terawatts. The vast majority was oil, gas, and coal. Nuclear fission and biomass were also significant players, as was hydropower, but we have already tapped most of the available rivers and lakes. An incredibly small amount was solar, wind and geothermal, with geothermal composing the largest part.

Assuming a world population of 9 billion people in 2050 – as has been projected in the medium scenario of the UN World Population Revision of 2004 (UN 2005) – and giving all the level of energy prosperity of the developed world with a several kilowatt-hours per person, we would need to generate 60 terawatts or the equivalent of 900 mb of oil per day. Getting there will be incredibly difficult. If you go out tomorrow and turn on the switch of a new power plant that would produce a thousand megawatts of power from a new, carbon free energy source, you would have to turn on a new plant every day for 27 years before you generate even 10 terawatts of new power. Ten plus 14 terawatts would not even supply half of the 60 terawatts eventually needed. If we fail to build such power plants over the next one or two decades, the 21st century may become very unpleasant.

The problem of energy is intimately linked to climate change. According to the overwhelming opinion of climatologists, we should not allow the average temperature to rise above 2 °C of the pre-industrial value, an objective that corresponds to more or less 30 billion tons of CO₂ equivalent per year. Actually we

are at 24 billion tons per year, and we will probably arrive at 30 billion tons per year in 15 or 20 years time. Assuming that by then we will be 7 to 8 billion people in the world, and that all people have the basic right to use energy in a decent way, we can divide the 30 billion tons of CO₂ by 8 billion people, and we get a figure of roughly 3.8 tons of CO₂ per year and per capita. In 2005, the average American produced nearly 20, the average European roughly 10, and the average Indian one ton of CO₂ per year.

Therefore any future energy system must solve two equations: to supply enough cheap energy to everybody and to limit our CO₂ emissions, a condition that can only be fulfilled if everybody has an equal right to pollute the air with CO₂. Both equations are coupled. The future energy systems must be as carbon free as possible, but they must also be as cheap as possible. Both equations are linked to democracy and equality before nature. As we are confronted with a global problem we need to act with global consensus, in other words the final solution must solve the social problems, mainly poverty. Energy policy is not only applied physics, chemistry, and biology; it is also politics in the pure sense of the word.

32.6 Solutions?

What are the solutions? How can we find alternatives to oil? And how are these solutions compatible with our commitment to reduce the emissions of greenhouse gases? We could achieve some progress with conservation and efficiency. The potential to save energy is estimated to be 30 or 40 per cent in Europe. In other industrialized countries it is certainly of the same order of magnitude, in the US even more.

Let us take lighting as an example of energy saving. Pure white light-emitting diodes (LEDs) on the basis of gallium nitride (GaN) are no longer a dream and could replace our conventional lamps in five or ten years. They represent a tremendous saving of global energy-requirements, thanks to compound semiconductor material science. The success of LEDs lies in their longevity, energy efficiency, durability, low maintenance cost, and compact size. Replacing conventional lamps with LEDs in the US alone will bring energy benefits of up to \$100 billion by 2025, saving up to 120 gigawatts (GW) of electricity annually. If this figure is compared with the overall nuclear capacity of 100 GW in the US then the importance of these environmentally attractive new devices is easily understood. In the underdeveloped world, however, conser-

vation is meaningless, because so little energy is used. However, the industrialized world could help them to shorten the way from underdevelopment to a highly efficient modern society.

Some argue rightly that we could live in the future with not more than 2,000 watts (W) per person without giving up our standard of living, if we only used the most modern and sophisticated technology. If that were true then 10 billion people could live with 20 terawatt (TW), a third of our former figure. This is still a lot, and much more than our actual energy consumption, but much less than in a “business as usual” scenario. In the end the reality may be between both figures, depending on technology and economic growth.

Energy crops could be grown every year at a high rate to produce just one TW. This would require a revolution in agriculture at a time when we are struggling just to sustain our current production levels for food. But it could be made. We could also build a fleet of nuclear fission reactors, or even breeder reactors, we could develop accelerator driven systems working with thorium, but as the amount of capital is limited and the investment costs are high, even the nuclear option cannot solve all problems.

Another solution could be clean coal. According to an International Energy Agency study (IEA 2004) CO₂ capture and sequestration could drastically reduce emissions. Coal and lignite could last for another 200 years if production is expanded. With capture and sequestration coal could become compatible with our climate strategy. However, the IEA study highlights the fact that large-scale uptake of capture and sequestration technologies is probably 10 years off and that, without a major increase in R&D efforts, the technology will not be in place to realize its full potential as an emissions mitigation tool from 2030 onwards. The share of renewables including geothermal energy could be increased. There is a consensus among energy specialists that renewables deserve more development. But if their costs remain high these technologies have a very limited scope in developing countries, even in the highly industrialized countries where other alternatives exist. More energy could be provided for the world, more efficiently, and the outcome be that we would not need the 60 GW, but much less.

In a nutshell this is our actual energy vision. We use the appropriate energy technology, develop new ones, we count on future and still unknown devices, we develop worldwide systems of CO₂-emissions trading, bringing the developed and underdeveloped

world together, and thus we become more interdependent. Interdependency increases stability although everybody tries to be as independent as possible. Energy is traded like other goods and services. And the ecological costs are taken into account by the price we give to CO₂. Waste gets a price and can also be traded worldwide because CO₂ is a global problem. Some want to do it with nuclear energy, others without, but nearly everybody agrees that a mixture of different energy technologies is the best and cheapest way to provide the world with enough energy.

But what comes after oil and gas? Will coal replace the two other fossil fuels? Or will we rely on oil sands or methane hydrates? Will nuclear fission – and in 50 years nuclear fusion – provide us with sufficient energy? Or will we invent something completely new that allows us to increase our efficiency tenfold? We will find new technologies and devices if we invest enough in fundamental research. There is no limit to knowledge. Why should it not be possible to provide the world with a high standard of living with lower consumption of energy and raw materials? This is the vision of a sustainable growth.

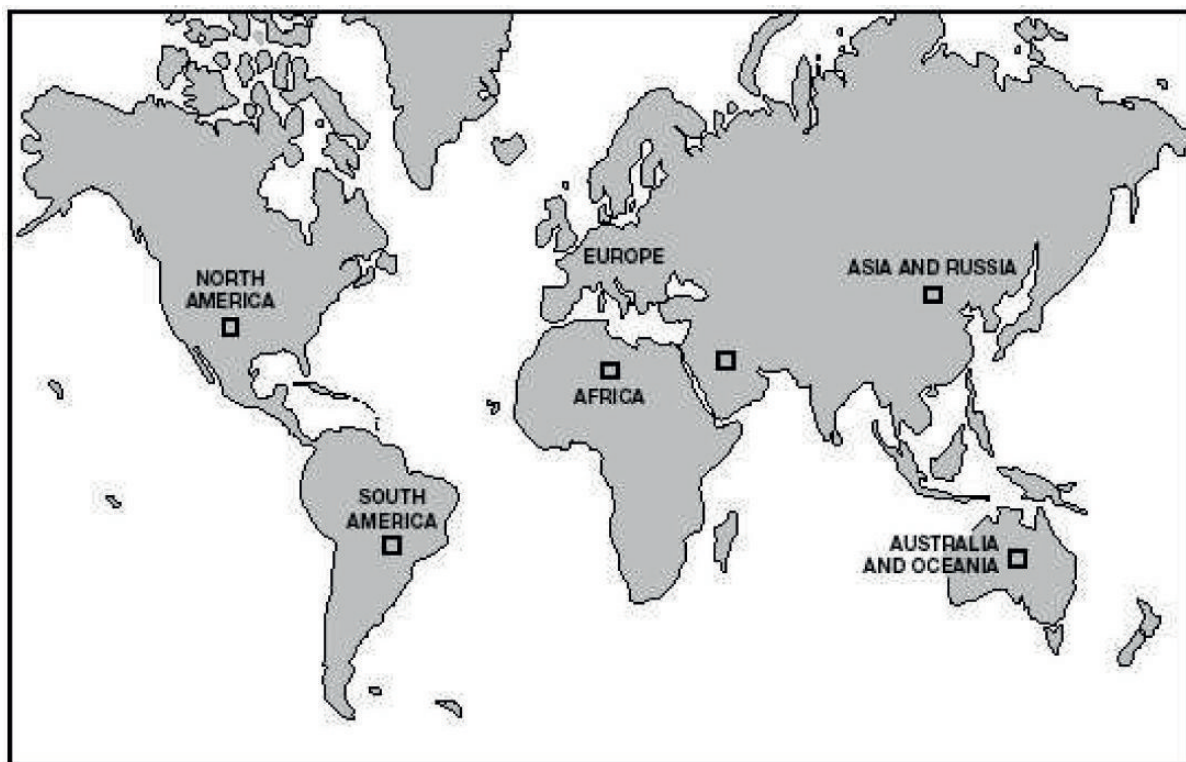

32.7 Solar Visions

Apart from nuclear fission or nuclear fusion reactors there is a hydrogen fusion reactor, the sun. Daily 165,000 TW of power has hit the earth for already over 4 billion years, and this will probably continue providing energy for several billion years.

A square of 100 km each, in areas of high solar radiation, covered with photovoltaic panels with an efficiency of 10 per cent, could provide 3.3 TW of electricity. Six such sites, in different parts of the world, could produce roughly 20 TW, the equivalent of 60 TW total energy power with a 33 per cent energy conversion. Our energy problems would be solved for ever, and we could concentrate on other problems for the rest of this and the next centuries.

