Conversely, and as discussed in Chapter 6, more than 45 million U.S. citizens are uninsured and many millions more are underinsured. A major reason for bankruptcy filings is the inability to pay medical bills. Millions of citizens suffer death and disease because of ethnic disparities (Smedley, Stith, & Nelson, 2003), and there continues to be an imbalance in the ethnic makeup of our professional caregivers—nurses, physicians, dentists, and others (Sullivan Commission, 2004). Our medical care system is the most expensive in the world, but our longevity is lower than in countries that spend much less than we do for health care, and these countries are still able to provide care for their entire populations (Commonwealth Fund, 2004).

In the United States, infant mortality rates—a marker for quality of health care—are near the bottom of industrialized nations, with a rate of 6.4 per 1,000 births (State of the World's Mothers Index, 2006). Our publicly financed health system—Medicaid and Medicare—is constantly under siege, and increasing numbers of medical errors are harming 1.5 million patients per year (Institute of Medicine, 2000, 2006). The changing demographics of our society, along with other issues such as immigration, shortages of professional health care workers, the increased use of alternative medicine and, most importantly, the shift from a nonprofit to a for-profit health care system, affects our society in innumerable ways (Leape & Berwick, 2005; Milstein & Smith, 2006).

## Economic Effects

The 1990s ushered in an era of health care reform, and with it came downsizing—registered nurses (RNs) in the acute care setting were thought to be dispensable and were replaced by less-prepared staff (American Nurses Association, 1994; Seago, Spetz, & Mitchell, 2004). The core functions of public health—assessment, assurance, and policy development—became underfunded and underappreciated by local and state governments. As this is written, health departments continue to be in crisis as a result of economic downturns that have necessitated nursing staff layoffs. Also, due to the normal attrition of licensed staff, a substantial reduction in programs and services has occurred (Hall, 2006). More critically, schools of nursing have closed or been reduced in size (Kovner, Fairfield, & Jacobson, 2006). We have yet to recover from this dramatic downsizing, and these problems are further exacerbated by the current nursing shortage. The cyclical changes in health workforce patterns are accentuated by the aging of our health care workforce—the average age of public health employees is 47 (National Council of State Legislators, 2004). Additionally, the shortages of nursing faculty hinder our nursing schools from accommodating students interested in entering nursing (National League for Nursing, 2006).

Federal nursing programs, including the Nurse Reinvestment Act, Title VIII funding of the Public Health Service Act, and various state funding programs are attempting to address these issues. For example, California and Florida have loan forgiveness programs in return for a commitment to work in designated areas, notably state facilities or underserved areas, for a designated period of time. Additionally, California is offering loan forgiveness for graduate students to become nursing instructors for 3 to 5 years. Many other states are offering various incentives to attract and retain their public health personnel (American Association of Colleges of Nursing, 2006).

The reality of today's health care arena is managed care, which when first developed, offered a population-based approach to care that included the assurances of preventive care and early intervention necessary for maintaining a healthy patient (Barr, 2004). Physicians within this system were paid based on an agreed-upon fee (per member, per month) to provide all needed services. This system, then called *prepaid group practice*, was first developed by Kaiser Permanente in the 1920s to care for its employees in remote locations and later refined in 1973 when the federal government passed the *Health Maintenance Organization Assistance Act*. Prepaid group practice was touted as an example of wellness care, not sick care. It was to be a combination of insurance and health care, quite different from indemnity plans, which would lower health care costs. Signed into law by President Nixon, the plan was seen by one of its proponents—Representative Ted Kennedy—as the first step toward universal care. However, as this model evolved, its emphasis shifted from prevention to cost containment. Reductions in reimbursement, particularly for disadvantaged patients (e.g., those covered under Medicaid and Medicare), reductions in the choice of practitioners, and limitations on the types of care available drastically transformed the system from its original concept. Most managed care today is for profit, thus setting up a dichotomy between the insured and the owners/investors (Baker, 2000; Friedman, 1999; Kovner & Knickman, 2005; Robinson, 2001).

Health care coverage and access are ongoing policy discussions in the United States, with the cost of care high and growing each year, according to the latest information from the National Coalition on Health Care (2004). Health care insurance coverage is often provided through employers, and as costs rise, employers are passing on more costs to the worker. Co-pays and deductibles have increased, with workers paying an increase of 10% over 2004 (see Chapter 6). As the numbers of elderly Americans increase, costs to provide health coverage for them are growing exponentially.

### Need for Action to Change

Most people agree that health care policy in the United States must change, but there is little agreement among policy makers and citizens about how this should occur (Gordon, 2003). Some believe market forces should be allowed to work this problem out, others believe the government should assume responsibility—as in other countries—and ensure that all have access to health care coverage. Public health activists believe that if every person adhered to healthful lifestyles, the need for medical care would lessen.

Policy discussions at the state and local level determine access to care for their residents; other issues, such as high rates of unemployment, health care allotments in state and local budgets, and increasingly incendiary discussions on the role that undocumented residents play in the costs of health care, affect how health care is delivered. The latter issue is a discussion that occurs more frequently in those states with significant numbers of undocumented workers (see Chapter 29). Nonetheless, the numbers of uninsured or underinsured result in patients who lack access to primary care, or who delay care, thus resulting in higher morbidity, mortality, and expense. Disadvantaged populations are more likely to be uninsured because of unemployment or underemployment, resulting in low or no income, health disparities, poor housing, and neighborhoods that may be unsafe (see Chapter 25). Recent studies document that uninsured or underinsured patients have difficulty maintaining economic and social stability (Himmelstein, Warren, Thorne, & Woolhandler, 2005; Institute of Medicine, 2002a, 2003).

Himmelstein, Warren, Thorne, and Woolhandler (2005) reported that over half of personal bankruptcy filings were the result of medical bills and/or loss of health coverage. “These were working-class or middle-class people, and 76% of them had health insurance when they first got sick . . . (although) many lost this coverage because the insurance was through their jobs, so it disappeared when they couldn’t work. Half of the bankruptcies were caused, in part, by illness and medical debt . . . and the major part of that debt was payments to doctors and hospitals. Families initially tried to pay the debt for several months . . . 61% went without needed medical care to make payments, 30% had a utility shut off, and 22% percent cut back on their food” (p. 6).

Larger employers complain that they are subsidizing those firms that don’t provide coverage, and this also drives up the cost of the premiums they have to pay. Loss of insurance coverage leads to increases in charity care which, in turn, impacts health care facilities’ ability to continue to provide care. People with health insurance pay higher deductibles and co-pays as a result of the lack of universal health coverage.

Disproportionate-share hospitals are closing, while others are implementing diversion policies to ensure greater equity in the care of patients without sufficient health care insurance.

As an example of a deteriorating health care system, despite advances in caring for and addressing infectious diseases, one of the scourges of an earlier time, tuberculosis (TB), has resurfaced. Although the increased incidence of AIDS accounts for some of this resurgence, drug resistance to the TB bacillus and the influx of immigrants from endemic areas, coupled with budget cuts, have impeded the labor-intensive measures of tracking patients, directly observing therapy, and providing continuous follow-up for these patients (see Chapter 8).

Despite the availability of vaccines against childhood diseases, the numbers of children fully vaccinated is inadequate—only about 76% of 2-year-olds are appropriately immunized (Centers for Disease Control and Prevention [CDC], 2006). Because of a complicated vaccination schedule, coupled with access issues, many youngsters are not fully immunized; consequently, periodic outbreaks of childhood diseases (e.g., mumps, pertussis, meningitis) occur. With the increased emphasis on terrorism, public health departments are being called on to provide the critical disaster preparedness plans that each state and local jurisdiction will need in the event of a major disaster (Khan, Morse, & Lillibridge, 2000; Geberding, Hughes, & Koplan, 2002).

With the health care arena in a state of flux, nurses are beginning to take on more of a role in influencing health policy. Currently, three former RNs are in Congress: Lois Capps (D-CA); Eddie Bernice Johnson (D-TX), the first nurse to be elected to U.S. House of Representatives; and Carolyn McCarthy (D-NY). These representatives carry on the legacy of nurses involved in influencing health policy in the United States since the 19th century. They have proved, as others before them, to be instrumental in the introduction and passage of policies that affect the health of all Americans (Roberts & Group, 1995).

## FOUNDATIONS OF POLITICAL ACTION AND ADVOCACY

The basic concepts of public health have evolved over the last 150 years. From an emphasis on the individual to a population focus, policy development aims for a broader effect encompassing “healthy policies—education, adequate and affordable housing, living wage, and environmental concerns” (Institute of Medicine [IOM], 2002b, p. 46).

### Public Health

The concept of social justice is seen as the very foundation of public health nursing (Fahrenwald, 2003; Keller, Strohschein, Lia-Hoagberg, & Schaffer, 1998). The American Association of Colleges of Nursing (2003) emphasizes that the guiding values of nursing include social justice, and the American Nurses Association (ANA) *Code of Ethics with Interpretative Statements* (2001, preface) states that “nurses should act to change those aspects of society that detract from health and well-being.” The many definitions of social justice depend on the discipline involved; for purposes of this chapter, **social justice** is “both a process and a goal which includes a vision of society that is equitable and all members are physically and psychologically safe and secure” (Adams,

Bell, & Griffin, 1997, p. 1). However, it has been noted that nurses “lack a multi-disciplinary vocabulary to discuss, critique and strategize about injustice” (Boutain, 2005, p. 10). You may be caught in a “Catch-22,” working within a market-based system that is inherently unfair and often leads to health and social disparities for ethnic and other disadvantaged groups, while having pledged to alleviate suffering within the groups you serve (Fahrenwald, 2003).

