FOREWORD

The American Institute of Steel Construction, founded 1921, is the non-profit technical specifying and trade organization for the fabricated structural steel industry in the United States. Executive and engineering headquarters of AISC are maintained in Chicago.

The Institute is supported by four classes of membership: Active Members engaged in the fabrication, production, and sale of structural steel; Associate Members, who include Erectors, Detailers, Industry-Related Consultants, Software Developers, and Steel Product Manufacturers; Professional Members, who are individuals or firms engaged in the practice of architecture or engineering, including architectural and engineering educators; and Affiliate Members, who include General Contractors, Building Inspectors, and Code Officials. The continuing financial support and active participation of Members in the engineering, research and development activities of the Institute make possible the publishing of this *Steel Construction Manual.*

The Institute's objective is to make structural steel the material of choice, by being the leader in structural-steel-related technical and market-building activities, including: specification and code development, research, education, technical assistance, quality certification, standardization, and market development. AISC has a long tradition of service to the steel construction industry providing timely and reliable information.

To accomplish these objectives, the Institute publishes manuals, design guides, and specifications. Best known and most widely used is the *Steel Construction Manual*, which holds a highly respected position in engineering literature. Outstanding among AISC standards are the *Specification for Structural Steel Buildings* and the *Code of Standard Practice for Steel Buildings and Bridges.*

The Institute also publishes technical information and timely articles in its *Engineering Journal*, Design Guide series, *Modern Steel Construction* magazine, and other design aids, research reports, and journal articles. Almost all of the information AISC publishes is available for download from the AISC web site at www.aisc.org.

PREFACE

This Manual is the thirteenth major update of the AISC *Steel Construction Manual*, which was first published in 1927. With this revision, the previously separate Allowable Stress Design and Load and Resistance Factor Design methods have been combined. Thus, this Manual replaces both the 9th Edition ASD Manual and the 3rd Edition LRFD Manual. Much of the HSS Connections Manual has also been incorporated and updated in this Manual.

The following specifications, codes and standards are printed in Part 16 of this Manual:

- 2005 AISC *Specification for Structural Steel Buildings*
- 2004 RCSC *Specification for Structural Joints Using ASTM A325 or A490 Bolts*
- 2005 AISC *Code of Standard Practice for Steel Buildings and Bridges*

The following resources are also included on the CD included with this Manual:

- *AISC Design Examples*, which illustrates the application of tables and specification provisions that are included in this Manual.
- *AISC Shapes Database V13.0 and V13.0H*
- Background and supporting literature for the *AISC Steel Construction Manual*

The following major improvements have been made in this revision:

- The number of design examples has been expanded and included in a companion CD.
- All tabular information has been updated to comply with the *2005 Specification for Structural Buildings* and the standards and other documents referenced therein.
- Shape information has been updated to ASTM A6-05, including the new W36 shape series.
- Design methods have been delineated by making use of a dual-color format, with numbers indicated in blue type representing LRFD design values, and numbers indicated in green shading representing ASD design values. Tabulated values presented in black type are independent of design method.
- Information on HSS connections has been integrated throughout this Manual.
- W8 members have been reintegrated into design tables with cautionary statements regarding accessibility and dimensional constraints for connections made to them.
- Shapes with special design considerations, such as slenderness in compression or noncompactness in flexure, have been indicated throughout the member selection tables with footnotes.
- Workable flat dimensions of HSS members have been tabulated.
- Design properties for Pipe are now tabulated using the same wall thickness reduction factor used for HSS.
- An overview of provisions and a simplified method have been included for second-order analysis and stability requirements.
- New information has been added on corrosion protection and compatibility of dissimilar metals.
- Charts have been added for shear strength of plate girders.
- Lower-bound strengths for eccentrically loaded single angles have been tabulated.
- Tables have been added for the critical buckling stress of compression members.

- Tables for members subjected to combined axial load and bending have been expanded and improved.
- A table has been provided for calculating the strength of concentrically loaded weld groups.
- A direct calculation method has been added for calculating the buckling strength of double-coped members.
- Prying action provisions have been modified so that the tensile strength is used in the calculation rather than the yield strength.
- Beam bearing constants have been expanded to include all crippling and yielding cases.
- Revised design procedures for single-plate shear connections have been adopted, including a new design procedure for extended single-plate shear connections.
- An updated design procedure for moment end-plate connections has been adopted based upon yield-line analysis.
- The uniform force method weld ductility factor has changed from 1.4 to 1.25.
- Guidance on washer selection for anchor rods has been expanded.
- The design of bracket plates has been modified so that the plastic section modulus is used rather than the elastic section modulus.
- The AISC Design Guide Series and other supporting references have been further integrated through indexing and references to this material, where appropriate.

In addition, many other improvements have been made throughout this Manual.

By the AISC Committee on Manuals and Textbooks,

SCOPE

The dimensions and properties for structural products commonly used in steel building design and construction are given in this Part. For availability and proper material specifications for these products, as well as general specification requirements and other design considerations, see Part 2. For the design of members, see Parts 3 through 6. For the design of connections, see Parts 7 through 15. For AISC Specifications and Codes, see Part 16. For other miscellaneous information, see Part 17. For torsional and flexural-torsional properties of rolled shapes see AISC Design Guide 9, *Torsional Analysis of Structural Steel Members*. For surface areas, box perimeters and areas, *W*/*D* ratios and *A*/*D* ratios, see AISC Design Guide 19, *Fire Resistance of Structural Steel Framing*.

STRUCTURAL PRODUCTS

W-, M-, S-, and HP-Shapes

Four types of H-shaped (or I-shaped) members are covered in this Manual:

- W-shapes, which have essentially parallel inner and outer flange surfaces.
- M-shapes, which are H-shaped members that are not classified in ASTM A6 as W-, S-, or HP-shapes. M-shapes may have a sloped inside flange face or other cross-section features that do not meet the criteria for W-, S-, or HP-shapes.
- S-shapes (also known as American standard beams), which have a slope of approximately 16²/₃ percent (2 on 12) on the inner flange surfaces.
- HP-shapes (also known as bearing piles), which are similar to W-shapes, except their webs and flanges are of equal thickness and the depth and flange width are nominally equal for a given designation.

These shapes are designated by the mark W, M, S or HP, nominal depth (in.) and nominal weight (lb/ft). For example, a W24×55 is a W-shape that is nominally 24 in. deep and weighs 55 lb/ft.

The following dimensional and property information is given in this Manual for the W-, M-, S-, and HP-shapes covered in ASTM A6:

- Design dimensions, detailing dimensions, axial properties, and flexural properties are given in Tables 1–1, 1–2, 1–3, and 1–4 for W-, M-, S-, and HP-shapes, respectively.
- SI-equivalent designations are given in Table 17–1 for W-shapes and in Table 17–2 for M-, S-, and HP-shapes.

Tabulated decimal values are appropriate for use in design calculations, whereas fractional values are appropriate for use in detailing. All decimal and fractional values are similar with one exception: Because of the variation in fillet sizes used in shape production, the decimal value, k_{des}, is conservatively presented based on the smallest fillet used in production, and the fractional value, k_{det}, is conservatively presented based on the largest fillet used in production. For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

When appropriate, this Manual presents tabulated values for the Workable Gage of a section. The term Workable Gage refers to the gage for fasteners in the flange that provides for entering and tightening clearances and edge distance and spacing requirements. When the listed value is footnoted, the actual size, combination, and orientation of fastener components should be compared with the geometry of the cross-section to ensure compatibility. Other gages that provide for entering and tightening clearances and edge distance and spacing requirements can also be used.

Channels

Two types of channels are covered in this Manual:

- C-shapes (also known as American standard channels), which have a slope of approximately $16^2/_3$ percent (2 on 12) on the inner flange surfaces.
- MC-shapes (also known as miscellaneous channels), which have a slope other than $16^2/_3$ percent (2 on 12) on the inner flange surfaces.

These shapes are designated by the mark C or MC, nominal depth (in.) and nominal weight (lb/ft). For example, a C12×25 is a C-shape that is nominally 12 in. deep and weighs 25 lb/ft.

The following dimensional and property information is given in this Manual for the channels covered in ASTM A6:

- Design dimensions, detailing dimensions, and axial, flexural, and torsional properties are given in Tables 1–5 and 1–6 for C- and MC-shapes, respectively.
- SI-equivalent designations are given in Table 17–3.

For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

Angles

Angles (also known as L-shapes) have legs of equal thickness and either equal or unequal leg sizes. Angles are designated by the mark L, leg sizes (in.) and thickness (in.). For example, an L4×3×$^1/_2$ is an angle with one 4-in. leg, one 3-in. leg, and $^1/_2$-in. thickness.

The following dimensional and property information is given in this Manual for the angles covered in ASTM A6:

- Design dimensions, detailing dimensions, and axial, flexural, and flexural-torsional properties are given in Table 1–7. The effects of leg-to-leg and toe fillet radii have been considered in the determination of these section properties. Workable gages on angle legs are tabulated at the end of Table 1–7.
- SI-equivalent designations are given in Table 17–4.

For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

Structural Tees (WT-, MT-, and ST-Shapes)

Three types of structural tees are covered in this Manual:

- WT-shapes, which are made from W-shapes.
- MT-shapes, which are made from M-shapes.
- ST-shapes, which are made from S-shapes.

These shapes are designated by the mark WT, MT, or ST, nominal depth (in.) and nominal weight (lb/ft). WT-, MT-, and ST-shapes are split (sheared or thermal-cut) from W-, M-, and S-shapes, respectively, and have half the nominal depth and weight of that shape. For example, a WT12×27.5 is a structural tee split from a W-shape (W24×55), is nominally 12 in. deep and weighs 27.5 lb/ft. Although off-center splitting or splitting on two lines can be obtained by special order, the resulting nonstandard shape is not covered in this Manual.

The following dimensional and property information is given in this Manual for the structural tees cut from the W-, M-, and S-shapes covered in ASTM A6:

- Design dimensions, detailing dimensions, and axial, flexural, and torsional properties are given in Tables 1–8, 1–9, and 1–10 for WT-, MT-, and ST-shapes, respectively.
- SI-equivalent designations are given in Table 17–5 for WT-shapes and in Table 17–6 for MT- and ST-shapes.

For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

Hollow Structural Sections (HSS)

Three types of HSS are covered in this Manual:

- Rectangular HSS, which have an essentially rectangular cross-section, except for rounded corners, and uniform wall thickness, except at the weld seam(s).
- Square HSS, which have an essentially square cross-section, except for rounded corners, and uniform wall thickness, except at the weld seam(s).
- Round HSS, which have an essentially round cross-section and uniform wall thickness, except at the weld seam(s).

In each case, ASTM A500 covers only electric-resistance-welded (ERW) HSS with a maximum periphery of 64 in. The coverage of HSS in this Manual is similarly limited.

Rectangular HSS are designated by the mark "HSS," overall outside dimensions (in.), and wall thickness (in.), with all dimensions expressed as fractional numbers. For example, an HSS10×10×1/2 is nominally 10 in. by 10 in. with a 1/2-in. wall thickness. Round HSS are designated by the term "HSS," nominal outside diameter (in.) and wall thickness (in.) with both dimensions expressed to three decimal places. For example, an HSS10.000×0.500 is nominally 10 in. in diameter with a 1/2-in. nominal wall thickness.

Per AISC Specification Section B3.12, the wall thickness used in design, t_{des}, is taken as 0.93 times the nominal wall thickness, t_{nom}. The rationale for this requirement is explained in the corresponding Commentary Section B3.12.

In calculating the tabulated b/t and h/t ratios, the outside corner radii are taken as $1.5t_{des}$ for rectangular and square HSS, per AISC Specification Section B4.2. In other tabulated design dimensions, the corner radii are taken as $2t_{des}$. In the tabulated workable flat dimensions of rectangular (and square) HSS, the outside corner radii are taken as $2.25t_{nom}$. The term Workable Flat refers to a reasonable flat width or depth of material for use in making connections to HSS. The workable flat dimension is provided as a reflection of current industry practice, although the tolerances of ASTM A500 allow a greater maximum corner radius of $3t_{des}$.

The following dimensional and property information is given in this Manual for the HSS covered in ASTM A500, A501, A618 or A847:

- Design dimensions, detailing dimensions, and axial, strong-axis flexural, weak-axis flexural, torsional and flexural-torsional properties are given in Tables 1–11 and 1–12 for rectangular and square HSS, respectively.
- Design dimensions, detailing dimensions, and axial, flexural, and torsional properties are given in Table 1–13 for round HSS.
- SI-equivalent designations are given in Tables 17–7, 17–8, and 17–9 for rectangular, square, and round HSS, respectively.

For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

Pipe

Pipes have an essentially round cross-section and uniform thickness, except at the weld seam(s) for welded pipe.

Pipes up to and including NPS 12 are designated by the term "Pipe," nominal diameter (in.) and weight class (Std., x-strong, xx-strong). NPS stands for "nominal pipe size." For example, Pipe 5 Std. denotes a pipe with a 5-in. nominal diameter and a 0.258-in. wall thickness, which corresponds to the standard weight series. Pipes with wall thicknesses that do not correspond to the foregoing weight classes are designated by the term "Pipe," outside diameter (in.), and wall thickness (in.) with both expressed to three decimal places. For example, Pipe 14.000×0.375 and Pipe 5.563×0.500 are proper designations.

Per AISC Specification Section B3.12, the wall thickness used in design, t_{des}, is taken as 0.93 times the nominal wall thickness, t_{nom}. The rationale for this requirement is explained in the corresponding Commentary Section B3.12.

The following dimensional and property information is given in this Manual for the pipes covered in ASTM A53:

- Design dimensions, detailing dimensions, and axial, flexural, and torsional properties are given in Table 1–14.
- SI-equivalent designations are given in Table 17–10.

For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

Double Angles

Double angles (also known as 2L-shapes) are made with two angles that are interconnected through their back-to-back legs along the length of the member, either in contact for the full length or separated by spacers at the points of interconnection.

These shapes are designated by the mark 2L, the sizes and thickness of their legs (in.), and their orientation when the angle legs are not of equal size (LLBB or SLBB).[1] For example, a 2L4×3×$^1/_2$ LLBB has two angles with one 4-in. leg and one 3-in. leg and the 4-in. legs are back-to-back; a 2L4×3×$^1/_2$ SLBB is similar, except the 3-in. legs are back-to-back. In both cases, the legs are $^1/_2$ in. thick.

---

[1] LLBB stands for long legs back-to-back. SLBB stands for short legs back-to-back. Alternatively, the orientations LLV and SLV, which stand for long legs vertical and short legs vertical, respectively, can be used.

The following dimensional and property information is given in this Manual for the double angles built-up from the angles covered in ASTM A6:

- Design dimensions, detailing dimensions, and axial, strong-axis flexural, weak-axis flexural, torsional, and flexural-torsional properties are given in Table 1–15 for equal-leg, LLBB and SLBB angles. In each case, angle separations of zero in., 3/8 in., and 3/4 in. are covered. The effects of leg-to-leg and toe fillet radii have been considered in the determination of these section properties. For workable gages on legs of angles, see Table 1–7.

For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

Double Channels

Double channels (also known as 2C- and 2MC-shapes) are made with two channels that are interconnected through their back-to-back webs along the length of the member, either in contact for the full length or separated by spacers at the points of interconnection.

These shapes are designated by the mark 2C or 2MC, nominal depth (in.), and nominal weight per channel (lb/ft). For example, a 2C12×25 is a double channel that consists of two channels that are each nominally 12 in. deep and each weigh 25 lb/ft.

The following dimensional and property information is given in this Manual for the double channels built-up from the channels covered in ASTM A6:

- Design dimensions, detailing dimensions, and axial, strong-axis flexural, and weak-axis flexural properties are given in Tables 1–16 and 1–17 for 2C- and 2MC-shapes, respectively. In each case, channel separations of zero, 3/8 in., and 3/4 in. are covered.

For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

W-Shapes and S-Shapes with Cap Channels

Common combined sections made with W- or S-shapes and channels (C- or MC-shapes) are tabulated in this Manual. In either case, the channel web is interconnected to the W-shape or S-shape top flange, respectively, with the flange toes down. The interconnection of the two elements must be designed for the horizontal shear, q, where

$$q = \frac{VQ}{I}$$

where

q = horizontal shear, kips/in.
V = vertical shear, kips.
Q = first moment of the channel area about the neutral axis of the combined cross section, in.^{3}
I = moment of inertia of the combined cross-section, in.^{4}

The effects of other forces, such as crane horizontal and lateral forces, may also require consideration, when applicable.

The following dimensional and property information is given in this Manual for combined sections, built-up from the W-shapes, S-shapes, and cap channels covered in ASTM A6:

- Design dimensions, detailing dimensions, and axial, strong-axis flexural and weak-axis flexural properties of W-shapes with cap channels are given in Table 1–19.
- Design dimensions, detailing dimensions, and axial, strong-axis flexural and weak-axis flexural properties of S-shapes with cap channels are given in Table 1–20.

For the definitions of the tabulated variables, refer to the Nomenclature section at the back of this Manual.

Plate Products

Plate products may be ordered as sheet, strip, or bar material. Sheet and strip are distinguished from structural bars and plates by their dimensional characteristics, as outlined in Table 2–2.

The historical classification system for structural bars and plates suggests that there is only a physical difference between them based upon size and production procedure. In raw form, flat stock has historically been classified as a bar if it is less than or equal to 8 in. wide and as a plate if it is greater than 8 in. wide. Bars are rolled between horizontal and vertical rolls and trimmed to length by shearing or thermal cutting on the ends only. Plates are generally produced using one of two methods:

1. Sheared plates are rolled between horizontal rolls and trimmed to width and length by shearing or thermal cutting on the edges and ends; or
2. Stripped plates are sheared or thermal cut from wider sheared plates.

There is very little, if any, structural difference between plates and bars. Consequently, the term “plate” is becoming a universally applied term today and a PL$^1/_2$×4$^1/_2$×1′-3″, for example, might be fabricated from plate or bar stock.

For structural plates, the preferred practice is to specify thickness in $^1/_{16}$-in. increments up to $^3/_8$-in. thickness, $^1/_8$-in. increments over $^3/_8$-in. to 1-in. thickness, and $^1/_4$-in. increments over 1-in. thickness. The current extreme widths for sheared plates is 200 in. Because mill practice regarding plate widths vary, individual mills should be consulted to determine preferences.

For bars, the preferred practice is to specify width in $^1/_4$-in. increments, and thickness and diameter in $^1/_8$-in. increments.

Raised-Pattern Floor Plates

Weights of raised-pattern floor plates are given in Table 1–18. Raised-pattern floor plates are commonly available in widths up to 120 in. For larger plate widths, see literature available from floor plate producers.

Crane Rails

Although crane rails are not listed as structural steel in Code of Standard Practice Section 2.1, this information is provided because some fabricators may choose to provide crane rails. Crane rails are designated by unit weight in lb/yard. Dimensions and properties for the crane rails shown are given in Table 1–21. Crane rails can be either heat treated or end hardened to reduce wear. For additional information or for profiles and properties of crane rails not listed, manufacturer’s catalogs should be consulted. For crane-rail connections, see Part 15.

Other Structural Products

The following other structural products are covered in this Manual as indicated:

- High-strength bolts, common bolts, washers, nuts, and direct-tension-indicator washers are covered in Part 7.
- Welding filler metals and fluxes are covered in Part 8.
- Forged steel structural hardware items, such as clevises, turnbuckles, sleeve nuts, recessed-pin nuts, and cotter pins are covered in Part 15.
- Anchor rods and threaded rods are covered in Part 14.

STANDARD MILL PRACTICES

The production of structural products is subject to unavoidable variations relative to the theoretical dimensions and profiles, due to many factors, including roll wear, roll dressing practices, and temperature effects. Such variations are limited by the dimensional and profile tolerances as summarized below.

Hot-Rolled Structural Shapes

Acceptable dimensional tolerances for hot-rolled structural shapes (W-, M-, S-, and HP-shapes), channels (C- and MC-shapes), and angles are given in ASTM A6 Section 13 and summarized in Tables 1–22 through 1–26. Supplementary information, including permissible variations for sheet and strip and for other grades of steel, can also be found in literature from steel plate producers and the Association of Iron and Steel Technology.

Hollow Structural Sections

Acceptable dimensional tolerances for HSS are given in ASTM A500 Section 10, A501 Section 11, A618 Section 8, or A847 Section 10, as applicable, and summarized in Tables 1–27 and 1–28, for rectangular and round HSS, respectively. Supplementary information can also be found in literature from HSS producers and the Steel Tube Institute, such as *Recommended Methods to Check Dimensional Tolerances on Hollow Structural Sections (HSS) Made to ASTM A500.*

Pipe

Acceptable dimensional tolerances for pipes are given in ASTM A53 Section 12 and summarized in Table 1–28. Supplementary information can also be found in literature from pipe producers.

Plate Products

Acceptable dimensional tolerances for plate products are given in ASTM A6 Section 13 and summarized in Table 1–29. Note that plate thickness can be specified in inches or by weight per square foot, and separate tolerances apply to each method. No decimal edge thickness can be assured for plate specified by the latter method. Supplementary information, including permissible variations for sheet and strip and for other grades of steel, can also be found in literature from steel plate producers and the Association of Iron and Steel Technology.

[c] Shape is slender for compression with $F_y = 50$ ksi.

[h] Flange thickness greater than 2 in. Special requirements may apply per AISC Specification Section A3.1c.

[v] Shape does not meet the h/t_w limit for shear in Specification Section G2.1a with $F_y = 50$ ksi.

[c] Shape is slender for compression with $F_y = 50$ ksi.

[g] The actual size, combination, and orientation of fastener components should be compared with the geometry of the cross-section to ensure compatibility.

[h] Flange thickness greater than 2 in. Special requirements may apply per AISC Specification Section A3.1c.

[v] Shape does not meet the h/t_w limit for shear in Specification Section G2.1a with $F_y = 50$ ksi.

[c] Shape is slender for compression with $F_y = 50$ ksi.

[g] The actual size, combination, and orientation of fastener components should be compared with the geometry of the cross-section to ensure compatibility.

[h] Flange thickness greater than 2 in. Special requirements may apply per AISC Specification Section A3.1c.

[v] Shape does not meet the h/t_w limit for shear in Specification Section G2.1a with $F_y = 50$ ksi.

[c] Shape is slender for compression with $F_y = 50$ ksi.

[f] Shape exceeds compact limit for flexure with $F_y = 50$ ksi.

[g] The actual size, combination, and orientation of fastener components should be compared with the geometry of the cross-section to ensure compatibility.

[h] Flange thickness greater than 2 in. Special requirements may apply per AISC Specification Section A3.1c.

[c] Shape is slender for compression with $F_y = 50$ ksi.

[f] Shape exceeds compact limit for flexure with $F_y = 50$ ksi.

[g] The actual size, combination, and orientation of fastener components should be compared with the geometry of the cross-section to ensure compatibility.

[h] Flange thickness greater than 2 in. Special requirements may apply per AISC Specification Section A3.1c.

[c] Shape is slender for compression with F_y = 50 ksi.
[f] Shape exceeds compact limit for flexure with F_y = 50 ksi.
[g] The actual size, combination, and orientation of fastener components should be compared with the geometry of the cross-section to ensure compatibility.
[v] Shape does not meet the h/t_w limit for shear in Specification Section G2.1a with F_y = 50 ksi.

[c] Shape is slender for compression with $F_y = 36$ ksi.

[f] Shape exceeds compact limit for flexure with $F_y = 36$ ksi.

[g] The actual size, combination, and orientation of fastener components should be compared with the geometry of the cross-section to ensure compatibility.

[t] Shape has tapered flanges while other M-shapes have parallel flange surfaces.

[v] Shape does not meet the h/t_w limit for shear in Specification Section G2.1b(i) with $F_y = 36$ ksi.

— Flange is too narrow to establish a workable gage.

[c] Shape is slender for compression with F_y = 36 ksi.

[g] The actual size, combination, and orientation of fastener components should be compared with the geometry of the cross-section to ensure compatibility.

— Flange is too narrow to establish a workable gage.

[c] Shape is slender for compression with $F_y = 50$ ksi.

[h] Flange thickness greater than 2 in. Special requirements may apply per Specification Section A3.1c.

[v] Shear strength controlled by buckling effects ($C_v < 1.0$) with $F_y = 50$ ksi.

[c] Shape is slender for compression with $F_y = 50$ ksi.
[h] Flange thickness greater than 2 in. Special requirements may apply per Specification Section A3.1c.
[v] Shear strength controlled by buckling effects ($C_v < 1.0$) with $F_y = 50$ ksi.

[c] Shape is slender for compression with $F_y = 50$ ksi.

[g] The actual size, combination, and orientation of fastener components should be compared with the geometry of the cross-section to ensure compatibility.

[h] Flange thickness greater than 2 in. Special requirements may apply per Specification Section A3.1c.

[v] Shear strength controlled by buckling effects ($C_v < 1.0$) with $F_y = 50$ ksi.

[c] Shape is slender for compression with $F_y = 50$ ksi.

[f] Shape exceeds compact limit for flexure with $F_y = 50$ ksi.

[g] The actual size, combination, and orientation of fastener components should be compared with the geometry of the cross-section to ensure compatibility.

[h] Flange thickness greater than 2 in. Special requirements may apply per Specification Section A3.1c.

[v] Shear strength controlled by buckling effects ($C_v < 1.0$) with $F_y = 50$ ksi.

[c] Shape is slender for compression with $F_y = 50$ ksi.

[g] The actual size, combination, and orientation of fastener components should be compared with the geometry of the cross-section to ensure compatibility.

[h] Flange thickness greater than 2 in. Special requirements may apply per Specification Section A3.1c.

[v] Shear strength controlled by buckling effects ($C_v < 1.0$) with $F_y = 50$ ksi.

[c] Shape is slender for compression with $F_y = 50$ ksi.
[f] Shape exceeds compact limit for flexure with $F_y = 50$ ksi.
[g] The actual size, combination, and orientation of fastener components should be compared with the geometry of the cross-section to ensure compatibility.
[h] Flange thickness greater than 2 in. Special requirements may apply per Specification Section A3.1c.

[c] Shape is slender for compression with $F_y = 50$ ksi.
[f] Shape exceeds compact limit for flexure with $F_y = 50$ ksi.
[g] The actual size, combination, and orientation of fastener components should be compared with the geometry of the cross-section to ensure compatibility.
[h] Flange thickness greater than 2 in. Special requirements may apply per Specification Section A3.1c.
[v] Shear strength controlled by buckling effects ($C_v < 1.0$) with $F_y = 50$ ksi.

[c] Shape is slender for compression with $F_y = 50$ ksi.

[f] Shape exceeds compact limit for flexure with $F_y = 50$ ksi.

[g] The actual size, combination, and orientation of fastener components should be compared with the geometry of the cross-section to ensure compatibility.

[c] Shape is slender for compression with F_y = 36 ksi.
[f] Shape exceeds compact limit for flexure with F_y = 36 ksi.
[g] The actual size, combination, and orientation of fastener components should be compared with the geometry of the cross-section to ensure compatibility.
[t] This shape has tapered flanges while all other MT-shapes have parallel flange surfaces.
[v] Shape does not meet the h/t_w limit for shear in Specification Section G2.1a with F_y = 36 ksi.
— Flange is too narrow to establish a workable gage.

[c] Shape is slender for compression with $F_y = 36$ ksi

[g] The actual size, combination and orientation of fastener components should be compared with the geometry of the cross-section to ensure compatibility.

— Flange is too narrow to establish a workable gage.