We need new energy technologies at a competitive price. Presently solar electricity, produced by photovoltaics, is ten times more expensive than electricity produced by conventional power systems. Solar thermal power may be a promising technology and also be cheaper, but we do not have enough experience yet. The oil price will probably go up and gas will become more expensive. Even coal prices rise and with clean coal technology, with capture and sequestration of CO₂ the price of electricity would also go up. New technologies and an economy of scale will bring the

Figure 32.1: Solar cell land requirements where six boxes (100 km on a side), in areas of high solar radiation, can each provide 3.3 TW of electrical power. **Source:** Smalley (2005).

price of solar electricity down. When the costs of both options are comparable the solar vision becomes a reality.

A recent study of the Scientific Council of the German Government for Global Environmental Change (WBGU 2004) recommends a strategic partnership between the European Union (EU), the Middle East, and North Africa. The basic idea is to create an economic area between Europe and the Middle East including North Africa, combining the different geographical advantages and renewable energy sources. The potential of wind, geothermal and biomass is estimated at about 0.25 TW. The potential of solar power is much larger than the total world electricity demand (figure 28.4).

The energy output of renewables is fluctuating; some more like wind, some less like hydroelectricity. Only geothermal energy can provide a steady flow of electricity. Thus, a combination of different renewable energy sources, supported by fossil power stations, mainly gas, can overcome this shortcoming. A close-meshed electricity grid, linking all countries and energy sources with the consumers, may overcome this deficiency. New technologies and concepts of solar power may store heat overnight, and nanotechnol-

ogies, new materials, and possibly new physics might help us to develop even local energy storage in the future (figure 28.5).

Such a local energy storage has been proposed by Richard E. Smalley (2005), a Nobel laureate in chemistry (1996) without giving technical details. As a vision it is useful. If we had an economic solution for local energy storage it would enable an extremely robust delocalized energy system. But so far, nobody knows whether we can develop local energy storage. But had anybody anticipated very efficient and fast computers in nearly every household at low cost some 50 years ago? Richard Smalley discovered the fullerenes, an infinite new class of carbon molecules - who could have foreseen it before? The laws of physics do not prevent local energy storage from becoming a reality in the future.

Although we cannot exclude an energy system relying solely on renewables, combining the geographical advantages of different parts of the world and using still unknown, but possible technologies, nevertheless it is still far from being a reality. But it seems to be possible. An energy partnership between Europe, the Middle East, and North Africa has another advantage. It makes us more interdependent,

thus stabilizing peace, and it brings investment and development into a region where stagnation and underdevelopment seems to be the rule. The vision of an energy partnership goes much beyond the supply of electricity. It is a political vision. But why does it not work yet? Where are the drawbacks? What are the major obstacles?

32.8 Reality Does Not Necessarily Follow Our Scenarios

The model to avoid conflicts with renewables seems to be simple. It consists of the following observations, assumptions, and hypotheses.

1. Solar energy has the potential to make the world independent from other energy sources like uranium, coal, oil or gas.
2. The more we rely on renewable energy sources the lesser we risk resource wars.
3. Energy interdependence guarantees peace and development.

From a purely physical point of view the first hypothesis is true. Solar insolation provides us with abundant energy that needs simply to be tapped. This observation is scientifically true.

So where is the problem? The technology of this new energy world is not yet available at a reasonable cost, otherwise every hedge fund would invest in photovoltaic or in an electricity grid in the Sahara. Even mass production will not bring down the costs to a level comparable to the costs of conventional energy, and storage is still lacking a practical solution. Another objection refers to the choice of technology. Why are exclusively renewable energy sources needed? If CO₂ abatement is the objective, why are nuclear or clean coal, or CO₂ capture and sequestration excluded? As long as we have cheap fossil fuels and can produce electricity without CO₂ emissions, why are these energy technologies excluded? The sole choice of renewables may be interesting and should be tested, but it has no scientific base. People make political choices. An energy vision based solely on renewables may be in line with public opinion in some countries that is changing, and power stations must last for 30 to 60 years.

Third, it is dangerous to put all your eggs in one basket, particularly if you do not even know whether the basket is strong enough. We do not yet know all the drawbacks of renewables and there might still be a lot of unpleasant surprises. For instance, how effi-

cient is an energy system based solely on renewables? How reliable is it? What about the inevitable losses due to reserve capacity, regulation, additional grids, transport, etc.?

The hydrogen story is an example of how visions are taken as reality without taking science into account. Justi (1965), Bockris (1980), and Dahlberg (1982) proposed a hydrogen economy, based solely on renewable sources. Justi proposed an energy bridge between the Sahara and Europe. The basic idea was to produce solar electricity, transform it into hydrogen, pump the hydrogen to Europe, and transfer it again into electricity. Had we followed his recommendation we would have had losses of 75 per cent or more by transferring electricity into hydrogen, liquefy it, pump it, store it, and transform it again into electricity (Bossel 2004). The losses in an energy chain are often overlooked. People are fascinated with a technology whose advantages seem obvious and forget the drawbacks. One reason for the comeback of nuclear power might be the disillusionment with the so-called benign and miraculous energy systems which are by definition sustainable, solar, peaceful, democratic, and cheap. In the future they may be superior to our conventional systems, but more time is needed to be on the safe side.

Another problem refers to statistics. If equal distribution of available goods would solve the problems, we would have neither poverty nor hunger in the world. By dividing existing resources among all people one may easily solve every distribution problem, e.g. dividing the global GNP of 34,491.5 billion US \$ in 2003 by a world population of 6.3 billion people. Thus, one gets 5,474.8 US \$ per year and per person, which is much less than we earn in industrialized countries but enough to live modestly above the poverty line. By the same calculation you can feed all hungry people in the world. You sum up all crops and all available food, you distribute it equally among the people, and everybody can eat and drink.

Unfortunately, such a utopia does not exist. Rather, we are far from being equal. I still remember the debates in the European Parliament when we discussed the future of our water supply. The Austrians and the Swedes categorically refused to pump water from their mountains to Spain or Greece in pipelines yet to be built. Water, they argued, is not a commodity as cars or textiles, and therefore does not fall under the freedom of the Common Market. Thus, we will not share our water resources with our neighbours. If even in Europe we do not want to share our water resources, how can we expect others to behave differ-

ently? Nor do we want to share our wealth. The rich are getting richer while the poor get poorer. Although we know that a democratic society cannot live for ever with inequality, redistribution of wealth is unpopular. We prefer to rely on growth, on equal chances, but only on a limited distribution of this growth.

The real world does not allow us to divide simply the resources by the number of people who need them. The oil rich do not want to share their oil with us. Nor do we want to share our production of cars with others. Who wants to have something has to pay the market or the seller's price. A modern society cannot be built on charity. Hence, statistics may be physically true, but they don't necessarily help us. They are often politically incorrect. Nevertheless, there might be a solution. The problem can be solved by common interest. You trade resources and technologies like other commodities. Trade is not restricted to renewables. It must be open to all technologies as long as they reduce the emission of greenhouse gases.

On the second problem, is the relationship between resource scarcity and wars really true? Does underdevelopment and scarcity of resources result in conflicts and war? Hunger is not necessarily caused by environmental disasters. According to Armatya Sen (1981), famines can be avoided. In 1974 Bangladesh produced sufficient food but nevertheless many people suffered malnutrition and died. They were too poor to buy the available food. In 2005, the Republic of Congo suffered from famine although the country could produce more than to feed its people. Zimbabwe, once the granary of Southern Africa, suffers hunger because of dryness whereas neighbouring South Africa – suffering under similar environmental problems – harvests record crops. And why is it that India, although confronted with a growing population and sometimes great ecological catastrophes, never suffered famines since independence? Famines can be avoided even after natural hazards. The states suffering hunger do not have a free press. Their governments are not committed to the well-being of their people. Thus, the main reason for the existence of famine is bad government.

Without good government, without the commitment to serve the people and not the ruling class or family clan, even the best technology is ineffective. Technology as such does not make a society better or worse. Its usefulness depends on the safety rules, the efficiency, the quality, the maintenance, in other words on human behaviour. Therefore, it is more than doubtful to tag a technology with a label democratic or undemocratic as some try to do with nuclear en-

ergy. Is a nuclear Finland a less democratic society than a non-nuclear Austria?

But lack of good governance can be an obstacle to development. In 1995, at the Euro-Mediterranean summit in Barcelona the Foreign Ministers of 15 EU and 12 MENA countries agreed on a new cooperation in the Mediterranean basin aiming at a security partnership, a free trade area until 2010, and deeper social, cultural, and humanitarian relations to bring the Mediterranean countries closer to each other and to foster links between countries and people. Energy, telecommunications, and transportation issues were chosen. It was believed the integration into a common economic area would make room for a new and prosperous neighbourhood (Brauch/Marquina/Biad 2000). The Barcelona process was more onerous than pessimists thought, but it could neither solve the Palestinian problem nor the quarrels between Turkey, Greece and Cyprus, nor could it foster cooperation among the Maghreb countries. The MENA countries were not ready for political reasons to share their future with their neighbours.

From the European experience underdevelopment has been less a state of technical under equipment than a mental problem. It took Europe two world wars to overcome its deeply rooted nationalism, but we cannot exclude a return of an atavistic behaviour. It will take time to convince countries that it is wiser to share sovereignty with neighbours than to defend against them.

On the third hypothesis, does energy interdependence really generate peace and development? If this were true we would already live in a better world. Our interdependency is growing due to progress in transport and telecommunication technology, a worldwide system of trade and finance, or in a nutshell, due to globalization. Europe imports today 50 per cent of its energy needs; in 2030 it will probably be 70 per cent or more. Particularly oil and gas, but also coal and uranium must be imported. By 2030 we will experience the same energy dependence as in 1973 when a painful price was paid for our energy vulnerability during the oil crisis.