As a community health nurse, you are expected to give voice to the disparities found in the communities you serve (e.g., substandard housing, high rates of unemployment, death and disability)—disparities that often could be prevented or alleviated at early stages. Your efforts through nursing interventions can address not only health issues but also the educational, social, and economic issues that give rise to these disparities (Cohen, de la Vega, & Watson, 2001). The Minnesota Department of Public Health Nursing Section has developed a public health interventions model that gives a broad overview of public health nursing. The model is based on the type of intervention and level of practice that allows a range of activities, such as advocacy, community organizing, coalition building, case management, and policy development, that you as a public health practitioner can activate (see Chapter 14). The nexus between social justice, advocacy, and policy is interesting, complex, and one that will affect every aspect of your community health nursing career.

## History of Public Health Nursing Advocacy

Nurses have a long history of action in social justice and **advocacy**, which can be defined as pleading the case of another or championing a cause. A more encompassing definition has been proposed by the Advocacy Institute in its publication *Advocacy for Social Justice: A Global Action and Reflection Guide* (Cohen, de la Vega, & Watson, 2001, p. 7): “Advocacy is the pursuit of influencing outcomes—including public policy and resource allocation decisions within political, economic, and social systems and institutions—that directly affect people’s lives. . . .”

Advocacy is a process, not an outcome, one that includes identifying an issue, collecting information, identifying who can be influenced/who can make the decision sought, building support, and taking action. Advocacy can present itself in a variety of ways—self-advocacy, which is advocating for one’s self; individual advocacy, which is pleading the case of others; and legislative advocacy, which is changing or modifying state or federal laws. Advocacy also includes litigation and public education campaigns. Finally, advocacy is also the process of empowering those less able to present their views or needs, with the goal of giving them a voice and/or achieving their objectives. Nurses have long been advocates for their patients, and advocacy can and does affect the larger systems of care (Diers, 2004). **Community health advocacy** refers to efforts aimed at creating awareness of and generating support for meeting the community’s health needs. Both nurses and communities have a common goal—the best possible health services for all.

The term and concept of *public health nursing* was coined in 1893 by Lillian Wald, who described public health nurses (PHNs) as “those nurses working outside the hospital in poor and middle-class communities” (Jewish

Women’s Archive, 2006 ¶ 2). These nurses “specialized in both preventative care and the preservation of health, these nurses responded to referrals from physicians and patients, and received fees based on the patient’s ability to pay” (¶ 2). In 1893, Lillian Wald and Mary Brewster established the Visiting Nurses Service, and a year later the famed Henry Street Settlement House was established (see Chapter 2).

Public health as a concept grew out of Wald’s exposure to the plight of newly arrived immigrants to the lower east side of Manhattan and their appalling living conditions. She was determined that these immigrants and other poor people, regardless of ethnicity or religious affiliation, would have access to health care and adequate housing. Remarkably, Henry Street Settlement (2006) still provides many of the services established by Wald and her associates—currently, the organization advocates for the homeless, builds AIDS awareness, fights illiteracy and domestic violence, and provides youth and senior programs. Understanding the critical concepts of primary care, prevention, and early intervention, and the role they played in assuring a healthy childhood, Lillian Wald advocated for the hiring of public school nurses. In 1902, Lina Rogers became the first school nurse in New York City “as a one month experiment,” and within 1 year’s time New York City had hired an additional 12 school nurses (Woodfill & Beyrer, 1991, p. 5). Wald also went on to encourage the establishment of the Department of Nursing and Health at Columbia University’s Teachers College through a series of lectures she presented starting in 1910. She also was instrumental in creating the U.S. Children’s Bureau in 1912, an agency that oversaw fair child labor laws.

The importance of these nurses—Lillian Wald and her compatriots, Sojourner Truth, Margaret Sanger, Clara Barton, Mary Seacole, Susie King Taylor, Mary Mahoney, and others—is that they wielded influence at a time when women were not even allowed to vote. In fact, many women in the 1800s, regardless of socioeconomic status, did not attend school. African American women in the early 20th century were legally forbidden to learn to read and write (Hall-Long, 1995).

Historically, women—both Black and White—volunteered their services during crises (Carnegie, 1986), although nursing as a profession didn’t exist. For these women to be successful and influential during the 19th century is a tribute to their ability to take on the system in which they lived and to triumph over it. Women during these times rarely, if ever, voiced their opinions about issues affecting their lives, the lives of their children, their families, or their communities; it was neither expected nor accepted. These early pioneers also are seen as feminists, and the entrance of these women into the political arena opened the way for others. By 2006, 23% of state elected officials were women, and 82 women had been elected to the U.S. Congress, 14 in the Senate and 68 in the House of Representatives (Center for American Women & Politics, 2006). Despite nursing’s early history of political activism and the fact that nurses are the largest group of health care providers in the United States, widespread political involvement has yet to be realized (Feldman & Lewenson, 2006; Sapp & Bliesmer, 1995; Des Jardin, 2001). Nor is nursing thought of as a major player in Washington when discussing health care policy (Sharp, 1997; Des Jardin, 2001).

## Professional Advocacy

Membership in professional organizations has provided the most important way for nurses to advocate for change. The late 19th century may be seen as the beginning of nurse activism. The National Associated Alumnae of the United States and Canada and the American Society of Superintendents of Training Schools of the United States and Canada were formed in the 1890s. Out of these groups came the ANA and the National League for Nursing (Woodfill & Beyrer, 1991). Large professional organizations have the resources, relationships with policy makers, success at coalition building, and reputation for the ability to compromise needs to assure viable outcomes. Being a part of your professional organization demonstrates your professionalism, promotes your organization's viability, and demonstrates your social responsibility to advocate for the needs of your patients. Nurses must take advantage of how the public views the profession: a 2006 Harris Poll ranked nurses highly for trustworthiness (Donelan, Buerhaus, Desroches, Dittus, & Dutwin, 2008).

The pursuit of personal agendas over the common good results in a piecemeal approach to problems and promotes polarization. **Polarization** is the process by which a group is severely split into two or more factions over a political issue. Polarization can be so intense that people perceive one another as good or wicked, depending on their ideological opinions. One of the primary goals of a professional nursing association is to build a collective voice for nurses. A strong professional association limits polarization by developing the political skills of its members and ensuring that its structure and processes equitably meet the needs of its constituencies. This is the essence of politics: people must listen to one another, learn from others' viewpoints, and compromise to ensure the most positive outcomes from their endeavors (Mason & Leavitt, 2006).

Despite criticism about special interest and professional organizations "protecting their turf," professional nursing organizations demonstrate how a critical mass can be influential and successful in moving the discussion forward on health care. These organizations have raised the level of professionalism in nursing, given voice to the inequities that affect our society, and developed the paradigms that influence and affect public health at the institutional, state, and national level in the 21st century (Hein, 2001). A united voice on public policy is more powerful than individual nurses pleading with their legislators.

## CURRENT PUBLIC HEALTH NURSING ADVOCACY

Representatives Lois Capps, Eddie Bernice Johnson, and Carolyn McCarthy, all ran for Congress because of their commitment to improving the lives of their constituents. How they came to serve in Congress exemplifies the history of dedicated people wanting to make a difference for their communities. For example, when Carolyn McCarthy's husband was killed and her son badly injured by the same gunman, she began to work on the assault weapons ban—and when her congressman voted against it, she was so outraged she decided to run for office. She won with strong **grassroots** support (defined as a political movement driven by

community members, a bottom-up rather than a top-down process). Eddie Bernice Johnson ran for office because she believed her work as a volunteer in a low-income immunization program could be expanded, and again, with a grassroots movement behind her, she won and is now serving her seventh term in the House of Representatives. Lois Capps' story is similar. Her husband, who was the representative for California's 23rd Congressional district, died suddenly and she was drafted to run in his place. Capps, a former school nurse, and the 91-member Congressional Nursing Caucus that she founded, supported the National Nurse Act HR 4903. According to her, this legislation "will improve public awareness of health issues and the role of nurses in improving healthcare" (Polick, 2006, p. 3). A national nurse would be an "advocate for nursing issues at a time when our profession faces growing demands for its skills and an increasing shortage of qualified personnel to meet those challenges" (Polick, 2006, p. 3). Therese Polick and Teri Mills, both RNs, are the impetus behind HR 4903. In a desire to do something about the health care crisis, Teri Mills called for an Office of the National Nurse in a *New York Times* Op-Ed piece; after reading it, Polick joined with her to form the National Nurse Team. Together, they headed to Capitol Hill (Polick, 2006).

What Teri and Therese engaged in is called **lobbying**—the process of influencing legislators or other policy makers to make decisions on policy issues. Professional organizations or other **special interest groups**—individuals who share a common interest and work politically to make their goals a reality—may have paid lobbyists on staff. **Lobbyists**—professionals who engage in lobbying—know the rules governing the state or federal political process, have or develop relationships with policy makers, provide guidance for members of the organizations employing them on how to impact public policy decisions, and work behind the scenes to influence policy discussions and outcomes. States and the federal government have laws and regulations that determine the legal actions of lobbyists as well as the organizations that employ them (Mason & Leavitt, 2006; Milstead, 1999).