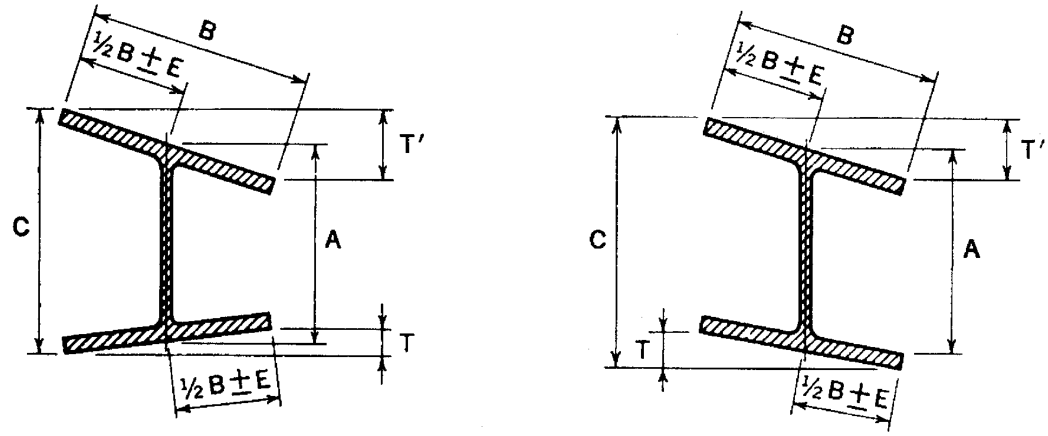
Table 1–22
ASTM A6 Tolerances for W Shapes and HP Shapes



Permissible Cross-Sectional Variations

Nominal Depth, in.	*A* Depth at Web Centerline, in.		*B* Flange Width, in.		*T* + *T′* Flanges Out of Square, Max. in.	*E*[a] Web Off Center, in.	*C*, Max. Depth at any Cross-Section over Theoretical Depth, in.
	Over	Under	Over	Under			
To 12, incl.	1/8	1/8	1/4	3/16	1/4	3/16	1/4
Over 12	1/8	1/8	1/4	3/16	5/16	3/16	1/4

Permissible Variations in Length

Nominal Depth[b], in.	Variations from Specified Length for Lengths Given, in.			
	30 ft and Under		Over 30 ft	
	Over	Under	Over	Under
Beams 24 in. and under	3/8	3/8	3/8 plus 1/16 for each additional 5 ft or fraction thereof	3/8
Beams over 24 in. All columns	1/2	1/2	1/2 plus 1/16 for each additional 5 ft or fraction thereof	1/2

Mill Straightness Tolerances[c]

Sizes	Length	Permissible Variation from Straight, in.	
		Camber	Sweep
Flange width equal to or greater than 6 in.	All	$\frac{1}{8}\text{ in.} \times \frac{\text{(total length, ft)}}{10}$	
Flange width less than 6 in.	All	$\frac{1}{8}\text{ in.} \times \frac{\text{(total length, ft)}}{10}$	$\frac{1}{8}\text{ in.} \times \frac{\text{(total length, ft)}}{5}$
Certain sections with a flange width approx. equal to depth & specified on order as columns[d]	45 ft and under	$\frac{1}{8}\text{ in.} \times \frac{\text{(total length, ft)}}{10}$ with $\frac{3}{8}$ in. max.	
	Over 45 ft	$\frac{3}{8}\text{ in.} + \left[\frac{1}{8}\text{ in.} \times \frac{\text{(total length, ft} - 45)}{10}\right]$	

Other Permissible Rolling Variations

Area and Weight	± 2.5 percent theoretical or specified amount.
Ends Out of Square	1/64 in., per in. of depth, or of flange width if it is greater than the depth.

[a] Variation of 5/16 in. max. for sections over 426 lb/ft.

[b] For shapes specified in the order for use as bearing piles, the permitted variations are plus 5 in. and minus 0 in.

[c] The tolerances herein are taken from ASTM A6 and apply to the straightness of members received from the rolling mill, measured as illustrated in Figure 1–1. For tolerance on induced camber and sweep, see Code of Standard Practice Section 6.4.4.

[d] Applies only to W8×31and heavier, W10×49 and heavier, W12×65 and heavier, W14×90 and heavier, HP8×36, HP10×57, HP12×74 and heavier, and HP14×102 and heavier. If other sections are specified on the order as columns, the tolerance will be subject to negotiation with the manufacturer.

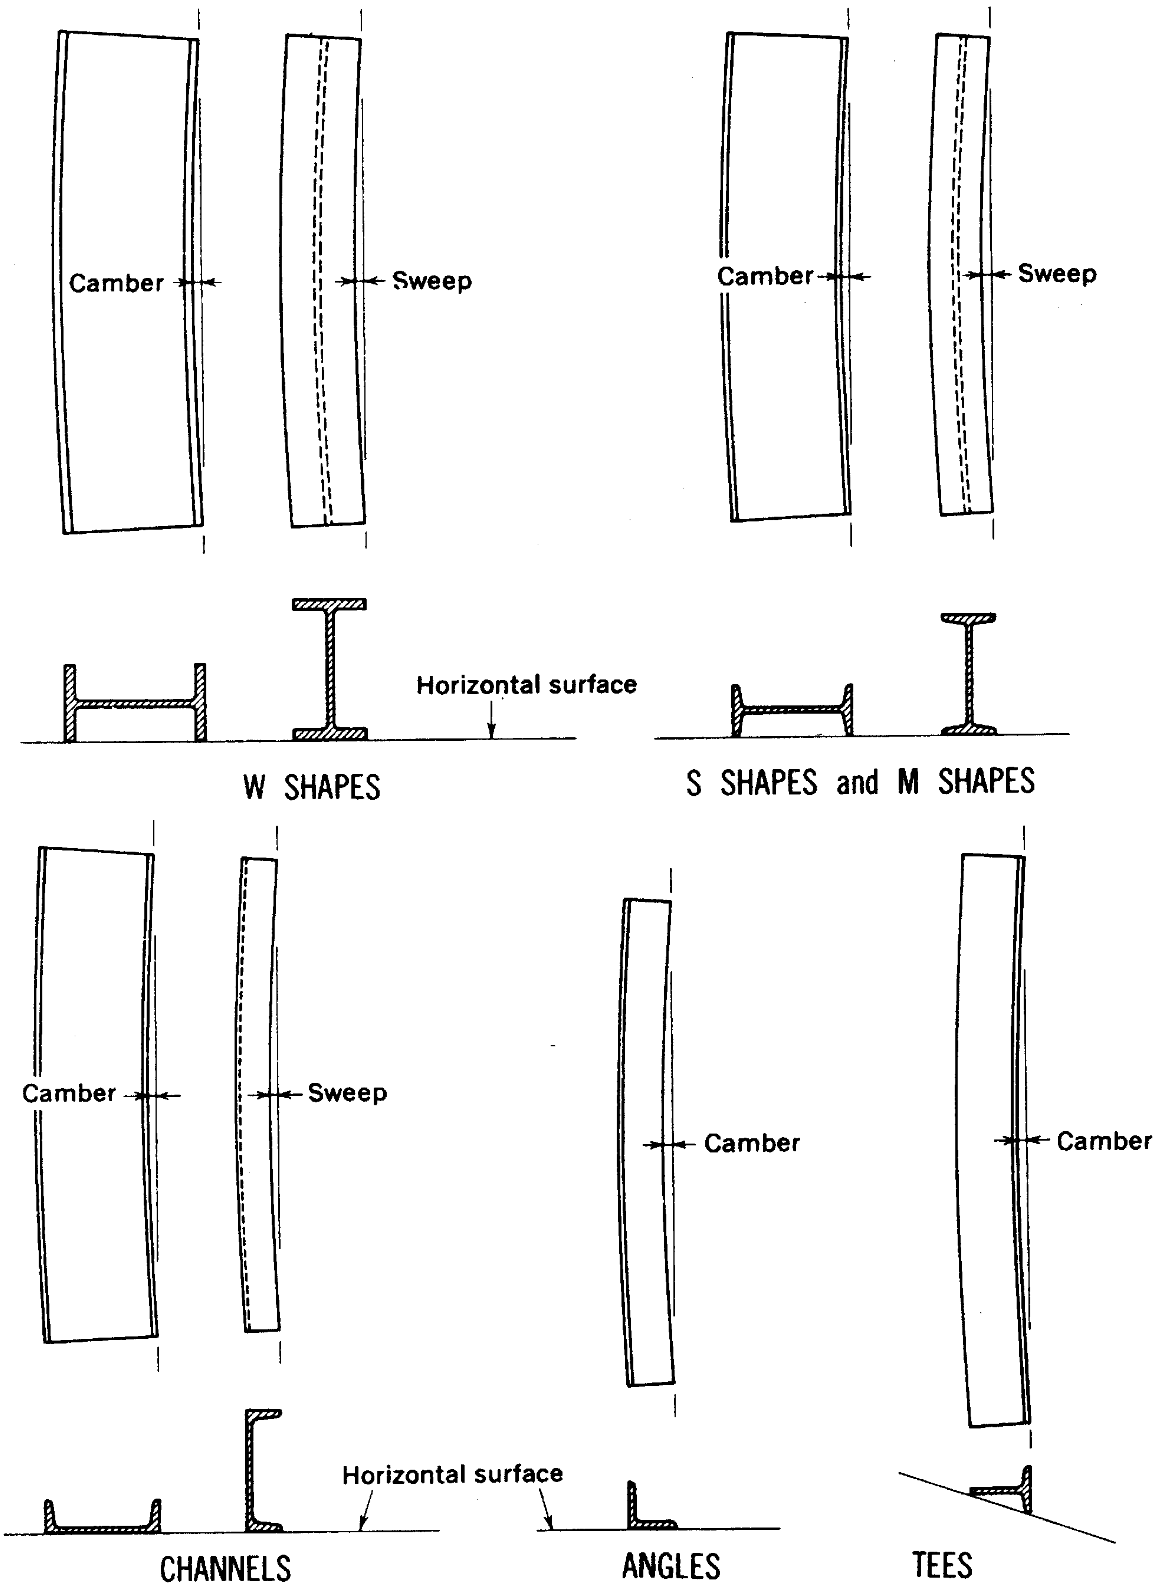


Figure 1–1. Positions for Measuring Straightness.

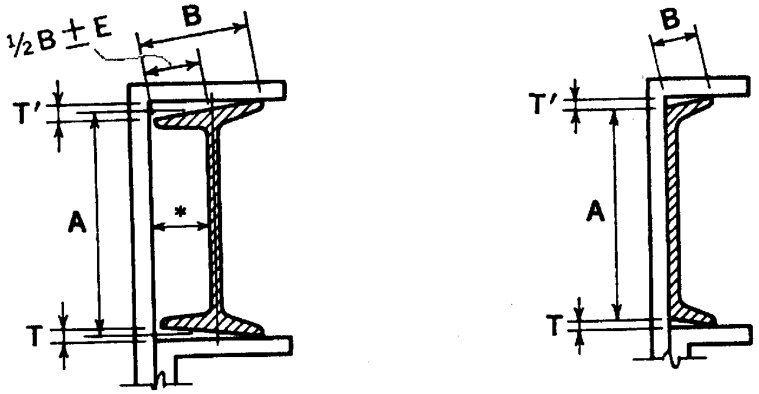
Table 1–23
ASTM A6 Tolerances for S Shapes, M Shapes, and Channels



*Back of square and centerline of web to be parallel when measuring "out-of-square"

Permissible Cross-Sectional Variations

Shape	Nominal Depth, in.	A[a] Depth, in.		B Flange Width, in.		T + T′[b] Flanges Out of Square, per in. of B, in.	E Web Off Center, in.
		Over	Under	Over	Under		
S shapes and M shapes	3 to 7, incl.	3/32	1/16	1/8	1/8	1/32	3/16
	Over 7 to 14, incl.	1/8	3/32	5/32	5/32		
	Over 14 to 24, incl.	3/16	1/8	3/16	3/16		
Channels	3 to 7, incl.	3/32	1/16	1/8	1/8	1/32	—
	Over 7 to 14, incl.	1/8	3/32	1/8	5/32		
	Over 14	3/16	1/8	1/8	3/16		

Permissible Variations in Length

Shape	Variations from Specified Length for Lengths Given[c], in.					
	5 to 10 ft, excl.	10 to 20 ft, excl.	20 to 30 ft, incl.	Over 30 to 40 ft, incl.	Over 40 to 65 ft, incl.	Over 65 ft
All	1	1 1/2	1 3/4	2 1/4	2 3/4	—

Mill Straightness Tolerances[d]

Camber	$\frac{1}{8}\text{ in.} \times \frac{\text{(total length, ft)}}{10}$
Sweep	Due to the extreme variations in flexibility of these shapes, permitted variations for sweep are subject to negotiation between the manufacturer and purchaser for the individual sections involved.

Other Permissible Rolling Variations

Area and Weight	± 2.5 percent theoretical or specified amount.
Ends Out of Square	S Shapes, M Shapes and Channels 1/64 in., per in. of depth.

— Indicates that there is no requirement.

[a] A is measured at center line of web for beams and at back of web for channels.

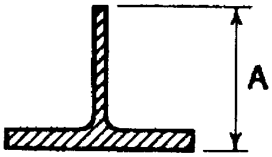
[b] T + T′ applies when flanges of channels are toed in or out.

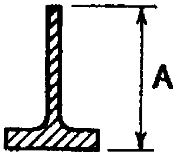
[c] The permitted variation under the specified length is 0 in. for all lengths. There are no requirements for lengths over 65 ft.

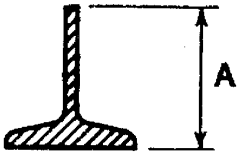
[d] The tolerances herein are taken from ASTM A6 and apply to the straightness of members received from the rolling mill, measured as illustrated in Figure 1–1. For tolerance on induced camber and sweep, see Code of Standard Practice Section 6.4.4.

Table 1–24

ASTM A6 Tolerances for WT, MT, and ST Shapes







Permissible Variations in Depth

Dimension A may be approximately one-half beam depth or any dimension resulting from off-center splitting or splitting on two lines, as specified in the order.

Depth of Shape from which Tee is Split, in.	Variations in Depth A, Over and Under
To 6, excl.	$^1/_8$
6 to 16, excl.	$^3/_{16}$
16 to 20, excl.	$^1/_4$
20 to 24, excl.	$^5/_{16}$
24 and over	$^3/_8$

The above variations in depths of tees include the permissible variations in depth for the beams before splitting

Mill Straightness Tolerances[a]

Camber and Sweep	$^1/_8$ in. × $\frac{\text{(total length, ft)}}{5}$

Other Permissible Rolling Variations

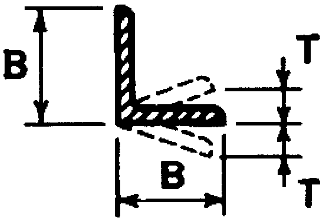
Other permissible variations in cross section as well as permissible variations in length, area, weight, ends out-of-square, and sweep will correspond to those of the beam before splitting.

— Indicates that there is no requirement.

[a] The tolerances herein are taken from ASTM A6 and apply to the straightness of members received from the rolling mill, measured as illustrated in Figure 1–1. For tolerance on induced camber and sweep, see Code of Standard Practice Section 6.4.4.

Table 1–25

ASTM A6 Tolerances for Angles, Structural Size



Permissible Cross-Sectional Variations

Shape	Nominal Leg Size[a], in.	*B* Leg Size, in.		*T* Out of Square per in. of *B*, in.
		Over	Under	
Angles	3 to 4, incl.	1/8	3/32	3/128[b]
	Over 4 to 6, incl.	1/8	1/8	
	Over 6	3/16	1/8	

Permissible Variations in Length

Variations Over Specified Length for Lengths Given[c], in.

5 to 10 ft, excl.	10 to 20 ft, excl.	20 to 30 ft, incl.	Over 30 to 40 ft, incl.	Over 40 to 65 ft, incl.
1	1 1/2	1 3/4	2 1/4	2 3/4

Mill Straightness Tolerances[d]

Camber	$\frac{1}{8}$ in. × $\frac{\text{(total length, ft)}}{5}$, applied to either leg
Sweep	Due to the extreme variations in flexibility of these shapes, permitted variations for sweep are subject to negotiation between the manufacturer and purchaser for the individual sections involved.

Other Permissible Rolling Variations

Area and Weight	± 2.5 percent theoretical or specified amount.
Ends Out of Square	3/128 in. per in. of leg length, or 1 1/2 degrees. Variations based on the longer leg of unequal angle.

[a] For unequal leg angles, longer leg determines classification.

[b] 3/128 in. per in. = 1 1/2 degrees.

[c] The permitted variation under the specified length is 0 in. for all lengths. There are no requirements for lengths over 65 ft.

[d] The tolerances herein are taken from ASTM A6 and apply to the straightness of members received from the rolling mill, measured as illustrated in Figure 1–1. For tolerance on induced camber and sweep, see Code of Standard Practice Section 6.4.4.

Table 1–26
ASTM A6 Tolerances for Angles, Bar Size[a]

Permissible Cross-Sectional Variations

Specified Leg Size[b], in.	Variations in Thickness for Thicknesses Given, Over and Under, in.			*B* Leg Size, Over and Under, in.	*T* Out of Square per Inch of *B*, in.
	3/16 and Under	Over 3/16 to 3/8 incl.	Over 3/8		
1 and Under	0.008	0.010	—	1/32	3/128[c]
Over 1 to 2, incl.	0.010	0.010	0.012	3/64	
Over 2 to 3, excl.	0.012	0.015	0.015	1/16	

Permissible Variations in Length

Section	Variations Over Specified Length for Lengths Given[d], in.				
	5 to 10 ft, excl.	10 to 20 ft, excl.	20 to 30 ft, incl.	Over 30 to 40 ft, incl.	40 to 65 ft, incl.
All bar-size angles	5/8	1	1 1/2	2	2 1/2

Mill Straightness Tolerances[e]

Camber	1/4 in. in any 5 ft, or 1/4 in. × $\frac{(\text{total length, ft})}{5}$, applied to either leg
Sweep	Due to the extreme variations in flexibility of these shapes, permitted variations for sweep are subject to negotiation between the manufacturer and purchaser for the individual sections involved.

Other Permissible Rolling Variations

Ends Out of Square	3/128 in. per in. of leg length, or 1 1/2 degrees. Variations based on the longer leg of unequal angle.

— Indicates that there is no requirement.

[a] A member is "bar size" when its greatest cross-sectional dimension is less than 3 inches.

[b] For unequal angles, longer leg determines classification.

[c] 3/128 in. per in. = 1 1/2 degrees.

[d] The permitted variation under the specified length is 0 in. for all lengths. There are no requirements for lengths over 65 ft.

[e] The tolerances herein are taken from ASTM A6 and apply to the straightness of members received from the rolling mill, measured as illustrated in Figure 1–1. For tolerance on induced camber and sweep, see Code of Standard Practice Section 6.4.4.

Notes:

1. The longer dimension specified is considered the length, and permissible variations in flatness along the length should not exceed the tabular amount for the specified width in plates up to 12 ft in length, or in any 12 ft for longer plates.
2. The flatness variations across the width should not exceed the tabular amount for the specified width.
3. When the longer dimension is under 36 in., the permissible variation should not exceed 1/4 in. When the longer dimension is from 36 to 72 in., inclusive, the permissible variation should not exceed 75 percent of the tabular amount for the specified width, but in no case less than 1/4 in.
4. These variations apply to plates which have a specified minimum tensile strength of not more than 60 ksi or comparable chemistry or hardness. The limits in the table are increased 50 percent for plates specified to a higher minimum tensile strength or comparable chemistry or hardness.
5. For plates 8 in. and over in thickness or 120 in. and over in width, see ASTM A6 Table 13.

Permissible Variations in Camber[a] for Carbon Steel Sheared and Gas Cut Rectangular Plates

Maximum permissible camber, in. (all thicknesses) = $\frac{1}{8}\text{ in.} \times \frac{\text{(total length, ft)}}{5}$

Permissible Variations in in Camber[a] for High-Strength Low-Alloy and Alloy Steel Sheared, Special-Cut, or Gas-Cut Rectangular Plates

Dimension, in.		Camber for Thicknesses and Widths Given
Thickness	Width	
To 2, incl.	All	$\frac{1}{8}\text{ in.} \times \frac{\text{(total length, ft)}}{5}$
Over 2 to 15, incl.	To 30, incl.	$\frac{3}{16}\text{ in.} \times \frac{\text{(total length, ft)}}{5}$
	Over 30 to 60, incl.	$\frac{1}{4}\text{ in.} \times \frac{\text{(total length, ft)}}{5}$

[a] Camber as it relates to plates is the horizontal edge curvature in the length, measured over the entire length of the plate in the flat position.

SCOPE

The specification requirements and other design considerations summarized in this Part apply in general to the design and construction of steel buildings. For seismic force resisting systems in which the seismic response modification factor, R, is taken greater than 3, the requirements in the AISC *Seismic Provisions for Structural Steel Buildings* also apply. The AISC *Seismic Provisions for Structural Steel Buildings* is available in Part 6 of the AISC *Seismic Design Manual* from the American Institute of Steel Construction, Inc. at www.aisc.org.

APPLICABLE SPECIFICATIONS, CODES, AND STANDARDS

Specifications, Codes, and Standards for Structural Steel Buildings

Subject to the requirements in the applicable building code and the contract documents, the design, fabrication, and erection of structural steel buildings is governed as indicated in the AISC Specification Sections A1 and B2 as follows:

1. ASCE 7: *Minimum Design Loads for Buildings and Other Structures,* SEI/ASCE 7-02. Available from the American Society of Civil Engineers, ASCE 7 provides the general requirements for loads, load factors, and load combinations.
2. AISC Specification: The 2005 AISC *Specification for Structural Steel Buildings*, included in Part 16 of this Manual and available at www.aisc.org, provides the general requirements for design and construction.
3. Code of Standard Practice: The 2005 AISC *Code of Standard Practice for Steel Buildings and Bridges*, included in Part 16 of this manual and available at www.aisc.org, provides the standard of custom and usage for the fabrication and erection of structural steel.

Other referenced standards include:

1. RCSC Specification: The 2004 RCSC *Specification for Structural Joints Using ASTM A325 or A490 Bolts*, reprinted in Part 16 of this Manual with the permission of the Research Council on Structural Connections and available at www.boltcouncil.org, provides the additional requirements specific to bolted joints with high-strength bolts.
2. AWS D1.1: *Structural Welding Code—Steel,* AWS D1.1:2004. Available from the American Welding Society, AWS D1.1 provides additional requirements specific to welded joints. Requirements for the proper specification of welds can be found in AWS A2.4: *Standard Symbols for Welding, Brazing, and Nondestructive Examination.*
3. ACI 318: *Building Code Requirements for Structural Concrete.* Available from the American Concrete Institute, ACI 318 provides additional requirements for reinforced concrete, including in composite design and the design of steel-to-concrete anchorage.

Various other specifications and standards from ASME, ASTM, and ACI are also referenced in AISC Specification Section A2.

Additional Requirements for Seismic Applications

The 2005 AISC *Seismic Provisions for Structural Steel Buildings* apply when the seismic response modification factor, R, is taken greater than 3, or when required by the applicable building code. This specification is available in Part 6 of the AISC *Seismic Design Manual* and at www.aisc.org. When R is taken equal to or less than 3, these additional requirements do not apply.

Other AISC Reference Documents

The following other AISC publications may be of use in the design and construction of structural steel buildings:

1. AISC *Design Examples* is a CD-based companion to this Manual and includes design examples outlining the application of design aids and Specification provisions developed in coordination with this Manual.
2. AISC's *Detailing for Steel Construction*, Second Edition, covers the standard practices and recommendations for steel detailing, including preparation of shop and erection drawings.
3. The AISC *Seismic Design Manual* provides guidance on steel design in seismic applications, in accordance with the AISC Seismic Provisions.

Additionally, the following AISC Design Guides are available at www.aisc.org for in-depth coverage of specific topics in steel design:

1. *Column Base Plates*, AISC Design Guide No. 1 (DeWolf, 1990).
2. *Design of Steel and Composite Buildings with Web Openings*, AISC Design Guide No. 2 (Darwin, 1990).
3. *Serviceability Design Considerations for Low-Rise Buildings*, AISC Design Guide No. 3 (West and Fisher, 2003).
4. *Extended End-Plate Moment Connections*, AISC Design Guide No. 4 (Murray, 2004).
5. *Design of Low- and Medium-Rise Steel Buildings*, AISC Design Guide No. 5 (Allison, 1991).
6. *Load and Resistance Factor Design of W-Shapes Encased in Concrete*, AISC Design Guide No. 6 (Griffis, 1992).
7. *Industrial Buildings: Roofs to Column Anchorage*, AISC Design Guide No. 7 (Fisher, 2005).
8. *Partially Restrained Composite Connections*, AISC Design Guide No. 8 (Leon, Hoffman, and Staeger, 1996).
9. *Torsional Analysis of Structural Steel Members*, AISC Design Guide No. 9 (Seaburg and Carter, 1997).
10. *Erection Bracing of Low-Rise Structural Steel Frames*, AISC Design Guide No. 10 (Fisher and West, 1997).
11. *Floor Vibrations Due to Human Activity*, AISC Design Guide No. 11 (Murray, Allen and Ungar, 1997).
12. *Modification of Existing Welded Steel Moment Frames for Seismic Resistance*, AISC Design Guide No. 12 (Gross, Engelhardt, Uang, Kasai, and Iwankiw, 1999).
13. *Wide-Flange Column Stiffening at Moment Connections: Wind and Seismic Applications*, AISC Design Guide No. 13 (Carter, 1999).
14. *Staggered Truss Framing Systems,* AISC Design Guide No. 14 (Wexler and Lin, 2001).
15. *AISC Rehabilitation and Retrofit Guide: A Reference for Historic Shapes and Specifications*, AISC Design Guide No. 15 (Brockenbrough, 2002).
16. *Flush and Extended Multiple-Row Moment End-Plate Connections*, AISC Design Guide No. 16 (Murray and Shoemaker, 2002).

17. *High-Strength Bolts—A Primer for Structural Engineers,* AISC Design Guide No. 17 (Kulak, 2002).
18. *Steel-Framed Open-Deck Parking Structures,* AISC Design Guide No. 18 (Churches, Troup, and Angeloff, 2003).
19. *Fire Resistance of Structural Steel Framing,* AISC Design Guide No. 19 (Ruddy, Marlo, Ioannides, and Alfawakhiri, 2003).

OSHA REQUIREMENTS

OSHA Safety and Health Standards for the Construction Industry, 29 CFR 1926 Part R Safety Standards for Steel Erection, must be addressed in the design, detailing, fabrication, and erection of steel structures. These regulations became effective on July 18, 2001, except for requirements for slip-resistance certification of painted surfaces (see "Walking/Working Surfaces" below), which are expected to become effective on July 18, 2006. A brief summary of selected provisions is available (Barger and West, 2001). The full text of the regulations should be consulted and can be found at www.osha.gov.

USING THE 2005 AISC SPECIFICATION

The 2005 AISC *Specification for Structural Steel Buildings* (AISC 360-05) unifies the design provisions formerly presented in the 1989 *Specification for Structural Steel Buildings: Allowable Stress Design and Plastic Design* and the 1999 *Load and Resistance Factor Design Specification for Structural Steel Buildings.* It also integrates into a single document the information previously provided in the 1993 *Load and Resistance Factor Design Specification for Single-Angle Members* and the 1997 *Specification for the Design of Steel Hollow Structural Sections.* This new unified specification, in combination with the 2005 *Seismic Provisions for Structural Steel Buildings* (AISC 341-05), brings together all of the provisions needed for the design of structural steel in buildings and other structures.

The 2005 AISC Specification presents two approaches for the design of structural steel members and connections. Chapter B establishes the general requirements for analysis and design. It states that, "designs shall be made according to the provisions for Load and Resistance Factor Design (LRFD) or to the provisions for Allowable Strength Design (ASD)." These two approaches are equally valid for any structure for which the Specification is applicable. There is no preference stated or implied in the provisions.

The required strength of structural members and connections may be determined by elastic, inelastic, or plastic analysis for the load combinations associated with either LRFD or ASD and as stipulated by the applicable building code. In all cases, the available strength must exceed the required strength. The AISC Specification gives provisions for determining the available strength as summarized below.

Load and Resistance Factor Design (LRFD)

Load and Resistance Factor Design according to the 2005 AISC Specification is essentially the same as LRFD according to the previous three LRFD specifications. Although some of the provisions have changed from previous specifications, the overall approach has remained constant. If there is a desire to use the LRFD provisions in the form of stresses, the strength provisions can be transformed into stress provisions by factoring out the appropriate section property.

The load combinations appropriate for LRFD are given in the applicable building code or, in its absence, ASCE 7 Section 2.3. For LRFD, the available strength is referred to as the design strength. All of the LRFD provisions are structured so that the design strength must equal or exceed the required strength. This is presented in Section B3.3 as

$$R_u \leq \phi R_n$$

In this equation, R_u is the required strength determined by analysis for the LRFD load combinations, R_n is the nominal strength determined according to the specification provisions, and ϕ is the resistance factor given by the specification for a particular limit-state. Throughout this Manual, tabulated values of ϕR_n, the design strength, are given for LRFD. These values are tabulated as blue numbers in columns with the heading LRFD.

Allowable Strength Design (ASD)

Allowable Strength Design is similar to what is known as Allowable Stress Design in that they are both carried out at the same load level. Thus, the same load combinations are used. The difference is that for strength design, the primary provisions are given in terms of forces or moments rather than stresses. In every situation, these strength provisions can be transformed into stress provisions by factoring out the appropriate section property.

The load combinations appropriate for ASD are given by the applicable building code or, in its absence, ASCE 7 Section 2.4. For ASD, the available strength is referred to as the allowable strength. All of the ASD provisions are structured so that the allowable strength must equal or exceed the required strength. This is presented in Section B3.4 as

$$R_a \leq R_n/\Omega$$

In this equation, R_a is the required strength determined by analysis for the ASD load combinations, R_n is the nominal strength determined according to the specification provisions, and Ω is the safety factor given by the specification for a particular limit-state. Throughout this Manual, tabulated values of R_n/Ω, the allowable strength, are given for ASD. These values are tabulated as black numbers on a green background in columns with the heading ASD.