Or is that danger only due to our oil and gas import dependence? Would it be different with electricity imported from the Sahara? Is it really unthinkable that the countries hosting the new solar power plants will not cut the electricity lines as today they may stop selling us oil at a decent price? There is no scientific reason to believe in such a hypothesis. Without changing the societal conditions and the political relations, without good governance and common val-

ues, we would simply replace oil and gas with electricity. Europe would continue to depend on energy imports. Hydrocarbons would be replaced by electrons. Such a replacement does not per se provide us with a peaceful future.

So is it hopeless? Is energy cooperation really useless in solving problems? Is autonomy or self-reliance the answer? Certainly not! But we can definitely exclude the hypothesis of an automatically safer world by energy interdependence. You need more than technology.

32.9 What Will or Might be a Realistic Perspective?

The Barcelona process did not bear the fruits many people expected. Hence, the European Union has started its European Neighbourhood Policy (ENP). One major element of ENP is a strategic energy partnership. This includes security of supply and energy safety as well as security. As the world's largest oil and gas importer and the second largest consumer, the European Union is surrounded by the world's most important reserves of oil and natural gas. As Europe will increasingly depend on imports, neighbouring countries play a vital role in the security of energy supply. On the other hand many countries seek improved access to the EU energy market, either as current or future suppliers (Russia, Egypt, Libya, and Algeria) or as transit countries (Ukraine, Belarus, Morocco, Tunisia). Improving energy network connections between them and the EU, as well as the legal and regulatory convergence, are of strong mutual interest. Moreover, increased energy cooperation provides mutual business opportunities and can contribute to socio-economic development and improvement to the environment.

Europe has an excellent record in market-driven energy policy. Electricity and gas networks bring the producers and the consumers together, regulated access to the unbundled electricity and gas grid improve competition, and the preferential access of green electricity to the grid enhances the chances of renewable energy sources. Since the Treaty of Maastricht there is an article on the Trans European Networks (TENs).

To increase the energy dialogue and cooperation, Action Plans are developed to foster gradual convergence of energy policies and of legal and environmental provisions. These Action Plans include energy efficiency and energy savings, as well as renewable energy and cooperation on energy technologies, including

clean coal. There are possibilities to participate in the Intelligent Energy Programme and in the research programmes, as well as in the European Gas and Electricity Regulatory fora. These Action Plans build on existing bilateral or regional initiatives, such as

- the EU-Russia Energy Dialogue;
- the Tacis-funded Inogate programme dealing with the Caspian basin;
- the energy cooperation in the context of the Euro-Mediterranean partnership, in particular the creation of a Euro-Maghreb electricity market and the already agreed Euro-Mediterranean energy networks;
- enhanced energy co-cooperation between Israel and the Palestinian Authority;
- increased gas cooperation in the Mashriq region (in the Euro-Mediterranean context); and
- the South Eastern Europe Regional Energy Community which involves Albania, Bosnia-Herzegovina, Bulgaria, Croatia, Kosovo (UNMIK), Macedonia (FYROM), Romania, Serbia and Montenegro, Turkey, and with the added involvement of Austria, Hungary, Italy and Slovenia, and Moldova as an observer.

The South Eastern Europe Regional Energy Community is the first example of where the EU extends in a legally binding manner its legislation to other non-member states. The countries concerned must implement the EU directives on the internal market for electricity and gas, as well as relevant environmental laws such as the Directive on Large Combustion Plants reducing thereby emissions and improving efficiency standards.

The European Neighbourhood Policy in general and the Action Plans in particular are assisted by financial instruments. Until 2007, Tacis and MEDA will remain the main financial instruments for assisting partner countries. Lending has also been reinforced. In November 2003, in the context of the mid-term review of the EIB external lending mandate, the Council agreed to the Commission proposal to increase the lending ceiling for the Mediterranean countries by € 2,180 million. A similar extension has been agreed to cover Russia and the western New Independent States (NIS).

In the period 2000–2003 the financial assistance to ENP partners under Tacis totalled € 1,332.2 million, whereas countries covered by MEDA received altogether € 3,716.1 million. This can only be explained by the vital interest of the European Union to develop a good neighbourhood policy with adjacent states.

Some of them may join the European Union in the years to come, like the Balkan states or possibly Turkey, others like the Mashriq and Maghreb states might become part of an economic space, comparable to the European Economic Space whose members are Norway, Liechtenstein, and Iceland. In this case they would fully participate in the functioning of the internal market, would respect the common values, and participate in an always deeper cultural and human relationship. We are still years away from this objective. Some progress was made but national interests and the lack of democracy in many countries slowed down this promising process.

If in ten, twenty, or thirty years the EU and her neighbours should succeed in creating an integrated energy space, with common competition rules and a common environmental policy, then all partners would be linked by big electricity grids and gas pipelines and a solid financial and business framework fostering trade. If they also had a common vision on their future they could start thinking about a new energy era.

But we could even start to think beyond. Our actual energy relationship is mainly based on oil and gas. Europe is increasingly the buyer; our neighbours sell or transfer oil and gas by pipelines or LNG-tankers. But oil and gas will not last for ever. Particularly cheap oil will soon reach its production peak and gas will follow soon afterwards. We do not yet know the exact time but both resources are limited. Then the question is what comes after oil and gas, what comes in the second half of the 21st century?

According to what we know today we will probably run out of cheap oil and gas, coal will still be available at decent prices, and CO₂-free clean coal technologies will be available at reasonable costs, new and intrinsically safe nuclear power stations will be operable and nuclear fission may become a reality, renewable energy sources including storage technologies may be available at affordable costs – and last but not least, we will all participate in a greenhouse gas emissions trading system. Greenhouse gases, mainly CO₂, will have a price, and this price will have a major impact on our energy policy. Most probably there will remain three competitive energy sources: nuclear, clean coal, and renewables. They will compete with each other to provide the necessary energy, water, and other commodities. If nuclear were to be rejected by one or the other reason we will have two remaining energy sources, or if in a further future even coal would become scarce, renewables might be the last hope. But it could also be the other way round. If oil and gas

would run out and renewables would still be too expensive, then the whole area would have to rely much more on clean coal and nuclear, a nightmare for those who believe in renewables only, but not far from reality and certainly achievable. In this case Europe would provide a bigger share of common energy needs. Europe would again become an energy exporter. But how can the African countries pay their energy bill? It therefore makes sense to help them develop new indigenous energy sources.

But why do they have to develop only renewable energy sources? Why can they not import cheap coal from opencast mines and build clean coal power stations on their coasts? And why should they not build high temperature nuclear reactors, like the one South Africa is developing? Countries like our immediate neighbours who have very limited resources will look for the cheapest and most economic solution. If the renewables are to win the energy race they must become competitive. It is not excluded that this may happen if the alternative becomes too expensive and if new discoveries are made.

Whatever happens, it makes sense to develop the renewable energy technologies, and perhaps they may play in the future a major role in our energy security policy. It is in the interest of the Europeans as of their neighbours to knit the network ever closer, to develop technologies jointly, to create confidence by cooperation and success. We Europeans should include the neighbouring countries into our energy strategy. As the solar irradiation is three times bigger in the Sahara than in Central Europe, it makes sense to build a solar power plant there and not here. Particularly thermal solar power stations must be built in these hot spots of our globe.

Better sooner than later these countries should be included in the European Emissions Trading System, because it promotes investment in technologies that reduce the emissions of greenhouse gases. Already today, in the first phase of Europe's National Allocation Plans, more than 300 million tons of CO₂ have to be acquired by CO₂ credits in Third World countries. Let us assume an average CO₂ price of € 10 per ton then the EU-member states have to buy CO₂ credits at a cost of 3 billion per year. This sum will go up in the future and will soon reach the amount of several tens of billion euros in the forthcoming decades. CO₂ credits might soon become the currency of our sunny neighbours, and it will help them to finance investment in renewables or other CO₂-free technologies (Brauch 2000a).

32.10 Summary and Conclusions

Let me summarize the answers to the initial questions: Will a North-South energy partnership contribute to energy security? Yes, if we extend the partnership to all categories of life - environment, human rights, democracy, and good governance. Can we avoid conflicts by exploiting exclusively renewable energy sources? The answer is no. There is no historical or scientific proof for such a hypothesis, but it is also impossible to falsify this hypothesis. The best approximation is probably a market-driven approach including all technologies and greenhouse gas abatement costs. The European Neighbourhood Policy has all the merits to develop into such a new relationship between North and South and deserves sympathy and political backing.

33 Food as a New Human and Livelihood Security Challenge

Úrsula Oswald Spring

33.1 Introduction¹

As a result of a process of “regressive globalization”² (Kaldor/Anheier/Glasius 2003; Oswald 2008b) and of an increasing concentration of wealth in few hands, the economic gap has widened between North and South and within the countries between rich and poor, which has often affected the survival of social groups. This inequality is one of the core elements of failure in the eradication of hunger and poverty. Therefore, many multilateral organizations, such as the *World Bank* (WB), the *International Monetary Fund* (IMF), and regional associations like the *Economic Commission for Latin America and the Caribbean* (CEPAL), the *Inter-American Development Bank* (IDB), the *Asian Development Bank* (ADB), and the *African Development Bank* (AfDB) and the *East African Development Bank* (EADB), have recommended to the governments to reduce the internal gap and to dedicate more resources for human development. They should address basic food production systems with job creation, increase low salaries and

subsidies for the marginalized and promote cheap prices of basic food for the urban poor.