Universal health and social issues affecting communities include health care access, affordable housing, safe neighborhoods, domestic and youth violence, safe schools, gun control, and many others. Dr. Deborah Prothrow-Stith, a young physician in the mid-1980s, was weary of seeing young victims of violence in the emergency rooms of inner-city Boston, so she started a movement that swept across the country. She changed the way youth violence was viewed by recognizing that youth violence was a public health issue, not merely a criminal issue. She believed that applying public health principles of prevention could decrease the incidence of violence. She wrote about this in her groundbreaking book *Deadly Consequences: How Violence Is Destroying Our Teenage Population and a Plan to Begin Solving the Problem*. Because of her belief in prevention and early intervention, she developed a discipline that is now recognized and taught throughout the country and the world—*violence prevention*. Dr. Prothrow-Stith also developed the precursor to violence prevention curricula for schools and communities. *The Violence Prevention Curriculum for Adolescents* (Biography, 2006) is still used by many today.

## POLICY

Community health nursing, as it has evolved, puts nurses where the people are—in schools, homes, neighborhood centers, and churches. Community health nurses are in a position to see and understand the issues affecting people at an individual and group level. With this access to information and the issues affecting the communities they serve, who better than nurses to advocate for policy changes in the health care system? **Policy** is defined as a plan of action or an agenda that outlines steps or actions to implement a stated goal or objective. Policies are laws, regulations, or administrative rulings; when issued by national, state, or local governments they are called **public policy**. **Health policy** refers to specific policies involving health care. The legislative and regulatory process may start with lofty goals, but the final product is usually the result of compromise often encouraged by special interest groups, coalition groups, political realities, or the current economic environment. Although the study of politics has a long history, the systematic study of public policy, on the other hand, can be said to be a 20th century creation. According to Daniel McCool, in his classic treatise on policy (1995), study of public policy dates to 1922, when political scientist Charles Merriam sought to “connect the theory and practices of politics to understanding the actual activities of government, which is public policy” (p. 4).

Health policies can be distributive or regulatory. A **distributive health policy** promotes nongovernmental activities that are thought to be beneficial to society as a whole. An example of a distributive policy is the Nurse Training Act, Title VIII of the Public Health Service Act, which was established in 1965 and provided federal subsidies for nursing education in an effort to address the need for more nurses. A **redistributive health policy** changes the allocation of resources from one group to another, usually to a broader or different group. Medicare is an example of redistributive policy, in that provisions under Medicare were expanded to provide a broader range of benefits and coverage to needy groups—such as those older than age 65 and the permanently disabled of any age (Wieczorik, 1985).

A **regulatory health policy** is one that attempts to control the allocation of resources by directing those agencies or persons who offer resources or provide public services. For example, certain government regulations set standards for the licensure of health care organizations (e.g., hospitals) and health care providers (e.g., nurses). Regulatory public health policy is often used to protect the health of the community (Kovner & Knickman, 2005). In the United States, one example is the mandatory reporting of certain communicable diseases. On the international level, regulatory health policy has a broad scope, including areas such as international communicable disease control, trade, human rights, armed conflict and arms control, and the environment (Fidler, 1999; Gunn, Mansourian, Davies, Piel & Sayers, 2005; also see Chapter 16).

Regulatory policy can be further categorized as either competitive or protective. *Competitive regulation* limits, or structures, the provision of health services by designating who can deliver them. *Protective regulations* set conditions under which various private activities can be undertaken. Although professional licensure is most commonly identified as having the primary purpose of protecting the public, such policy is really competitive regulation in terms of its

social impact. Protective regulation is more clearly evident in utilization review organizations, regulatory bodies that critically examine health agency utilization patterns, or certificates of need, the legal requirement that a potential provider agency demonstrate the need for its services before a license to practice is granted (see Chapter 6).

As the medical system slowly moves from an emphasis on diagnosis and treatment to prevention and health promotion, nurses are uniquely situated to provide guidance in developing health policy. The aforementioned activities are fundamentally nursing functions, and we must realize that public policy affects nursing practice regardless of venue (Murphy, Canales, Norton, & DeFilippis, 2005). Nurses must have a voice in the development of policy (Conn & Armer, 1996; Spenceley, Reutter, & Allen, 2006).

Policy can also be viewed as the key interests of professional organizations (e.g., *Nursing's Agenda for Healthcare Reform*, American Nurses Association, 1994); government agencies (e.g., *Healthy People 2010*); think tanks, such as the Heritage Foundation (e.g., *Massachusetts Health Plan: Lessons for the States*, Woolhandler & Himmelstein, 2006); or advocacy groups, such as the Children's Defense Fund—the originators of the *Leave No Child Behind*<sup>®</sup> movement that advocates for legislation and policies that ensure every child a “healthy start, a head start, a fair start, a safe start, and a moral start” (2007, ¶1). These disparate groups reflect various political persuasions that influence which policies are debated at the national and state levels (Murphy, Canales, Norton, & DeFilippis, 2005). How effective these groups are in influencing policy development and implementing change is also tied to the political environment, or more specifically, to who is in power. Each major political party has differing political agendas that impact the policies that eventually become law.

Workplaces also implement policy, such as workplace rules and regulations that affect how the workplace functions and what is required of an employee (e.g., dress code, policies and procedures manual, hours of work, who has access to e-mail, what is acceptable behavior in the workplace, and so forth). One of the most contentious issues recently, the roles and responsibilities of unlicensed versus licensed personnel, is also a health care workplace issue that generates policy development (see Display 13.1, *A Ruling Affecting Nursing*).

Policies affect our daily lives, regardless of whether they are health- or work-related. So, community health nurses must have an understanding of health policy to better understand the issues affecting the communities they serve. It must be recognized that nurses have differing opinions on health policy, even down to the basic premise of whether nurses should become involved in political issues and the political process. According to Plato, “One of the penalties for refusing to participate in politics is that you end up being governed by your inferiors.”

## Process of Public Policy

The development of public policy is rarely easy, straightforward, or even rational. Myriad concerns determine whether one is successful with any attempt to make policy. Increasingly, the complexity of public–private interactions play a strong role in how policy is developed, both because of the privatization of health care and the increased consolidation of

## DISPLAY 13.1

## A RULING AFFECTING NURSING

An October 2006 ruling by the National Labor Relations Board (NLRB) determines which employees are seen as “supervisors” or staff employees. This ruling has been interpreted by one nursing union as a policy that will severely impact who can belong to a union, based on their job classification. This ruling grew out of a 2001 Supreme Court case that stated that an NLRB ruling in a Kentucky nursing facility case was flawed. The board at that time, comprised mainly of Democrats, ruled that the RNs at the

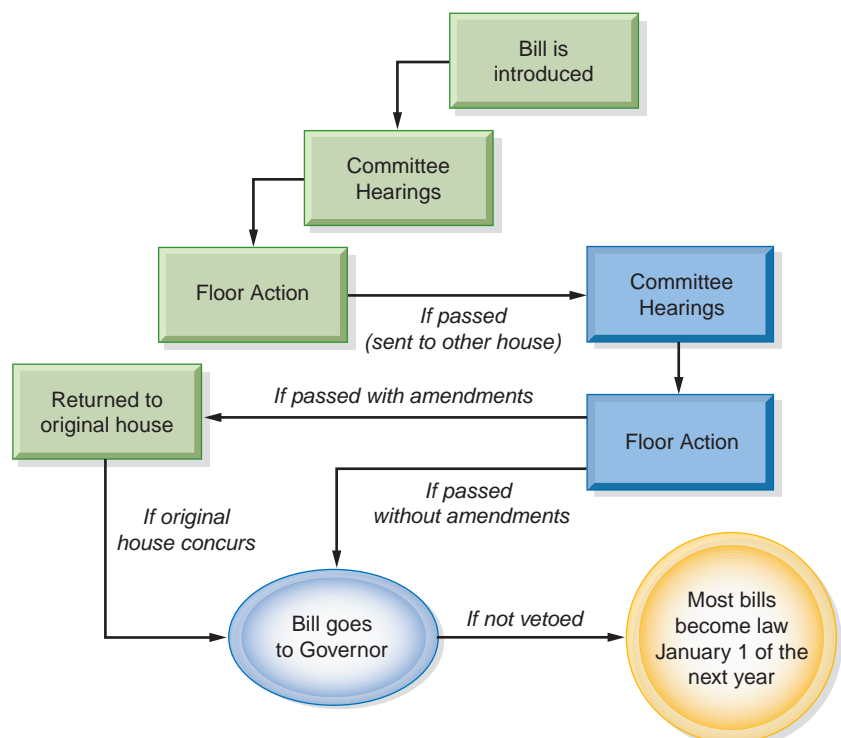

nursing home were not supervisors because they did not “exercise independent judgment.” The Supreme Court, in reviewing the case, sent it back to the board, stating that the role and duties of a supervisor should be more carefully reviewed. At the time of the ruling, the NLRB was comprised mainly of Republicans. The American Hospital Association is in favor of the decision.

From George Raine, San Francisco Chronicle, July 13, 2006.