DESIGN FUNDAMENTALS

It is commonly believed that ASD was an elastic design method based entirely in a stress format without limit-states and LRFD was an inelastic design method based entirely in a strength format with limit-states. Traditional ASD was based in limit-states principles too, but without the use of the term. Additionally, either method can be formulated in a stress or strength basis, and both take advantage of inelastic behavior. The 2005 AISC Specification highlights how similar LRFD and ASD are in its formulation, with identical provisions throughout for LRFD and ASD.

Design according to the 2005 Specification, whether it is according to LRFD or ASD, is based on limit states design principles, which define the boundaries of structural usefulness. Strength limit states relate to load carrying capability and safety. Serviceability limit-states relate to performance under normal service conditions. Structures must be proportioned so that no applicable strength or serviceability limit-state is exceeded.

Normally, several limit-states will apply in the determination of the nominal strength of a structural member or connection. The controlling limit-state is normally the one that results in the least available strength. As an example, the controlling limit-state for bending of a simple beam may be yielding, local buckling, or lateral-torsional buckling for strength, or deflection or vibration for serviceability. The tabulated values may either reflect a single limit-state or a combination of several limit-states. This will be clearly stated in the introduction to the particular tables.

Loads, Load Factors, and Load Combinations

Based on Specification Sections B3.3 and B3.4, the required strength (either P_u, M_u, V_u, etc. for LRFD or P_a, M_a, V_a, etc. for ASD) is determined for the appropriate load magnitudes, load factors, and load combinations given in the applicable building code. These are usually based on ASCE-7, which may be used when there is no applicable building code. The common loads found in building structures are:

D = dead load
L = live load due to occupancy
L_r = roof live load
S = snow load
R = nominal load due to initial rainwater or ice exclusive of the ponding contribution
W = wind load
E = earthquake load

Load and Resistance Factor Design

For LRFD, the required strength is determined from the following factored combinations[1], which are based on ASCE-7 Section 2.3:

$$1.4D \quad (1)$$
$$1.2D + 1.6L + 0.5(L_r \text{ or } S \text{ or } R) \quad (2)$$
$$1.2D + 1.6(L_r \text{ or } S \text{ or } R) + (0.5L \text{ or } 0.8W) \quad (3)$$
$$1.2D + 1.6W + 0.5L + 0.5(L_r \text{ or } S \text{ or } R) \quad (4)$$
$$1.2D \pm 1.0E + 0.5L + 0.2S \quad (5)$$
$$0.9D \pm (1.6W \text{ or } 1.0E) \quad (6)$$

The load combinations for LRFD recognize that, when several transient loads act in combination, only one assumes its maximum lifetime value[2], while the other(s) are at their "arbitrary-point-in-time" (APT) values. Each combination models the total design loading condition when a different load is at its maximum. Thus, the maximum-lifetime load effect is amplified by an amount that is proportional to its relative variability and the APT load effect(s) are factored to their mean value(s). With this approach, the margin of safety varies with the load combination yielding a more uniform reliability than would be expected when nominal loads are combined directly.

Dead load, D, is present in each load combination with a load factor of 1.2, except in load combination 1, where it is the dominant (only) load effect, and load combination 6, where it is reduced for calculation of the overturning or uplift effect. The 1.2 load factor accounts

---

[1] Exception: Per ASCE 7, the load factor on L in combinations 3, 4, and 5 shall equal 1.0 for garages, areas occupied as places of public assembly, and all areas where the live load is greater than 100 psf.

[2] Usually based upon a 50-year recurrence, except for seismic loads.

for the statistical variability of the dead load. The designer must independently account for other contributions to dead load, such as the weight of additional concrete, if any, added to adjust for concrete ponding effects (Ruddy, 1986) or differing framing elevations.

Allowable Strength Design

For ASD, the required strength is determined from the following combinations, which are also based on ASCE-7 Section 2.4:

$$D \qquad (1)$$
$$D + L \qquad (2)$$
$$D + (L_r \text{ or } S \text{ or } R) \qquad (3)$$
$$D + 0.75L + 0.75(L_r \text{ or } S \text{ or } R) \qquad (4)$$
$$D \pm (W \text{ or } 0.7E) \qquad (5)$$
$$D + 0.75(W \text{ or } 0.7E) + 0.75L + 0.75(L_r \text{ or } S \text{ or } R) \qquad (6)$$
$$0.6D \pm (W \text{ or } 0.7E) \qquad (7)$$

The load combinations for ASD combine the code-specified nominal loads directly with no factors for those cases where loads with minimal variation with time are combined, cases 1, 2, and 3. For those cases where multiple time-variable loads are included, a 0.75 reduction factor is applied to the time-variable loads only. Since all of the safety in an ASD design comes through the introduction of the safety factor on the resistance side of the equation, each load case uses the same safety factor for a given limit-state.

In ASD, when considering members subjected to gravity loading only, it is clear that the controlling load combination is the one that adds the larger live load to the dead load. Thus, for a floor that does not carry roof load, the controlling combination will be $D + L$, while, for a roof, the controlling combination will be $D + (L_r \text{ or } S \text{ or } R)$. For gravity columns, after live load reductions have been accounted for, the floor and roof live loads may be reduced to 0.75 of their nominal values. A similar reduction is permitted for live loads in combination with lateral loads.

Superposition of Loads in Load Combinations

Whether the loads themselves or the effects of those loads are used in these combinations, LRFD or ASD, the results are the same, provided the principle of superposition is valid. This is true when deflections are small and the stress-strain behavior is nominally elastic. However, when second-order effects are significant or the behavior is inelastic, superposition is not valid and the loads, rather than the load effects, should be used in these combinations.

Nominal Strengths, Resistance Factors, Safety Factors, and Available Strengths

The 2005 AISC Specification requires that the available strength must be greater than the required strength for any element. The available strength is a function of the nominal strength given by the specification and the corresponding resistance factor or safety factor. As discussed earlier, the required strength can be determined either with LRFD or ASD load combinations.

The available strength for LRFD is the design strength, which is calculated as the product of the resistance factor ϕ and the nominal strength (ϕP_n, ϕM_n, ϕV_n, etc.) The available strength for ASD is the allowable strength, which is calculated as the quotient of the nominal strength and the corresponding safety factor Ω (P_n/Ω, M_n/Ω, V_n/Ω, etc.)

In LRFD, the margin of safety for the loads is contained in the load factors, and resistance factors, ϕ, account for unavoidable variations in materials, design equations, fabrication, and erection. In ASD, a single margin of safety for all of these effects is contained in the safety factor, Ω.

The resistance factors, ϕ, and safety factors, Ω, in the AISC Specification are based upon research (Galambos et al., 1978), and the experience and judgment of the AISC Committee on Specifications. In general, ϕ is less than unity and Ω is greater than unity. The higher the variability in the test data for a given nominal strength, the lower its ϕ factor and the higher its Ω factor will be. Some examples of ϕ and Ω factors for steel members are as follows:

ϕ = 0.90 for limit-states involving yielding
ϕ = 0.75 for limit-states involving rupture
Ω = 1.67 for limit-states involving yielding
Ω = 2.00 for limit-states involving rupture

The general relationship between the safety factor, Ω, and the resistance factor, ϕ, is

$$\Omega = \frac{1.5}{\phi}$$

Serviceability

Serviceability requirements of the 2005 AISC Specification are found in Section B3.7 and Chapter L. The serviceability limit-states should be selected appropriately for the specific application, as discussed in the Specification Commentary to Chapter L. Serviceability limit-states and the appropriate load combinations for checking their conformance to serviceability requirements can be found in ASCE 7 Appendix B and its Commentary. It should be noted that the load combinations in ASCE 7 Sections 2.3 for LRFD and 2.4 for ASD are both for strength design, and are not necessarily appropriate for consideration of serviceability.

Guidance is also available in the Commentary on the 2005 AISC Specification, both in general and for specific criteria, including camber, deflection, drift, vibrations, wind induced motion, expansion and contraction, and connection slip. Additionally, the applicable building code may provide some further guidance or establish requirements. See also the serviceability discussions in Parts 3 through 6, AISC Design Guide No. 3 *Serviceability Design Considerations for Steel Buildings* (Fisher and West, 2004), and AISC Design Guide No. 11 *Floor Vibrations Due to Human Activity* (Murray et al., 1997).

Required Strength, Stability, Effective Length, and Second-Order Effects

As previously discussed, the Specification requires that the required strength must be less than or equal to the available strength in the design of every member and connection. Chapter C also requires that stability shall be provided for the structure as a whole and each of its elements. Any method that considers the influence of second-order effects, also known as P-delta effects, may be used. Thus, required strengths must be determined including second-order effects, as described in Specification Section C2.1 or Appendix 7. Note that Specification Section C2.1 and Appendix 7 permit an amplified first-order analysis as one method of second-order analysis.

Second-order effects are the additional forces, moments, and displacements resulting from the applied loads acting in their displaced positions as well as the changes from the undeformed to the deformed geometry of the structure. Second-order effects are obtained by considering equilibrium of the structure within its deformed geometry. There are numerous ways of accounting for these effects. The commentary to AISC Specification Appendix 7 provides some guidance on methods of second-order analysis and suggests several benchmark problems for checking the adequacy of analysis methods.

Since the mid-1960s, there have been provisions in the AISC Specifications to account for second-order effects. Initially, these provisions were embedded in the interaction equations. In past ASD Specifications, second-order effects were accounted for by the term

$$\frac{1}{1-\frac{f_a}{F'_e}}$$

found in the interaction equation. In the previous three LRFD Specifications, the factors B_1 and B_2 from Chapter C of those specifications were used to amplify moments to account for second-order effects. B_1 was used to account for the second-order effects due to member curvature and B_2 was used to account for second-order effects due to sidesway. In both specifications, more exact methods were permitted.

The 2005 AISC Specification fully integrates the provisions for stability design with specified methods of second-order analysis. Section C1.3a provides that in braced frames, the effective length factor, K, may be taken as 1.0 and Section C1.3c provides that for gravity-only framing systems, K may also be taken as 1.0. For moment frames, Section C1.3b requires that a critical buckling analysis be performed according to Section C2. The determination of effective length is directly linked to the approach taken for second-order analysis. This is discussed in more detail in Commentary Section C2. Section C2 of the Specification details the requirements for determination of required strengths and, along with Appendix 7, provides three approaches that may be followed.

- The *Direct Analysis Method* is provided in Appendix 7. This is the most comprehensive and, as the name suggests, most direct approach to incorporating all necessary factors in the analysis. Through the use of notional loads, reduced stiffness, and a second-order analysis, the design can be carried out with the forces and moments from the analysis and an effective length equal to the member length, $K = 1.0$.
- The *Effective Length Method* is given in Section C2.2a. In this method, all gravity-only load cases have a minimum lateral load equal to 0.2 percent of the story gravity load applied. A second-order analysis is carried out and, depending on the ratio of the second-order drift to the first-order drift, the effective length may be taken as the member length, $K = 1.0$, or may have to be determined from analysis.
- The *First-Order Analysis Method* is given in Section C2.2b. With this approach, second-order effects are captured through the application of an additional lateral load equal to at least 0.42 percent of the story gravity load applied in each load case. No further second-order analysis is necessary. The required strengths are taken as the forces and moments obtained from the analysis and the effective length factor is $K = 1.0$.

When a second-order analysis is called for in the above methods, Section C2.1a allows any method that properly considers P-delta effects. This may be a true second-order analysis or a simplified approach. One such method is the Amplified First-Order Elastic Analysis provided in Section C2.1b. This is a modified carry over of the B_1/B_2 approach used in the previous LRFD Specification, which was an extension of the simple approach taken in past ASD Specifications.

Simplified Determination of Required Strength

The features of each of the foregoing methods are summarized and compared in Table 2–1. When a fast, conservative solution is desired, the following simplification of the Effective Length Method can be used.

The Effective Length Method and the Amplified First-Order Elastic Analysis approach of Section C2.1b can be used to accomplish the second-order analysis. The User Note in Section C2.1b indicates that for members where the member amplification (P-δ) factor is small, that is, $B_1 \leq 1.05$, it is conservative to amplify the total moment and force by B_2. Thus, equations C2-1a and C2-1b become

LRFD	ASD
$M_r = B_1 M_{nt} + B_2 M_{lt} = B_2 M_u$ $P_r = P_{nt} + B_2 P_{lt} = B_2 P_u$	$M_r = B_1 M_{nt} + B_2 M_{lt} = B_2 M_a$ $P_r = P_{nt} + B_2 P_{lt} = B_2 P_a$

To use this Simplified Method, B_1 should not exceed B_2. For members not subject to transverse loading between their ends, it is very unlikely that B_1 would be greater than 1.0. In addition, the simplified approach is not valid if the amplification factor $B_2 > 1.5$. It is up to the engineer to ensure that the frame is proportioned appropriately to use this simplified approach. In most designs, it is not advisable to have a final structure where the second-order amplification is greater than 1.5, although it is acceptable. In those cases, one should consider stiffening the structure.

Step 1: Perform a first-order elastic analysis. Gravity load cases must include a minimum lateral load at each story equal to 0.002 times the story gravity load where the story gravity load is the load introduced at that story, independent of any loads from above.

Step 2: Establish the design story drift limit and determine the lateral load that produces that drift. This is intended to be a measure of the lateral stiffness of the structure.

Step 3: Determine the ratio of the total story gravity load to the lateral load determined in Step 2. For an ASD design, this ratio must be multiplied by 1.6 before entering the Table below.

Design Story Drift Limit	**Load Ratio from Step 3 (times 1.6 for ASD, 1.0 for LRFD)**										
	0	**5**	**10**	**20**	**30**	**40**	**50**	**60**	**80**	**100**	**120**
H/100	1	1.1	1.1	1.3	1.5	–	–	–	–	–	–
H/200	1	1	1.1	1.1	1.2	1.3	1.4	1.5	–	–	–
H/300	1	1	1	1.1	1.1	1.2	1.2	1.3	1.5	–	–
H/400	1	1	1	1.1	1.1	1.1	1.2	1.2	1.3	1.4	1.5
H/500	1	1	1	1	1.1	1.1	1.1	1.2	1.2	1.3	1.4

Step 4: Multiply all of the forces and moments from the first-order analysis by the value obtained from the Table below. Use the resulting forces and moments as the required strengths for the designs of all members and connections.

Step 5: For all cases where the multiplier is 1.1 or less, shown shaded in the table above, the effective length may be taken as the member length, $K = 1.0$. For cases where the multiplier is greater than 1.1 but does not exceed 1.5, determine the effective length factor through analysis, such as with the alignment charts of the Commentary. For cases where no value is shown for the multiplier, the structure must be stiffened in order to use this simplified approach.

Step 6: Ensure that the drift limit set in Step 2 is not exceeded and revise design as needed.

STABILITY BRACING

Beams, girders, and trusses must be restrained against rotation about their longitudinal axes at points of support (a basic assumption stated in the preamble of Specification Chapter F). Additionally, stability bracing with adequate strength and stiffness must be provided consistent with that assumed at braced points in the analysis for frames, columns, and beams (see Appendix 6). Some guidance for special cases follows:

Simple-Span Beams

In general, adequate lateral bracing is provided to the compression flange of a simple-span beam by the connections of infill beams, joists, concrete slabs, metal deck, concrete slabs on metal deck, and similar framing elements.

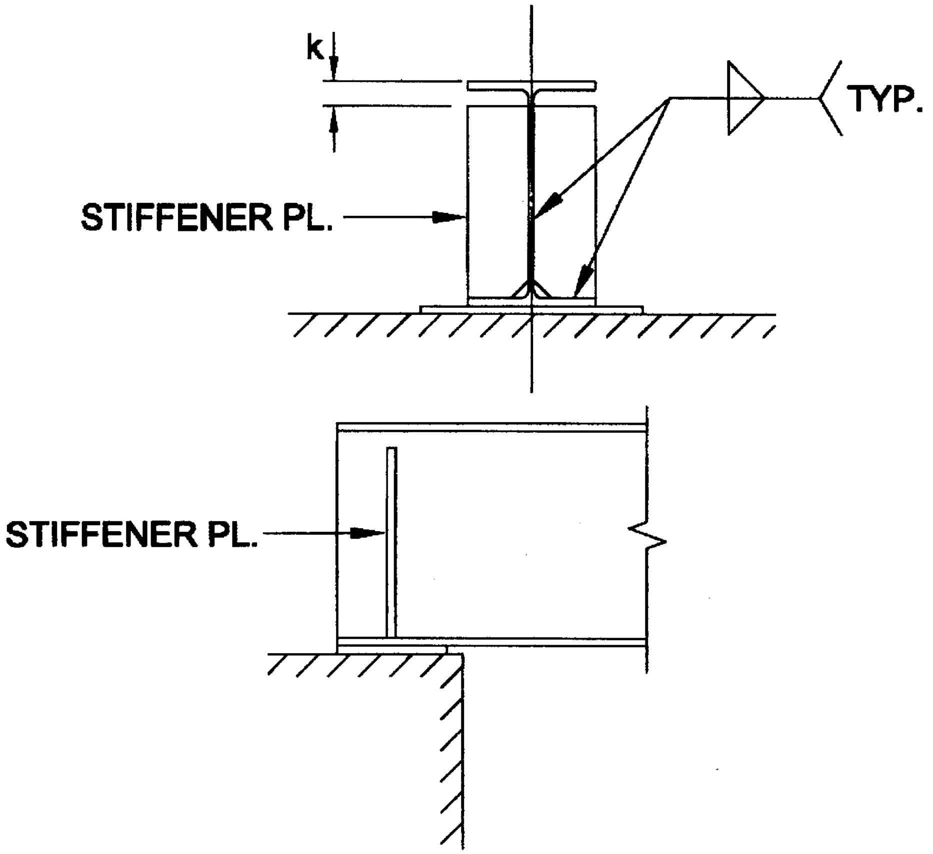
Beam Ends Supported on Bearing Plates

The stability of a beam end supported on a bearing plate can be provided in one of several ways (see Figure 2-1):

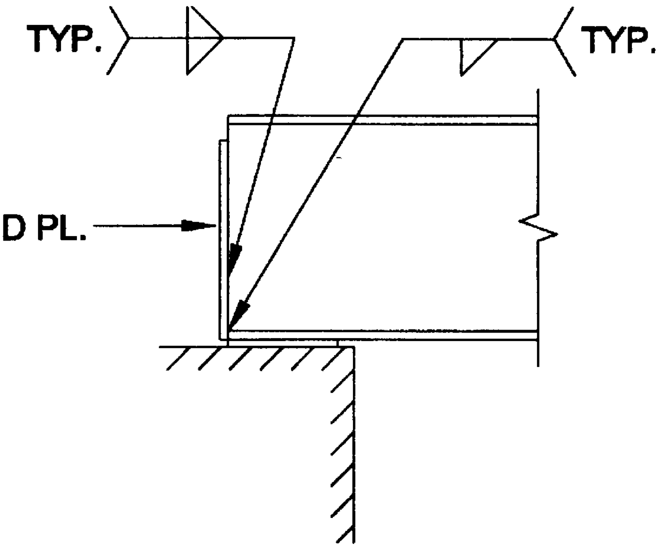
1. The beam end can be built into solid concrete or masonry using anchorage devices.
2. The beam top flange can be stabilized through interconnection with a floor or roof system, provided that system is itself anchored to prevent its translation relative to the beam bearing.
3. A top-flange stability connection can be provided.
4. An end-plate or transverse stiffeners located over the bearing plate extending to near the top-flange *k*-distance can be provided. Such stiffeners must be welded to the top of the bottom flange and to the beam web, but need not extend to or be welded to the top flange.

In each case, the beam and bearing plate must also be anchored to the support. For the design of beam bearing plates, see Part 14.

In atypical framing situations, such as when very deep beams are used, the strength and stiffness requirements in AISC Specification Appendix 6 can be applied to ensure the stability of the assembly. It may also be possible to demonstrate in a limited number of cases, such as with beams with thick webs and relatively shallow depths, that the beam has been properly designed without providing the details described above. In this case, the beam and bearing plate must still be anchored to the support. In any case, it should be noted that the assembly must also meet the requirements in AISC Specification Section J11.



(a) Stability provided with transverse stiffeners.



(b) Stability provided with an end-plate.

ANCHOR BEAM AND/OR
BEARING PL. AS REQUIRED

Figure 2–1. Beam end supported on bearing plate.

Beams and Girders Framing Continuously Over Columns

Roof framing is commonly configured with cantilevered beams that frame continuously over the tops of columns to support drop-in beams between the cantilevered segments (Rongoe, 1996; CISC, 1989). It is also commonly desirable to provide an assembly in which the intersection of the beam and column can be considered a braced point for the design of both the continuous cantilevering beam and the column top. The required stability can be provided in several ways (see Figure 2–2):

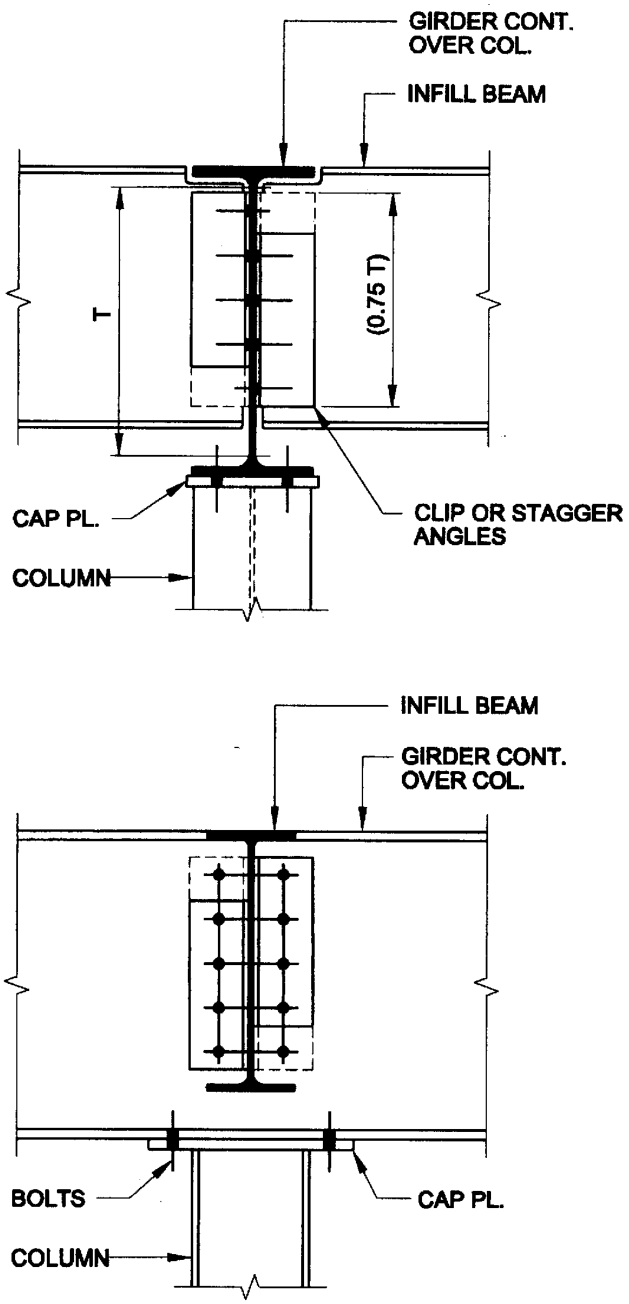


Figure 2–2a. Beam framing continuously over column top, stability provided with connections of infill beams.

1. When an infill beam frames into the continuous beam at the column top, the required stability normally can be provided by using connection element(s) for the infill beam that cover three-quarters or more of the T-dimension of the continuous beam. Alternatively, connection elements that cover less than three-quarters of the T-dimension of the continuous beam can be used in conjunction with partial-depth stiffeners in the beam web along with a moment connection between the column top and beam bottom to maintain alignment of the beam/column assembly. A cap plate of reasonable proportions and four bolts will normally suffice.

   In either case, note that OSHA requires that, if two framing infill beams share common holes through a column web or the web of a beam that frames continuously over the top of a column[3], the beam erected first must remain attached while connecting the second.

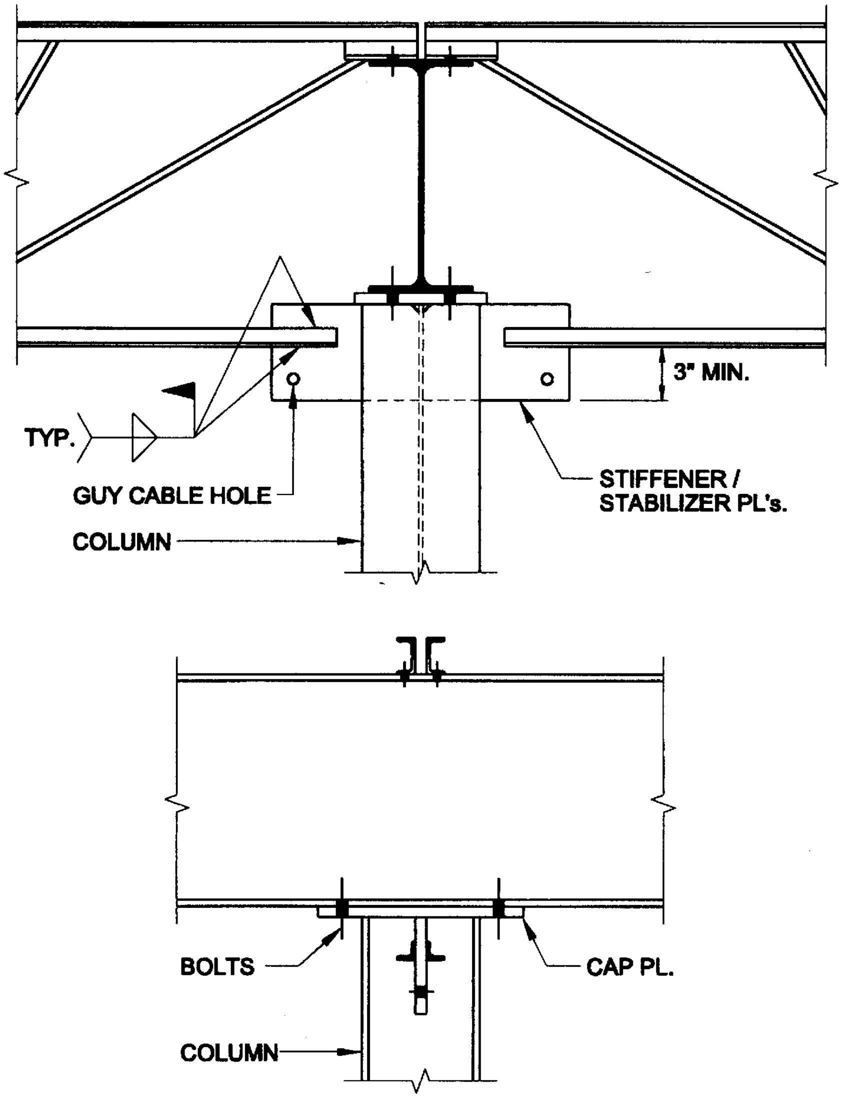

Figure 2–2b. Beam framing continuously over column top, stability provided with welded joist-chord extensions at column top.

---

[3] This requirement applies only at the location of the column, not at locations away from the column.

2. When joists frame into the continuous beam or girder, the required stability normally can be provided by using bottom chord extensions connected to the column top. The resulting continuity moments must be reported to the joist supplier for their use in the design of the joists and bridging. Note that the continuous beam must still be checked for the concentrated force due to the column reaction per AISC Specification Section J11.

   The position of the bottom chord extension relative to the column cap plate will affect the bottom chord connection detail. When the extension aligns with the cap plate, the load path and force transfer is direct. When the extension is below the column cap plate, the column must be designed to stabilize the beam bottom flange and the connection between the extension and the column must develop the continuity/brace force. When the extension is above the column top, the beam web must have the necessary strength and stiffness to adequately brace the beam bottom/column top.