These recommendations have directly linked ‘food security’³ to the wider concept of ‘human security’⁴ (Brauch 2008; Oswald 2008b, 2008d; Brauch/Oswald/Mesjasz/Grin/Dunay/Behera/Chourou/Kameri-Mbote/Liotta 2008). ‘Freedom from want’ requires sufficient food (‘food security’) and water (‘water security’), and both are key demands of any human security concept as a necessity for survival, and thus it has become a basic human right. Human security requires not only a quality of life and a decent livelihood, but also health and stable productive conditions for almost half of the world population living in marginal rural and urban areas (see part IX and chap. 74 to 96).

In the early 21st century, more than 2 billion persons depend on food self-sufficiency and another billion peasants suffer from eroded and polluted land, are unable to satisfy basic human needs, and are often forced to migrate to shanty towns or to cross illegally the borders to industrialized countries in search of jobs and quality of life (Schteingart 2006; Oswald 2006a). Thus, in this author’s understanding ‘food sovereignty’ goes beyond the physical conditions of production and market, and involves *social* (Campos 1995; Strahm/Oswald 1990), *cultural* (Arizpe 2004), *economic* (Calva 2008/a; Martínez 2003; Cadena

1 This article has been substantially improved as a result of an international cooperation. I want to thank two anonymous reviewers for helpful comments and Hans Günter Brauch for his critical input to the first draft. He also compiled box 33.1 and systematized important parts of box 33.3. I am immensely grateful for his careful editing and style correction and to Ronnie Lappin for his language editing.

2 Regressive globalization is understood in this context as a doctrine, rooted in the confidence of the efficacy, institutional building and moral authority of US power, allied with transnational capital in the sphere of communication, military, commerce, finance, and productive system. Using the term democracy and progress it is promoting a liberal global world order, favouring international capital and transnational productive systems. In the poor countries this process creates greater poverty, technological dependency, debts, massive rural migration and often loss of food sovereignty, while a small elite benefits from this alliance.

3 For the definition of and the scientific debate on the term ‘security’ in English and Spanish see Albrecht/Brauch (2008, 2008a); Brauch (2002a, 2003, 2008, 2008a, 2008b, 2008c, 2008e, 2008f); and Oswald/Brauch (2008, 2008c). The author will not use the term ‘food security’ developed during the past four decades (see part 34.2, where the debate in the FAO and World Bank has been briefly documented and criticized as a too technological and top-down approach), but will develop a wider concept of ‘food sovereignty’.

4 The author has developed in chap. 90 her proposal for a new and wider policy-relevant security concept that combines *human*, gender and *environmental* security (HUGE) dangers and concerns.

2003, 2005), *political* (Kaplan 2003), and *identity* factors (Serrano 2004; and chap. 89).

On this dual political and conceptual background, this chapter addresses the following research problem: food represents not only a security issue of intake of nutrients, but it forms part of a holistic understanding of life and a constituting element of any civilization. Thus it includes networks of connectedness (vertical: patron-client, and horizontal: social groups), belonging, relationship of trust, reciprocity, cooperation and exchange. It creates social benefits and risk reduction, but also innovative activities through a wider access to information and learning. It is a process of anchoring of personal and group identity (see chap. 90 by Oswald on HUGE), where social relations reaffirm the integration of a person inside a community with clear rights and obligations, such as access to land, credit, technology, training, market, life quality and rituals. Besides guaranteeing the physical and cultural survival, food also creates new opportunities for people-centred poverty alleviation and new understanding of 'rurality'. It represents a critical response to the past development and modernization paradigms and opens ways for diverse rural life processes, where agricultural activities and environmental services coexist with services, technology, and industries.

In addressing this research question, this chapter links the concept of food security with food sovereignty, a term developed by peasant movements, especially *Via Campesina*⁵ that was later also taken up by FAO. It first reviews basic concepts such as food security, food sovereignty, survival strategies, self-sufficiency, and livelihood (33.2). Then it scrutinizes the contradiction that in a world with increasing production and a diverse offer of food, hunger is still one of the most important causes of illness and death, because an important part of food is used for livestock and for industrial purposes. Recently, biofuels have aggravated the scarcity of food worldwide and regionally, affecting above all vulnerable groups such as poor peasants and marginalized urban people in the South

and North. This part reviews the internal food intake not only globally, but also for Latin America and in a case study of Mexico that focuses on the remote indigenous regions of Chiapas, Oaxaca, and Guerrero where undernourishment is still high and one of the causes of child mortality (33.3).

Part 4 explores three global models of food production: a) the productive paradigm, represented by the 'green revolution' that emerged in Mexico; b) the new paradigm of the 'life sciences', where *transnational enterprises* (TNE) have converted food not only into a commodity, but also into health and medical items; c) the third paradigm refers to 'organic agriculture' that cannot be globalized. It uses traditional agricultural methods developed in each region; recycles organic waste, produces soil enrichment with compost and uses biopesticides and natural seeds. The transformation of food uses long-established techniques and avoids the use of chemicals for conservation. This production system not only conserves the natural nutritional values of food and soils, but it is also an alternative for the self-sufficiency of poor peasants worldwide (33.4).

In the concluding part these three models are compared and related to its repercussion on environmental, gender, and human security (Oswald 2001, 2006a and chap. 90 below on HUGE). It links 'food security' with some traditional models of self-sufficiency that were proposed by Julius Nyerere in his 'ujamaa' philosophy and by ecofeminists (Mies 1998; Shiva/Mies 1997; D'Eaubonne 1974). It was taken up by *Via Campesina*, the most important world peasant movement and developed into a 'food sovereignty' paradigm. This approach is able to link up small producers from South and North, East and West, and to produce enough food for a livelihood with dignity. This approach integrates democratic land reforms, local market structures, green agriculture, and natural seeds as the patrimony of peasants and communities, with a culturally diverse livelihood (Shiva 2008, see preface essay in this vol.).

5 *Via Campesina* is a world organization of peasants and small producers and fishermen from the South and North with sub regional association such as *Latin American Peasant Organizations* (CLOC in Spanish), in Latin America, North America, Europe, Asia and Africa. Their goal is to defend an integral process of rural livelihood including agriculture, livestock, orchards, fishing, hunting and recollection, including direct producers, rural workers, women, elders and the young. Their executive committee is democratically elected and regionally representative, caring about gender and youth equity.

33.2 Conceptual Considerations and Clarifications

Why is food important for humans? Food, water, and air are the crucial elements of survival for humans. Food creates energy required for growth, sustenance, and biological and physical activities; it acts within the cells and it purveys the structural and catalytic components to build anabolism.⁶ Whenever one of these

functions fails, organisms substitute it with another process (Oswald 2006: 663–664).

Food is the generic term used for vegetal and animal nourishment as a whole, in parts or its different versions (flowers, fruits, leaves, roots, milk, eggs, muscles, kidney, blood, etc.). It can be distinguished from nutrition, which is the process through which food is absorbed and transformed. Food intake is a biological necessity, determining the quality of life and health of a human being, and its nutritional requirements vary according to age, sex, physical activities, climatic factors, and health conditions.

Nutrition refers to the process of absorption of food by living organisms.⁷ It starts with ingestion, continues with digestion, where the proteins are transformed into amino acids and keeps on with the absorption of nutrients in the intestine. Once integrated into the blood, they are assimilated by the body and transformed metabolically in each cell. The last phase is the excreta of faecal material and urine, where also toxins are eliminated from the body.

Nevertheless, food cannot be reduced only to this physiological process. It is a holistic experience where different senses intervene (smell, flavour, touch, view). Each civilization has developed a culture of tra-

ditional, ritual and food specialties linked to religious and civil events. Different diets and food preparation, but also taboos, ceremonies and rituals, are able to reinforce the cultural and territorial identity of people.

33.2.1 Food Security

Maxwell and Smith (1992) had counted more than 200 definitions of ‘food security’ (FAO 2003a, 2005c). Within the Food and Agricultural Organization (FAO) the food security concept has gradually been developed as a guiding concept for FAO’s evolving food policy (box 33.1).

The general definition of ‘food security’ that was inspired by FAO is related to the personal right to sufficient food for a person and a nation, discounting no-food uses.⁸ The US Department of Agriculture (USDA) evaluates national food security by measuring the gaps between actual food consumption, domestic production, plus commercial imports, minus unused food and consumption targets. Sometimes, nutrition gaps are also measured by the minimal daily nutritional requirements in relation to age, sex, and activities. Thus, food security is assuring the physical availability and the economic accessibility to enough food in an environmentally and socially sustainable manner, where adequate quantity and quality, but also culturally acceptable food for everybody at any time is able to guarantee a healthy and active life. Quantity refers to amount, distribution, calories and proteins, and quality to safe, innocuous, nutritious balanced, good and culturally accepted food. Among the many

6 Anabolism is the process which builds up complex molecules from smaller units, able to give the body the required energy that is coming from glucose and fatty acids. Therefore, it refers to chemical reactions that produce a combination of different molecules. The result of anabolism is the creation of new cellular material (enzymes, proteins, cells and its membrane, organs and tissues). Thus, anabolism is crucial for growth, maintenance, and reparation of tissue.

7 An optimal functioning of an organism or of its cells requires about a hundred different substances located in the environment. Their function is to maintain the structure and to control the metabolism. Metabolism means the sum of chemical changes taking place inside an organism by which food is transformed and utilized by the organisms, and water products are eliminated. Generally, there are chemical components with high molecular weight (proteins, sugar, fibres, salts, starch), which are transformed into nutrients in the intestines. Once liberated, they are absorbed by cells into the blood circulation. Essential chemical elements for the human body are – depending of the weight of the body – 65 per cent oxygen, 18 per cent carbon, 10 per cent hydrogen, 3 per cent nitrogen, 2 per cent calcium, 1.1 per cent phosphorus, 0.25 per cent sulphur, 0.20 per cent potassium, 0.15 per cent sodium and chlorine, 0.05 per cent magnesium, 0.004 per cent lead and traces of copper, manganese, zinc, cobalt, silicon, molybdenum and others (Oswald 2006: 664).