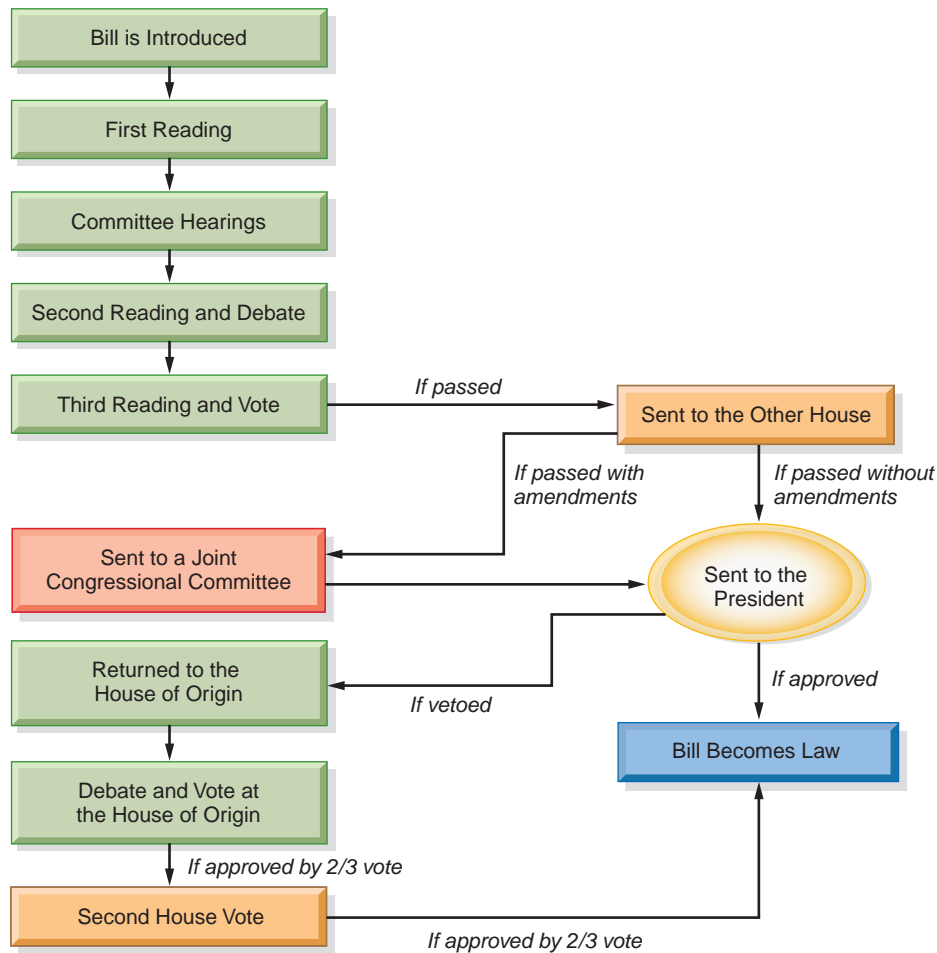

health care providers and insurers. As noted earlier, managed care that is regulated by federal and state policies has a direct effect on how health care is delivered at the local level. Many states have applied for waivers that allow them to demonstrate how they can better provide access, save money, and increase the numbers of people covered if they don't have to follow the existing federal regulations. This has, in some cases, created unforeseen problems. For example, during the 1990s, 27 states under the federal state children's health insurance program (SCHIP) established new non-Medicaid programs and, as a result, the states were not able to collect Vaccines for Children (VFC) funds for those in managed care because the Centers for Medicare and Medicaid Services interpreted the new laws to mean that these children were in private health plans. The providers of vaccines for children, who obtained their care through Medicaid's Early Periodic Screening Diagnosis and Treatment (EPSDT), were eligible to acquire vaccines through the VFC program, as were

providers of care to Native Americans, the uninsured, and rural or federally qualified health clinics. The states were not eligible to capture VFC funds and were financially responsible for paying for immunizations for those children enrolled in the non-Medicaid plans. This demonstrates the unintended consequences of regulatory and legislative changes if all aspects are not known or adequately investigated or if disagreement arises regarding interpretation.

The public policy process is similar to advocacy or **political action** and involves a number of steps that are synonymous with the nursing process. The policy/advocacy process may appear linear, but it involves overlap, reordering of priorities, mobilization of resources, and development of stakeholders. The overarching issues in advocacy or public policy development are timing, funding, and politics. Each year, thousands of measures at the state and federal level are introduced, but only a fraction of them complete the legislative process (see Figs. 13.1 and 13.2). This fall off can be attributed to a number of

**FIGURE 13.1** How a bill becomes a law—state process. The process may vary by state, but generally the schematic shows how the process unfolds. Source: California Legislative Counsel.

1. **Bill is Introduced.** Ideas for laws can come from a legislator, constituent, staff member, or organization.
2. **First Reading.** A legislator introduces the bill, and sends it to the clerk of his or her corresponding body (Senate or House), who gives it a number and title. This is the *first reading*, and the bill is referred to the proper committee.
3. **Committee Hearings.** The committee may decide the bill is unwise or unnecessary and *table* it, thus killing it at once. Or it may decide the bill is worthwhile and hold hearings to listen to facts and opinions presented by experts and other interested persons. After members of the committee have debated the bill and perhaps offered amendments, a vote is taken; if the vote is favorable, the bill is sent back to the floor of the house.
4. **Second Reading and Debate.** The clerk reads the bill sentence by sentence to the house; this is known as the *second reading*. Members may then debate the bill and offer amendments.
5. **Third Reading and Vote.** The *third reading* is by title only, and the bill is put to a vote, which may be by voice or roll call, depending on circumstances and parliamentary rules.
6. **Sent to the Other House.** The bill then goes to the other house of Congress, where it may be defeated or passed, with or without amendments.
7. **Sent to a Joint Congressional Committee.** If the bill is passed with amendments, a joint congressional committee must be appointed by both houses to resolve the differences.
8. **Sent to the President.** After its passage by both houses, the bill is sent to the president.
9. **Returned to the House of Origin.** If the president *vetoes* the bill, it is sent back to the house of origin with his reasons for the veto.
10. **Debate and Vote at the House of Origin.** The president's objections are read and debated, and a roll-call vote is taken.
11. **Second House Vote.** If the bill receives a two-thirds vote or greater in the house of origin, it is sent to the other house for a vote.
12. **Bill Becomes Law.** If the president approves the bill, or if his veto is overridden by a 2/3 vote in both houses, the bill becomes a law.

**Note:** Should the president desire neither to sign nor to veto the bill, he may retain it for ten days (Sundays excepted) after which time it automatically becomes a law without signature. However, if Congress has adjourned within those ten days, the bill is automatically killed, that process of indirect rejection being known as a *pocket veto*.

**FIGURE 13.2** How a bill becomes a law—federal process.

reasons: conflicting sides of the issue with the strongest side winning out, timing of bill introduction or an unwillingness to put it on the agenda based on other influences or competing issues, or the inability to identify a funding source.

### How and Where to Start

It can be very tricky to come into a community and determine that a problem exists that can be addressed politically. If you are aware of the problems, there are no doubt others who are also aware. It would be incumbent on you to identify the leaders or elders of the community and determine if they have previously addressed the issue and, if so, what the outcome was. It is helpful to ask if they feel that the issue is something that should be reopened if they were not successful, or if they were satisfied with the previous outcome. It helps to know how these problems relate to the priorities of the city or county, and if there are stakeholders who are willing to become engaged in the issue. Costs or possible effects of addressing these issues must be considered. These are by no means exhaustive questions, but should be considered prior to assuming leadership in addressing the issues or problems affecting a community.

If you determine you are on safe ground and others are willing to be involved, various steps can be used to put forth the

agenda of issues or problems the community will be addressing and may agree to take forward to their political representatives. Nurses can take several approaches when analyzing a policy that affects the health of a community or target population (Diers, 2004). They can look at the reasons for policy formulation, the groups of people affected by the policy, or the policy's possible long-range consequences. When analyzing policy, nurses need to answer two general questions: Who benefits from this policy? Who loses from this policy? Whether the policy should be advocated by the community as a whole depends on the degree to which the policy benefits the community without being detrimental to individuals or the country.

Figure 13.3 provides a simple model for studying health policy. If nurses know something about the forces shaping health policy and the policy process, they are in a better position to influence policy outcomes. The model identifies four major stages in the policy process: formulation, adoption, implementation, and evaluation.

- ◆ *Policy formulation* involves identifying goals, problems, and potential solutions.
- ◆ *Policy adoption* involves the authorized selection and specification of means to achieve goals, resolve problems, or both.