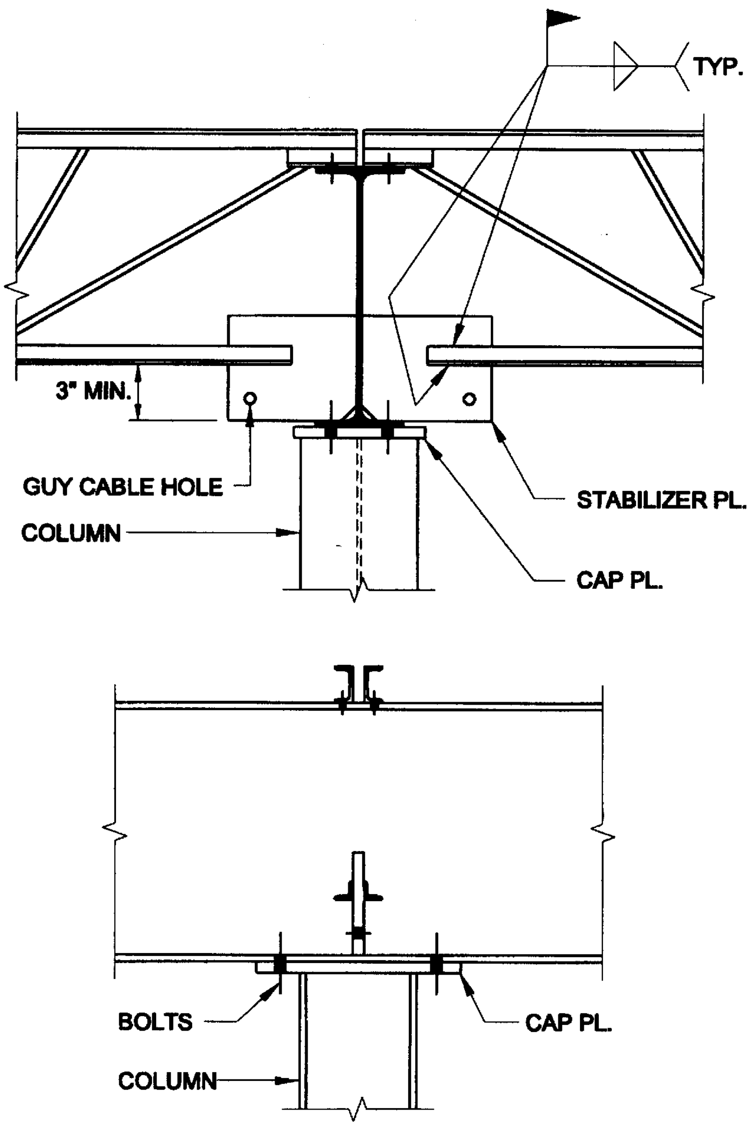

Figure 2–2c. Beam framing continuously over column top, stability provided with welded joist-chord extensions above column top.

3. If connection of the joist bottom chord extensions to the column must be avoided, the required stability can be provided with a diagonal brace that satisfies the strength and stiffness requirements in AISC Specification Appendix 6. Providing a relatively shallow angle with respect to the horizontal can minimize gravity-load effects in the diagonal brace.

   Alternatively, the required stability can be provided with stiffeners in the beam web along with a moment connection between the column top and beam bottom to maintain alignment of the beam/column assembly. A cap plate of reasonable proportions and four bolts will normally suffice.

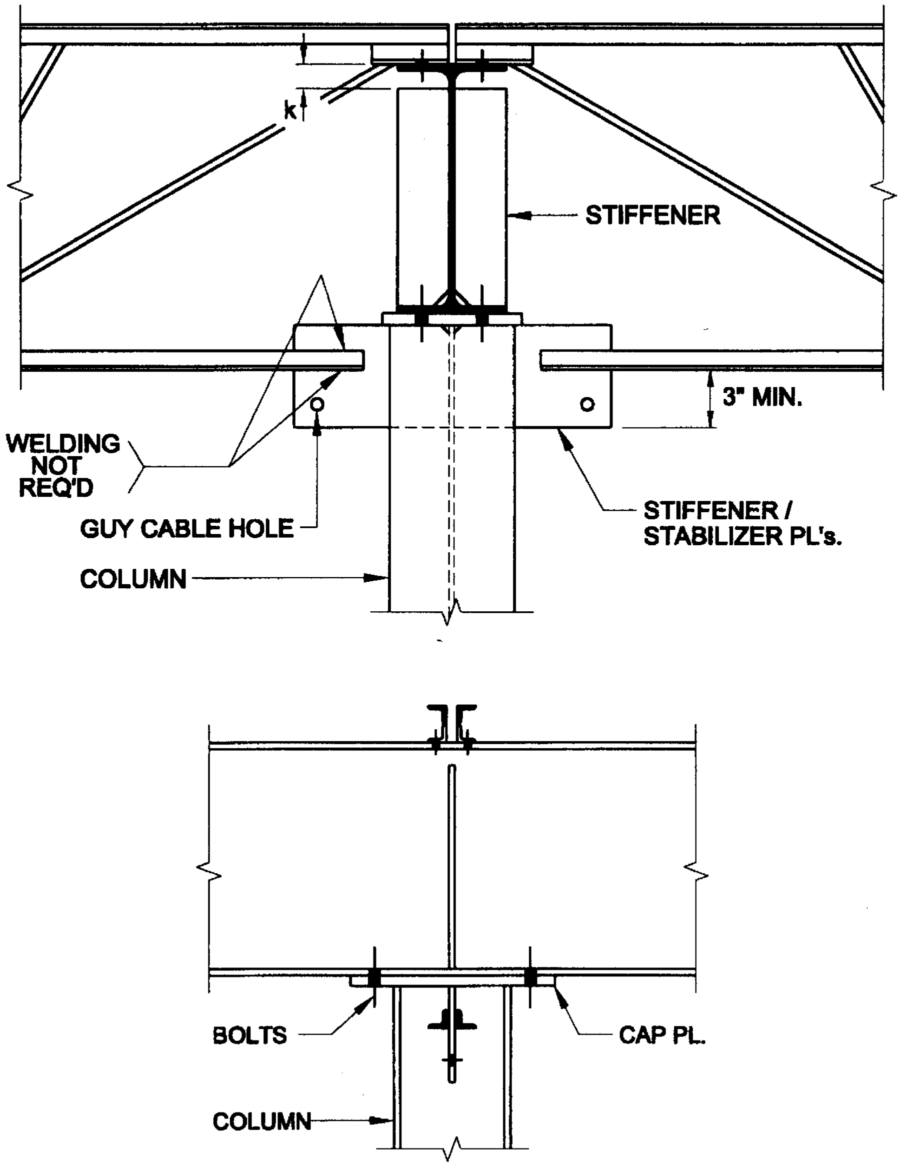

Figure 2-2d. Beam framing continuously over column top, stability provided with transverse stiffeners, joist-chord extensions located at column top not welded.

In atypical framing situations, such as when very deep girders are used, the strength and stiffness requirements in AISC Specification Appendix 6 can be applied for both the beam and the column to ensure the stability of the assembly. It may also be possible to demonstrate in a limited number of cases, such as with continuous beams with thick webs and relatively shallow depths, that the column and beam have been properly designed without providing infill beam connections, connected joist extensions, stiffeners, or diagonal braces as described above. In this case, a properly designed moment connection is still required between the beam bottom flange and the column top. In any case, it should be noted that the assembly must also meet the requirements in AISC Specification Section J11.

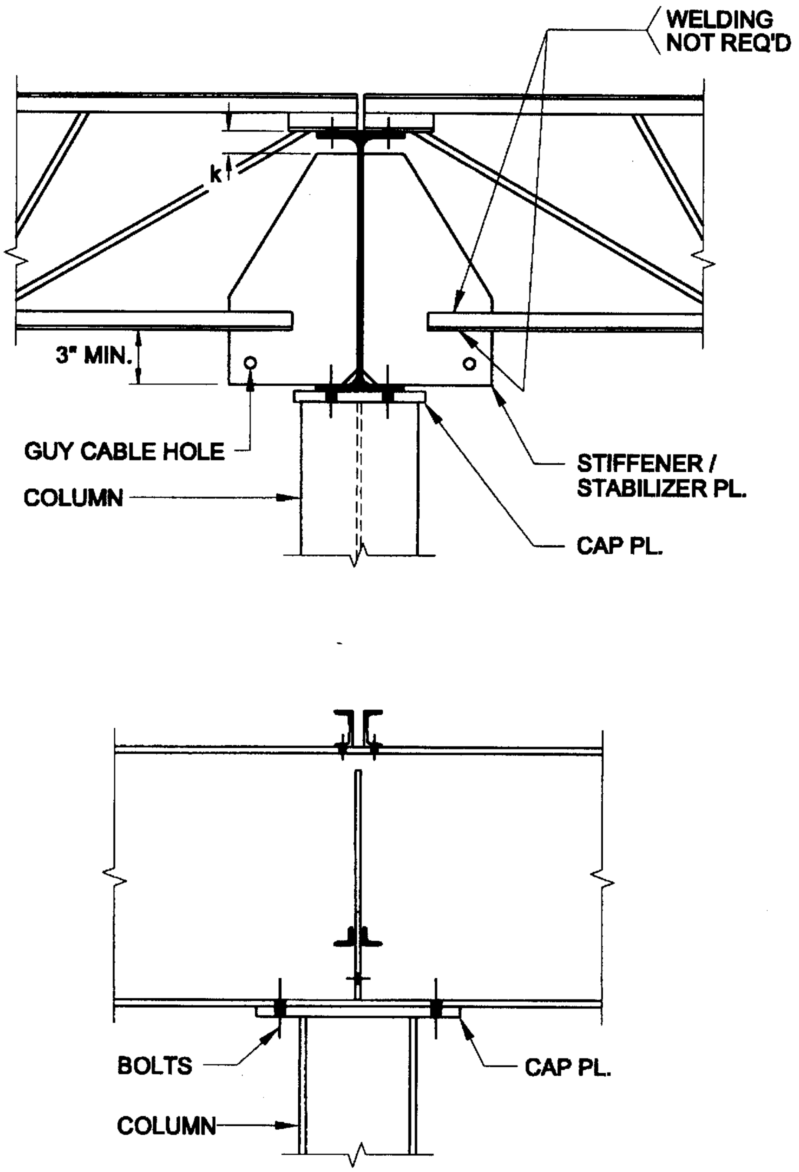

Figure 2–2e. Beam framing continuously over column top, stability provided with stiffener plates, joist-chord extensions located above column top not welded.

PROPERLY SPECIFYING MATERIALS

Availability

The general availability of structural shapes, HSS, and pipe is determined by an annual AISC survey of producers and summarized in AISC's *Modern Steel Construction* magazine. The availability summary for W-, M-, S-, and HP-shapes, channels, and angles is published in the January issue. The availability summary for HSS and pipe is published in the July issue. This information is also available at www.aisc.org.

Material Specifications

Applicable material specifications are as shown in the following tables:

- Structural shapes in Table 2–3.
- Plate and bar products in Table 2–4.
- Fastening products in Table 2–5.

Preferred material specifications are indicated in black shading. Other applicable material specifications are as shown in grey shading. The availability of grades other than the preferred material specification should be confirmed prior to their specification.

Cross-sectional dimensions and production tolerances are addressed as indicated under "Standard Mill Practices" in Part 1.

Other Products

Raised-Pattern Floor Plates

ASTM A786 is the standard specification for rolled steel floor plates. As floor-plate design is seldom controlled by strength considerations, ASTM A786 "commercial grade" is commonly specified. If so, per ASTM A786 Section 5.1.2, "the product will be supplied 0.33 percent maximum carbon and without specified mechanical properties." Alternatively, if a defined strength level is desired, ASTM A786 raised-pattern floor plate can be ordered to a defined plate specification, such as ASTM A36, A572, or A588; see ASTM A786 Sections 5.1.2, Section 8, and Appendix Table X1.1.

Sheet and Strip

Sheet and strip products, which are generally thinner than structural plate and bar products (see Table 2–2), are produced to such ASTM specifications as A570, A606, or A607.

Filler Metal

The appropriate filler metal for structural steel is as summarized in ANSI/AWS D1.1-2004 Table 3.1 for the various combinations of base metal specification, and grade and electrode specification. Weld strengths in this Manual are based upon a tensile strength level of 70 ksi.

Shear-Stud Connectors

As specified in ANSI/AWS D1.1 Chapter 7 (Section 7.2.6 and Table 7.1), Type B shear stud connectors made from ASTM A108 material are used for the interconnection of steel and concrete elements in composite construction ($F_u = 65$ ksi).

Open-Web Steel Joists

The AISC Code of Standard Practice does not include steel joists in its definition of structural steel. Steel joists are designed and fabricated per the requirements of specifications published by the Steel Joist Institute. Refer to SJI literature for further information.

Castellated Beams

Castellated beams, also known as cellular beams, are members constructed by cutting along a staggered pattern down the web of a wide-flange member, offsetting the resulting pieces such that the deepest points of the cut are in contact, and welding the two pieces together, thereby creating a member with holes along its web. Castellated beams are currently designed and fabricated as a proprietary product. For more information, contact the manufacturer.

Steel Castings and Forgings

Steel castings are specified as ASTM A27 grade 65-35 or ASTM A148 grade 80-35. Steel forgings are specified as ASTM A668.

Forged Steel Structural Hardware

Forged steel structural hardware products, such as clevises, turnbuckles, eye nuts, and sleeve nuts, are occasionally used in building design and construction. These products are generally forged according to ASTM A668 Class A requirements. ASTM A29, grade 1035 material is commonly used in the manufacture of clevises and turnbuckles. ASTM A29, grade 1030 material is commonly used in the manufacture of steel eye nuts and steel eye bolts. ASTM A29 grade 1018 material is commonly used in the manufacture of sleeve nuts. Other products, such as steel rod ends, steel yoke ends and pins, cotter pins, and coupling nuts are commonly provided generically as "carbon steel."

The dimensional and strength characteristics of these devices are fully described in the literature provided by their manufacturer. Note that manufacturers usually provide strength characteristics in terms of a "safe working load" with a safety factor as high as 5, assuming that the product will be used in rigging or similar applications subject to dynamic loading. The manufacturer's safe working load may be overly conservative for permanent installations and similar applications subject to static loading only.

If desired, the published safe working load can be converted into an available strength with reliability consistent with that of other statically loaded structural materials. In this case, the nominal strength, R_n, is determined as:

$$R_n = (\textit{safe working load}) \times (\textit{manufacturer's safety factor})$$

and the available strength, ϕR_n or R_n/Ω, is determined using

$$\phi = 0.50 \text{ (LRFD)} \qquad \Omega = 3.00 \text{ (ASD)}$$

Crane Rails

Crane rails are furnished to ASTM A759, ASTM A1 and/or manufacturer's specifications and tolerances.

Most manufacturers chamfer the top and sides of the crane-rail head at the ends, unless specified otherwise, to reduce chipping of the running surfaces. Often, crane rails are ordered as end-hardened, which improves the resistance of the crane-rail ends to impact that occurs as the moving wheel contacts it during crane operation. Alternatively, the entire rail can be ordered as heat-treated. When maximum wheel loading or controlled cooling is needed, refer to manufacturers' catalogs. Purchase orders for crane rails should be noted "for crane service."

Light 40-lb rails are available in 30-ft lengths, 60-lb rails in 30-, 33-, or 39-ft lengths, standard rails in 33- or 39-ft lengths, and crane rails up to 80 ft. Consult manufacturer for availability of other lengths. Rails should be arranged so that joints on opposite sides of the crane runway will be staggered with respect to each other and with due consideration to the wheelbase of the crane. Rail joints should not occur at crane girder splices. Odd lengths that must be included to complete a run or obtain the necessary stagger should be not less than 10 ft long. Rails are furnished with standard drilling in both standard and odd lengths, unless stipulated otherwise on the order.

CONTRACT DOCUMENT INFORMATION

Design Drawings, Specifications, and Other Contract Documents

CASE Document 962D *A Guideline Addressing Coordination and Completeness of Structural Construction Documents*, (Council of American Structural Engineers, American Council of Engineering Companies, 2003) provides comprehensive guidance on the preparation of structural design drawings.

Most provisions in the AISC Specification, RCSC Specification, AWS D1.1, and the Code of Standard Practice are written in mandatory language. Some provisions require the communication of information in the contract documents, some provisions are invoked only when specified in the contract documents, and some provisions require the approval of the owner's designated representative for design if they are to be used. Following is a summary of these provisions in the AISC Specification, RCSC Specification, and Code of Standard Practice:

Required Information

The following communication of information is required in the contract documents:

1. Required drawing information, per Code of Standard Practice Sections 3.1 and 3.1.1 through 3.1.6. and RCSC Specification Section 1.4 (bolting products and joint type).
2. Drawing numbers and revision numbers, per Code of Standard Practice Section 3.5.
3. Structural system description, per Code of Standard Practice Section 7.10.1.
4. Installation schedule for non-structural steel elements in the structural system, per Code of Standard Practice Section 7.10.2.
5. Project schedule, per Code of Standard Practice Section 9.5.1.

Information Required Only When Specified

The following provisions are invoked only when specified in the contract documents:

1. Special material notch-toughness requirements, per AISC Specification Section A3.1c and Section A3.1d.
2. Special connections requiring pretension, per AISC Specification Section J1.10.

3. Bolted joint requirements, per AISC Specification Section J3.1 and RCSC Specification Section 1.4.
4. Special cambering considerations, per AISC Specification Section L2.
5. Special contours and finishing requirements for thermal cutting, per AISC Specification Sections M2.2 and M2.3, respectively.
6. Corrosion protection requirements, if any, per AISC Specification Sections M3.1, M3.2, and M3.5, and Code of Standard Practice Sections 6.5, 6.5.2, and 6.5.3.
7. Responsibility for field touch-up painting, if painting is specified, per AISC Specification Section M4.6 and Code of Standard Practice Section 6.5.4.
8. Special quality assurance and inspection requirements, per AISC Specification Sections M5 and M5.3, and Code of Standard Practice Sections 8.1.3, 8.2, and 8.3.
9. Evaluation procedures, per AISC Specification Section B6.
10. Fatigue requirements, if any, per AISC Specification Section B3.9.
11. Modifications, if any, to the Code of Standard Practice, per Code of Standard Practice Section 1.1.
12. Submittal schedule for shop and erection drawings, per Code of Standard Practice Section 4.2.
13. Mill order timing, special mill testing, and special mill tolerances, per Code of Standard Practice Sections 5.1, 5.2, and 5.2, respectively.
14. Removal of backing bars and run-off-tabs, per Code of Standard Practice Section 6.3.2
15. Special erection mark requirements, per Code of Standard Practice Section 6.6.1.
16. Special delivery and erection sequences, per Code of Standard Practice Sections 6.7.1 and 7.1, respectively.
17. Special field splice requirements, per Code of Standard Practice Section 6.7.4.
18. Specials loads to be considered during erection, per Code of Standard Practice Section 7.10.3.
19. Special safety protection treatments, per Code of Standard Practice Section 7.11.1.
20. Identification of adjustable items, per Code of Standard Practice Section 7.13.1.3.
21. Cuts, alterations, and holes for other trades, per Code of Standard Practice Section 7.15.
22. Revisions to the contract, per Code of Standard Practice Section 9.3
23. Special terms of payment, per Code of Standard Practice Section 9.6.
24. Identification of architecturally exposed structural steel, per Code of Standard Practice Section 10.

Approvals Required

The following provisions require the approval of the owner's designated representative for design, if they are to be used:

1. Bolted-joint-related approvals per RCSC Commentary Section 1.4.
2. Use of electronic or other copies of the design drawings by the fabricator, per Code of Standard Practice Section 4.3.
3. Use of stock materials not conforming to specified ASTM specification, per Code of Standard Practice Section 5.2.3.
4. Correction of errors, per Code of Standard Practice Section 7.14.
5. Inspector-recommended deviations from contract documents, per Code of Standard Practice Section 8.5.6.
6. Contract price adjustment, per Code of Standard Practice Section 9.4.2.

Establishing Criteria for Connections

Code of Standard Practice Section 3.1.2 provides two methods for the establishment of connection criteria.

In the first, the complete design of all connections is shown in the structural design drawings. In this case, Code of Standard Practice Commentary Section 3.1.2 provides a summary of the information that must be included in the structural design drawings.

This method has the advantage that there is no need to provide connection loads, since the connections are completely designed in the structural design drawings. Additionally, it favors greater accuracy in the bidding process, since the connections are fully described in the contract documents.

In the second, the fabricator is allowed to select or complete the connections while preparing the shop and erection drawings, using the information provided by the owner's designated representative for design per Code of Standard Practice Section 3.1.2. In this case, Code of Standard Practice Commentary Section 3.1.2 clarifies the intention that connections that can be selected or completed by the fabricator include those for which tables appear in the contract documents or the Manual. Other connections should be shown in detail in the structural design drawings.

This method has the advantage that the fabricator's standard connections normally can be used, which often leads to project economy. However, the loads or other connection design criteria must be provided in the structural design drawings. Design loads and required strengths for connections should be provided in the structural design drawings and the design method used in the design of the frame (ASD or LRFD) must be indicated on the drawings.

In either method, the resulting shop and erection drawings must be submitted to the owner's designated representative for design for review and approval. Following is additional guidance for the communication of connection criteria to the connection designer.

Simple Shear Connections

The full force envelope should be given for each simple shear connection. Because of the potential for overestimation—and underestimation—inherent in approximate methods (Thornton, 1992), actual beam end reactions should be indicated on the design drawings. The most effective method to communicate this information is to place a numeric value at each end of each span in the framing plans.

In the past, beam end reactions were sometimes specified as a percentage of the tabulated uniform load in Manual Part 3. This practice can result in either over- or under-specification of connection reactions and should not be used. The inappropriateness of this practice is illustrated in the following four examples:

1. When beams are selected for serviceability considerations or for shape repetition, the uniform load tables will often result in heavier connections than would be required by the actual design loads.
2. When beams have relatively short spans, the uniform load tables will often result in heavier connections than would be required by the actual design loads.
3. When beams support other framing beams or other concentrated loads occur on girders supporting beams, the end reactions can be higher than 50 percent of the total uniform load.
4. For composite beams, the end reactions can be higher than 50 percent of the total uniform load. The percentage requirement can be increased for this condition, but the resulting approach is still subject to the above considerations.

Moment Connections

The full force envelope should be given for each moment connection. If the owner's designated representative for design can select the governing load combination, its effect alone should be provided. Otherwise, the effects of all appropriate load combinations should be indicated. Additionally, the maximum moment imbalance should also be given for use in the check of panel-zone web shear.

Because of the potential for overestimation—and underestimation—inherent in approximate methods, it is recommended that the actual beam end reactions (moment, shear, and other reactions, if any) be indicated in the structural design drawings. The most effective method to do so may be by tabulation for each joint and load combination.

Although not recommended, beam end reactions can be specified by more general criteria, such as by function of the beam strength. It should be noted, however, that there are several situations in which this approach is not appropriate. For example:

1. When beams are selected for serviceability considerations or for shape repetition, this approach will often result in heavier connections than would be required by the actual design loads.
2. When the column(s) or other members that frame at the joint could not resist the forces and moments determined from the criteria so specified, this approach will often result in heavier connections than would be required by the actual design loads.

In some cases, the structural analysis may require that the actual connections be configured to match the assumptions used in the model. For example, it may be appropriate to release weak-axis moments in a beam-column joint where only strong-axis beam moment strength is required. Such requirements should be indicated in the structural design drawings.

Truss Connections

The full force envelope should be given for each truss-member end connection. If the owner's designated representative for design can select the governing load combination for the entire truss, its effect alone should be provided. Otherwise, the effects of all appropriate load combinations should be indicated in tabular form. This approach will allow a clear understanding of all of the forces on any given joint.

Because of the potential for overestimation—and underestimation—inherent in approximate methods, it is recommended that the actual reactions at the truss member end (axial force and other reactions, if any) be indicated in the structural design drawings. It is also recommended that transfer forces, if any, be so indicated. The most effective method to do so may be by tabulation for each truss member end and load combination.

Although not recommended, truss member end reactions can be specified by more general criteria, such as by maximum member forces (tension or compression) or as a function of the member strength. It should be noted, however, that there are several situations in which such approaches are not appropriate. For example:

1. The specification of maximum member forces does not permit a check of the member forces at a joint if there are different load combinations governing the member designs at that joint. Nor does it reflect the possibility of load reversal as it may influence the design.
2. The specification of a percentage of member strength may not properly account for the interaction of forces at a joint or the transfer force through the joint. Additionally, it may not allow for a cross-check of all forces at a joint.

In either case, this approach will often result in heavier connections than would be required by the actual design loads.

Note that it is not necessary to specify a minimum connection strength as a percent of the member strength as a default. However, when trusses are shop assembled or field assembled on the ground for subsequent erection, consideration should be given to the loads that will be induced during handling, shipping, and erection.

Horizontal and Vertical Bracing Connections

The recommendations for truss connections above also apply in general to bracing connections with the following additional comments.

Bracing connections may involve the interaction of gravity and lateral loads on the frame. In some cases, such as V- and inverted V-bracing (also known as Chevron bracing), gravity loads alone may govern design of the braces and their connections. Thus, clarity in the specification of loads and reactions is critical to properly consider the potential interaction of gravity and lateral loads at floors and roofs.

Strut and Tie Connections

Floor and roof members in braced bays and adjacent bays may function as struts or ties in addition to carrying gravity loads. Therefore the recommendations for simple shear connections and bracing connections above apply in combination.

Column Splices

Column splices may resist moments, shears, and tensions in addition to gravity forces. Typical column splices are discussed in Part 14. As in the case of the other connections discussed above, unless the column splices are fully designed in the Construction Documents, forces and moments for the splice designs should be provided in the Construction Documents. Since column splices are located away from the girder/column joint and moments vary in the height of the column, an accurate assessment of the forces and moments at the column splices will usually significantly reduce their cost and complexity.

TOLERANCES

The effects of mill, fabrication, and erection tolerances all require consideration in the design and construction of structural steel buildings. However, the accumulation of the mill tolerances and fabrication tolerances shall not cause the erection tolerances to be exceeded, per Code of Standard Practice Section 7.12.

Mill Tolerances

Mill tolerances are those variations that could be present in the product as-delivered from the rolling mill. These tolerances are given as follows:

1. For structural shapes and plates, see ASTM A6.
2. For HSS, see ASTM A500 (or other applicable ASTM specification for HSS).
3. For pipe, see ASTM A53.

A summary of standard mill practices is also given in Part 1.

Fabrication Tolerances

Fabrication tolerances are generally provided in AISC Specification Section M2 and Code of Standard Practice Section 6.4. Additional requirements that govern fabrication are as follows:

1. Compression joint fit-up, per AISC Specification Section M4.4.
2. Roughness limits for finished surfaces, per Code of Standard Practice Section 6.2.2.
3. Straightness of projecting elements of connection materials, per Code of Standard Practice Section 6.3.1.
4. Finishing requirements at locations of removal of run-off tabs and similar devices, per Code of Standard Practice Section 6.3.2.

Erection Tolerances

Erection tolerances are generally provided in AISC Specification Section M4 and Code of Standard Practice Section 7.13. Note that the tolerances specified therein are predicated upon the proper installation of the following items by the owner's designated representative for construction:

1. Building lines and benchmarks, per Code of Standard Practice Section 7.4.
2. Anchorage devices, per Code of Standard Practice Section 7.5.
3. Bearing devices, per Code of Standard Practice Section 7.6.
4. Grout, per Code of Standard Practice Section 7.7.

Building Façade Tolerances

The preceding mill, fabrication, and erection tolerances can be maintained with standard equipment and workmanship. However, the accumulated tolerances for the structural steel and the building façade must be accounted for in the design so that the two systems can be properly mated in the field. This is normally accomplished by specifying adjustable connections in the contract documents, per Code of Standard Practice Section 7.13.1.3.

The required adjustability normally can be determined from the building façade tolerances and the accumulation of mill, fabrication, and erection tolerances at the mid-span point of the spandrel beam. The actual locations of the anchor-rod group and column base, the actual slope of the columns, and the actual sweep of the spandrel beam all affect the accumulation of tolerances in the structural steel at this critical location. Even if each of these is properly within the permitted envelope, significant variations will normally occur.

Figures 2–3a, 2–4a, and 2–5a illustrate details that are not recommended because they do not provide for adjustment. Figures 2–3b, 2–4b, and 2–5b illustrate recommended alternative details that do provide for adjustability. Note that diagonal structural and stability bracing elements have been omitted in these details to improve the clarity of presentation regarding adjustability. Also, note that all elements beyond the slab edge are normally not structural steel, per Code of Standard Practice Section 2.2, and are shown for the purposes of illustration only.

The bolted details in Figures 2–4b and 2–5b can be used to provide field adjustability with slotted holes as shown. Further adjustability can be provided in these details, if necessary, by removing the bolts and clamping the connection elements for field-welding. Alternatively, when the slab edge angle or plate in Figure 2–4b is shown as field-welded and identified as adjustable in the contract documents, it can be provided to within a horizontal tolerance of ±3/8 in., per Code of Standard Practice Section 7.13.1.3. However, if the item were not shown as field-welded and identified as adjustable in the contract documents, it would likely be attached in the shop or attached in the field to facilitate the concrete pour and not be suitable to provide for the necessary adjustment.