8 Today, less than a third of the grain produced worldwide is directly used in human consumption. The rest is transformed into animal food and industrial inputs. With biofuel the situation will worsen. In Mexico the price of corn per ton rose from 1,400 Mexican pesos in September 2006 to 3,500 pesos in December 2006. The International Monetary Fund indicated that the price of white corn was US\$ 102.7 per ton in the USA. As a quarter of the corn was used for biofuel, the price increased to US\$ 144, but in October 2007 the price rose by 18.2 per cent compared with September, and in November it rose again by 15.4 per cent compared with October, achieving US\$ 164. Peasant organizations explain that the corn is bought from the peasants for 1,400 Mexican pesos and sold in the towns to the tortilla factories for 3,400 pesos, due to speculative practices of monopolies of the TNE Cargill and the Mexican enterprise Maseca, together with other smaller speculators involved in corn importation and tortilla transformation (see at: <<http://www.jorgezepeda.net/13-01-2007/la-tortilla-para-entender-el-aumento-del-precio/>>).

Box 33.1: The evolution of the concept of food security within the FAO. Text is in the public domain.

According to FAO (2003a) the food security concept gradually emerged in the mid-1970's when the initial focus was on:

food supply problems – of assuring the availability and to some degree the price stability of basic foodstuffs at the international and national level. That supply-side, international and institutional set of concerns reflected the changing organization of the global food economy that had precipitated the crisis. A process of international negotiation followed, leading to the World Food Conference of 1974, and a new set of institutional arrangements covering information, resources for promoting food security and forums for dialogue on policy issues (ODI 1997).

Focus was put on productivity, within a frame of Green Revolution, independent of social, environmental, and political costs. The problems of famine, hunger, and food crises were analysed in detail, resulting in a “redefinition of food security, which recognized that the behaviour of potentially vulnerable and affected people was a critical aspect” (FAO 2003a). The insight that the green revolution “did not automatically and rapidly lead to dramatic reductions in poverty and levels of malnutrition ... were recognized as the result of lack of effective demand” (FAO 2003a). Food security was defined in 1974 as:

‘availability at all times of adequate world food supplies of basic foodstuffs to sustain a steady expansion of food consumption and to offset fluctuations in production and prices’ (UN 1975). In 1983, FAO expanded its concept to include securing access by vulnerable people to available supplies, implying that attention should be balanced between the demand and supply side of the food security equation: ‘ensuring that all people at all times have both physical and economic access to the basic food that they need’ (FAO 1983a).

The commoditization of inputs and food markets widened the existing social gap, giving support to large-scale industrial agriculture and expelling millions of peasants from their land. An influential World Bank (1986) report on *Poverty and Hunger* addressed the temporal dynamics of food insecurity and introduced the “distinction between chronic food insecurity, associated with problems of continuing or structural poverty and low incomes, and transitory food insecurity, which involved periods of intensified pressure caused by natural disasters, economic collapse or conflict” (FAO 2003a). The food security concept evolved to: “access of all people at all times to *enough food* for an *active, healthy life*” (World Bank 1986: chap. 2). In the mid-1990's, this definition was widened:

to incorporate food safety and also nutritional balance, reflecting concerns about food composition and minor nutrient requirements for an active and healthy life. Food preferences, socially or culturally determined, now became a consideration. The poten-

tially high degree of context specificity implies that the concept had both lost its simplicity and was not itself a goal, but an intermediating set of actions that contribute to an active and healthy life.

In UNDP's (1994) human security concept, food security was one of its seven aspects. In 1996, the World Food Summit adopted an even more complex definition:

Food security, at the individual, household, national, regional and global levels [is achieved] when all people, at all times, have physical and economic access to sufficient, *safe and nutritious* food to meet their dietary needs and *food preferences* for an active and healthy life (FAO 1996b).

In 2001, the FAO again refined this concept in: *The State of Food Insecurity 2001*:

Food security [is] a situation that exists when all people, at all times, have physical, *social* and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life (FAO 2002).

This new emphasis on consumption was influenced by Amartya Sen (1981) who stressed entitlements of individuals and households. A study of FAO (2003a) described:

food security ... as a phenomenon relating to individuals. It is the nutritional status of the individual household member that is the ultimate focus, and the risk of that adequate status not being achieved or becoming undermined. The latter risk describes the vulnerability of individuals in this context. ... Useful working definitions are described below.

Food security exists when all people, at all times, have physical, social and economic access to sufficient, safe and nutritious food which meets their dietary needs and food preferences for an active and healthy life. Household food security is the application of this concept to the family level, with individuals within households as the focus of concern.

Confronted with new models of fast food, people began to suffer more from obesity, cardio-vascular accidents, diabetes and cancer. Thus the concept of food security shifted again, now to healthy and innocuous food, able to maintain a person vigorous and active by reducing the intake of animal fat, sweet beverages, and junk food. But when confronted still with 825 million hungry people, food insecurity was addressed, together with the fact that 80 per cent of the poor live in rural areas and agriculture employs almost 50 per cent of them:

Rural development is critical for improving food security. The traditional agriculture sector has low productivity due to the lack of investment, inadequate water supply and scarce arable land. Rapid depletion of groundwater resources may be the most serious problem facing the countries (FAO 2006: 20).

definitions of 'food security' used in the scientific and policy oriented food discourse those selected here indicate its scope:

- "when people do not need to live with hunger or fear starvation"⁹;
- "physical and economic access, at all times, to sufficient, safe and nutritious food to meet dietary needs and food preferences for an active and healthy life"¹⁰;
- "the ability of individuals to obtain sufficient food on a day-to-day basis"¹¹;
- "the notion that all people, especially the most vulnerable, have dignified and unthreatened access to the quality and quantity of culturally appropriate food" that will fully support their physical, emotional, and spiritual health (Wolfe/Frongillo/Valois 2003);
- "state in which all persons obtain a nutritionally adequate, culturally acceptable diet at all times through local non-emergency sources" (Riely/Mock/Cogill/Bailey/Kenefick 1999);
- "condition of having enough food to provide adequate nutrition for a healthy and productive life" (USAID, Bureau for Africa 1986a).

USAID defined 'food security' as:

all people at all times have both physical and economic access to sufficient food to meet their dietary needs for a productive and healthy life. Achieving food security requires that the aggregate availability of physical supplies of food is sufficient, that households have adequate access to those food supplies through their own production, through the market or through other sources, and that the utilization of those food supplies is appropriate to meet the specific dietary needs of individuals.

Achieving food security requires that the aggregate availability of physical supplies of food is sufficient, that household have adequate access to those food supplies through their own production, through the market or through other sources, and that the utilization of those food supplies is appropriate to meet the specific dietary needs of individuals (Riely/Mock/Cogill/Bailey/Kenefick 1999: 2-3).

The *US Food and Drug Administration* (FDA 2003) defined 'food security' as the daily balanced intake of proteins, carbohydrates, vitamins and minerals re-

quired for a healthy life. The disequilibrium in quantity and polluted food, or with toxins, could generate illnesses and limit the physical and mental development of children. Finally, food security is also related to food safety such as hygiene and prevention of illnesses caused by food in bad conditions or food-borne sicknesses.¹² According to WHO, bacteria are the main threat for innocuous food that are present in the domestic and professional food chain.

33.2.2 Food Sovereignty

Food security, as defined by FAO, does not include social and cultural factors of food and nutrition, nor land rights, seeds, credits, family ties, social relations of productive and consumption pattern together with communitarian cohesion. Therefore, *Via Campesina* understood 'food sovereignty' as "the right of peoples, communities, and countries to define their own agricultural, labour, fishing, food and land policies, which are ecologically, socially, economically and culturally appropriate to their unique circumstances. It includes the true right to food and to produce food, which means that all people have the right to safe, nutritious and culturally appropriate food and to food producing resources and the ability to sustain themselves and their societies" (*Food Sovereignty: A Right For All*, Political Statement of the NGO/CSO Forum for Food Sovereignty, Rome, June 2002).

Thus important elements of food as a cultural and not only as a technical process are lacking in the FAO definitions. The concept of "food sovereignty represents both a social and a personal right of individuals and communities to healthy, culturally appropriate and permanent food" (Oswald 2006: 664), but includes also the process of production, land tenure, local native seeds, access to water and to other natural resources, storage processes, transformation of food, eating, fiestas and rituals in which women play a key role.

Social movements such as *Via Campesina* have used in their daily struggle the concept of food sovereignty, including geopolitical, socio-economic, identity and cultural aspects (box 33.2).

This new concept of 'food sovereignty' that differs significantly from the concept of 'food security' (box 33.1) that is being used by FAO and the food aid community has been taken up by the *UN Forum for Indigenous Peoples* during its sixth session, 14-25 May 2007 that defined food sovereignty as:

12 See; US FDA (2003); at: <<http://www.fda.gov/OHRMS/DOCKETS/98fr/01d-0583-nad00002.pdf>>.

9 See: Medicine.Net.com; at: <<http://www.medterms.com/script/main/art.asp?articlekey=32945>>.

Box 33.2: Concept of food sovereignty as developed by social movements. Text is in the public domain.