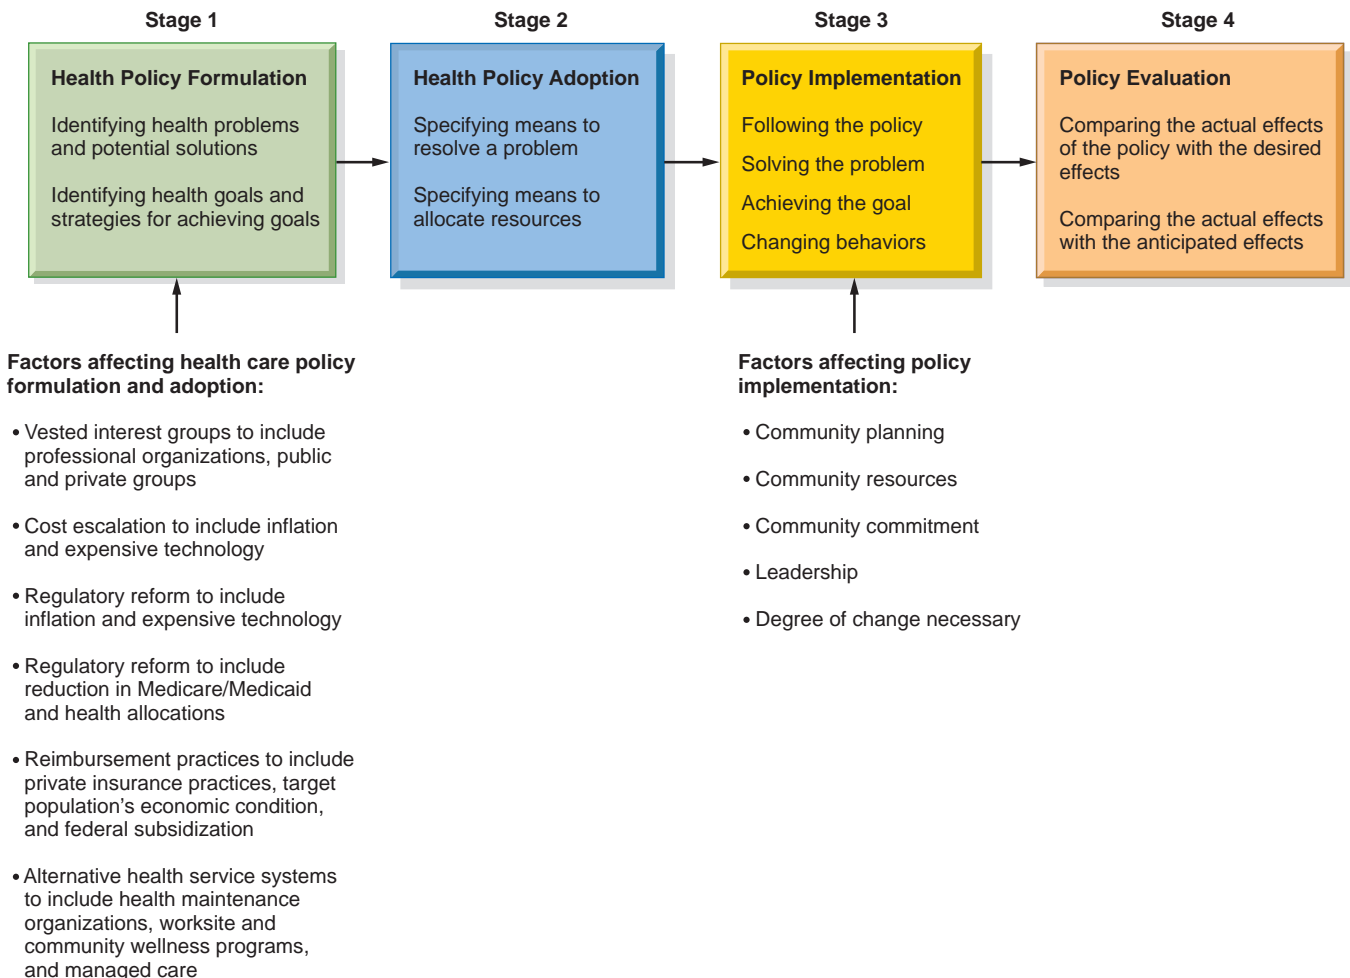

FIGURE 13.3 Policy analysis model.

- ◆ *Policy implementation* follows adoption and occurs when the policy is put to use.
- ◆ *Policy evaluation* compares policy outcomes or effects with the intended or desired effects.

### Stages 1 and 2: Policy Formulation and Adoption

*Health policy formulation* is the stage at which a policy is conceptualized and ultimately defined. It is approached in at least two ways. Most commonly, a health problem is identified, such as the increased infant mortality rate associated with teenage pregnancy, and health policy is developed to correct that particular problem. Another approach to policy formulation emphasizes health planning more than corrective actions, at least initially (Murphy, Canales, Norton, & DeFilippis, 2005). This is a goal-oriented approach. Health goals and strategies for achieving the goals are identified. In this more proactive approach, resources may be created as well as allocated for health services. Although either approach to policy formulation may lead to the solution of a health problem, the goal-oriented approach is less reactive in that it does not require problem identification before creating health policy.

The social and political conditions that affect policy formulation are limitless, but public need and public demand *should* be the strongest influences (Kovner & Knickman, 2005). Health care providers can stimulate a community to identify its health needs and demand health policies to fulfill its needs. During this process, the community health nurse should recognize that each community is unique, with its own mix of health services and public expectations.

### Stage 3: Policy Implementation

*Implementation* of health policy occurs when an individual, group, or community puts the policy into use. It involves overt behavior changes as the policy is put into nursing practice. The extent of compliance with a policy is the most direct measure of the policy's implementation (Harrington & Estes, 2004). *Noncompliance* refers to conscious or unconscious refusal to follow the policy directives. Community health nurses have always been health policy implementers and, recently, evaluators, regardless of whether these roles were consciously chosen.

Implementation of health policy is an essential part of effective, comprehensive client care for many documentable reasons. It should now be apparent that policies come in many forms and can have statutory or nonstatutory origins. Nurses are most cognizant of the latter, in the form of procedure manuals and institutional guidelines. Communities are most aware of policies that limit or restructure their activities and growth, such as curfews and zoning regulations.

Once a health policy is written and adopted, its successful implementation depends heavily on the manipulation of many variables. For example, the implementation of day care standards depends, in part, on how they are interpreted and what resources are available to enforce them. As an implementer, the community health nurse assesses the capacity of the community to formulate and define strategies that will enhance the community's compliance with the policy. This phase of policy analysis does not focus on the merits or shortcomings of the policy, in contrast to policy formulation, adoption, and evaluation.

### Stage 4: Policy Evaluation

Comparing what a policy does with what it is supposed to do is *evaluation*. Evaluation of a policy should result in continuation of the policy in its original form, revision or modification of the policy, or termination of the policy. Laws and policies are created to express the collective and powerful interests of the political system that generated them (Kovner & Knickman, 2005; Murphy, Canales, Norton, & DeFilippis, 2005). The need for a particular health policy may be temporary, but a policy is difficult to change once it is adopted and implemented. Once a policy system is in operation, vested interests evolve as a result and become political influences. These vested interests, under the guise of jobs, positions, titles, and wealth, are perceptibly jeopardized by any change in the health policy that helped create them. Hence, tradition, in the form of old policies, tends to prevail.

One form of policy evaluation examines the health outcomes that are believed to be attributable to the health policy. Indicators such as mortality and morbidity statistics are used. However, the manner in which the outcomes are defined and measured is highly political and is more subjective than many recognize. For example, mortality statistics are often treated as objective data, yet the way in which the data are collected and the formulas used can often render them subjective. For example, if data regarding driving under the influence of alcohol or drugs are not included in data on deaths from motor vehicle crashes, or if smoking data are left out of data on deaths from lung cancers, policy decisions based on such data may be seriously misdirected.

Perhaps the major premise that should underlie policy evaluation is that the goal of health policy is to design a system wherein health services are equitably distributed and appropriate care is given to the right people at a reasonable cost (National Association of County and City Health Officials, 2002). This premise leads to the following basic criteria for evaluation:

1. Are the health services appropriate and acceptable to the population?
2. Are the health services accessible (physically and financially)?
3. Are the health services comprehensive?
4. Is there continuity of care?
5. Is the quality of the services adequate?
6. Is the efficiency of the services adequate?
7. Is there an ongoing (formative) evaluation of the services?
8. Is there a final (summative) evaluation of the services?
9. Is appropriate action taken based on the findings of the evaluations?

Regardless of the factors that affect policy evaluation, continual comparison is necessary between what a community believes and wants in health care and what it is getting. Nurses have a responsibility to increase community awareness of health issues. They help the community make sure that its health needs are met through productive, desirable health policies. See Display 13.2 for steps in policy analysis and development, and places where influence can be applied.

## DISPLAY 13.2

## STEPS IN POLICY ANALYSIS AND DEVELOPMENT

A number of models can be used to address these issues; the following steps are an amalgamation of models available for policy/advocacy development:

**Policy Analysis.** Looking at public problems and determining the appropriate solution—may consist of the following steps:

1. **Define the problem.** What is the problem and how will you solve it? It should be succinctly worded, so that those not familiar with the issue can understand it. A concept or issue paper may assist in clarifying the ideas and thoughts of the group.
2. **Gather information.** Be sure that information is accurate. Can you identify trends—increase or decrease over time, demographics? There must be agreement on the analysis of the facts and data.
3. **Find alternatives to your approach.** Don't reinvent the wheel. Have other communities solved this problem? How did they address it? Will their approach work in this community? If not, what is necessary to make it workable in your situation? There should be multiple alternatives, but the fewer the better to make it more manageable. There should also be agreement on consequence.
4. **Choose the most appropriate approach.** Which objectives will work, either long- or short-term? What is the cost of your approach and where will you get the funding? Can you determine the consequences of your actions? The approach must be strong and the message clear and understandable.

**Strategy development** will tell you where you are, where you want to go, and how to get there. It is best to determine:

1. **Objective.** Clear and concise goals and objectives as determined by the policy analysis process. Objectives must be measurable.
2. **Audience.** Who is the audience that you must influence? Is this an issue addressed by local authorities—city, (city council) or county (board of supervisors)—or by state (legislature, state agencies) or federal (Congress, federal agencies) authorities? Is this an issue that warrants people's attention?
3. **Message.** Frame the discussion. The message should be accurate and reflect the self-interest of the receiver. Receptivity also depends on whether the people are ready to hear the message. Messages should be tailored to each audience. Get the message out in various ways, e.g., press conferences, letter writing, public presentations, and the like. Timing is critical in getting the message out.
4. **Messenger.** The messenger must be creditable—a member of the community or someone with ties to the community. Messengers can be seen as “experts” or speaking from experience. How does the group assist the messenger?
5. **Resources.** What do you already have, and what do you need to be successful? Build on the resources you currently have and determine what gaps exist.