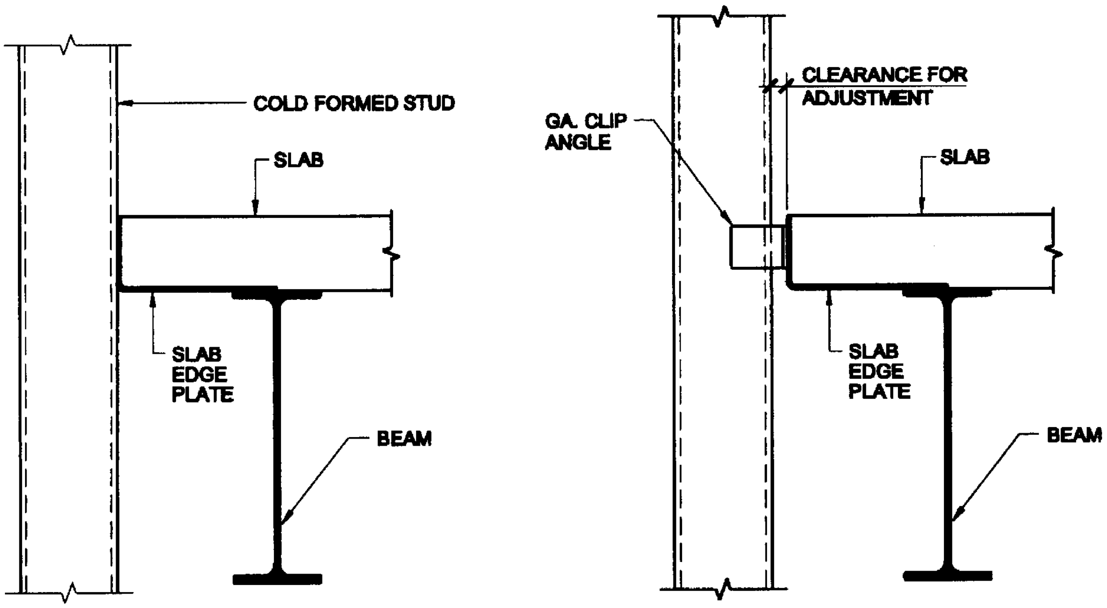
With adjustable connections specified in design and provided in fabrication, the actions taken on the job site will allow for a successful façade installation. Per the Code of Standard Practice definition of established column line (see Code of Standard Practice Glossary), proper placement of this line by the owner's designated representative for construction based upon the actual anchor-rod/column-center locations will assure that all subcontractors are working from the same information. When sufficient adjustment cannot be accommodated within the adjustable connections provided, a common solution is to allow the building façade to deviate (or drift) from the theoretical location to follow the as-built locations of the structural steel framing and concrete floor slabs. A survey of the as-built locations of these elements can be used to adjust the placement of the building façade accordingly. In this case, the adjustable connections can serve to ensure that no abrupt changes occur in the façade.

CAMBER, SWEEP, AND STRAIGHTENING

Beam Camber and Sweep

Camber denotes a curve in the vertical plane. Sweep denotes a curve in the horizontal plane. Camber and sweep are provided in beams, when required, by the fabricator per Code of Standard Practice Section 6.4.4, either by cold bending or by hot bending.

Cambering and sweeping induce residual stresses similar to those that develop in rolled structural shapes, as elements of the shape cool from the rolling temperature at different rates. In general, these residual stresses do not affect the design strength of structural members, since the effect of residual stresses is considered in the provisions of the AISC Specification.



(a) WITHOUT ADJUSTMENT [NOT RECOMMENDED]

(b) WITH ADJUSTMENT [RECOMMENDED]

Figure 2–3. Attaching cold-formed steel façade systems to structural steel framing.

Cold Bending

The inelastic deformations required in common cold-bending operations, such as for beam cambering, normally fall well short of the strain-hardening range. Specific limitations on cold-bending capabilities should be obtained from those that provide the service. However, the following general guidelines may be useful in the absence of other information:

1. The minimum radius for camber induced by cold bending in members up to a nominal depth of 30 in. is between 10 and 14 times the depth of the member. Deeper members may require a larger minimum radius.
2. Cold bending may be used to provide sweep in members to practically any radius desired.
3. A length limit of 40 to 50 ft is practical.

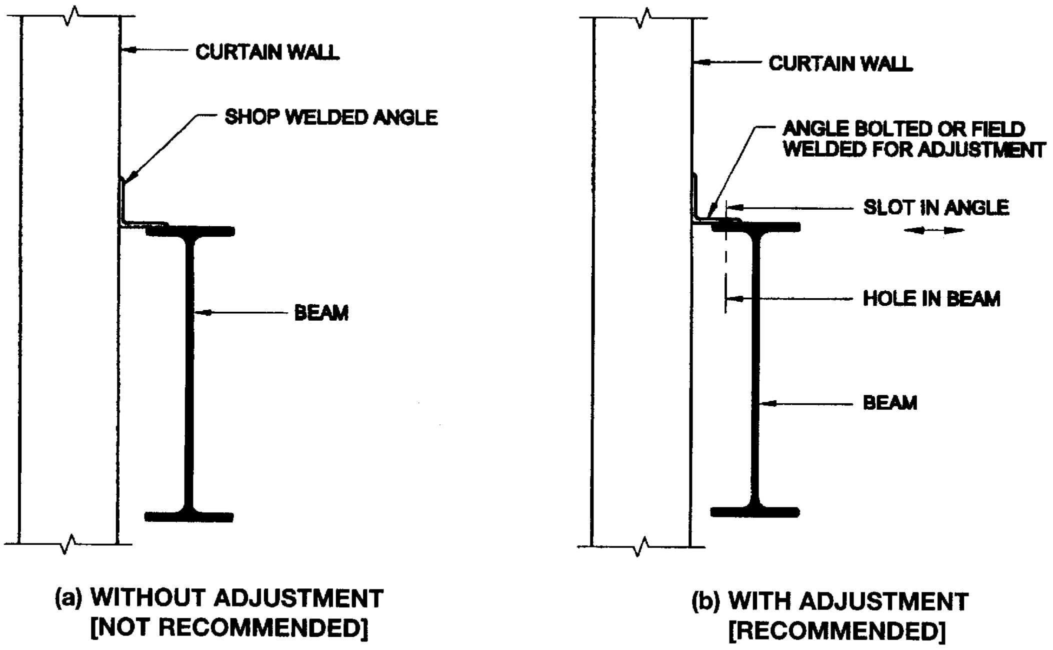
When curvatures and the resulting inelastic deformations are significant and corrective measures are required, the effects of cold work on the strength and ductility of the structural steels largely can be eliminated by thermal stress relief or annealing.

Hot Bending

The controlled application of heat can be used in the shop and field to provide camber or sweep. The member is rapidly heated in selected areas that tend to expand, but are restrained by the adjacent cooler areas, causing inelastic deformations in the heated areas and a change in the shape of the cooled member.

The mechanical properties of steels are largely unaffected by such heating operations, provided the maximum temperature does not exceed the temperature limitations given in AISC Specification Section M2.1. Temperature-indicating crayons or other suitable means should be used during the heating process to ensure proper regulation of the temperature.

Heat curving induces residual stresses that are similar to those that develop in hot-rolled structural shapes as they cool from the rolling temperature because all parts of the shape do



(a) WITHOUT ADJUSTMENT [NOT RECOMMENDED]

(b) WITH ADJUSTMENT [RECOMMENDED]

Figure 2–4. Attaching curtain-wall façade systems to structural steel framing.

not cool at the same rate. The residual stresses from heating operations generally do not affect the design strength of structural members, since the effect of residual stresses is considered in the provisions of the AISC Specification.

Truss Camber

Camber is provided in trusses, when required, by the fabricator per Code of Standard Practice Section 6.4.5, by geometric relocation of panel points and adjustment of member lengths based upon the camber requirements as specified in the contract documents.

Straightening

All structural shapes are straightened at the mill after rolling, either by rotary or gag straightening, to meet the aforementioned mill tolerances. Similar processes and/or the controlled application of heat can be used in the shop or field to straighten a curved or distorted member. These processes are normally applied in a manner similar to those used to induce camber and sweep, as described above.

FIRE PROTECTION AND ENGINEERING

Complete coverage of fire protection and engineering for steel structures is included in AISC Design Guide 19, *Fire Resistance of Structural Steel Framing* (Ruddy et. al., 2003).

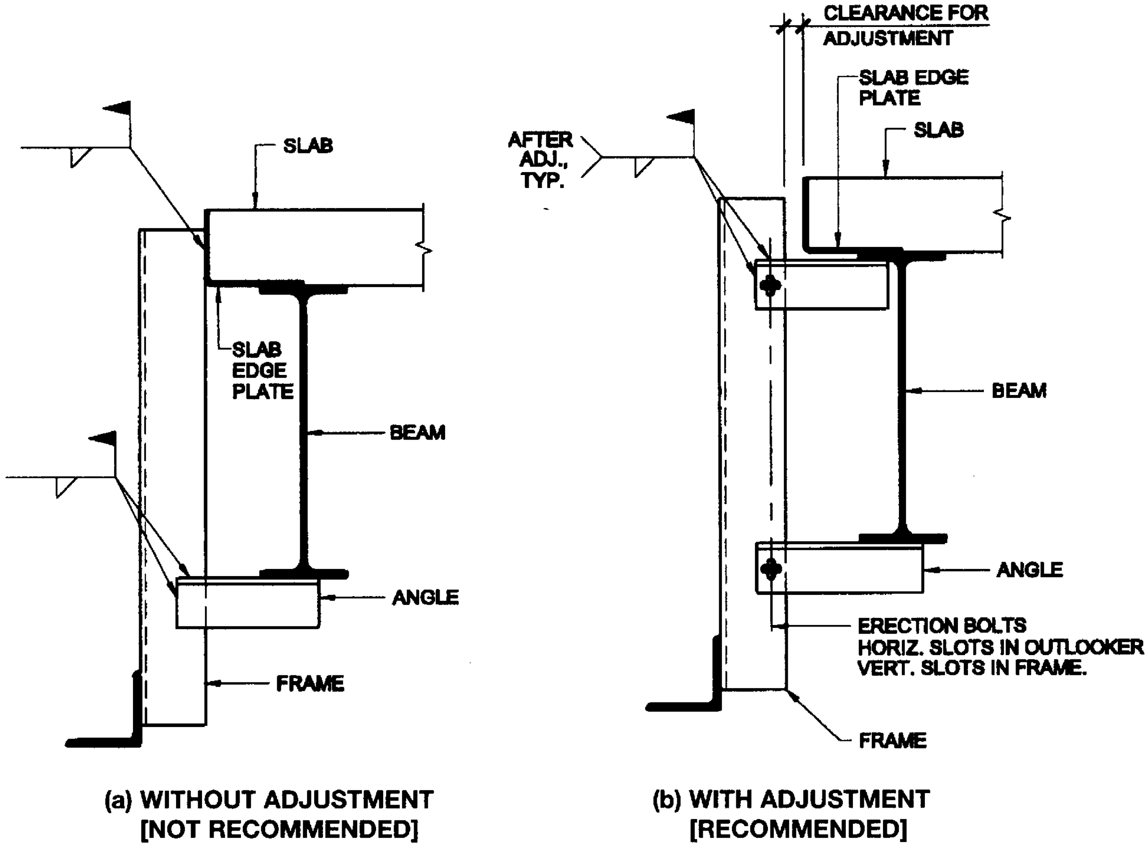


Figure 2–5. Attaching masonry façade systems to structural steel framing.

CORROSION PROTECTION

In building structures, corrosion protection is not required for steel that will be enclosed by building finish, coated with a contact-type fireproofing, or in contact with concrete. When enclosed, the steel is trapped in a controlled environment and the products required for corrosion are quickly exhausted, as indicated in AISC Commentary Section M3. A similar situation exists when steel is fireproofed or in contact with concrete. Accordingly, shop primer or paint is not required unless specified in the contract documents, per AISC Specification Section M3.1. Per Code of Standard Practice Section 6.5, steel that is to remain unpainted need only be cleaned of heavy deposits of oil and grease by appropriate means after fabrication.

Corrosion protection is required, however, in exterior exposed applications. Likewise, steel must be protected from corrosion in aggressively corrosive applications, such as a paper processing plant, a structure with oceanfront exposure, or when temperature changes can cause condensation. Corrosion should also be considered when connecting steel to dissimilar metals. Guidance on steel compatibility with metal fasteners is provided in Table 2–6.

When surface preparation other than the cleaning described above is required, an appropriate SSPC grade of cleaning should be specified in the contract documents. A summary of the SSPC surface preparation specifications (SSPC, 2000) is provided in Table 2–7. SSPC SP 2 is the normal grade of cleaning when cleaning is required.

For further information, refer to the publications of SSPC: The Society for Protective Coatings, the American Galvanizers Association (AGA), and the National Association of Corrosion Engineers International (NACE).

RENOVATION AND RETROFIT OF EXISTING STRUCTURES

The provisions in AISC Specification Section B6 govern the evaluation of existing structures. Historical data on available steel grades and hot-rolled structural shapes, including dimensions and properties, is available in AISC Design Guide 15 *Rehabilitation and Retrofit Guide* (Brockenbrough, 2002), and the companion database of historic shape properties from 1873-1999, titled *AISC Search Utility for Structural Steel Shapes* (AISC, 2003). See also Ricker (1988) and Tide (1990).

THERMAL EFFECTS

Expansion and Contraction

The average coefficient of expansion e for structural steel between 70 and 100 degrees F is 0.0000065 for each degree F. This value is a reasonable approximation of the coefficient of thermal expansion for temperatures less than 70 degrees F. For temperatures from 100 to 1,200 degrees F, the change in length per unit length per degree F, ε, is:

$$\varepsilon = (6.1 + 0.0019t)10^{-6}$$

where t is the initial temperature in degrees F. The coefficients of expansion for other building materials can be found in Table 17–11.

Although buildings are typically constructed of flexible materials, expansion joints are often required in roofs and the supporting structure when horizontal dimensions are large. The maximum distance between expansion joints is dependent upon many variables, including ambient temperature during construction and the expected temperature range during the lifetime of the building.

Figure 2–6 (Federal Construction Council, 1974) provides guidance based on design temperature change for maximum spacing of structural expansion joints in beam-and-column-framed buildings with pinned column bases and heated interiors. The report includes data for numerous cities and gives five modification factors to be applied as appropriate:

1. If the building will be heated only and will have pinned column bases, use the maximum spacing as specified;
2. If the building will be air-conditioned as well as heated, increase the maximum spacing by 15 percent, provided the environmental control system will run continuously;
3. If the building will be unheated, decrease the maximum spacing by 33 percent;
4. If the building will have fixed column bases, decrease the maximum spacing by 15 percent;
5. If the building will have substantially greater stiffness against lateral displacement in one of the plan dimensions, decrease the maximum spacing by 25 percent.

When more than one of these design conditions prevail in a building, the percentile factor to be applied is the algebraic sum of the adjustment factors of all the various applicable conditions. Most building codes include restrictions on location and maximum spacing of fire walls, which often become default locations for expansion joints.

The most effective expansion joint is a double line of columns that provides a complete and positive separation. Alternatively, low-friction sliding elements can be used. Such systems, however, are seldom totally friction-free and will induce some level of inherent restraint to movement.

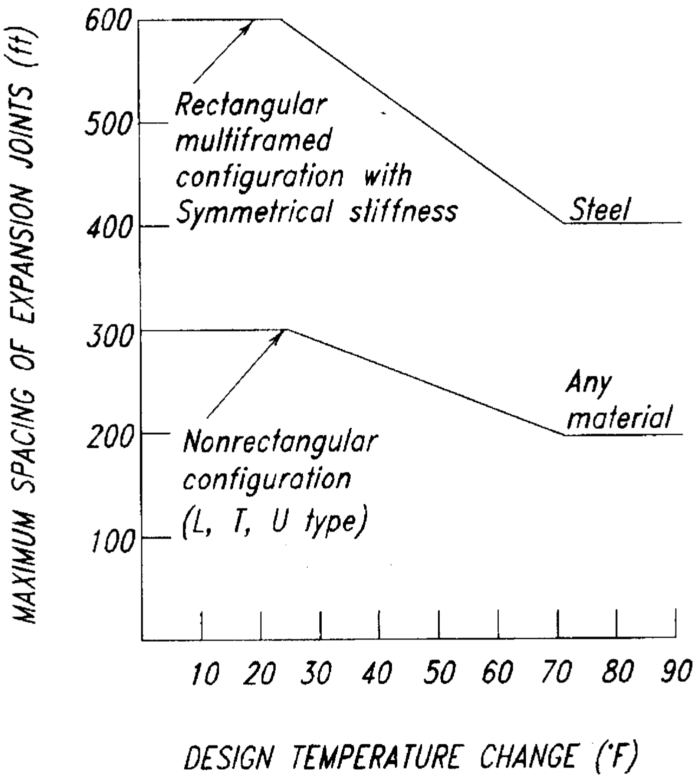

Figure 2–6. Recommended maximum expansion-joint spacing.

Elevated-Temperature Service

For applications involving short-duration loading at elevated temperature, the variations in yield strength, tensile strength, and modulus of elasticity are given AISC Design Guide 19. For applications involving long-duration loading at elevated temperatures, the effects of creep must also be considered. For further information, see Brockenbrough and Merritt (1999; pp. 1.20-1.22).

FATIGUE AND FRACTURE CONTROL

Avoiding Brittle Fracture

By definition, brittle fracture occurs by cleavage at a stress level below the yield strength. Generally, a brittle fracture can occur when there is a sufficiently adverse combination of tensile stress, temperature, strain rate, and geometrical discontinuity (notch). The exact combination of these conditions and other factors that will cause brittle fracture cannot be readily calculated. Consequently, the best guide in selecting steel material that is appropriate for a given application is experience.

The steels listed in AISC Specification Section A3.1a, Section A3.1c, and Section A3.1d have been successfully used in a great number of applications, including buildings, bridges, transmission towers, and transportation equipment, even at the lowest atmospheric temperatures encountered in the United States. Nonetheless, it is desirable to minimize the conditions that tend to cause brittle fracture: triaxial state-of-stress, increased strain rate, strain aging, stress risers, welding residual stresses, areas of reduced notch toughness, and low-temperature service.

1. Triaxial state-of-stress: While shear stresses are always present in a uniaxial or biaxial state-of-stress, the maximum shear stress approaches zero as the principal stresses approach a common value in a triaxial state-of-stress. A triaxial state-of-stress can also result from uniaxial loading when notches or geometrical discontinuities are present. A triaxial state-of-stress will cause the yield stress of the material to increase above its nominal value, resulting in brittle fracture by cleavage, rather than ductile shear deformations. As a result, in the absence of critical-size notches, the maximum stress is limited by the yield stress of the nearby unaffected material. Triaxial stress conditions should be avoided, when possible.
2. Increased strain rate: Gravity loads, wind loads, and seismic loads have essentially similar strain rates. Impact loads, such as those associated with heavy cranes, and blast loads normally have increased strain rates, which tend to increase the possibility of brittle fracture. Note, however, that a rapid strain rate or impact load is not a required condition for the occurrence of brittle fracture.
3. Strain aging: Cold-working of steel and the strain aging that normally results generally increases the likelihood of brittle fracture, usually due to a reduction in ductility and notch toughness. The effects of cold-work and strain aging can be minimized by selecting a generous forming radius to eliminate or minimize strain hardening.
4. Stress risers: Fabrication operations, such as flame-cutting and welding, may induce geometric conditions or discontinuities that are crack-like in nature, creating stress risers. Intersecting welds from multiple directions should be avoided with properly sized weld access holes to minimize the interaction of these various stress fields. Such conditions should be avoided, when possible, or removed or repaired when they occur.

5. Welding residual stresses: In the as-welded condition, residual stresses near the yield strength of the material will be present in any weldment. Residual stresses and the possible accompanying distortions can be minimized through controlled welding procedures and fabrication methods, including the proper positioning of the components of the joint prior to welding, the selection of welding sequences that will minimize distortions, the use of preheat as appropriate, the deposition of a minimum volume of weld metal with a minimum number of passes for the design condition, and proper control of interpass temperatures and cooling rates. In fracture-sensitive applications, notch toughness should be specified for both the base metal and the filler metal.
6. Areas of reduced notch toughness: Such areas can be found in the core areas of heavy shapes and plates and the k-Area of rotary-straightened W-shapes. Accordingly, AISC Specification Sections A3.1c and Section A3.1d include special requirements for material notch toughness.
7. Low-temperature service: While steel yield strength, tensile strength, modulus of elasticity, and fatigue strength increase as temperature decreases, ductility and toughness decrease. Furthermore, there is a temperature below which steel subjected to tensile stress may fracture by cleavage, with little or no plastic deformation, rather than by shear, which is usually preceded by considerable inelastic deformation. Note that cleavage and shear are used in the metallurgical sense to denote different fracture mechanisms.

When notch toughness is important, Charpy V-notch testing can be specified to ensure a certain level of energy absorption at a given temperature, such as 15 ft-lbs at 70 degrees F. Note that the appropriate test temperature may be higher than the lowest operating temperature depending upon the rate of loading. Although it is primarily intended for bridge-related applications, the information in ASTM A709 Section S83 (including Tables S1.1, S1.2, and S1.3) may be useful in determining the proper level of notch toughness that should be specified.

In many cases, weld metal notch toughness exceeds that of the base metal. Filler metals can be selected to meet a desired minimum notch toughness value. For each welding process, electrodes exist that have no specified notch toughness requirements. Such electrodes should not be assumed to possess any minimum notch toughness value. When notch toughness is necessary for a given application, the desired value or an appropriate electrode should be specified in the contract documents.

For further information, refer to Fisher et al. (1998), Barsom and Rolfe (1999), and Rolfe (1977).

Avoiding Lamellar Tearing

Although lamellar tearing is less common today, the restraint against solidified weld deposit contraction inherent in some joint configurations can impose a tensile strain high enough to cause separation or tearing on planes parallel to the rolled surface of the element being joined. The incidence of this phenomenon can be reduced or eliminated through greater understanding by designers, detailers, and fabricators of the inherent directionality of rolled steel, the importance of strains associated with solidified weld deposit contraction in the presence of high restraint (rather than externally applied design forces), and the need to adopt appropriate joint and welding details and procedures with proper weld metal for through-thickness connections.

Research by Melendrez and Dexter (Dexter and Melendrez, 2000) demonstrates that W-shapes are not susceptible to lamellar tearing or other through-thickness failures when welded tee joints are made to the flanges at locations away from member ends. When needed for other conditions, special production practices can be specified for steel plates to assist in reducing the incidence of lamellar tearing by enhancing through-thickness ductility. For further information, refer to ASTM A770. However, it must be recognized that it is more important and effective to properly design, detail, and fabricate to avoid highly restrained joints. AISC (1973) provides guidelines that minimize potential problems.

WIND AND SEISMIC DESIGN

In general, nearly all building design and construction can be classified into one of two categories: wind and low-seismic applications, and high-seismic applications.

Wind and Low-Seismic Applications

Wind and low-seismic applications are those in which the seismic response modification factor R may be taken as equal to or less than 3 for design purposes. Such buildings are designed to meet the provisions in the AISC Specification based upon the code-specified forces distributed throughout the framing, assuming a nominally elastic structural response. The resulting systems have normal levels of ductility.

The seismic response modification factor, R, essentially represents the ratio of the forces that would develop under the specified ground motion if the structure had an entirely linearly elastic response to the prescribed design forces (BSSC, 2001).

High-Seismic Applications

High-seismic applications are those in which R is taken greater than 3, and the building is designed to meet the provisions in both the Seismic Provisions and AISC Specification. Note that it does not matter if wind or earthquake controls in this case. The use of R greater than 3 in the calculation of the seismic base shear requires the use of a seismically detailed system that is compatible with R even if wind effects control. High-seismic design and construction will generally cost more than wind and low-seismic design and construction, as the resulting systems are designed to have high levels of ductility.

High-seismic lateral framing systems are configured to be capable of withstanding strong ground motions as they undergo controlled ductile deformations to dissipate energy. Consider the following three examples:

1. Special Concentrically Braced Frames (SCBF)—SCBF are generally configured so that any inelasticity will occur by tension yielding and/or compression buckling in the braces. The connections of the braces to the columns and beams, and between the columns and beams themselves must then be proportioned to remain nominally elastic, as they undergo these deformations.
2. Eccentrically Braced Frames (EBF)—EBF are generally configured so that any inelasticity will occur by shear yielding and/or flexural yielding in the link. The beam outside the link, connections, braces, and columns must then be proportioned to remain nominally elastic, as they undergo these deformations.

3. Special Moment Frames (SMF)—SMF are generally configured so that any inelasticity will occur by flexural yielding in the girders near, but away from, the connection of the girders to the columns. The connections of the girders to the columns and the columns themselves must then be proportioned to remain nominally elastic as they undergo these deformations. Intermediate Moment Frames (IMF) and Ordinary Moment Frames (OMF) are also configured to provide improved seismic performance, although successively lower than that for SMF.

The code-specified base accelerations used to calculate the seismic forces are not necessarily maximums, but rather, they represent the intensity of ground motions that have been selected by the code-writing authorities as reasonable for design purposes. Accordingly, the requirements in both the Seismic Provisions and the AISC Specification must be met so that the resulting frames can then undergo controlled deformations in a ductile, well-distributed manner.

The design provisions for high-seismic systems are also intended to result in distributed deformations throughout the frame, rather than the formation of story mechanisms, so as to increase the level of available energy dissipation and corresponding level of ground motion that can be withstood.

The member sizes in high-seismic frames will be larger than those in wind and low-seismic frames. The connections will also be much more robust so they can transmit the member-strength-driven force demands. Net sections will often require special attention so as to avoid having fracture limit-states control. Special material requirements, design considerations, and construction practices must be followed. For further information on the design and construction of high-seismic systems, see the Seismic Provisions, which are available from the American Institute of Steel Construction, Inc. at www.aisc.org.

Table 2-1
Summary Comparison of Methods for Stability Analysis and Design

	Direct Analysis Method	Effective Length Method	First-Order Analysis Method
Limitations on Use[1]	None	$\Delta_{2nd}/\Delta_{1st} \leq 1.5$	$\Delta_{2nd}/\Delta_{1st} \leq 1.5$ $\alpha P_r/P_y \leq 0.5$
Analysis Type	Second-order elastic[2]		First-order elastic
Geometry of Structure	All three methods use the undeformed geometry in the analysis.		
Minimum or Additional Lateral Loads Required in the Analysis	Minimum[3]; 0.2% of the story gravity load	Minimum; 0.2% of the story gravity load	Additive; at least 0.42% of the story gravity load
Member Stiffnesses Used in the Analysis	Reduced *EA* and *EI*	Nominal *EA* and *EI*	
Design of Columns	$K = 1$ for all frames	$K = 1$ for braced frames. For moment frames, determine K from sidesway buckling analysis[4]	$K = 1$ for all frames[5]
Specification Reference for Method	Appendix 7	Section C2.2a	Section C2.2b

[1] $\Delta_{2nd}/\Delta_{1st}$ is the ratio of second-order drift to first-order drift, which can be taken to be equal to B_2 calculated per Section C2.1b. $\Delta_{2nd}/\Delta_{1st}$ is determined using LRFD load combinations or a multiple of 1.6 times ASD load combinations.

[2] Either a general second-order analysis method or second-order analysis by amplified first-order analysis (the "B_1-B_2 method" described in Section C2.1b) can be used.

[3] This notional load is additive if $\Delta_{2nd}/\Delta_{1st} > 1.5$.

[4] K=1 is permitted for moment frames when $\Delta_{2nd}/\Delta_{1st} \leq 1.1$.

[5] An additional amplification for member curvature effects is required for columns in moment frames.

☐ = Material specification does not apply.

---

[a] Minimum unless a range is shown.

[b] For shapes over 426 lb/ft, only the minimum of 58 ksi applies.

[c] For shapes with a flange thickness less than or equal to 1½ in. only. To improve weldability a maximum carbon equivalent can be specified (per ASTM Supplementary Requirement S78). If desired, maximum tensile stress of 90 ksi can be specified (per ASTM Supplementary Requirement S79).

[d] If desired, maximum tensile stress of 70 ksi can be specified (per ASTM Supplementary Requirement S91).

[e] For shapes with a flange thickness less than or equal to 2 in. only.

[f] ASTM A618 can also be specified as corrosion-resistant; see ASTM A618.

[g] Minimum applies for walls nominally ¾-in. thick and under. For wall thicknesses over ¾ in., F_y = 46 ksi and F_u = 67 ksi.

[h] If desired, maximum yield stress of 65 ksi and maximum yield-to-tensile strength ratio of 0.85 can be specified (per ASTM Supplementary Requirement S75).

[i] A maximum yield-to-tensile strength ratio of 0.85 and carbon equivalent formula are included as mandatory in ASTM A992.

[j] For shapes with a flange thickness greater than 2 in. only.

[k] For shapes with a flange thickness greater than 1½ in. and less than or equal to 2 in. only.

[l] For shapes with a flange thickness less than or equal to 1½ in. only.

[a] Minimum unless a range is shown or maximum (max.) is indicated.

[b] Special washer requirements may apply per RCSC Specification Table 6.1 for some steel-to-steel bolting applications and per Part 14 for anchor-rod applications.

[c] See AISC Specification Section A3.3 for limitations on use of ASTM A449 bolts.

[d] When atmospheric corrosion resistance is desired, Type 3 can be specified.

[e] For anchor rods with temperature and corrosion resistance characteristics.