Via Campesina, social movements, ecofeminists and indigenous organizations define food sovereignty as an integral process of production, commercialization, transformation and intake related to the family and community culture of food, proper of any region, social class and nations. Their understanding of food sovereignty includes:

- a.) local production and trade of agricultural products with access to land, water, native seeds, credits, technical support and financial facilities for all participants;
- b.) women are the main food producers worldwide¹⁾ and they are often in charge of transformation and local trade;
- c.) therefore, access to land, credit and basic production means for women and girls at home and in the community is a guarantee of food security, but it is also able to overcome the violent and unjust patriarchal structures within families, communities, social organizations, countries, and global economic systems;
- d.) inclusion of the indigenous, women, and peasants in regional and national rural policy and decision-making processes related to agriculture and food sovereignty;
- e.) the basic right to consume safe, sufficient, and culturally accepted non-toxic food, locally produced, transformed and sold, since food is more than intake of proteins and calories: it is a cultural act of life;
- f.) the rights of regions and nations to establish compensations and subsidies to get protection from dumping and artificial low prices as a result of subsidies in industrialized countries;
- g.) the obligation of national and local governments to improve the food disposal of its citizens through stimulus of production and transformation of food, subsidies, and economic programmes to achieve food sovereignty in basic crops; discounts in urban poor regions, able to guarantee the basic food basket; popular kitchens; breakfast in schools, and special food for undernourished babies and pregnant mothers;
- h.) governments should guarantee an adequate nutrition above all for babies, infants, and pregnant women, offering food supply for poor people;
- i.) during bad harvests the importation of basic crops from the world market, and when countries are threatened by famine, with the advice and support from the World Food Programme;
- j.) clean water and sewage facilities to eliminate parasites, viruses, helminth and protozoa²⁾;
- k.) links among environmental services, agriculture, territorial planning and democratic participation in the decision-making process to guarantee the livelihood and dignity of the most vulnerable in rural areas. They create opportunities for rural population to stay on their field without pressure for migration. The sum of these processes reinforce for each citizen the basic rights of life, but also the right of non-migration, thanks to sustainable life with dignity in its own communities and countries.

-
- 1) In most countries of Sub-Saharan Africa (SSA), women represent: 33 per cent of the rural labour force; 70 per cent of paid rural daily work; 60–80 per cent of self-subsistence crops and local sale; 100 per cent of food transformation; 80 per cent of harvest, transportation from the fields to the community and food storing; 90 per cent of weaving and hooking; 60 per cent of market activities (FAO/SDWW 1999: 2)
 - 2) Helminths are worms and their eggs living inside of a human organism or animals. Protozoa are single cell organism able to divide within a host organism. Malaria is caused by protozoa called *Plasmodium*. Other frequent protozoa parasites are *Giardia* and *Toxoplasma*.

the right of Peoples to define their own policies and strategies for the sustainable production, distribution, and consumption of food, with respect for their own cultures and their own systems of managing natural resources and rural areas, and is considered to be a precondition for Food Security.¹³

This concept has also been discussed by several NGOs, such as the *Africa Europe Faith and Justice Network* (AEFJN) that adopted a food sovereignty

document in September 2005 that points to many shortcomings of the food security concept (box 33.3).

These definitions on food sovereignty by social movements representing the interest of farmers in the South (*Via Campesina*, box 33.2) and of an African-European Catholic group (box 33.3) are just two exemplary snapshots that point to major shortcomings of the debate on food security during the past three decades. They are also responsible for the lack of progress against hunger since until today 25,000 people, above all small children, die daily of hunger. The next two concepts of 'survival strategies' and 'livelihood' that have been developed in the South address different means for the marginalized poor to achieve 'food security' with 'food sovereignty'.

Box 33.3: Food Sovereignty Document, September 2005. **Source:** <http://www.aefjn.be/index.php?option=com_content&task=view&id=31&Itemid=37>. Text is in the public domain.

On 7 July 2005 some representatives of AEFJN met ... to discuss the principles of food sovereignty as a possible framework for the work of AEFJN.

Food Sovereignty:

The discussion stimulated interesting reflections about the definition of the term, the difference with other mainstream concepts such as the right to food and food security, weaknesses and strengths of this paradigm, and the specific aspects that can relate food sovereignty to Catholic Social Teaching, Human Rights and policymaking. We would like to summarize here some of our findings. Life is the most precious gift. The right to life is therefore the most fundamental right for any human being. An essential condition to sustain life is food. Access to food is recognized as a basic human right.

Right to Food:

The right to food was recognized in the Universal Declaration of Human Rights in 1948. It is also included in the International Covenant on Economic, Social and Cultural Rights of 1976:

"Everyone has the right to a standard of living adequate for the health and well-being of himself and of his family, including food..." (Universal Declaration of Human Rights, Art. 25.1)

Therefore the right to food is an integral component of human rights, based on existing international law and protected by a legally binding framework in international law. Also important are the FAO "Voluntary Guidelines" (November 2004) formally accepted by FAO members states as a useful tool to challenge unwilling governments to take their internal and external responsibilities serious.

Food Security:

The concept of food security has long dominated the discussion about the question how to diminish and eliminate poverty and hunger. Coined in the context of the UN specialized agencies, such as FAO, the term has been used since the 1970's. Although there is a definition agreed by all, the 1996 World Food Summit defined Food Security as 'the situation in which all people, at all times, have physical and economic access to safe and nutritious food that meets their dietary needs and food preferences for a healthy life'. Though it refers to having enough food to eat, it doesn't talk about where the food comes from, who produces it, how and under which conditions it has been grown.

Food sovereignty is a global or national vision oriented towards production, rather than access to food by deprived persons and groups. The way to have access to food can be different: to grow food, to have

paid work to buy food, or to receive welfare in case of inability. This allows the big food producers both in the North and South to argue that the best way for poor countries to achieve food security for their people is to import cheap food from abroad rather than trying to produce it themselves. It does not question the existing relations of inequality and processes that increase these social gaps, within a country by landlords and outside by TNE.

In spite of the green revolution, improved productivity and tremendous efforts to provide food security, the number of hungry people in the world has been growing. Surprisingly, the very people who grow food, the small peasant farmers, particularly women, are afflicted by hunger and can no longer make a living on their land. To speak only of food security is no longer enough. We have to look at the question of what kind of food is produced, how it is produced, for whom it is produced. Food security is a definition of a goal rather than a programme with specific policies that aim at the eradication of the causes of hunger and malnutrition. Therefore a more comprehensive notion is under discussion today to ensure the daily food for all through food sovereignty.

Food Sovereignty:

There are several definitions of 'food sovereignty':

Food sovereignty is the right of people, communities, and countries to define their own agricultural, pastoral, labour, fishing, food and land policies which are ecologically, socially, economically, and culturally appropriate to their unique circumstances. It includes the right to food and to produce food, which means that all people have the right to safe, nutritious, and culturally appropriate food, and to food-producing resources and the ability to sustain themselves and their societies.

Food sovereignty also refers to the right of states to protect their population by restricting the dumping of products in their markets and through the control of the domestic market.

The notion of food sovereignty has not been invented by intellectuals. It comes from the grassroots, from peasant farmers and indigenous people in Latin America who started to reflect on the root causes of their misery and to look for a way to live a dignified life. Farmers associations in Asia took up the concept. Today farmers in Europe are threatened as well in their existence by the effects of globalization. They, too, begin to accept food sovereignty as a revolutionary alternative to the dominant neo-liberal model, which tends to look at reality exclusively from an economic and a commercial angle.

More important, the concept of 'food sovereignty' wants to integrate the welfare of people/human beings as well as/and to integrate the notions of the common good of society and ecological sustainability into concepts of the market economy.

The concept of food sovereignty is not necessarily opposed to that of food security, but it goes beyond it. Food sovereignty actually expands the focus by looking at the causes of hunger rather than concentrating only on the effects. Food sovereignty can be an alternative to the current mainstream thinking on food production. It is people-centred as it looks at people not only as consumers of food, but at active agents in the production of food.

Elements of Food Sovereignty:

There are various definitions of food sovereignty. We want to look at the definition accepted by the Forum for Food Sovereignty in Rome in 2002.

Food sovereignty is the right of people, communities, and countries to define their own agricultural, pastoral, labour, fishing, food and land policies which are ecologically, socially, economically, and culturally appropriate to their unique circumstances. It includes the right to food and to produce food, which means that all people have the right to safe, nutritious and culturally appropriate food and to food-producing resources and the ability to sustain themselves and their societies."

Let us analyse the most important elements:

The *democratic principle* (who decides what we grow and eat?):

At present the decision concerning what is grown on farms and sold in supermarkets is taken by a few powerful transnational companies, which control much of the food production and distribution. Their principle aim is to produce and sell as cheaply and as profitably as possible. The concept of food sovereignty wants to give back to states or groups of states and agricultural communities and farmers the possibility to decide what kinds of food they want to grow and how to grow it. States are to remain "sovereign" and need to have a political space in order to implement their own agricultural policies.

The *question of ownership* (who controls the means of production?):

With the advance of industrialized farming the means of production (land, water, and seed) are taken over by companies, turning farmers into underpaid slave labour or slum dwellers. In an economy of food sovereignty the state will provide small farmers with the resources needed to grow their own food. Agrarian reform and redistribution of land is the most appropriate means to achieve that. In contrast to the social-

ist model (state ownership of the means of production) and the capitalist model (the capital is owner) food sovereignty demands that it is the producers who remain in control of their resources. Food is a social and personal right.