How can resources be increased if necessary? Are your coalitions reflective of the groups within the community and if not, how can others be brought aboard? Maintain open communication with all involved.

6. **Evaluation.** Is this working? Is your message meeting with success, and how is the audience responding? Review the goals and objectives and change if necessary. Ask what isn't working? Are we getting support on these issues?

**How to Influence Public Policy.** Several arenas exist in which one can influence public policy:

1. **Legislative.** Influence in this arena is done through bills or measures introduced by our representatives but may be the result of issues brought to them by individuals, professional organizations, or state/federal agencies. If these measures can complete the legislative process and be signed by the governor or president, these measures become law. This is a process for the development and passage of the majority of our laws or statutes. The process whereby this occurs is called the *legislative process*, and the public must be involved to ensure that the needs of various communities are met. Laws/policies determine how the society functions, how services and programs are distributed, and who can access them. Public comment and involvement allow for the development of sound public policy, hopefully with few unintended consequences. Each state has a nurse practice act that determines the roles and responsibilities of RNs and how they can legally function. One approach to addressing the nursing shortage was initiated by the National Council of Boards of Nursing–Nurse Licensure Compacts. By changing the laws and regulations of each state it allows nurses licensed and in good standing to practice in another state if both are “compact states.” These nurses have “multi-state licenses.” Currently, more than 20 states have changed their laws to allow nurses to move from one state to another while licensed in only one state.
2. **Judicial.** In the judicial arena, disputes relating to laws and/or regulations are brought before the court for affirmation or invalidation. Scope of practice and licensing laws, many times, are played out judicially. Professional organizations, employers, and unions may be more likely than individuals to use the courts for rulings on licensing, scope of practice, and workplace rules. However, there have been rulings on controversial health and social issues, such as minors' access to abortions and same-sex marriages, as well as findings relating to medical malpractice.
3. **Regulatory.** The regulatory arena involves implementation of existing laws. Codes of Regulations are issued by the agency that has oversight of the laws passed by the legislature. Regulations provide the specificity of the statute; for example, regulations accompanying a state nurse practice act provide the

(continued)

detail of how the act is to be implemented. The process allows for public comment prior to implementation; it is critical for nurses be involved in the regulatory process, as many have a direct effect on individual nursing practice. For example, a California regulation—California Standards of Competence, Title 16, Section 1443.5 (6)—states that nurses must be patient advocates.

4. **Executive Order.** This order can be issued only by presidents or governors. President Bush in August 2006 issued an executive order that instructed administrative agencies to increase the use of health information technology and transparency in measuring the quality of health services as well as the more efficient administration of health programs.
5. **Initiative.** An initiative is also called a *referendum* or *proposition*. It is a local process in which groups can qualify an issue for the ballot by collecting a percentage of names of voters, usually based on the numbers of voters in the last election. This is an example of

direct democracy by voters bypassing our representative process. As an example, in 2006, four states placed tobacco initiatives on the ballot that would increase tobacco taxes to fund health and education programs.

6. **Budgetary.** The budgetary arena involves federal or state plan/legislation for funding services and programs. The federal or state budgets are reflective of what policy makers or those who are influential deem important. Being involved in the budget process is important for the implementation of various policies, as *most* policies require funding to be effective. The state–federal health programs of Medicaid and Medicare are affected by the funding appropriated in the state budgets. The SCHIP is a children’s health program instituted to cover those children who qualify based on certain criteria. This is a state–federal program; the amount of money coming from the federal government is based on the amount of money allocated by the state, this is called a “match.”

## POLITICS AS USUAL

Communities are the places of employment for community health nurses and, as such, any advocacy on your part and/or policy changes will affect those within the communities you serve (Deschaine & Schaffer, 2003). Your role is to be responsive to the needs of the community you serve and its attendant politics. **Politics** is defined as the art or science of government, or governing of a political entity. It can be and is often defined as the art of using influence to bring about change. However, you may already be aware that politics can represent the machinations in which groups or individuals engage to influence, gain power, or get their way. Politics can also be labeled as the relationships between elected officials and their constituents; it can also be seen as the interplay between staff nurses and their head nurse or nursing supervisor. Aroskar, Moldow, and Good (2004) see politics as the practice of public ethics. A clear example of this is the conflict between individual needs and the needs of a community—such as the debate around assisted suicide or the continuing debate regarding universal health care. Within communities, it may be the debate on whether to have and/or where to locate a family planning clinic, or the most appropriate and effective methods to address teen pregnancy issues. As stated by the late Massachusetts congressman and former Speaker of the House, Tip O’Neill, “*All politics is local.*”

Public health practice is inherently political because it involves the different values and worldviews that exist in communities because of their specific ethnicities, languages, and cultures. The primacy of these perspectives influences the community’s needs and what will be done about public policy issues. Be aware that issues change over time; for example, chronic disease management and safety and quality issues take front stage currently, but in the 1970s substance abuse was a high priority and in the 1990s, it was violence prevention. These shifts reflect the

dynamic nature of public health policy and how differing policies attract public attention and funding. The funding issues for public health have also changed over time with private funding (e.g., managed care) now providing much of the care for low-income populations. This funding shift has also encouraged a swing back to the primary mission of public health—assurance, assessment, and policy development (see Chapter 1). It is imperative to understand that policy and politics go hand in hand; neither exists without the other.

## POWER AND EMPOWERMENT

Eliciting services and programs for unserved or underserved populations is a never-ending issue. Citizen participation is never particularly easy in communities that are excluded from political or economic resources. Sherry Arnstein, in her classic 1969 treatise *A Ladder of Citizen Participation*, stated that “citizen participation is citizen power,” and without access to information about how the system functions, these populations cannot obtain the resources they need to make their communities livable and nurturing (p. 217). Arnstein goes on to point out that those in power prevent those in need from accessing the process:

The idea of citizen participation is a little like eating spinach: no one is against it in principle because it is good for you. Participation of the governed in their government is, in theory, the cornerstone of democracy—a revered idea that is vigorously applauded by virtually everyone. The applause is reduced to polite hand claps, however, when this principle is advocated by the have-not Blacks, Mexican Americans, Puerto Ricans, Indians, Eskimos, and Whites. When the have-nots define participation as redistribution of power, the American consensus on the fundamental principle explodes into many shades of outright racial, ethnic, ideological, and political opposition (p. 216).

Although Arnstein writes about the anger disenfranchised populations feel, she does offer possible solutions that allow each party to “share power through partnership,” as outlined by engaging in the process discussed in her treatise (p. 217). **Power** can be defined as the ability to act or produce an effect, possession of control, or authority or influence over others. As public health professionals, nurses have a commitment to social justice and working with disadvantaged communities. This means that nurses have a responsibility to ensure community participation in issues affecting them, and they must continually examine the relationship and position they hold within these communities. The term **empowerment** has been used to explain a process of assisting communities to come together to express their values and ideas to those outside the community (Bernstein, Wallerstein, Braithwaite, et al., 1994; Weis, Schank, & Matheus, 2006). Generally, the issue of empowerment comes up when outside forces are behaving in a way that the community considers detrimental to its well-being. The various definitions of empowerment and the expansion of the definition of health, which now includes the social, political, and economic determinants of health, have changed our thinking on how best to interact with the communities we serve. Theorists have suggested that if power is the ability to control, predict, and participate in one’s environment, then empowerment is the process whereby individuals and communities take power and transform their lives (Robertson & Minkler, 1994; Hooser, 2002) (see Perspectives: Student Voices). This also suggests a change in the relationship between professionals and communities; a change from the customary hierarchical patient–provider relationship to one of a partnership (Robertson & Minkler, 1994; Yoo et al., 2004; Messias, DeJong, & McLoughlin, 2005). However, one must be mindful that professionals hold the power and authority by virtue of their place in the bureaucracy. They have access to information, are better connected politically, and are more cognizant of how to make the system positively respond to the issues they bring forth.

How does one make sure that preconceived ideas about what should be the community’s concerns are not forced on the community in order to meet the goals and objectives of the public health agency? Some may argue that “much of current health promotion practice meets the bottom rung of Arnstein’s ladder by using the rhetoric of community participation but in fact the professionals are setting the agenda for the community” (Labonte, 1990, p. 7). Robertson and Minkler state “that health promotion practitioners facilitate empowerment by assisting individuals and communities in articulating their problems and solutions to address them . . . by providing access to information, supporting indigenous leadership, and by assisting them to overcome bureaucratic hurdles to action, they are truly increasing the communities’ problem-solving abilities” (1994, p. 301). This is a concept also enforced in the Institute of Medicine (2002b) report, *The Future of the Public’s Health in the 21st Century*.

## INFLUENCING POLICY

So, how can community health nurses influence policies that affect the communities they serve? We have discussed how you, as a professional, can empower your communities, based on your knowledge of how to influence others and your ability to encourage those within your communities to join with you in advocating policies that positively impact their lives. Health care policies are usually the result of legislative action at the state and federal levels, and the regulations that are implemented as a result of this legislation provide the specifics of how each law is to be carried out. So, how do we influence policy makers to hear our concerns and act on them?