Table 2–6

Metal Fastener Compatibility to Resist Corrosion

Fastener Metal Base Metal	Zinc and Galvanized Steel	Aluminum and Aluminum Alloys	Steel and Cast Iron	Brasses, Copper, Bronzes, Monel	Martensitic Stainless Steel (Type 410)	Austenitic Stainless Steel (Type 302/304, 303, 305)
Zinc and Galvanized Steel	A	B	B	C	C	C
Aluminum and Aluminum Alloys	A	A	B	C	Not Recommended	B
Steel and Cast Iron	A, D	A	A	C	C	B
Terne (Lead-Tin) Plated Steel Sheets	A, D, E	A, E	A, E	C	C	B
Brasses, Copper, Bronzes, Monel	A, D, E	A, E	A, E	A	A	B
Ferritic Stainless Steel (Type 430)	A, D, E	A, E	A, E	A	A	A
Austenitic Stainless Steel (Type 302/304)	A, D, E	A, E	A, E	A, E	A	A

KEY

A. The corrosion of the base metal is not increased by the fastener.
B. The corrosion of the base metal is marginally increased by the fastener.
C. The corrosion of the base metal may be markedly increased by the fastener material.
D. The plating on the fastener is rapidly consumed, leaving the bare fastener metal.
E. The corrosion of the fastener is increased by the base metal.

NOTE: Surface Treatment and environment can change activity. For a more thorough understanding of metal corrosion in construction materials, please consult a full listing of the galvanic series of metals and alloys.

Note: Reprinted from the Specialty Steel Industry of North America Stainless Steel Fasteners Designer's Handbook.

Table 2–7
Summary of Surface Preparation Specifications

SSPC Specification No.	Title	Description
SP1	Solvent Cleaning	Removal of oil, grease, dirt, soil, salts, and contaminants by cleaning with solvent, vapor, alkali, emulson, or steam.
SP2	Hand-Tool Cleaning	Removal of all loose rust, loose mill scale, and loose paint to degree specified, by hand-chipping, scraping, sanding, and wire brushing.
SP3	Power-Tool Cleaning	Removal of all loose rust, loose mill scale, and loose paint to degree specified, by power-tool chipping, descaling, sanding, wire brushing, and grinding.
SP5/NACE No.1	Metal Blast Cleaning	Removal of all visible rust, mill scale, paint, and foreign matter by blast-cleaning by wheel or nozzle (dry or wet) using sand, grit, or shot. (For very corrosive atmospheres where high cost of cleaning is warranted.)
SP6/NACE No.3	Commercial Blast-Cleaning	Blast-cleaning until at least two-thirds of the surface area is free of all visible residues. (For conditions where thoroughly cleaned surface is required.)
SP7/NACE No. 4	Brush-Off Blast-Cleaning	Blast-cleaning of all except tightly adhering residues of mill scale, rust, and coatings, exposing numerous evenly distributed flecks of underlying metal.
SP8	Pickling	Complete removal of rust and mill scale by acid-pickling, duplex-pickling, or electrolytic pickling.
SP10/NACE No.2	Near-White Blast-Cleaning	Blast-cleaning to nearly White Metal cleanliness, until at least 95% of the surface area is free of all visible residues. (For high humidity, chemical atmosphere, marine, or other corrosive environments.)
SP11	Power-Tool Cleaning to Bare Metal	Complete removal of all rust, scale, and paint by power tools, with resultant surface profile.

SCOPE

The specification requirements and other design considerations summarized in this Part apply to the design of flexural members subject to uniaxial flexure without axial forces or torsion. For the design of members subject to biaxial flexure and/or flexure in combination with axial tension or compression and/or torsion, see Part 6. For flexural members that are part of a seismic force resisting system in which the seismic response modification factor, R, is taken greater than 3, the requirements in the AISC *Seismic Provisions for Structural Steel Buildings* also apply. The AISC *Seismic Provisions for Structural Steel Buildings* is available in Part 6 of the AISC *Seismic Design Manual* from the American Institute of Steel Construction, Inc. at www.aisc.org.

SECTION PROPERTIES AND AREAS

For Flexure

Flexural design properties are based upon the full cross section with no reduction for bolt holes when the limitations in AISC Specification Section F13.1(a) are satisfied. Otherwise, the flexural design properties are based upon a flexural rupture check given in AISC Specification Section F13.1(b).

For Shear

For shear, the area is determined per AISC Specification Chapter G.

FLEXURAL STRENGTH

The nominal flexural strength of W-shapes is illustrated as a function of the unbraced length, L_b, in Figure 3–1. The available strength is determined as ϕM_n or M_n/Ω, which must equal or exceed the required strength (bending moment), M_u or M_a, respectively. The available flexural strength, ϕM_n or M_n/Ω, is determined per AISC Specification Chapter F. User Note F1.1 outlines the sections of Chapter F and the corresponding limit states applicable to each member type.

Braced, Compact Flexural Members

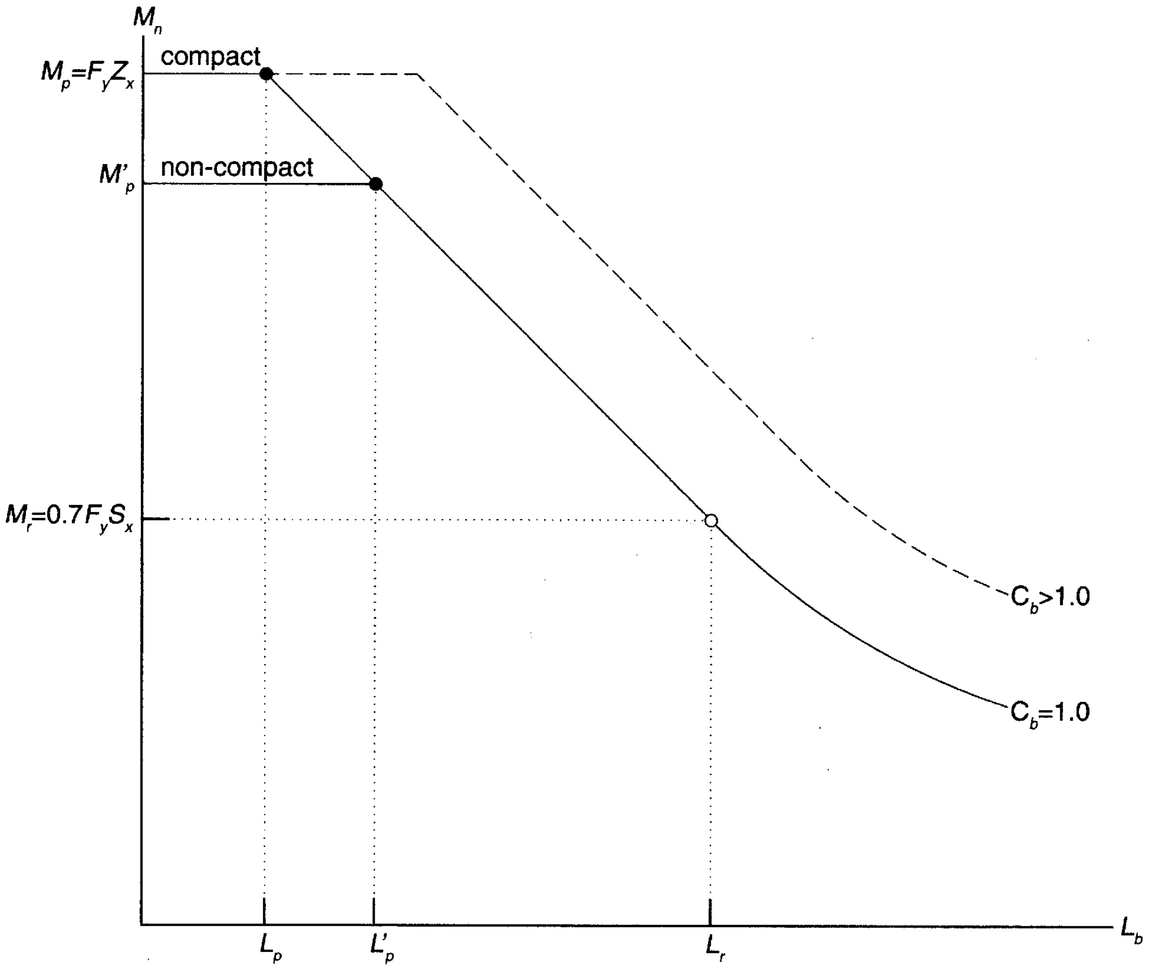
When flexural members are braced ($L_b \leq L_p$) and compact ($\lambda \leq \lambda_p$), yielding must be considered in the nominal moment strength of the member, in accordance with the requirements of AISC Specification Chapter F.

Unbraced Flexural Members

When flexural members are unbraced ($L_b > L_p$), have flange width-thickness ratios such that ($\lambda > \lambda_p$), or have web width-thickness ratios such that ($\lambda > \lambda_p$), lateral-torsional and elastic buckling effects must be considered in the calculation of the nominal moment strength of the member.

Non-Compact or Slender Cross-Sections

For flexural members that have width-thickness ratios such that ($\lambda>\lambda_p$), local buckling must be considered in the calculation of the nominal moment strength of the member.



$$L_p = 1.76r_y\sqrt{\frac{E}{F_y}}$$

$$L_r = 1.95r_{ts}\frac{E}{0.7F_y}\sqrt{\frac{Jc}{S_xh_o}}\sqrt{1+\sqrt{1+6.76\left(\frac{0.7F_y}{E}\frac{S_x}{J}\frac{h_o}{c}\right)^2}}$$

For non-compact cross-sections:

$$M'_p = M_p - \left(M_p - 0.7F_yS_x\right)\frac{\left(\lambda-\lambda_p\right)}{\left(\lambda_r-\lambda_p\right)}$$

$$L'_p = L_p + \left(L_r - L_p\right)\frac{\left(M_p - M'_p\right)}{\left(M_p - M_r\right)}$$

Figure 3–1. General available flexural strength of beams.

Available Flexural Strength for Weak-Axis Bending

The design of flexural members subject to weak-axis bending is similar to that for strong-axis bending, except that lateral-torsional buckling does not apply. See AISC Specification Section F6.

LOCAL BUCKLING

Determining the Width-Thickness Ratios of the Cross-Section

Flexural members are classified for flexure on the basis of the width-thickness ratios of the various elements of the cross-section. The width-thickness ratio λ is calculated for each element of the cross-section per AISC Specification Section B4.

Classification of Cross-Sections

Cross-sections are classified as follows:

- Flexural members are compact (the plastic moment can be reached without local buckling) when λ is equal to or less than λ_p and the flange(s) are continuously connected to the web(s).
- Flexural members are non-compact (local buckling will occur, but only after initial yielding) when λ exceeds λ_p but is equal to or less than λ_r.
- Flexural members are slender-element cross-sections (local buckling will occur prior to yielding) when λ exceeds λ_r.

The values of λ_p and λ_r are determined per AISC Specification Section B4.

LATERAL-TORSIONAL BUCKLING

Classification of Spans for Flexure

Flexural members bent about their strong axis are classified on the basis of the length L_b between braced points. Braced points are points at which support resistance against lateral-torsional buckling is provided per AISC Specification Appendix 6.3. Classifications are determined as follows:

- If $L_b \leq L_p$, flexural member is not subject to lateral-torsional buckling
- If $L_p < L_b \leq L_r$, flexural member is subject to inelastic lateral-torsional buckling
- If $L_b > L_r$, flexural member is subject to elastic lateral-torsional buckling

The values of L_p and L_r are determined per AISC Specification Chapter F. These values are presented in Tables 3–2, 3–6, 3–7, 3–8, and 3–9.

Lateral-torsional buckling does not apply to flexural members bent about their weak axis or HSS bent about either axis, per AISC Specification Sections F6, F7 and F8.

Consideration of Moment Gradient

When $L_b > L_p$, the moment gradient between braced points can be considered in the determination of the available strength using the beam bending coefficient C_b. In the case of a uniform moment between braced points causing single-curvature of the member, $C_b = 1$. This represents the worst case and C_b can be conservatively taken as unity for use with the maximum moment between braced points in all designs per AISC Specification Section F1. However, when desired, a non-uniform moment gradient between braced points can be considered using C_b calculated as given in AISC Specification Equation F1–1. Exceptions are provided as follows:

1. As an alternative, when the moment diagram between braced points is a straight line, C_b can be calculated as given in AISC Commentary Equation C–F1.1.
2. For cantilevered members where the free end is unbraced, C_b must be taken as unity per AISC Specification Section F1.
3. For tees with the stem in compression, C_b should be taken as unity as recommended in AISC Commentary Section F9.

AVAILABLE SHEAR STRENGTH

For flexural members, the available shear strength, ϕV_n or V_n/Ω, which must equal or exceed the required strength, V_u or V_a, respectively, is determined in accordance with the AISC Specification Chapter G.

STEEL W-SHAPE BEAMS WITH COMPOSITE SLABS

The following pertains to W-shapes with composite concrete slabs in regions of positive moment. For composite flexural members in regions of negative moment, see AISC Specification Chapter I. For further information on composite design and construction, see Viest et al. (1997).

Concrete Slab Effective Width

The effective width of a concrete slab acting compositely with a steel beam is determined per AISC Specification Section I3.1a.

Shear Stud Connectors

Material, placement and spacing requirements for shear stud connectors are given in AISC Specification Chapter I. The nominal shear strength, Q_n, of one shear stud connector is determined per AISC Specification Section I3.2d and is tabulated for common design conditions in Table 3–21.

Available Flexural Strength for Positive Moment

The available flexural strength of a composite beam subject to positive moment is determined per AISC Specification Section I3.2a assuming a uniform compressive stress of $0.85f_c'$ and zero tensile strength in the concrete, and a uniform stress of F_y in the tension area (and compression area, if any) of the steel section. The position of the plastic neutral axis (PNA) can then be determined by static equilibrium.

Per AISC Specification Section I3.2d, enough shear stud connectors must be provided between a point of maximum moment and the nearest point of zero moment to transfer the horizontal shear force V' between the steel beam and concrete slab, where V' is determined per AISC Specification Section I3.2d-1. For partial-composite design, the shear strength of the shear stud connectors ΣQ_n controls the available flexural strength of the composite flexural member.

Shored and Unshored Construction

The available flexural strength is identical for both shored and unshored construction. In unshored construction, issues such as lateral support during construction and construction-load deflection may require consideration.

Available Shear Strength

Per AISC Specification Section I3.1b, the available shear strength for composite beams is determined as illustrated previously for steel beams.

OTHER SPECIFICATION REQUIREMENTS AND DESIGN CONSIDERATIONS

The following other specification requirements and design considerations apply to the design of flexural members.

Special Requirements for Heavy Shapes and Plates

For beams with complete-joint-penetration groove welded joints and made from heavy shapes with a flange thickness exceeding 2 in., see AISC Specification Sections A3.1c

For built-up sections consisting of plates with a thickness exceeding 2-in., see Section A3.1d.

Serviceability

Serviceability requirements, per AISC Specification Chapter L, should be appropriate for the application. This includes an appropriate limit on the deflection of the flexural member and the vibration characteristics of the system of which the flexural member is a part. See also AISC Design Guide No. 3 *Serviceability Design Considerations for Low-Rise Buildings* (Fisher and West, 2004), AISC Design Guide No. 5 *Low- and Medium-Rise Steel Buildings* (Allison, 1991) and AISC Design Guide No. 11 *Floor Vibrations Due to Human Activity* (Murray, Allen and Ungar, 1997).

The maximum vertical deflection Δ, in., can be calculated using the equations given in Tables 3–22 and 3–23. Alternatively, for common cases of simple-span beams and I-shaped members and channels, the following equation can be used:

$$\Delta = ML^2 / (C_1 I_x)$$

where

M = maximum service-load moment, kip-ft
L = span length, ft
I_x = moment of inertia, in.^{4}
C_1 = loading constant (see Figure 3–2) which includes the numerical constants appropriate for the given loading pattern, E, which has units of ksi, and a ft-to-in. conversion factor of 1,728 in.^{3}/ft^3.

FLEXURAL DESIGN TABLES

Table 3–1. Beam Bending Coefficient C_b

Values of the beam bending coefficient C_b are given for various loading conditions on simple-span beams in Table 3–1.

W-SHAPE SELECTION TABLES

Table 3–2. W-Shapes—Selection by Z_x

W-shapes are sorted in descending order by strong-axis flexural strength and then grouped in ascending order by weight with the lightest W-shape in each range in bold. Strong-axis available strengths in flexure and shear are given for W-shapes with $F_y = 50$ ksi (ASTM A992). C_b is taken as unity.

For compact W-shapes, when $L_b \le L_p$, the strong-axis available flexural strength, M_{px}/Ω_b or $\phi_b M_{px}$, can be determined using the tabulated strength values. When $L_p < L_b \le L_r$, linearly interpolate between the available strength at L_p and the available strength at L_r as follows:

LRFD	ASD
$\phi_b M_n = C_b [\phi_b M_{px} - BF(L_b - L_p)] \le \phi_b M_{px}$	$\frac{M_n}{\Omega_b} = C_b \left[\frac{M_{px}}{\Omega_b} - BF(L_b - L_p)\right] \le \frac{M_{px}}{\Omega_b}$

When $L_b > L_r$, see Table 3–10. For non-compact W-shapes, the tabulated values of M_{px}/Ω_b, $\phi_b M_{px}$, and L_p have been adjusted to account for the non-compactness.

The strong-axis available shear strength, $\phi_v V_n$ or V_n/Ω_v can be determined using the tabulated value.

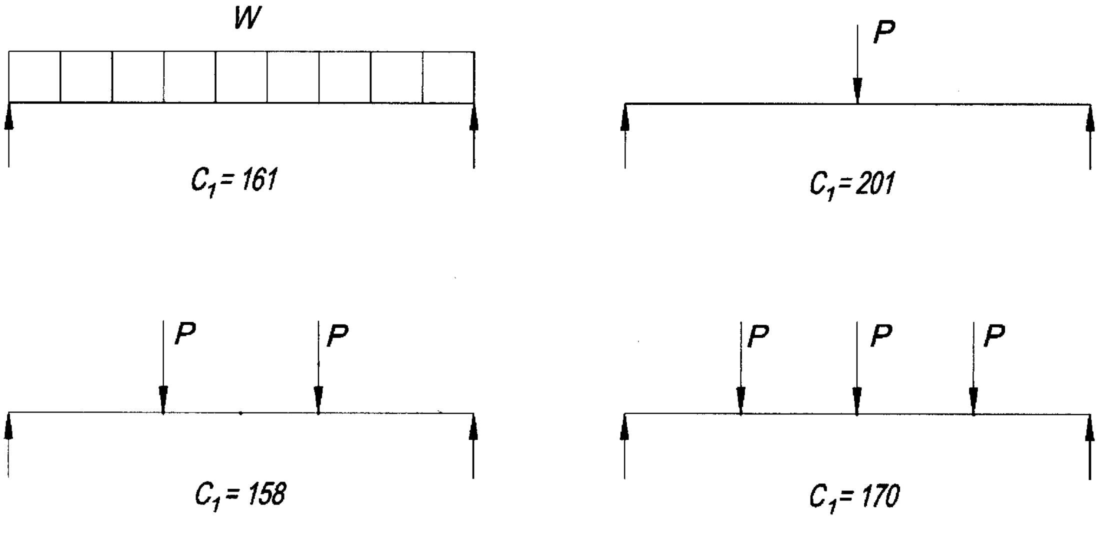


Figure 3–2. Loading constants for use in determining simple beam deflections.

Table 3–3. W-Shapes—Selection by I_x

W-shapes are sorted in descending order by strong-axis moment of inertia I_x and then grouped in ascending order by weight with the lightest W-shape in each range in bold.

Table 3–4. W-Shapes—Selection by Z_y

W-shapes are sorted in descending order by weak-axis flexural strength and then grouped in ascending order by weight with the lightest W-shape in each range in bold. Weak-axis available strengths in flexure are given for W-shapes with $F_y = 50$ ksi (ASTM A992). C_b is taken as unity.

For non-compact W-shapes, the tabulated values of M_{py}/Ω_b and $\phi_b M_{py}$ have been adjusted to account for the non-compactness.

The weak-axis available shear strength must be checked independently.

Table 3–5. W-Shapes—Selection by I_y

W-shapes are sorted in descending order by weak-axis moment of inertia I_y and then grouped in ascending order by weight with the lightest W-shape in each range in bold.

Table 3–1
Values for C_b for Simply Supported Beams

Load	Lateral Bracing Along Span	C_b
	None Load at midpoint		At load point	
	None Loads at third points		At load points Loads symmetrically placed		None Loads at quarter points		At load points Loads at quarter points		None		At midpoint		At third points		At quarter points		At fifth points	
Note: Lateral bracing must always be provided at points of support per AISC Specification Chapter F.

F_y = 50 ksi

[h] Flange thickness greater than 2 in. Special requirements may apply per AISC Specification Section A3.1c.

beam weight, which should be deducted when calculating the maximum uniform load the beam will support. C_b is taken as unity.

When the plotted curve is solid, the W-shape for that curve is the lightest cross-section for a given combination of available flexural strength and unbraced length. When the plotted curve is dashed, a lighter W-shape than that for the plotted curve exists. The plotted curves are arbitrarily terminated at a span-to-depth ratio of 30 in most cases.

L_p is indicated in each curve as a solid dot (•). L_r is indicated in each curve as an open dot (○).

Tables 3–11. C- and MC-Shapes—Plots of Available Moment vs. Unbraced Length

Table 3–11 is similar to Table 3–10, except it covers C- and MC-shapes with F_y = 36 ksi (ASTM A36).

AVAILABLE FLEXURAL STRENGTH OF HSS

Table 3–12. Rectangular HSS—Available Flexural Strength

The available flexural strength is tabulated for rectangular HSS with F_y = 46 ksi (ASTM A500 grade B). For non-compact and slender cross-sections, the tabulated values of M_p/Ω_b and $\phi_b M_p$ have been adjusted to account for the non-compactness or slenderness.

Table 3–13. Square HSS—Available Flexural Strength

Table 3–13 is similar to Table 3–12, except it covers square HSS with F_y = 46 ksi (ASTM A500 grade B).

Table 3–14. Round HSS—Available Flexural Strength

Table 3–14 is similar to Table 3–12, except it covers round HSS with F_y = 42 ksi (ASTM A500 grade B).

Table 3–15. Pipe—Available Flexural Strength

Table 3–15 is similar to Table 3–12, except it covers Pipe with F_y = 35 ksi (ASTM A53 grade B).

STRENGTH OF OTHER FLEXURAL MEMBERS

Tables 3–16 and 3–17. Available Shear Stress in Plate Girders

The available shear stress for plate girders is plotted as a function of a/h and h/t_w in Tables 3–16 (for F_y = 36 ksi) and 3–17 (for F_y = 50 ksi). In part a of each table, tension-field action is neglected. In part b of each table, tension-field action is considered.

Table 3–18. Floor Plates

The recommended maximum uniformly distributed loads are given in Table 3–18 based upon simple-span bending between supports. Table 3–18a is for deflection-controlled applications and should be used with the appropriate serviceability load combinations. The tabulated values correspond to a maximum deflection of $L/100$. Table 3–18b is for flexural-strength-controlled applications and should be used with LRFD or ASD load combinations. The tabulated values correspond to a maximum bending stress of 24 ksi in LRFD and 16 ksi in ASD.

COMPOSITE BEAM SELECTION TABLES

Table 3–19. Composite W-Shapes

The available flexural strength is tabulated for W-shapes with F_y = 50 ksi (ASTM A992). The values tabulated are independent of the specific concrete flange properties. The designer can then select an appropriate combination of concrete strength and slab geometry.

The location of the plastic neutral axis (PNA) is uniquely determined by the horizontal shear force ΣQ_n at the interface between the steel section and the concrete slab. With the knowledge of the location of the PNA and the distance to the centroid of the concrete flange force ΣQ_n, the available flexural strength can be computed.

Available flexural strengths are tabulated for plastic neutral axis (PNA) locations at the seven locations shown. Five of these PNA locations are in the beam flange. The seventh PNA location is computed at the point where ΣQ_n equals $0.25F_yA_s$, and the sixth PNA location is at the midpoint between five and seven. Use of beams with a PNA below location seven is discouraged.

Table 3–19 can be used to design a composite beam by entering with a required flexural strength and determining the corresponding required ΣQ_n. Alternatively, Table 3–19 can be used to check the flexural strength of a composite beam by selecting a valid value of ΣQ_n, using Table 3–21. With the effective width of the concrete flange b determined per AISC Specification Section I3.1a, the appropriate value of the distance from concrete flange force to beam top flange $Y2$ can be determined as

$$Y_2 = Y_{con} - \frac{a}{2}$$

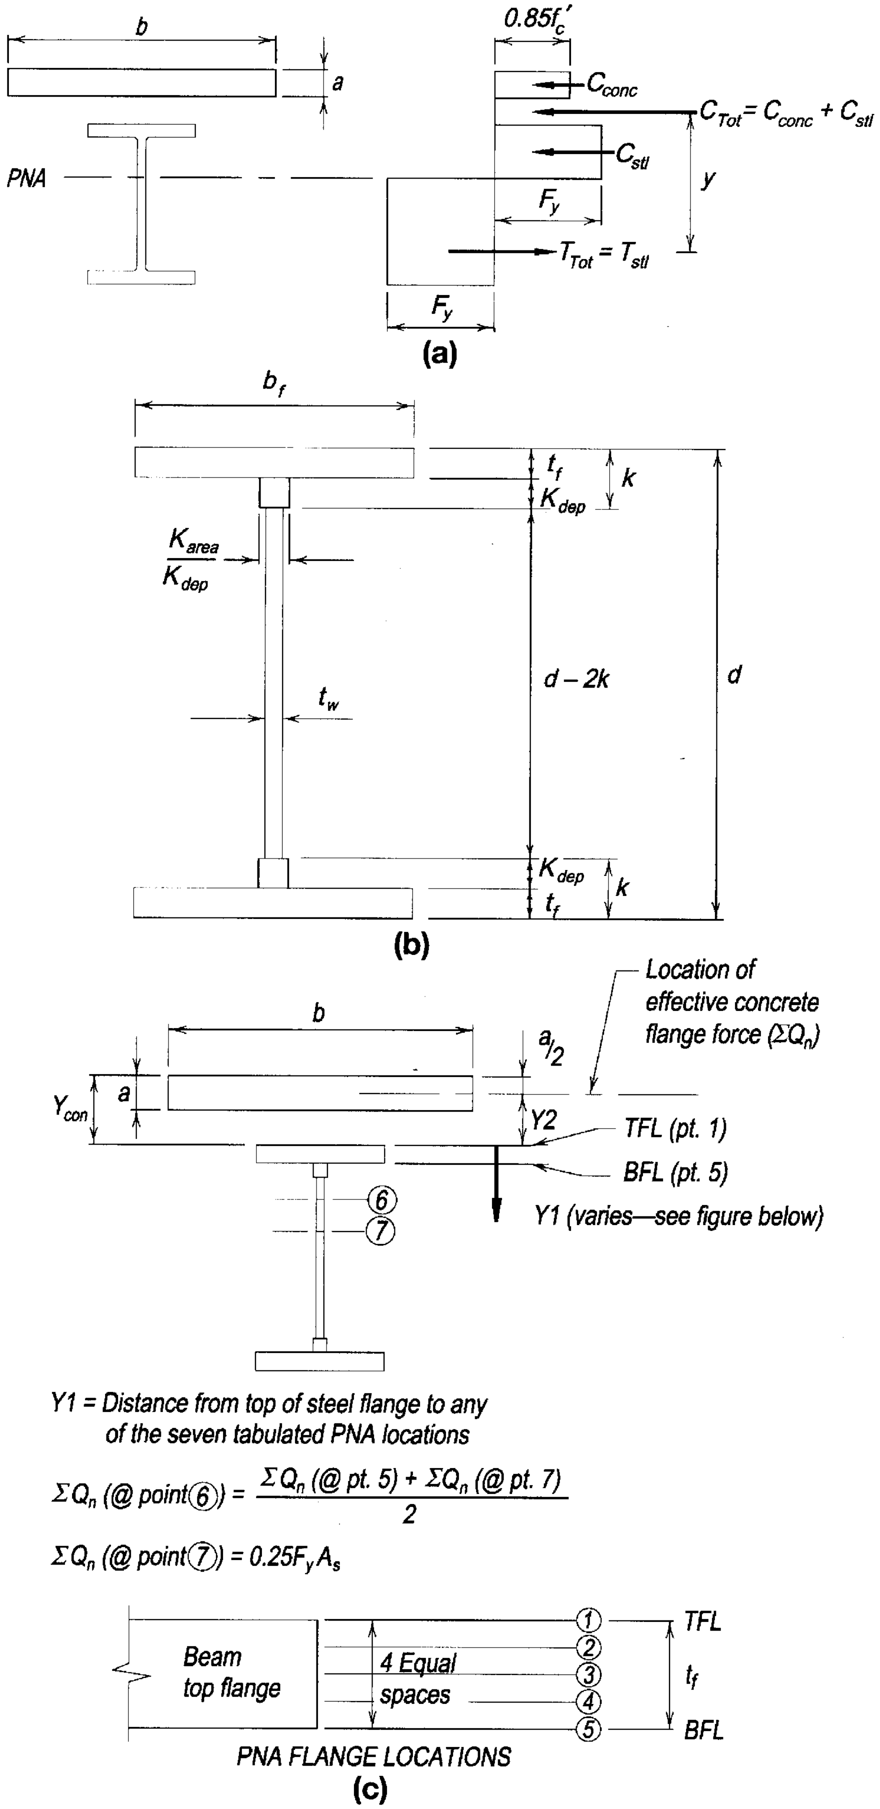
where

Y_{con} = distance from top of steel beam to top of concrete, in.

$$a = \frac{\Sigma Q_n}{0.85 f'_c b}$$

and the available flexural strength, $\phi_b M_n$ or M_n/Ω_b, can then be determined from Table 3–19. Values for the distance from the PNA to the beam top flange $Y1$ are also tabulated for convenience. The parameters $Y1$ and $Y2$ are illustrated in Figure 3–3. Note that the model of the steel beam used in the calculation of the available strength assumes that:

A_s = cross-sectional area of the steel section, in.^{2}
A_f = flange area = $b_f \times t_f$, in.^{2}
A_w = web area = $(d - 2k)t_w$, in.^{2}
$K_{dep} = k - t_f$, in.
$K_{area} = (A_s - 2A_f - A_w)/2$, in.^{2}



Y1 = Distance from top of steel flange to any of the seven tabulated PNA locations

$$\Sigma Q_n\ (@\ \text{point}⑥) = \frac{\Sigma Q_n\ (@\ \text{pt. }5) + \Sigma Q_n\ (@\ \text{pt. }7)}{2}$$

$$\Sigma Q_n\ (@\ \text{point}⑦) = 0.25F_yA_s$$

Figure 3–3. Strength design models for composite beams.