The *right to protection*:

Today the political choices made by the multilateral institutions, like IMF and WTO tend to protect the agribusiness industry both in the North and the South, and to destroy the livelihood of millions of subsistence and family farmers by controlling the food cycle all the way from agricultural inputs and the growing of the crops to the distribution, processing, and selling of food. The dumping of heavily subsidized agricultural products onto the world market thus drives local farmers into bankruptcy. This is the very vision of agriculture that the concept of food sovereignty challenges. Not only does this practice constitute a grave injustice, it contributes to the decline in food production and to the increase of hunger, and at the same time creates mass unemployment for millions of people. Food sovereignty stipulates the right of peoples to protect themselves against dumping through protective tariffs, to retain the capacity of receiving remunerative prices for their products and so remain masters of their own way of life.

The *principle of ecological sustainability* (who can best produce healthy food without destroying the environment?):

The present system of industrial monocultures is economically efficient and profitable. Yet, for the environment it is a disaster. Biodiversity and the nutritional value of the food are reduced. The destruction of the environment for the sake of profits destroys the irreplaceable richness of animal and plant life for future generations, and is thus a crime against them. Food sovereignty favours food production through family units who produce healthy food in respect of natural processes.

Another Vision of Life, Society, and The World:

Economic models are based on ideas and a vision of human nature, of the role of society, and of the purpose of creation. The present economic philosophy sees human beings mainly as producers and consumers. The social dimension which used to be part of the 'social market-economy' is gradually eliminated. The long-term ecological cost of our way of producing, transporting, and selling our goods is completely neglected. Food sovereignty wants to come back to a holistic view of the world and integrate the different dimensions that make up our reality. Economic activities have consequences for social relations and the environment that have to be considered.

33.2.3 Survival Strategies and Livelihood

The scientific modernization theories¹⁴, the economic recipes of the neoliberal ‘Chicago School’¹⁵, and the ‘Washington Consensus’¹⁶ offered by Northern theoreticians that have been implemented by many development agencies and *international financial institutions* (IFIs), especially by the Bretton Woods organizations (WB, IMF, IFC), have failed to achieve their goals in many parts of Africa, Asia, and Latin America. The implementation of these theories by governments in Latin America is reflected in three lost decades of development, while the policies have failed to eradicate poverty and to overcome hunger. In many cases these neoliberal concepts have worsened the situation of the rural and urban poor who still experience undernourishment with all the negative human, social, economic, and cultural effects.

Due to the low income of the marginalized poor as a result of underdevelopment, economic crises, the increase of productive costs and chemical inputs, the rise of prices for basic products when crop prices collapsed, erosion of soils and scarcity as well as pollution of water, the peasants started in Latin America in the 1950’s to migrate massively to big towns. In marginal slums, they have lived with *survival strategies* (box 33.4) that are defined by Diego Palma as “a sum of initiatives able to complement the salary in terms of the reproduction of their labour force” (Palma 1986: 28). Nevertheless, the origin of the concept started with Duque and Pastrana (1973) when they described the situation of rural migrants invading urban marginal land in Chile, and started to create their new livelihood. Susana Torado included in the concept “the procreation of family life cycle and labour migrations” and named them “strategies of family life” (nd: 2), a term that was amplified by the group of Quito as “strategies of existence” (PISPAL 1978).

Thus, ‘survival strategies’ were consolidated in the socio-economic crises of Latin America, when in the

1970’s the models of capital accumulation and of import substitution as post-war strategies were exhausted and the neoliberal globalization process was reinforced. On 11 September 1973, Chile experienced first with the military coup the neoliberal imposition of the Chicago school. Argentina followed with a military coup in 1975, and many other countries in South and Central America experienced this regressive globalization combined with repression and impoverishment of large social groups.

Mexico (like Venezuela and Ecuador) seemed to be exempted from these repressive coups due to its richness in hydrocarbons, however, with the fall in oil prices, and a corrupt financial management of the governments (oil rent), elites were unable to consolidate and distribute profits, and thus crashed the ‘Mexican wonder’. Confronted with the incapacity to pay the debt service, the IMF imposed its structural adjustment policies (SAP, see figure 33. 1).

From Mexico the crisis spread all over LA, Africa, and to several Asian countries. The affected nations were obliged though draconic policies to pay back at any cost their debts, and as a consequence public support and subsidies were drastically reduced. The adjustment costs of this failed policy were transferred to the workers and peasants, and later to the middle classes, which resulted in massive unemployment, loss of *purchase power*, increasing prices of the basic food basket, the elimination of controlled prices in basic products, a growing monopoly in the trade system, and a reduced purchase power parity (PPP) (Castillo 1991; Oswald 1991; Calva 2003, 2008a; Strahm/Oswald 1990). Keynes’ limited ‘welfare state’ collapsed. Without governmental support and high inflation, only complex survival strategies integrating the whole family were able to compensate for the loss of PPP. Poverty doubled in LA¹⁷ and the structural inequality avoided an improvement for poor people (CEPAL 2005)..

Without governmental support, during this crisis situation traditional networks broke apart and women above all organized themselves to survive. After an illegal occupation of risky land in urban marginal areas, they built shelters from precarious materials (waste), picked up from landfills (Schteingart 2006; Cantú 2003; De Mattos 2003). Chronic unemployment and missing opportunities for cash obliged them to get temporary precarious jobs. Simultaneously, they sold any unnecessary goods and borrowed from family

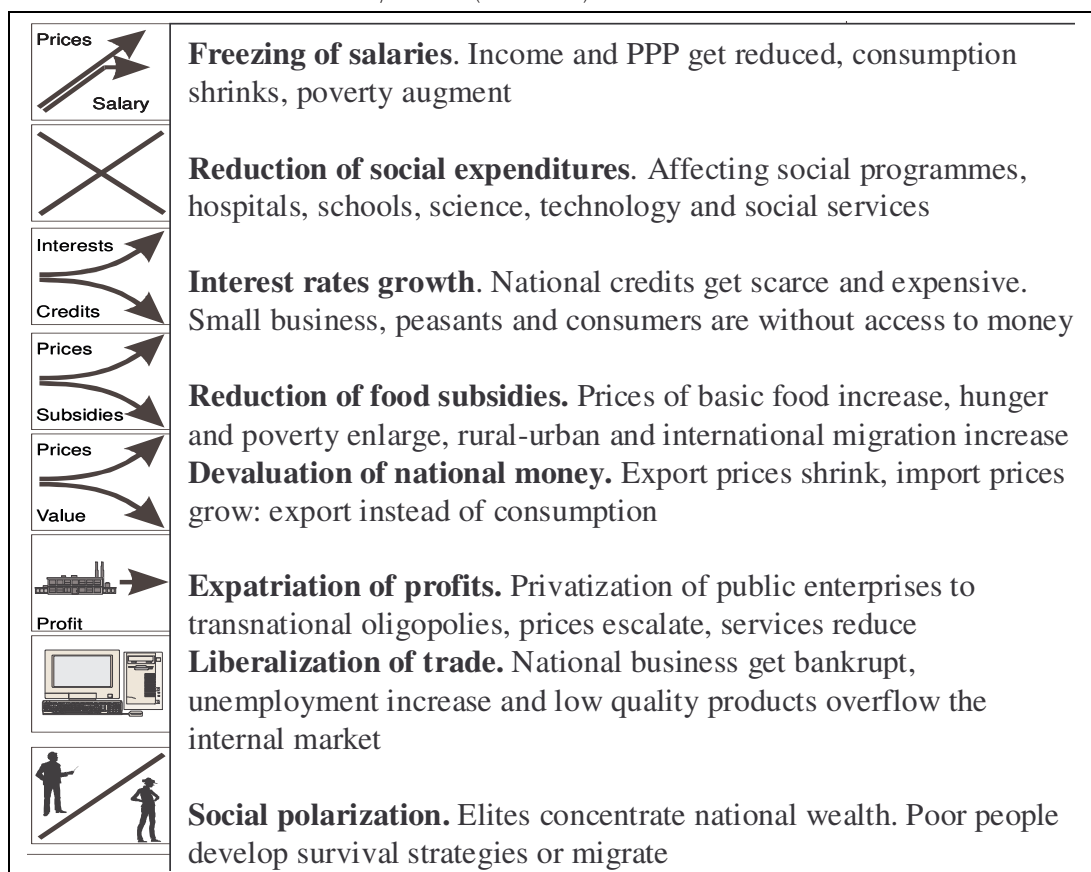

14 See references to the modernization theories and its critics in South (*dependencia*: Dos Santos 1978) and North (Sader 2005; Oswald 2008b; Shiva 2008; Saxe 2008; Dos Santos 1995; Mies 1998; Senghaas 1973).

15 See reference to Milton Friedman and the ‘Chicago school’ and its major critics (Calva 2008; Dabat 1994; Dos Santos 1993; Saxe 1999; Strahm/Oswald 1990; Omán 1994)

Figure 33.1: Conditions of the Structural Adjustment Policy (SAP) of the IMF for Debt Repayment in Developing Countries. **Source:** Strahm/Oswald (1990: 130).

members, neighbours, and from the corner shop. Soon, these possibilities disappeared due to the persistence of economic crisis, and food became scarce. Then, e.g. in Mexico City (Oswald 1991), women organized themselves, picking up half-perished products from the garbage of the central market and transformed these products into food in collective popular kitchens

Collective community work (kitchen, child rearing, pressure on public functionaries) was organized through a system of rotation. United, they fought for basic services (electricity, water, roads, security, health and community centres; Rosiques 2003) and the legalization of land and services. Due to lacking cash and jobs, they struggled also for public subsidies and poverty alleviation programmes (Ramírez 1991). Besides all these activities, women still found time for some temporary paid work as domestics, washing or ironing; others generated services, handicrafts, food selling, etc. to be able to maintain their families. Children, grandparents, and sometimes husbands supported these complex strategies, where poverty of

time was the highest cost paid by women (Damian 2002).