Seasoned advocates have developed skills in influencing policy decisions; ground rules also exist by which to play the game. Some call them the “ten commandments of lobbying” or the “ten commandments of politics” (Dodd, 1997, p. 417). However these steps are

## PERSPECTIVES STUDENT VOICES

### Advocacy for the Ages

I remember being told in nursing school that we needed to become “politically active” and should be prepared to “legislatively advocate for our clients.” I always thought that it would be up to someone else—someone older, more experienced, more eloquent, and knowledgeable. I didn’t really think they were talking about me. Well, I realize now that *anyone* can be a political advocate! I just read about Bria Brown, a 12-year-old girl from Florida who was diagnosed with osteosarcoma at age 6. She was an inpatient

at Miami Children’s Hospital for a year, and she still has regular visits there. But despite all of this, she and her family have found the time and energy to go to Washington, D.C., and meet with their congressman in order to seek help for children with cancer. What an inspiring story! She told Congressman Meek about 17 of her friends who died of cancer, and the congressman said that she was “one of the best spokespersons” he had ever seen and that he was “committed to this effort” (Meek, 2006, ¶ 2). If a young girl can be a political advocate and can lobby for health issues, I certainly need to rethink my priorities and get to work! After all, I have a wealth of knowledge and experiences I can share to help persuade my legislator to vote for issues and policies that I believe are important.

*Cara, Age 24, Oncology Nurse*

described, advocates adhere to the basic ideas inherent in the following:

1. **Honesty is the best policy.** Being known as someone who has integrity is a lasting virtue. Never mislead a legislator or someone who is likely to support your interests, as it is difficult to regain credibility once you lose it. Speaking beyond your level of expertise gets advocates into trouble. If you don't know the answer, say so; but if you promise to get the answer, then do so. Do not promise what you can't deliver.
2. **Start early.** Planning always takes longer than you think it will. Your interests are not everyone's interests and convincing others they should be involved always involves time. If you are planning policy change at the state or federal level, it is vital to know the legislative process and the critical time lines.
3. **Know what you want.** Be aware of all sides of the issue prior to approaching a policy maker; know the pros and cons, and be prepared to answer questions and provide data on both sides of the issue. Understand the role politics plays in getting what you want and how policy makers may respond to your issue. Targeting your story to the goals, emotions, and interests of the legislator is important and may result in a positive outcome. Be *clear* about what you are asking the legislator for—to carry legislation, or to vote no or yes on specific legislation. Asking your legislator to vote a certain way is perfectly legitimate, and if you don't ask, the opposition will.
4. **KISS (Keep it simple, stupid).** Be able to articulate your issues in a clear and concise manner. Do not confuse possible supporters with complicated arguments. Key issues should be concise and clear and on one page, no more than two. Leave behind an informational packet with pertinent information about the community and/or services and programs.
5. **No permanent enemies, no permanent friends.** Political affiliation doesn't always determine what interests a person has or whether they are likely to support your interests. It behooves you to speak with everyone on your issue; if nothing else, you may find out who they are and why they may oppose your concerns. Remember, in politics, there are only permanent interests.
6. **Know your opponents.** Visit with all possible supporters—just because someone opposed you in the past, doesn't mean they won't support you on a current issue. Respectful disagreement keeps the door open for future agreement and compromise.
7. **Compromise.** Ask for much more than you think you can get. When negotiating, you can give up something without hurting your priorities or your bottom line. In politics, rarely does anyone get all they want, but priority setting is key: What do we expect to accomplish with this activity?
8. **There is strength in numbers.** The more groups involved, the more likely you are to be successful.

Any opportunity for networking is an opportunity to enlarge your coalition. Including disparate groups means you may have accessed conflicting political persuasions. Additionally, having groups who can speak with those who are not seen as "friends" is useful. Cross-fertilization of groups is politically expedient, but understand that next time you or they may be in opposition.

9. **Work at the local level.** Legislators are interested in their constituents—these are the people who elected them to office and who will keep them in office. To be noticed by policy makers, sharing information with them about their constituents is the surest way to capture their attention. Information sharing should occur on issues both in the community where you live and the one where you work.
10. **Thank you.** Everyone loves to be told, "Job well done." To maintain your coalitions, always recognize the work of others. Spreading the credit is like sowing seeds: the wider the spread, the more bountiful the crop.

Finally, it is important for those new to policy development and influencing to understand one major influence on policy—*money*. Nurses must become more actively involved in the process of influencing policy. How many nurses understand that their practice acts, or portions thereof, are developed by legislators or special interest groups who don't have a background in health care? How many nurses know who their legislators are at either the state or federal level? How many nurses have written their legislators about pending health care legislation or legislation that affects nursing (e.g., Nurse Reinvestment Act or the National Nurse Act)? See Display 13.3.

In the 2006 midterm elections, much discussion was held about campaign finance reform because of the Abramoff scandal. Kickbacks, bribery, paying off legislators for their votes, or giving lucrative government contracts to those who gave large campaign contributions captured our attention (*Washington Post*, 2006). This was seen as the lobbying process run amuck. Although this was not a new occurrence, the amounts of money and the numbers of legislators and lobbyists caught in the web were one of the highest in U.S. history. Nonetheless, money is important in assuring that your legislator or candidate can maintain or win a seat—whether at the state or federal level. Campaign financing is important because TV ads, direct mailers, campaign staff (volunteers notwithstanding), and political consultants all require adequate funding. Anyone running for a political position knows that, in order to compete, money is required; those with the most financing can get their message out and encourage potential voters to elect them. Although spending the most money doesn't always guarantee success, without sufficient financing, you can be assured your message will *not* be heard. As stated by Jesse Unruh, the Speaker of the California Assembly in the 1960s, "*Money is the mother's milk of politics.*"

## Political Action Committees

One reason why nurses are less politically active can be tied to a lack of money. Nurses don't earn as much money or appear

## DISPLAY 13.3

## HOW TO HELP YOUR LEGISLATOR KNOW THE COMMUNITY

1. **Know who your legislators are—local, state, and federal:**
  - Include their contact information on your e-mail and regular mailing lists.
  - Develop a relationship with them or their staff.
2. **Assign a constituent to the legislator:**
  - Keep all critical information on legislators up to date.
  - What are the key committees they sit on?
3. **Keep legislators and staff informed:**
  - Keep them aware of any actions occurring in the community.
  - Share any printed materials.
  - Provide them with updated, current promotional information.
  - Send copies of news articles, radio interviews, alerts.
4. **When passing out awards, think of your legislators:**
  - If you have a website, blog, podcasts, etc., send URL.
  - Invite legislators to your facility or community tour for “show and tell.”
4. **When passing out awards, think of your legislators:**
  - Recognize any actions by legislators that benefit the community in which you serve.
  - Invite legislators to award ceremonies and/or community events.
5. **Communicate with your policy maker:**
  - Write your policy maker about issues important to the communities in which you serve or issues important to your profession.
  - Provide real stories or examples of the issue.
  - Use personal letters; postcards, phone calls, form letters, and e-mail are not always the most effective way to deliver your message.

not to have access to as much money as other health care interests (e.g., hospitals, physicians, insurance companies, and health care plans), and as such there is much less money for nursing organizations to use for lobbyists or to assist chosen candidates. The ANA has a **political action committee** (PAC) that supports federal candidates on a nonpartisan basis; candidates must demonstrate an interest in and willingness to vote for nursing issues or issues that nurses support (Dodd, 1997). To participate in the PAC, you must be a member of ANA (this also allows your family to contribute to the PAC). By giving to the ANA-PAC, one maximizes the contribution by joining with other nurses—this power in numbers increases our influence with those candidates we choose to endorse. However, giving to your personal legislator can keep you on their mailing list, and it may get you invited to local legislative activities. It also

lets your legislator know you are interested in whether she remains in office. Being in regular contact with your legislators provides an avenue for introducing legislation that impacts nursing or other health-related issues, and when you call to ask for a vote “for” or “against” an issue, the legislator is more likely to entertain your request. Aren’t you more likely to respond to someone you know, rather than someone who comes to you out of the blue to ask for a favor?

## Volunteering

Money is *not* the only way to build a relationship with your legislator. Volunteering your time can be just as important (see Perspectives: Voices from the Community). Candidates for office need bodies to get things done (e.g., phone

## PERSPECTIVES VOICES FROM THE COMMUNITY

### Volunteer Service for the Long Term

An RN who had been through what I called the women’s legislative career ladder—School Board, City Council, County Board of Supervisors—was now posed to run for the state legislature. Because we had had numerous contacts and I believed she would make a good state legislator and a voice for nursing and health care, I volunteered to work in her campaign office. I primarily answered the phones on the evenings I worked, but I met the office staff—many of whom were much younger than I. And, even once, she came in while I was

there. I talked with the staff about some of my experiences as a lobbyist, and they shared their experiences; many of them were fresh out of college.

She was successful in her run for office, and whenever I needed to meet with her or her staff, I was shown right in. I was also asked my opinion about the hiring of certain staff. Her staff knew me by name—many of them did not work on her campaign, but they were told about me by those campaign staff who were still around. After 3 years in office, she was appointed chairperson of a key committee, and I maintained access to her committee consultants and to her when necessary. We were able to work together quite successfully and, although we didn’t always agree on every policy issue, I think the weeks I put in volunteering 3 years earlier really paid off for the clients and the issues I was representing.