The beam end reactions for symmetrically loaded composite W-shapes can be determined as follows. When the properties of the composite concrete flange have been computed, ΣQ_n can be taken as the smaller of nQ_n, F_yA_s or $0.85f_c'A_c$. With $Y2$ taken as the distance from the top of the steel beam to the top of the concrete slab less $[\Sigma Q_n/(0.85f_c'b)]/2$, the value of available flexural strength, ϕ_bM_n or M_n/Ω_b, can be selected from Table 3-19 and the beam end reaction, R_u or R_a, can be determined as:

LRFD	**ASD**
$R_u = \phi_b M_n \dfrac{C_c}{L}$	$R_a = \dfrac{M_n}{\Omega_b}\dfrac{C_c}{L}$

where

C_c = coefficient from Figure 3–4

L = span length, ft

This value is then useful to check the shear strength.

When the properties of the composite concrete flange have not been computed, a conservative value for ΣQ_n can be taken as the smaller of F_sA_s or nQ_n, where n is the number of

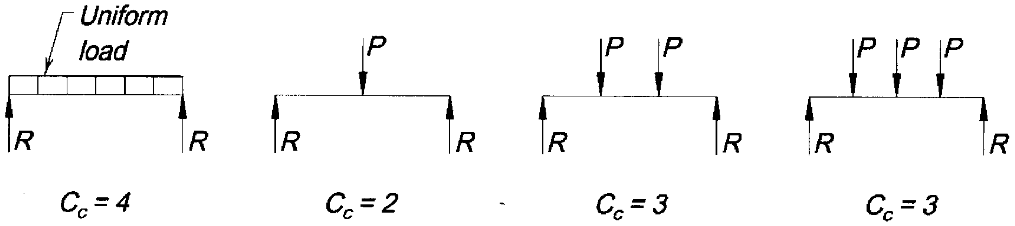


Figure 3–4. Coefficients for use in determining composite simple-beam end reactions.

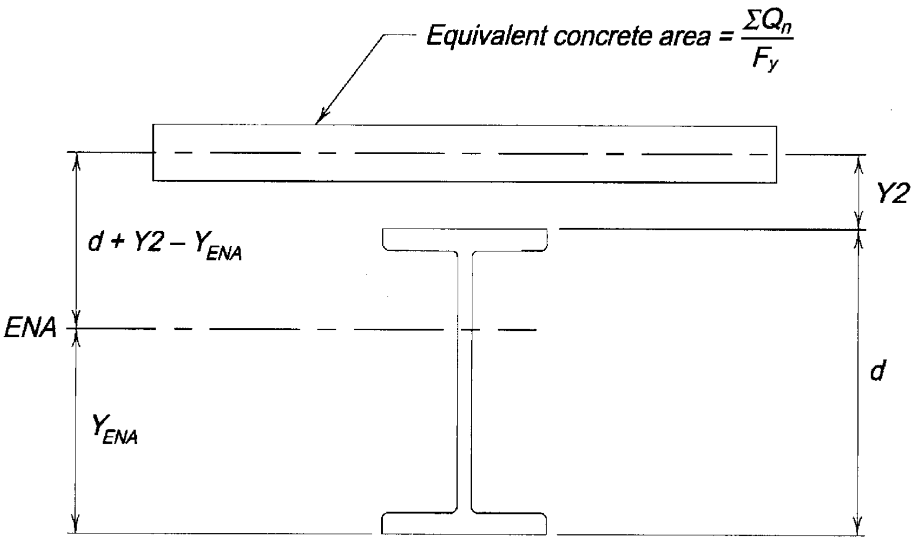

Figure 3–5. Deflection design model for composite beams.

shear stud connectors between the beam end and the point of maximum moment. In this case, *Y*2 is equal to the distance from the top of the steel beam to the top of the concrete slab.

Table 3–20. Lower-Bound Elastic Moments of Inertia

The lower-bound elastic moment of inertia of a composite beam can be used to calculate deflection. If calculated deflections using the lower-bound moment of inertia are acceptable, a more complete elastic analysis of the composite section can be avoided. The lower-bound elastic moment of inertia is based upon the area of the beam and an equivalent concrete area equal to $\Sigma Q_n/F_y$ as illustrated in Figure 3–5. The analysis includes only the horizontal shear force transferred by the shear connectors supplied. Thus, only the portion of the concrete flange used to balance ΣQ_n is included in the determination of the lower-bound moment of inertia.

The value for the lower bound moment of inertia can be calculated as illustrated in AISC Commentary Section I3.2a and Section I3.2b. The lower bound moment of inertia, therefore, is the moment of inertia of the cross-section at the required strength level. This is smaller than the corresponding moment of inertia at the service load where deflection is calculated.

Table 3–21. Nominal Horizontal Shear for One Shear Stud, Q_n

The nominal shear strength of stud shear connectors is given in Table 3–21, in accordance with AISC Specification Chapter I. Nominal horizontal shear strength values are presented based upon the position of the stud, profile of the deck, and orientation of the deck relative to the stud.

BEAM DIAGRAMS AND FORMULAS

Table 3–22a. Concentrated Load Equivalents

Concentrated load equivalents are given in Table 3–22a for beams with various support conditions and loading characteristics.

Table 3–22b. Cantilevered Beams

Coefficients are provided in Table 3–22b for cantilevered beams with various support conditions and loading characteristics.

Table 3-22c. Continuous Beams

Coefficients are provided in Table 3–22c for continuous beams with various support conditions and loading characteristics.

Table 3–23. Shears, Moments, and Deflections

Shears, moments and deflections are given in Table 3–23 for beams with various support conditions and loading characteristics.

[a] $Y1$ = distance from top of the steel beam to plastic neutral axis.

[b] $Y2$ = distance from top of the steel beam to concrete flange force.

[c] See Figure 3–3c for PNA locations.

[d] Value in parentheses is I_x (in.^{4}) of non-composite steel shape.

[a] $Y1$ = distance from top of the steel beam to plastic neutral axis.

[b] $Y2$ = distance from top of the steel beam to concrete flange force.

[c] See Figure 3–3c for PNA locations.

[d] Value in parentheses is I_x (in.^{4}) of non-composite steel shape.

[a] $Y1$ = distance from top of the steel beam to plastic neutral axis.

[b] $Y2$ = distance from top of the steel beam to concrete flange force.

[c] See Figure 3–3c for PNA locations.

[d] Value in parentheses is I_x (in.^{4}) of non-composite steel shape.

[a] $Y1$ = distance from top of the steel beam to plastic neutral axis.

[b] $Y2$ = distance from top of the steel beam to concrete flange force.

[c] See Figure 3–3c for PNA locations.

[d] Value in parentheses is I_x (in.^{4}) of non-composite steel shape.

F_u = 65 ksi

Table 3–21
Shear Stud
Nominal Horizontal Shear for One Stud, Q_n, kip

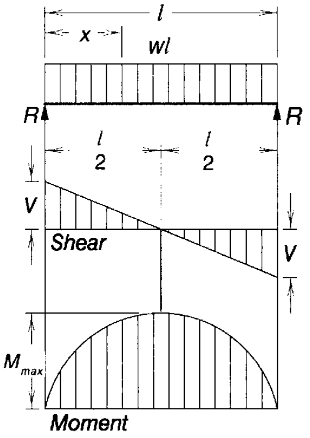
Table 3–23
Shears, Moments, and Deflections

1. SIMPLE BEAM — UNIFORMLY DISTRIBUTED LOAD



Total Equiv. Uniform Load .... $= wl$

$R = V$ .... $= \frac{wl}{2}$

V_x .... $= w\left(\frac{l}{2} - x\right)$

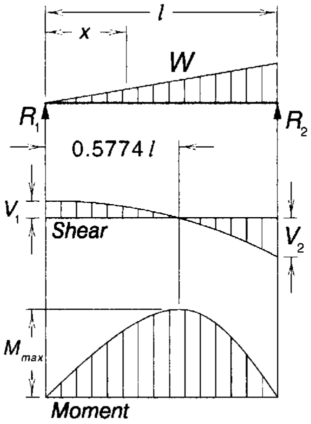
M_{max} (at center) .... $= \frac{wl^2}{8}$

M_x .... $= \frac{wx}{2}(l - x)$

Δ_{max} (at center) .... $= \frac{5wl^4}{384EI}$

Δ_x .... $= \frac{wx}{24EI}\left(l^3 - 2lx^2 + x^3\right)$

2. SIMPLE BEAM — LOAD INCREASING UNIFORMLY TO ONE END



Total Equiv. Uniform Load .... $= \frac{16W}{9\sqrt{3}} = 1.03\,W$

$R_1 = V_1$ .... $= \frac{W}{3}$

$R_2 = V_2 = V_{max}$ .... $= \frac{2W}{3}$

V_x .... $= \frac{W}{3} - \frac{Wx^2}{l^2}$

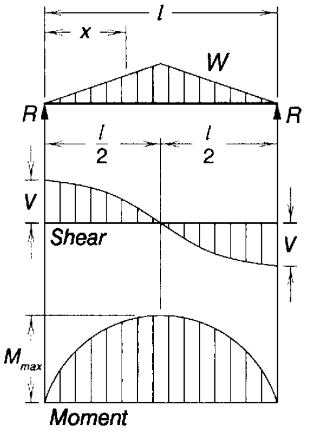
M_{max} $\left(\text{at } x = \frac{l}{\sqrt{3}} = 0.557\,l\right)$ .... $= \frac{2Wl}{9\sqrt{3}} = 0.128\,Wl$

M_x .... $= \frac{Wx}{3l^2}(l^2 - x^2)$

Δ_{max} $\left(\text{at } x = l\sqrt{1 - \sqrt{\frac{8}{15}}} = 0.519\,l\right)$ .... $= 0.0130\frac{Wl^3}{EI}$

Δ_x .... $= \frac{Wx}{180EIl^2}\left(3x^4 - 10l^2x^2 + 7l^4\right)$

3. SIMPLE BEAM — LOAD INCREASING UNIFORMLY TO CENTER



Total Equiv. Uniform Load .... $= \frac{4W}{3}$

$R = V$ .... $= \frac{W}{2}$

V_x (when $x < \frac{l}{2}$) .... $= \frac{W}{2l^2}\left(l^2 - 4x^2\right)$

M_{max} (at center) .... $= \frac{Wl}{6}$

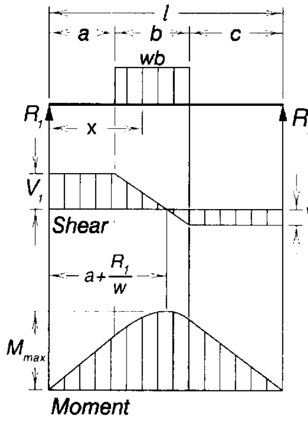
M_x (when $x < \frac{l}{2}$) .... $= Wx\left(\frac{1}{2} - \frac{2x^2}{3l^2}\right)$

Δ_{max} (at center) .... $= \frac{Wl^3}{60EI}$

Δ_x (when $x < \frac{l}{2}$) .... $= \frac{Wx}{480EIl^2}\left(5l^2 - 4x^2\right)^2$

Table 3–23 (continued)
Shears, Moments, and Deflections

4. SIMPLE BEAM — UNIFORM LOAD PARTIALLY DISTRIBUTED



$R_1 = V_1$ (max. when $a < c$) …………… $= \frac{wb}{2l}(2c+b)$

$R_2 = V_2$ (max. when $a > c$) …………… $= \frac{wb}{2l}(2a+b)$

V_x (when $x > a$ and $< (a+b)$) …. $= R_1 - w(x-a)$

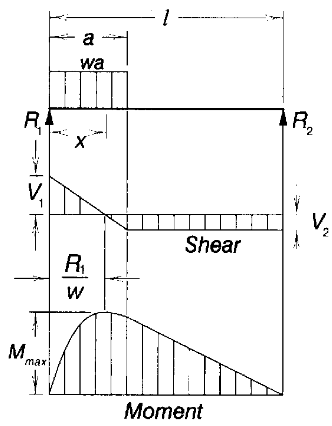
M_{max} $\left(\text{at } x = a + \frac{R_1}{w}\right)$ …………………… $= R_1\left(a + \frac{R_1}{2w}\right)$

M_x (when $x < a$) …………………… $= R_1 x$

M_x (when $x > a$ and $< (a+b)$) …. $= R_1 x - \frac{w}{2}(x-a)^2$

M_x (when $x > (a+b)$) ……………… $= R_2(l-x)$

5. SIMPLE BEAM — UNIFORM LOAD PARTIALLY DISTRIBUTED AT ONE END



$R_1 = V_1 = V_{max}$ ………………………………… $= \frac{wa}{2l}(2l-a)$

$R_2 = V_2$ ……………………………………………… $= \frac{wa^2}{2l}$

V_x (when $x < a$) ………………………… $= R_1 - wx$

M_{max} $\left(\text{at } x = \frac{R_1}{w}\right)$ ………………………… $= \frac{R_1^2}{2w}$

M_x (when $x < a$) ………………………… $= R_1 x - \frac{wx^2}{2}$

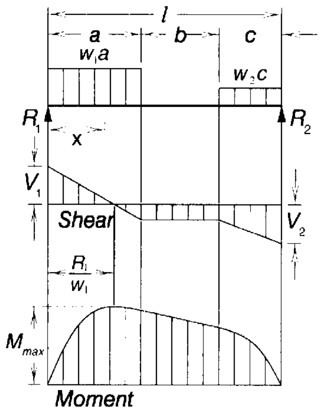
M_x (when $x > a$) ………………………… $= R_2(l-x)$

Δ_x (when $x < a$) ………………………… $= \frac{wx}{24EIl}\left(a^2(2l-a)^2 - 2ax^2(2l-a) + lx^3\right)$

Δ_x (when $x > a$) ………………………… $= \frac{wa^2(l-x)}{24EIl}\left(4xl - 2x^2 - a^2\right)$

6. SIMPLE BEAM — UNIFORM LOAD PARTIALLY DISTRIBUTED AT EACH END

$R_1 = V_1$ ……………………………………… $= \frac{w_1 a(2l-a) + w_2 c^2}{2l}$



$R_2 = V_2$ ……………………………………… $= \frac{w_2 c(2l-c) + w_1 a^2}{2l}$

V_x (when $x < a$) …………………… $= R_1 - w_1 x$

V_x (when $a < x < (a+b)$) ………… $= R_1 - w_1 a$

V_x (when $x > (a+b)$) ……………… $= R_2 - w_2(l-x)$

M_{max} $\left(\text{at } x = \frac{R_1}{w_1}, \text{when } R_1 < w_1 a\right)$ …. $= \frac{R_1^2}{2w_1}$

M_{max} $\left(\text{at } x = l - \frac{R_2}{w_2}, \text{when } R_2 < w_2 c\right)$ $= \frac{R_2^2}{2w_2}$

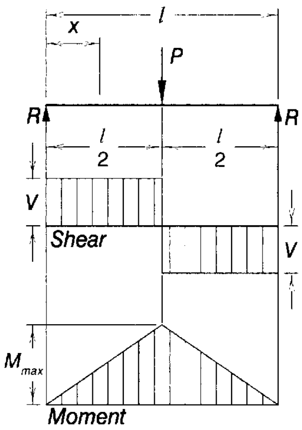
M_x (when $x < a$) …………………… $= R_1 x - \frac{w_1 x^2}{2}$

M_x (when $a < x < (a+b)$) ………… $= R_1 x - \frac{w_1 a}{2}(2x-a)$

M_x (when $x > (a+b)$) ……………… $= R_2(l-x) - \frac{w_2(l-x)^2}{2}$

Table 3–23 (continued)
Shears, Moments, and Deflections

7. SIMPLE BEAM — CONCENTRATED LOAD AT CENTER



Total Equiv. Uniform Load .... $= 2P$

$R = V$ .... $= \frac{P}{2}$

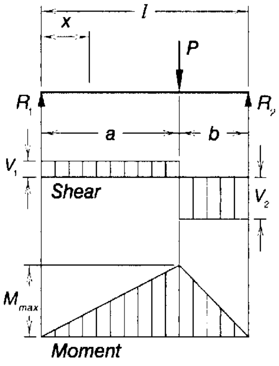
M_{max} (at point of load) .... $= \frac{Pl}{4}$

M_x (when $x < \frac{l}{2}$) .... $= \frac{Px}{2}$

Δ_{max} (at point of load) .... $= \frac{Pl^3}{48EI}$

Δ_x (when $x < \frac{l}{2}$) .... $= \frac{Px}{48EI}\left(3l^2 - 4x^2\right)$

8. SIMPLE BEAM — CONCENTRATED LOAD AT ANY POINT



Total Equiv. Uniform Load .... $= \frac{8Pab}{l^2}$

$R_1 = V_1$ ($= V_{max}$ when $a < b$) .... $= \frac{Pb}{l}$

$R_2 = V_2$ ($= V_{max}$ when $a > b$) .... $= \frac{Pa}{l}$

M_{max} (at point of load) .... $= \frac{Pab}{l}$

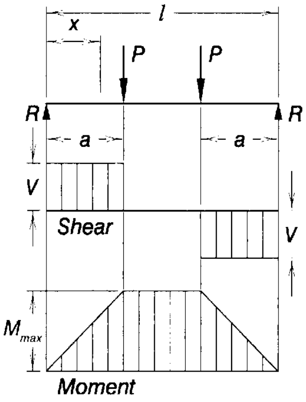
M_x (when $x < a$) .... $= \frac{Pbx}{l}$

Δ_{max} $\left(\text{at } x = \sqrt{\frac{a(a+2b)}{3}}, \text{when } a > b\right)$ .... $= \frac{Pab(a+2b)\sqrt{3a(a+2b)}}{27EIl}$

Δ_a (at point of load) .... $= \frac{Pa^2b^2}{3EIl}$

Δ_x (when $x < a$) .... $= \frac{Pbx}{6EIl}\left(l^2 - b^2 - x^2\right)$

9. SIMPLE BEAM — TWO EQUAL CONCENTRATED LOADS SYMMETRICALLY PLACED



Total Equiv. Uniform Load .... $= \frac{8Pa}{l}$

$R = V$ .... $= P$

M_{max} (between loads) .... $= Pa$

M_x (when $x < a$) .... $= Px$

Δ_{max} (at center) .... $= \frac{Pa}{24EI}\left(3l^2 - 4a^2\right)$

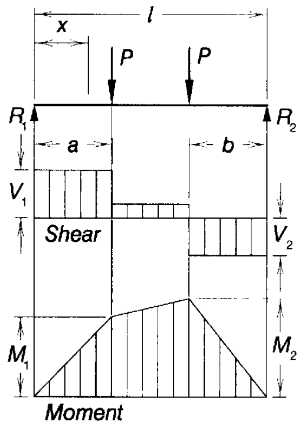
Δ_{max} (when $a = \frac{l}{3}$) .... $= \frac{Pl^3}{28EI}$

Δ_x (when $x < a$) .... $= \frac{Px}{6EI}\left(3la - 3a^2 - x^2\right)$

Δ_x (when $a < x < (l - a)$) .... $= \frac{Pa}{6EI}\left(3lx - 3x^2 - a^2\right)$

Table 3–23 (continued)
Shears, Moments, and Deflections

10. SIMPLE BEAM — TWO EQUAL CONCENTRATED LOADS UNSYMMETRICALLY PLACED



$R_1 = V_1$ ($= V_{max}$ when $a < b$) .... $= \frac{P}{l}(l - a + b)$

$R_2 = V_2$ ($= V_{max}$ when $a > b$) .... $= \frac{P}{l}(l - b + a)$

V_x (when $a < x < (l - b)$) .... $= \frac{P}{l}(b - a)$

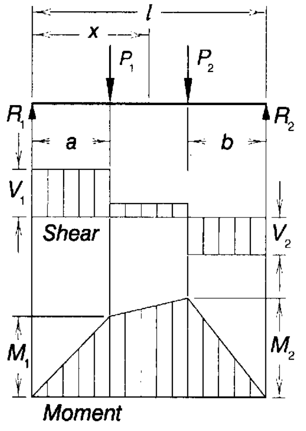
M_1 ($= M_{max}$ when $a > b$) .... $= R_1 a$

M_2 ($= M_{max}$ when $a < b$) .... $= R_2 b$

M_x (when $x < a$) .... $= R_1 x$

M_x (when $a < x < (l - b)$) .... $= R_1 x - P(x - a)$

11. SIMPLE BEAM — TWO UNEQUAL CONCENTRATED LOADS UNSYMMETRICALLY PLACED



$R_1 = V_1$ .... $= \dfrac{P_1(l - a) + P_2 b}{l}$

$R_2 = V_2$ .... $= \dfrac{P_1 a + P_2(l - b)}{l}$

V_x (when $a < x < (l - b)$) .... $= R_1 - P_1$

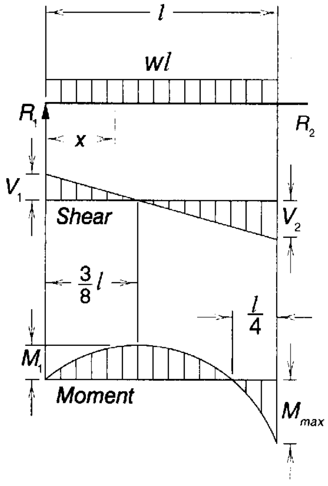
M_1 ($= M_{max}$ when $R_1 < P_1$) .... $= R_1 a$

M_2 ($= M_{max}$ when $R_2 < P_2$) .... $= R_2 b$

M_x (when $x < a$) .... $= R_1 x$

M_x (when $a < x < (l - b)$) .... $= R_1 x - P_1(x - a)$

12. BEAM FIXED AT ONE END, SUPPORTED AT OTHER — UNIFORMLY DISTRUBTED LOAD



Total Equiv. Uniform Load .... $= wl$

$R_1 = V_1$ .... $= \frac{3wl}{8}$

$R_2 = V_2 = V_{max}$ .... $= \frac{5wl}{8}$

V_x .... $= R_1 - wx$

M_{max} .... $= \frac{wl^2}{8}$

M_1 (at $x = \frac{3}{8}l$) .... $= \frac{9}{128}wl^2$

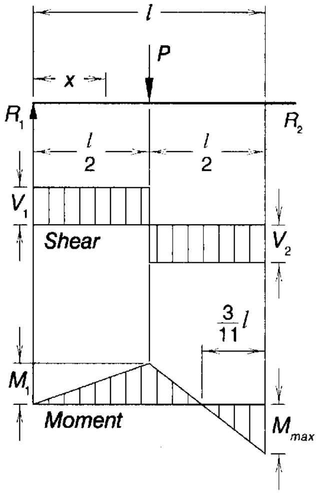
M_x .... $= R_1 x - \frac{wx^2}{2}$

Δ_{max} (at $x = \frac{l}{16}\left(1 + \sqrt{33}\right) = 0.422\,l$) .... $= \frac{wl^4}{185\,EI}$

Δ_x .... $= \frac{wx}{48\,EI}\left(l^3 - 3lx^2 + 2x^3\right)$

Table 3–23 (continued)
Shears, Moments, and Deflections

13. BEAM FIXED AT ONE END, SUPPORTED AT OTHER — CONCENTRATED LOAD AT CENTER



Total Equiv. Uniform Load .... $= \frac{3P}{2}$

$R_1 = V_1$ .... $= \frac{5P}{16}$

$R_2 = V_2 = V_{max}$ .... $= \frac{11P}{16}$

M_{max} (at fixed end) .... $= \frac{3Pl}{16}$

M_1 (at point of load) .... $= \frac{5Pl}{32}$

M_x (at $x < \frac{l}{2}$).. $= \frac{5Px}{16}$

M_x (when $x > \frac{l}{2}$)................................. $= P\left(\frac{l}{2} - \frac{11x}{16}\right)$

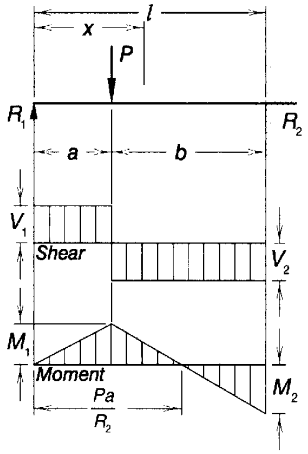
Δ_{max} (at $x = \frac{l}{\sqrt{5}} = 0.447\,l$) .... $= \frac{Pl^3}{48\,EI\sqrt{5}} = 0.00932\frac{Pl^3}{EI}$

Δ_x (at point of load) .... $= \frac{7Pl^3}{768\,EI}$

Δ_x (at $x < \frac{l}{2}$).. $= \frac{Px}{96\,EI}\left(3l^2 - 5x^2\right)$

Δ_x (at $x > \frac{l}{2}$).. $= \frac{P}{96\,EI}(x-l)^2\,(11x-2l)$

14. BEAM FIXED AT ONE END, SUPPORTED AT THE OTHER — CONCENTRATED LOAD AT ANY POINT



$R_1 = V_1$ .... $= \frac{Pb^2}{2l^3}(a+2l)$

$R_2 = V_2$ .... $= \frac{Pa}{2l^3}\left(3l^2 - a^2\right)$

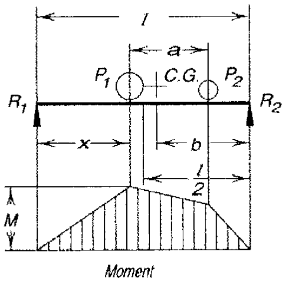
$$M_{\max}\begin{cases}\left[\text{under } P_1\text{, at } x = \frac{1}{2}\left(l - \frac{P_2 a}{P_1 + P_2}\right)\right] \ldots\ldots = (P_1 + P_2)\frac{x^2}{l} \\ \left[\begin{array}{l}M_{\max} \text{ may occur with larger} \\ \text{load at center of span and other} \\ \text{load off span (Case 43)}\end{array}\right] \ldots\ldots = \frac{P_1 l}{4}\end{cases}$$

GENERAL RULES FOR SIMPLE BEAMS CARRYING MOVING CONCENTRATED LOADS



The maximum shear due to moving concentrated loads occurs at one support when one of the loads is at that support. With several moving loads, the location that will produce maximum shear must be determined by trial.

The maximum bending moment produced by moving concentrated loads occurs under one of the loads when that load is as far from one support as the center of gravity of all the moving loads on the beam is from the other support.

In the accompanying diagram, the maximum bending moment occurs under load P_1 when $x = b$. It should also be noted that this condition occurs when the centerline of the span is midway between the center of gravity of loads and the nearest concentrated load.

PART 4 REFERENCES 4–9

SCOPE

The specification requirements and other design considerations summarized in this Part apply to the design of members subject to axial compression. For the design of members subject to eccentric compression or combined axial compression and flexure, see Part 6. For compression members that are part of a seismic force resisting system in which the seismic response modification factor, *R*, is taken greater than 3, the requirements in the AISC *Seismic Provisions for Structural Steel Buildings* also apply. The AISC *Seismic Provisions for Structural Steel Buildings* is available in Part 6 of the AISC *Seismic Design Manual* from the American Institute of Steel Construction, Inc. at www.aisc.org.

AVAILABLE COMPRESSIVE STRENGTH

The available strength of compression members, ϕP_n or P_n/Ω, which must equal or exceed the required strength, P_u or P_a, respectively, is determined according to AISC Specification Chapter E.

LOCAL BUCKLING

Determining the Width-Thickness Ratios of the Cross-Section

Steel compression members are classified on the basis of the width-thickness ratios of the various elements of the cross-section. The width-thickness ratio is calculated for each element of the cross-section per AISC Specification Section B4.