Furthermore, these popular colonies have not only been hazard-prone but also exposed to organized crime and gangs. Thus, only a strong social organization permitted them to fight against public insecurity, where often the police was involved in illegal activities. The sum of these complex actions empowered women, and therefore they were also able to fight against interfamilial violence. As a result these women were often abandoned by their partner, and as heads of household they had to struggle for the future of their children (INEGI 2005).

After a decade of intensive mobilization and organization, most of these quarters achieved some social and economic consolidation (Oswald 1991, 2007b), and their living conditions and livelihood improved. When they have been confronted with chronic unemployment, they integrated their micro-businesses vertically and horizontally (Cadena 2005) with popular savings banks, collective childhood, pre-

Box 33.4: Major survival strategies. **Source:** Oswald (1991, 2007b, 2008a).

These manifold survival strategies may be synthesized in the following scheme:

1. Massive rural migration to urban slums
2. Illegal occupation of marginal and risky land
3. Construction of shelter with precarious materials from waste
4. Chronic unemployment of men and lack of cash
5. Selling unnecessary goods
6. Credits from family members, neighbours, and local shops
7. Economic crises deepened and food became scarce
8. Collection of perished fruit and vegetables
9. Collective popular kitchen
10. Rotation of women in collective community work (kitchen, child rearing, paid jobs)
11. Common struggle for basic services (electricity, water, access, community centre)
12. Communal organization for the legalization of land and services
13. Struggle for public subsidies and poverty alleviation programmes
14. Temporary paid work
15. Multiple informal activities: services, handicraft, food, washing, ironing, services, prostitution
16. Social organization against organized crime and gangs
17. Empowerment and fight against interfamilial violence
18. Social and economic consolidation of the neighbourhood and the families

school attention, and collective sale of handicrafts.¹⁸ These are some of the alternatives to avoid perverse poverty and to improve their quality of life. .

In India, Bangladesh and Africa similar processes of survival strategies took place, all of them replete with criticism of the imposed liberal modernization and globalization process. "Over the past two decades every issue ... what the industrial economy calls 'growth' is really a form of theft from nature and people" (Shiva 2000: 1). After the slogan in Seattle "No new round, turnaround", she added that the real challenge is to "turn the rules of globalization and free trade around, and make trade subservient to higher values of the protection of the earth and people's livelihood" (Shiva 2000: 127). The future of the three billion impoverished people in the world lies on small farms, peasant and marginal urban livelihood, able to produce safe and culturally accepted food. This productive process is neither marginalized nor criminalized, and food sovereignty is a secure basis for regional sovereignty.

18 After five decades of development and the creation of multilateral organizations of the UN such as the FAO (Food and Agriculture Organization), WHO (World Health Organization), UNDP (UN Program of Development), UNICEF (UN Fund for Children) and UNIFEM (UN Fund for Women) among others, the achieved results are limited. Goals proposed were several times reduced, despite enormous advances in Science and Technology (S&T). During the 1980's, 35,000 died daily, a decade earlier the number was 41,000, and today the estimate is about 24,000 persons, above all children.

33.3 The State of Art of Food Security

There exists a vicious circle linking hunger and undernourishment with poverty and ignorance (figure 33.2).

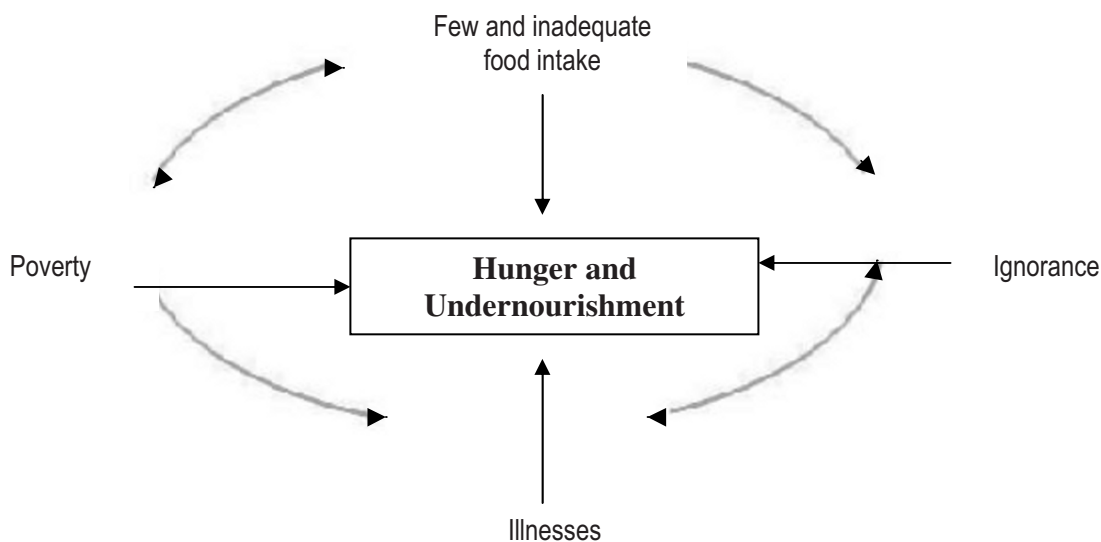

These authors analysed the food transition in the Mexican diet from traditional corn and bean intake to a modern food pattern that is rich in carbohydrates, fat and sugar, thus inducing illnesses, excess of weight, and hypertension which starts in the womb of mothers, creating chronic malnutrition and later obesity and associated epidemics. This phenomenon exists worldwide and has contributed to a deterioration of food, livelihood, and health security.

Thus, hunger is a complex interrelation where poverty is reinforced by ignorance and propaganda in the mass media, inducing people to buy junk food with their scarce money. Unhealthy food creates further health problems above all for children, limiting their brain and bone development and adversely creating modern illnesses and degenerative processes from childhood on.

33.3.1 The World

One billion persons suffer from hunger and undernourishment. Daily 24,000 persons die as a consequence of hunger; three quarters of them are children below five years. Furthermore, in half of the deaths among the 150 million undernourished children, malnutrition is the main cause. Between 1990 and 2003 undernourishment in children increased from 29 to 37 million, and only in East Asia hunger was reduced from 24 to 10 million (UN 2005a)¹⁹.

Figure 33.2: Vicious circle of hunger, undernourishment, poverty, and ignorance. **Source:** Chávez/Ávila/Shamah (2007: 208).

The FAO (2005a) estimated that there are still 468 million people suffering from hunger in poor countries, implying a loss of GDP of 30 billion dollars/year. Chronic infant undernourishment linked to a lack of iron and iodine reduces the intellectual capacity of infants by 10 to 15 per cent. Combining protein-calorie insufficiency with missing micro elements, the economic loss in poor countries affects 5 to 10 per cent of their GDP, equivalent to 500 bd/year. Regions threatened by war and internal conflicts are responsible for 10 per cent of deaths limited by famine. Nevertheless, malnutrition is basically concentrated in rural areas of poor countries and increasingly chronic undernourishment is present in urban slums, affecting also industrialized countries²⁰.

The global demand of food is estimated to increase between 70 to 85 per cent between 2000 and

2050, and simultaneously an increase of irrigation water of 15 to 35 per cent is estimated, due to an unsustainable management of aquifers. Water withdrawal is regionally limited and it will affect regions that have already today overexploited its reserves. This refers also to areas with high population growth and countries such as India, the south of the USA, and northern Mexico, Peru, to the south-east of Australia, to North Africa, Spain, the Sahel region, the Nile basin, East Africa, South Africa, Central Asia, the south of China, Pakistan and Mongolia (Millennium Ecosystem Assessment 2005). Thus, the future of food production increase is limited due to the availability of water, desertification processes, and loss of soil fertility, but also due to growing food prices since 2006 because of the promotion of biofuels. The trend towards an increasing undernourishment may grow when natural, population, and economic factors together become more urgent (figure 33.3).

In 1996, in countries with a high *human development index* (HDI) the intake was 3,347 calories (11.6 per cent more than in 1976) and 102.7 g of proteins (a 13 per cent increase); in countries with a medium HDI the intake was 2,696 calories (26.9 per cent increase) and 69.6 g of proteins (33.7 per cent increase) and in countries with low HDI the intake was 2,145 calories (1 per cent less) and 51.0 g of proteins (4.4 per cent less). Another indicator of life quality is the birth weight. In industrialized countries in 1997 seven per cent of babies had low weight, 17 per cent in countries with medium development and 20 per cent with low HDI (UNDP 1999: 172–175). According to UNDP

19 During three decades of crises, the popular sector of Mexico lost 80 per cent of its PPP and the relation of wealth between capital/work of GDP increase from 50 per cent to 85 per cent in favour of capital (Bank of Mexico 2006). This process reduced the workers' capacity to negotiate labour conditions and salaries, and the survival problems pulverized the labour struggles of a whole favor of capital.

20 In 1999, when on 1 June the rally against hunger started in the US, 31 million US citizens (12 million children) were exposed to food insecurity, meaning, they suffered from hunger or did not know how to get their next food. Hunger increased in African countries affected by war, but also in East and South Asia, and an increase of 23 million in Latin America.

Figure 33.3: Food Production, Prices, and Undernourishment. Globally an estimated 852 million people were undernourished in 2000-2002, up 37 million from the period 1997-1999. Only undernourishment in poor countries is plotted here. **Source:** FAOSTATS Millenium Ecosystem Assessment. This map is in the public domain.

(2006), still 46.8 per cent of children below 5 years were undernourished in poor countries and 14.7 per cent in medium HDI countries. These processes are

expressed in the Hunger Index summarized referred to in figure 34.4