Determining the Slenderness of the Cross-Section

When the width-thickness ratios of all compression elements are less than λ_r, the cross-section is non-slender, and Q, the reduction factor for slender compression elements (elastic local buckling effects), equals 1.0. When the width-thickness ratio of a compression element is greater than λ_r, the cross-section is a slender-element cross-section and $Q < 1.0$ must be included in the calculation of the available compressive strength. Q is determined per AISC Specification Section E7, and λ_r is determined per AISC Specification Section B4 and Table B4.1.

EFFECTIVE LENGTH AND COLUMN SLENDERNESS

Columns are designed for their slenderness, KL/r, per AISC Specification Section E2. The effective length, KL, is equal to L, the physical length between braced points (see AISC Specification Appendix 6) multiplied by K, which is determined per AISC Specification Section C2. In many cases, the stability provisions in AISC Specification Chapter C and Appendix 7 allow the use of $K = 1$. Otherwise, guidance on the proper selection of a value for K is given in AISC Commentary Section C, including the following:

1. For columns with idealized end conditions, recommended vales of K can be determined from AISC Commentary Table C-C2.1.
2. For columns in braced frames (or steel frames that lean on shear walls or another similar structural system) and compression members in trusses, K is normally taken as unity per AISC Specification Section C1.3a, unless a smaller value can be justified by

analysis. Although the alignment chart in AISC Commentary Figure C-C2.3 (sidesway inhibited—braced frames) could be used for that purpose, it should be noted that the stability bracing provisions in AISC Appendix 6 are based upon the use of $K = 1$.

3. For columns in moment frames, the alignment charts in AISC Commentary Figure C-C2.4 (sidesway uninhibited—moment frames) can be used. Per AISC Commentary Section C2, the stiffness reduction factor, τ_a, can be used in the determination of K for columns controlled by inelastic buckling.

As indicated in the User Note in AISC Specification Section E2, compression-member slenderness, KL/r, should preferably be limited to a maximum of 200. Note that this recommendation does not apply to members that are primarily tension members, but subject to incidental compression under other load combinations.

Further information is available in the SSRC *Guide to Stability Design Criteria for Metal Structures* (Galambos, 1998).

COMPOSITE COMPRESSION MEMBERS

For the design of reinforced-concrete-encased and concrete-filled steel compression members, see AISC Specification Section I2. See also AISC Design Guide No. 6 *Load and Resistance Factor Design of W-Shapes Encased in Concrete* (Griffis, 1992). For further information on composite design and construction, see also Viest et al. (1997).

STEEL COMPRESSION—MEMBER SELECTION TABLES

Table 4–1. W-Shapes in Axial Compression

Available strengths in axial compression are given for W-shapes with $F_y = 50$ ksi (ASTM A992). The tabulated values are given for the effective length with respect to the Y-Y axis $(KL)_y$. However, the effective length with respect to the X-X axis $(KL)_x$ must also be investigated. To determine the available strength in axial compression, the table should be entered at the larger of $(KL)_y$ and $(KL)_{y\,eq}$, where

$$(KL)_{y\,eq} = \frac{(KL)_x}{\dfrac{r_x}{r_y}}$$

Values of the ratio r_x/r_y and other properties useful in the design of W-shape compression members are listed at the bottom of Table 4–1. The variables P_{wo} and P_{wi} can be used in the calculation of the web local yielding available strength (AISC Specification Equation J10-2) for the column as follows:

LRFD	ASD
$\phi R_n = P_{wo} + P_{wi}N$	$R_n/\Omega = P_{wo} + P_{wi}N$

The variable P_{wb} can be used in the calculation of the available web compression buckling strength (AISC Specification Equation J10-8) for the column as follows:

LRFD	ASD
$\phi R_n = P_{wb}$	$R_n/\Omega = P_{wb}$

The variable P_{fb} can be used in the calculation of the available flange local bending strength (AISC Specification Equation J10-1) for the column as follows:

LRFD	ASD
$\phi R_n = P_{fb}$	$R_n/\Omega = P_{fb}$

Table 4–2. HP-Shapes in Axial Compression

Table 4–2 is similar to Table 4–1, except it covers HP-shapes with $F_y = 50$ ksi (ASTM A572 grade 50).

Table 4–3. Rectangular HSS in Axial Compression

Available strengths in axial compression are given for rectangular HSS with $F_y = 46$ ksi (ASTM A500 grade B). The tabulated values are given for the effective length with respect to the Y-Y axis $(KL)_y$. However, the effective length with respect to the X-X axis $(KL)_x$ must also be investigated. To determine the available strength in axial compression, the table should be entered at the larger of $(KL)_y$ and $(KL)_{y\,eq}$, where

$$(KL)_{y\,eq} = \frac{(KL)_x}{\frac{r_x}{r_y}}$$

Values of the ratio r_x/r_y and other properties useful in the design of rectangular HSS compression members are listed at the bottom of Table 4–3.

Table 4–4. Square HSS in Axial Compression

Table 4–4 is similar to Table 4–3, except that it covers square HSS.

Table 4–5. Round HSS in Axial Compression

Available strengths in axial compression are given for round HSS with $F_y = 42$ ksi (ASTM A500 grade B). To determine the available strength in axial compression, the table should be entered at KL. Other properties useful in the design of compression members are listed at the bottom of the available column strength tables.

Table 4–6. Pipe in Axial Compression

Table 4–6 is similar to Table 4-5, except it covers pipe with $F_y = 35$ ksi (ASTM A53 grade B).

Table 4–7. WT-Shapes in Axial Compression

Available strengths in axial compression are given for WT-shapes with $F_y = 50$ ksi (ASTM A992). Separate tabulated values are given for the effective lengths with respect to the

X-X and Y-Y axes, $(KL)_x$ and $(KL)_y$, respectively. Other properties useful in the design of WT-shape compression members are listed at the bottom of Table 4-7.

Table 4–8. Equal-Leg Double Angles in Axial Compression

Available strengths in axial compression are given for equal-leg double angles with $F_y = 36$ ksi (ASTM A36), assuming 3/8-in. separation between the angles. These values can be used conservatively when a larger separation is provided. Alternatively, the value of $(KL)_y$ can be multiplied by the ratio of (r_y for a 3/8-in. separation) to (r_y for the actual separation).

Separate tabulated values are given for the effective lengths with respect to the X-X and Y-Y axes, $(KL)_x$ and $(KL)_y$, respectively. For buckling about the X-X axis, the available strength is not affected by the number of intermediate connectors. However, for buckling about the Y-Y axis, the effects of shear deformations of the intermediate connectors must be considered. The tabulated values for $(KL)_y$ have been adjusted for the shear deformations in accordance with AISC Specification equation E6-2, which is applicable to welded and pretensioned bolted intermediate shear connectors. The number of intermediate connectors, n, is given in the table and the line of demarcation between the required connector values is dashed. Intermediate connectors are selected such that the available compression buckling strength about the Y-Y axis is equal to or greater than 90 percent of that for compression buckling of the two angles as a unit. If fewer connectors or snug-tightened bolted intermediate connectors are used, the available strength must be recalculated per AISC Specification Section E6. Per AISC Specification Section E6.2, the slenderness of the individual components of the built-up member based upon the distance between intermediate connectors, a, must not exceed three-quarters of the controlling slenderness of the overall built-up compression member.

Other properties useful in the design of double-angle compression members are listed at the bottom of Table 4–8.

Table 4–9. LLBB Double Angles in Axial Compression

Table 4–9 is the same as Table 4–8, except that it provides available strengths in axial compression for double angles with long legs back to back.

Table 4–10. SLBB Double Angles in Axial Compression

Table 4–10 is the same as Table 4–8, except that it provides available strengths in axial compression for double angles with short legs back to back.

Table 4–11. Concentrically Loaded Single Angles in Axial Compression

Available strengths in axial compression are given for single angles, loaded through the centroid of the cross-section, with $F_y = 36$ ksi (ASTM A36) based upon the effective length with respect to the Z-Z axis $(KL)_z$. Single angles may be assumed to be loaded through the centroid when the requirements of AISC Specification Section E5 are met, as in these cases the eccentricity is accounted for and the slenderness is reduced by the restraining effects of the support at both ends of the member.

Table 4–12. Eccentrically Loaded Single Angles in Axial Compression

Available strengths in axial compression are given for single angles with $F_y = 36$ ksi (ASTM A36). These tables present a lower-bound available axial strength for eccentrically loaded single angles without consideration of end restraint (Sakla, 2001) and may be used in the design of single angle compression members when the requirements of Specification Section E5 can not be met.

In the development of this table, *KL* is assumed to be the same on all axes (r_x, r_y, r_z, and r_w). To determine the available strength in axial compression, the table should be entered at the largest effective length between brace points. These tables consider combined biaxial bending about the principal axes with axial compression. The long leg of the angle is assumed to be attached to a gusset with a thickness of 1.5*t*. The tabulated values assume a load placed at the center of the gusset plate, at a distance of 0.75*t* from the long leg of the angle.

COMPOSITE COMPRESSION—MEMBER SELECTION TABLES

Table 4–13. Rectangular HSS Filled with 4-ksi Normal-Weight Concrete in Axial Compression

Available strengths in axial compression are given for rectangular HSS with F_y = 46 ksi (ASTM A500 grade B) filled with 4-ksi normal-weight concrete. The tabulated values are given for the effective length with respect to the Y-Y axis $(KL)_y$. However, the effective length with respect to the X-X axis $(KL)_x$ must also be investigated. To determine the available strength in axial compression, the table should be entered at the larger of $(KL)_y$ and $(KL)_{y\,eq}$, where

$$(KL)_{y\,eq} = \frac{(KL)_x}{\dfrac{r_{mx}}{r_{my}}}$$

Values of the ratio r_{mx}/r_{my} and other properties useful in the design of composite HSS compression members are listed at the bottom of Table 4–13. The variables r_{mx} and r_{my} are the radii of gyration for the composite cross-section. The ratio r_{mx}/r_{my} is determined as

$$\frac{r_{mx}}{r_{my}} = \sqrt{\frac{P_{ex}(K_xL_x)^2}{P_{ey}(K_yL_y)^2}}$$

Table 4–14. Square HSS Filled with 4-ksi Normal-Weight Concrete in Axial Compression

Table 4–14 is the same as Table 4–13, except that it provides available strengths in axial compression for square HSS filled with 4-ksi normal-weight concrete.

Table 4–15. Rectangular HSS Filled with 5-ksi Normal-Weight Concrete in Axial Compression

Table 4–15 is the same as Table 4–13, except that it provides available strengths in axial compression for rectangular HSS filled with 5-ksi normal-weight concrete.

Table 4–16. Square HSS Filled with 5-ksi Normal-Weight Concrete in Axial Compression

Table 4–16 is the same as Table 4–13, except that it provides available strengths in axial compression for square HSS filled with 5-ksi normal-weight concrete.

Table 4–17. Round HSS Filled with 4-ksi Normal-Weight Concrete in Axial Compression

Available strengths in axial compression are given for round HSS with F_y = 42 ksi (ASTM A500 grade B) filled with 4-ksi normal-weight concrete. To determine the available strength in axial compression, the table should be entered at the largest effective length, *KL*. Other properties useful in the design of compression members are listed at the bottom of the column available strength tables.

Table 4–18. Round HSS Filled with 5-ksi Normal-Weight Concrete in Axial Compression

Table 4–18 is the same as Table 4–17, except that it provides available strengths in axial compression for round HSS filled with 5-ksi normal-weight concrete.

Table 4–19. Pipe Filled with 4-ksi Normal-Weight Concrete in Axial Compression

Available strengths in axial compression are given for pipe with F_y = 35 ksi (ASTM A53 grade B) filled with 4-ksi normal-weight concrete. To determine the available strength in axial compression, the table should be entered at the largest effective length, *KL*. Other properties useful in the design of compression members are listed at the bottom of the column available strength tables.

Table 4–20. Pipe Filled with 5-ksi Normal-Weight Concrete in Axial Compression

Table 4–21 is the same as Table 4–20, except that it provides available strengths in axial compression for pipe filled with 5-ksi normal-weight concrete.

Table 4–21. Stiffness Reduction Factor τ_a

When column buckling occurs in the inelastic range, the use of the alignment charts in Chapter C of the Commentary usually gives conservative results. For more accurate solutions, inelastic *K*-factors can be determined from the alignment chart by using τ_a times the elastic modulus, E_c, of the columns in the equation for *G*. The stiffness reduction factor, τ_a, is the ratio of the tangent modulus, E_T , to the elastic modulus, *E*. Values are tabulated for steels with F_y = 35 ksi, 36 ksi, 42 ksi, 46 ksi, and 50 ksi.

Table 4–22. Available Critical Stress for Compression Members

Table 4–22 provides the available critical stress for various ratios of *Kl/r*, for materials with a minimum specified yield strength of 35 ksi, 36 ksi, 42 ksi, 46 ksi, and 50 ksi.

[a] For Y-Y axis, welded or pretensioned bolted intermediate connectors must be used.

[b] For required number of intermediate connectors, see the discussion of Table 4-8.

[c] Shape is slender for compression with F_y = 36 ksi.

Note: Heavy line indicates *Kl/r* equal to or greater than 200.

SCOPE

The specification requirements and other design considerations summarized in this Part apply to the design of members subject to static axial tension. For fatigue applications, see AISC Specification Appendix 3. For the design of members subject to eccentric tension or combined tension and flexure, see Part 6. For tension members that are part of a seismic force resisting system in which the seismic response modification factor, R, is taken greater than 3, the requirements in the AISC *Seismic Provisions for Structural Steel Buildings* also apply. The AISC *Seismic Provisions for Structural Steel Buildings* is available in Part 6 of the AISC *Seismic Design Manual* from the American Institute of Steel Construction, Inc. at www.aisc.org.

GROSS AREA, NET AREA, AND EFFECTIVE NET AREA

In the determination of the available strength of a tension member, the gross area, A_g, is needed for the tensile yielding limit state and the effective net area, A_e, is needed for the tensile rupture limit state.

Gross Area

The gross area, A_g, is determined as specified in AISC Specification Section D3.1.

Effective Net Area

The effective net area, A_e, is determined by multiplying the net area, A_n, by the shear lag coefficient, U, where A_n is determined for tension members per AISC Specification Section D3 and U is determined from AISC Specification Table D3.1. Shear lag parameters are illustrated in AISC Commentary Figure C-D3.1.

TENSILE STRENGTH

The limit-state of tensile yielding will control the available tensile strength over tensile rupture when the following relationship is satisfied:

LRFD	ASD
$0.9F_yA_g \leq 0.75F_uA_e$	$\dfrac{F_yA_g}{1.67} \leq \dfrac{F_uA_e}{2}$

These expressions are both reduced to:

$$\frac{A_e}{A_g} \geq 1.2\frac{F_y}{F_u}$$

Otherwise, the limit-state of tensile rupture will control over tensile yielding.

Yielding Limit State

The available tensile strength due to tensile yielding, which must equal or exceed the required strength, P_u or P_a, is determined for tension members, per AISC Specification Section D2(a), using Equation D2-1.

Rupture Limit State

The available tensile strength due to tensile rupture, which must equal or exceed the required strength, P_u or P_a, is determined for tension members, per AISC Specification Section D2(b) using Equation D2-2.

OTHER SPECIFICATION REQUIREMENTS AND DESIGN CONSIDERATIONS

Special Requirements for Heavy Shapes and Plates

For tension members with complete-joint-penetration groove welded joints and made from heavy shapes with a flange thickness exceeding 2 in. or built-up sections consisting of plates with a thickness exceeding 2 in., see AISC Specification Sections A3.1c and Section A3.1d.

Slenderness

Tension member slenderness, L/r, should preferably be limited to a maximum of 300 per the User Note in AISC Specification Section D1. The intent of this recommendation is explained in the corresponding Commentary.

STEEL TENSION MEMBER SELECTION TABLES

Available tensile strengths for various types of tension members (see individual descriptions below) are given in Tables 5–1 through 5–8 for the limit states of tensile yielding and tensile rupture. In each case, the tabulated values for available tensile rupture strength are based upon the assumption that $A_e = 0.75A_g$, which is arbitrarily selected as a value that is practical to achieve with typical end connections. Such consideration of the effective net area during the design of the member will simplify the design of its end connections, which can be difficult to configure and costly if tension members are selected based upon available tensile yielding strength only, without considering the reduction in strength due to the connection.

When $A_e > 0.75A_g$, either the tabulated values for available tensile rupture strength can be used conservatively or the available tensile rupture strength can be calculated based upon the actual value of A_e. When $A_e < 0.75A_g$, the tabulated values of the available tensile rupture strength cannot be used, but rather, must be calculated based upon the actual value of A_e.

Table 5–1. W-Shapes

Available strengths in axial tension are given for W-shapes with $F_y = 50$ ksi and $F_u = 65$ ksi (ASTM A992). Note that tensile rupture will control over tensile yielding given for W-shapes with $F_y = 50$ ksi and $F_u = 65$ ksi when $A_e/A_g < 0.923$. Otherwise, tensile yielding will control over tensile rupture.

Table 5–2. Single Angles

Available strengths in axial tension are given for single angles with $F_y = 36$ ksi and $F_u = 58$ ksi (ASTM A36). Note that tensile rupture will control over tensile yielding given for single angles with $F_y = 36$ ksi and $F_u = 58$ ksi when $A_e/A_g < 0.745$. Otherwise, tensile yielding will control over tensile rupture.

Table 5–3. WT-Shapes

Table 5–3 is similar to Table 5–1, except it covers WT-shapes with $F_y = 50$ ksi and $F_u = 65$ ksi (ASTM A992).

Table 5–4. Rectangular HSS

Available strengths in axial tension are given for rectangular HSS with $F_y = 46$ ksi and $F_u = 58$ ksi (ASTM A500 Grade B). Note that tensile rupture will control over tensile yielding given for rectangular HSS with $F_y = 46$ ksi and $F_u = 58$ ksi when $A_e/A_g < 0.952$. Otherwise, tensile yielding will control over tensile rupture.

Table 5–5. Square HSS

Table 5–3 is similar to Table 5–1, except it covers square HSS with $F_y = 46$ ksi and $F_u = 58$ ksi (ASTM A500 Grade B).

Table 5–6. Round HSS

Available strengths in axial tension are given for ASTM A500 round HSS with $F_y = 42$ ksi and $F_u = 58$ ksi (ASTM A500 Grade B). Note that tensile rupture will control over tensile yielding given for round HSS with $F_y = 42$ ksi and $F_u = 58$ ksi when $A_e/A_g < 0.869$. Otherwise, tensile yielding will control over tensile rupture.

Table 5–7. Steel Pipe

Available strengths in axial tension are given for steel pipe with $F_y = 35$ ksi and $F_u = 60$ ksi (ASTM A53 grade B). Note that tensile rupture will control over tensile yielding given for steel pipe with $F_y = 35$ ksi and $F_u = 60$ ksi when $A_e/A_g < 0.700$. Otherwise, tensile yielding will control over tensile rupture.

Table 5–8. Double Angles

Available strengths in axial tension are given for double angles with $F_y = 36$ ksi and $F_u = 58$ ksi (ASTM A36). Note that tensile rupture will control over tensile yielding given for double angles with $F_y = 36$ ksi and $F_u = 58$ ksi when $A_e/A_g < 0.745$. Otherwise, tensile yielding will control over tensile rupture.

F_y = 50 ksi
F_u = 65 ksi

Yielding	$\Omega_t = 1.67$	$\phi_t = 0.90$
Rupture	$\Omega_t = 2.00$	$\phi_t = 0.75$

[h] Flange thickness is greater than 2 in. Special requirements may apply per AISC Specification Section A3.1c.

Note: Tensile rupture on the effective net area will control over tensile yielding on the gross area unless the tension member is selected so that an end connection can be configured with $A_e \geq 0.923A_g$.

PART 6

DESIGN OF MEMBERS SUBJECT TO COMBINED LOADING

SCOPE 6–2

COMPACT, NON-COMPACT, AND SLENDER CROSS-SECTIONS 6–2

MEMBERS SUBJECT TO COMBINED AXIAL COMPRESSION AND FLEXURE . 6–2

MEMBERS SUBJECT TO COMBINED AXIAL TENSION AND FLEXURE 6–2

MEMBERS SUBJECT TO COMBINED TORSION, FLEXURE, SHEAR, AND/OR AXIAL FORCE 6–2

COMPOSITE MEMBERS SUBJECT TO COMBINED AXIAL COMPRESSION AND FLEXURE 6–2

OTHER SPECIFICATION REQUIREMENTS AND DESIGN CONSIDERATIONS 6–3

STEEL BEAM-COLUMN SELECTION TABLES 6–3

- Table 6–1. W-Shapes: Combined Axial and Bending 6–3
- Combined Compression and Flexure 6–3
- Combined Tension and Flexure 6–4

PART 6 REFERENCES 6–4

SCOPE

The specification requirements and other design considerations summarized in this Part apply to the design of members subject to combined loading. For the design of members subject to axial tension only, see Part 5. For the design of members subject to axial compression only, see Part 4. For the design of members subject to uniaxial flexure only, see Part 3. For members that are part of a seismic force resisting system in which the seismic response modification factor, R, is taken greater than 3, the requirements in the AISC *Seismic Provisions for Structural Steel Buildings* also apply. The AISC *Seismic Provisions for Structural Steel Buildings* is available in Part 6 of the AISC *Seismic Design Manual* from the American Institute of Steel Construction, Inc. at www.aisc.org.

COMPACT, NON-COMPACT, AND SLENDER-ELEMENT CROSS-SECTIONS

Based upon the types of load transmitted by the member, the discussions of width-thickness ratios in Part 4 for compression members and Part 3 for flexural members apply to the design of members subject to combined loading.

MEMBERS SUBJECT TO COMBINED AXIAL COMPRESSION AND FLEXURE

The interaction of the combined effects of the required strengths (axial compression and bending moment) must satisfy the unity check as follows:

1. For doubly symmetric and singly symmetric members, per AISC Specification Section H1.1.
2. For unsymmetric and other members, per AISC Specification Section H2.

MEMBERS SUBJECT TO COMBINED AXIAL TENSION AND FLEXURE

The interaction of the combined effects of the required strengths (axial tension and bending moment) must satisfy the unity check as follows:

1. For doubly symmetric and singly symmetric members, per AISC Specification Section H1.2.
2. For unsymmetric and other members, per AISC Specification Section H2.

MEMBERS SUBJECT TO COMBINED TORSION, FLEXURE, SHEAR, AND/OR AXIAL FORCE

The interaction of the combined effects of the required strengths (torsion, bending moment, shear force, and/or axial force) must satisfy the requirements of AISC Specification Section H3.

See also AISC Design Guide No. 9 *Torsional Analysis of Structural Steel Members*.

COMPOSITE MEMBERS SUBJECT TO COMBINED AXIAL COMPRESSION AND FLEXURE

For the design of composite members subject to combined axial compression and flexure, see AISC Specification Section I4.

OTHER SPECIFICATION REQUIREMENTS AND DESIGN CONSIDERATIONS

Based upon the types of load transmitted by the member, the specification requirements and design considerations given in Part 5 for tension members, Part 4 for compression members, and Part 3 for flexural members apply to the design of members subject to combined loading.

STEEL BEAM-COLUMN SELECTION TABLES

Table 6–1. W-Shapes in Combined Axial and Bending

The determination of the adequacy of W-shapes subject to combined axial and bending loads is facilitated by the use of this table. The AISC Specification Equations to check the adequacy of W-shapes with $F_y = 50$ ksi (ASTM A992) subject to combined axial force and flexure can be determined using the values of p, b_x, b_y, t_r and t_y, tabulated in Table 6-1. These variables are defined as follows:

	LRFD	ASD
Axial Compression	$p = \dfrac{1}{\phi_c P_n}$, (kips)$^{-1}$	$p = \dfrac{\Omega_c}{P_n}$, (kips)$^{-1}$
Strong Axis Bending	$b_x = \dfrac{8}{9\phi_b M_{nx}}$, (kip-ft)$^{-1}$	$b_x = \dfrac{8\Omega_b}{9M_{nx}}$, (kip-ft)$^{-1}$
Weak Axis Bending	$b_y = \dfrac{8}{9\phi_b M_{ny}}$, (kip-ft)$^{-1}$	$b_y = \dfrac{8\Omega_b}{9M_{ny}}$, (kip-ft)$^{-1}$
Tension Rupture	$t_r = \dfrac{1}{\phi_t 0.75 F_u A_g}$, (kips)$^{-1}$	$t_r = \dfrac{\Omega_t}{0.75 F_u A_g}$, (kips)$^{-1}$
Tension Yielding	$t_y = \dfrac{1}{\phi_c F_y A_g}$, (kips)$^{-1}$	$t_y = \dfrac{\Omega}{F_y A_g}$, (kips)$^{-1}$

Table 6-1 is normally used with iteration to determine an appropriate shape. After selecting a trial shape, the sum of the load ratios reveals if that trial shape is close (a sum nearly equal to 1.0), conservative (a sum less than 1.0), or unconservative (a sum greater than 1.0). When the trial shape is unconservative and axial effects dominate, the second trial shape should be one with a larger value of p. Similarly, when X-X axis or Y-Y axis flexural effects dominate, the second trial shape should be one with a larger value of b_x or b_y, respectively. This process can be repeated until an acceptable shape is determined.

An alternative approach for the initial selection of members may be found in Aminmansour (2000).

Combined Compression and Flexure

In this case, the compressive component of the combined force is accounted for by selecting the proper value of p based on the larger of the effective length for compression buckling about the Y-Y axis $(KL)_y$ and the effective length for compression buckling about the X-X axis $(KL)_{y\,eq}$, as described in Part 4. The tabulated values can be used directly, as the slenderness of the cross section is accounted for.

The bending component of the combined force is accounted for by selecting the proper value of b_x based on the unbraced length L_b, as described in Part 3. Because unbraced length is not a factor in weak-axis bending, a single value of b_y applies for any given W-shape.

When $P_r/P_c \geq 0.2$, the tabulated values of p, b_x, and b_y can be used as follows to solve the modified form of AISC Specification Equation H1-1a:

$$pP_r + b_xM_{rx} + b_yM_{ry} \leq 1.0$$

When $P_r/P_c < 0.2$, the tabulated values of p, b_x, and b_y can be used as follows to solve the modified form of AISC Specification Equation H1-1b:

$$\tfrac{1}{2}pP_r + \tfrac{9}{8}(b_xM_{rx} + b_yM_{ry}) \leq 1.0$$

The tabulated values of b_x and b_y assume that $C_b = 1.0$. These values may be modified in accordance with AISC Specification Section F1.

For further information, see Aminmansour (2000).

Combined Tension and Flexure

In this case, the axial component of the combined force is accounted for by selecting the larger value of t_y *or* t_r, for the critical case of available tension yield or available tension rupture strength, as described in Part 5. It is important to note that the tabulated values for t_r are based upon the assumption that $A_e = 0.75A_g$, which is arbitrarily selected as a value that is practical to achieve with typical end connections. When $A_e > 0.75A_g$, the tabulated values for t_r can be used conservatively. When $A_e < 0.75A_g$, the tabulated values of t_r cannot be used, but rather, must be calculated based upon the actual value of A_e.

The bending component of the combined force is accounted for by selecting the proper value of b_x for the unbraced length L_b, as described in Part 3. Because unbraced length is not a factor in weak-axis bending, a single value of b_y applies for any given W-shape.

When $P_r/P_c \geq 0.2$, the tabulated values of t_y, t_r, b_x, and b_y can be used as follows to solve the modified form of AISC Specification Equation H1-1a:

$$(t_y \text{ or } t_r)\, P_r + b_xM_{rx} + b_yM_{ry} \leq 1.0$$

When $P_r/P_c < 0.2$, the tabulated values of p, b_x, and b_y can be used as follows to solve the modified form of AISC Specification Equation H1-1b:

$$\tfrac{1}{2}(t_y \text{ or } t_r)\, P_r + \tfrac{9}{8}(b_xM_{rx} + b_yM_{ry}) \leq 1.0$$

The tabulated values of b_x and b_y assume that $C_b = 1.0$. These values may be modified in accordance with AISC Specification Sections F1 and H1.2.

[c] Shape is slender for compression with F_y = 50 ksi.

[h] Flange thickness greater than 2 in. Special requirements may apply per AISC Specification Section A3.1c.

Note: Heavy line indicates *Kl*/*r* equal to or greater than 200.

^{c} Shape is slender for compression with F_y = 50 ksi.

^{h} Flange thickness greater than 2 in. Special requirements may apply per AISC Specification Section A3.1c.

Note: Heavy line indicates Kl/r equal to or greater than 200.

^{c} Shape is slender for compression with F_y = 50 ksi.

^{h} Flange thickness greater than 2 in. Special requirements may apply per AISC Specification Section A3.1c.

Note: Heavy line indicates Kl/r equal to or greater than 200.

F_y = 50 ksi

^{c} Shape is slender for compression with F_y = 50 ksi.

Note: Heavy line indicates Kl/r equal to or greater than 200.