*L.B., Professional Lobbyist*

banking, stuffing mailers, answering phones, putting up flyers and campaign posters, walking door to door to spread the message, and assisting in the development of issue papers). Candidates develop issue papers to tell their constituents where they stand on key campaign concerns. Nurses have the expertise to assist legislators in developing an agenda on health care policy, or at the least to review and comment on issue papers.

*Relationships* are key in policy development. As demonstrated earlier, being a friend can reap huge benefits when health care policy is on the line. Being involved in local and state elections can take many forms. Voting, for instance, is vital—RNs represent one in 45 potential voters (Waldron, 2003). Joining your local and state professional organizations is vital to having the voice of nursing heard at all levels. You can become more actively involved by writing legislators about the health care issues that impact the communities, both where you live and work. It is also vital to understand the importance of critically timing those communications. Effective communications with legislators should be tied to times when the issues are being heard in policy committee—thus, you must know when your issue is scheduled to be discussed in committee. For example, it is prudent to send letters on your issue—via fax or regular mail—close to the time of the committee hearing. Holding a press conference or getting other media coverage when the bill is introduced, or on the day it will be heard in committee, is quite effective in drawing attention to your issue. Writing letters to the editor of your local newspaper on health issues, as well as writing articles for various publications, are also effective methods of persuading others to back your issue. Other methods for influencing health policy or nursing issues include applying for positions on boards and commissions; each local area has advisory committees for their locally elected officials at the city and county level. The state board of registered nurses needs nurses willing to sit on their board or to serve on various advisory committees and task forces. At your state capitols, there are usually vacancies on policy committees, or legislators may be looking for new staff—either personal or policy. And, who better to serve in this capacity than a nurse! Who else has more knowledge about health issues than nurses? When all else fails, *run for office*.

## A Call to Action

The need for health care reform has become critical as the costs of health care continue to rise. The United States spends a disproportionate percentage of the national budget on health care, yet major segments of the population still do not have adequate access to quality health services. Because of these economic concerns, health care reform and policy making have become politically charged issues involving many groups and factions, including not only health care providers and health care professionals but also government, third-party payers, insurance companies, and others with vested interests.

Many people are just beginning to realize that health care is a business. It has always been a business—we are just more aware of it now because of the scarcity of resources. Many believe that business interests and efforts to curb rising costs may divert public services away from community

health issues, such as preventive and primary care. Because community health nurses know community needs and the value of such services, they need to be a major force in the political arenas where health policy decisions are being made. Community health nurses need to become politically aware and active to ensure quality health services by working as community health advocates. They must collaborate with community constituents and with nurses and other professionals to ensure the safety and well-being of groups and populations at risk.

Health care is the talk of the nation, and nurses must be involved in the process of setting policy for themselves and their communities. Although nursing's influence has been limited in the recent past, we must learn how to empower our own profession, ourselves, and the communities with whom we work by becoming politically active and aware. If we are to fulfill our mission of promoting, protecting, and preserving the health of aggregates, we must become policy makers as well as policy implementers. We must learn to use policy systems and the political process, so that our voice is heard and we have influence in policy decision making. We must learn to formulate, implement, and evaluate health policies. We must understand the legislative process and how to influence that process. The politically involved nurse should aim to accomplish three primary goals: (1) generate support for one's views by communicating ideas effectively and getting to know and influence representatives at local, state, and national levels; (2) create professional legitimacy by keeping abreast of current issues in health care and nursing and becoming involved in professional nursing organizations, community boards or committees, or political office at the local, state, or national level; and (3) resolve conflict and effectively negotiate and compromise.

We have a rich history of advocacy, of using data and statistics to influence public policy, of speaking out about the injustices in our society and providing leadership in the development of services and programs that uplift and enrich the lives of the least among us. The inequities in our system, both socially and politically, add to the existing health disparities (National Association of County and City Health Officials, 2002).

Chapters 5 and 10 highlighted the need for cultural and linguistic competency, and it is clear that our institutions of higher learning must become more actively involved in developing and implementing curricula that educates and trains our health care providers with an understanding of, appreciation for, respect for, and competency in dealing with diverse cultures and languages. These programs must also challenge our individual values relating to other cultures and their worldviews. After all, these are the populations with whom you will work, and they will look to you for advice and leadership.

We also must do a better job of encouraging people of color to enter and complete courses of study in the health professions, for it is only when we have a critical mass of diverse providers and educators that we can hope to alleviate some of the health inequities that challenge us today. *It is not enough to be clinically competent; one must be culturally competent.*

Nurses, despite their numbers and past history of public health nursing advocacy, have not really challenged the society in which they function. This duality has also hindered

nurses' development as policy developers and advocates. Because of pressing health care concerns and the nursing shortage, we have begun to realize and encourage our profession to become politically aware and active. We are still gaining knowledge and experience in empowering the communities we serve by working with them to identify their strengths, examining the system rather than blaming the individual, and engaging with them in the development and implementation of preventive and health promotional behaviors that allow communities to grow and to become independent and self-reliant. When we “work with” communities, and do not “direct” them, we achieve personal growth as well.

Finally, community health nursing is a proud discipline with a rich foundation of helping the less fortunate and addressing issues that impact poorer communities. We are continually working toward empowering ourselves, our profession, and the larger communities that often suffer because of societal inequities. Community health nurses must honor this mandate to become policy advocates, to influence policy, and to learn how the policy process works, so that their voices and the voices of their communities are heard.

## Summary

This chapter has reviewed the political processes inherent in the development of health policies and the community health nurse's policy and advocacy roles within those processes. The foundations of political action and advocacy stem from a rich history of public health nurses, like Lillian Wald, who strived to provide a voice for vulnerable and disenfranchised populations. Social justice remains a pillar of our current practice.

Advocacy for our clients is always important, but professional advocacy through affiliation and activity in our professional nursing organizations, is also vital so that we, as PHNs, may have a “collective voice.” This chapter highlighted examples of nurses who have recently served or are still serving as elected officials—many of whom came to power through grassroots efforts. Politics may be uncomfortable and foreign to many of us, yet it provides the methods for needed change through lobbying or influencing legislators. Nurses and special interests groups can gain access to legislators individually or through the services of a professional lobbyist or PACs.

Policies are actions or agendas that can be used to implement important goals and objectives, such as the health objectives found in *Healthy People 2010*. Distributive, redistributive, and regulatory health policies were defined and discussed, along with the processes that can be used by PHNs to impact policy formulation, adoption, implementation, and evaluation. Tips on how to influence policy makers were outlined, and nurses may consider volunteering time to a candidate of their choice as a means of gaining greater access to the political process.

Community and public health nursing are, by nature, political because we deal with many issues that affect the health and well-being of diverse populations. Power and empowerment are important concepts to both public health nursing and politics, and the skills of political action and advocacy should be honed by every community health nurse. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Investigate a major health policy system in your community or state; discover how it works, and determine whether community health nurses are represented in this system. Areas to investigate include the boundaries of the system, the authority by which the system generates health policy, how the system receives input (formally and informally), resources the policy system uses and allocates to others, and the system's output over the past few years.
2. Describe a legislative bill related to community health at either the state or federal level and the issues involved in it. Identify who is sponsoring the bill, who is opposing it, and why. Determine who will be affected by the bill if it passes and in what ways they will be affected. Discuss what you, as a community health nurse, could do to be involved in this bill, and then develop a political action plan to support or oppose the bill. Write a letter to your legislator regarding your position.
3. Carefully review your own health care plan and determine whether you believe it is an adequate and equitable plan. Describe the plan and the issues involved in it. Include what health services are covered and who is authorized to provide services and receive direct reimbursement. Also determine who qualifies for the plan, who is excluded, and what conditions can disqualify a person or a family once they have been covered by the plan. Compare the cost of this plan to one proposed by a political candidate.
4. Attend a meeting of a professional organization, board of directors, government agency, or council when a health policy or health care issue is on the agenda. Analyze the positions of the major interest groups involved and describe to what extent economics comes into the discussion. Describe who controls the discussion and how this is done.
5. Interview a health care administrator in your local area and determine this person's position on health care reform and the rationale for his position. Determine at what levels this administrator is politically active and involved in influencing policy.
6. Several websites for government agencies and organizations are shared in this chapter. Contact two or three of them. What resources can you get from these sites? How can you use the political advocacy information as a community health nurse? Did these sites lead you to other sites? If they did, contact these additional sites and write down the additional website addresses in the margin of the chapter for future reference.
7. What issues or events occurred in the United States that lessened the willingness of nurses to speak out about health care issues? Examine the years starting with the 1930s. What events or issues changed, if

any, to reinvigorate nurses serving as political activists?

8. Are nurses the most qualified group to articulate national health care issues? If so, why? If not, why not?
9. Do you consider it an ethical or human rights issue to provide appropriate and accurate health information? If yes, why? If not, why not?
10. Who are your state legislators? What are the critical health issues in your state, and how have your legislators responded to the issues? If there has been health care-related legislation introduced:
  - What is the issue?
  - What party introduced the bill?
  - Where is the bill in the legislative process?
  - What groups support or oppose the legislation?
  - What is the reasoning for the groups' support or opposition?
11. How active is your state professional nursing organization in policy issues?
 

Are you a member of the organization? If not, why not?

What are the public policy issues the organization is involved in?

How successful have they been?

Does the group have a paid lobbyist or does it rely on volunteer lobbyists?

# THE COMMUNITY AS CLIENT

# 14

## Theoretical Basis of Community Health Nursing

### LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Discuss two essential characteristics of nursing service when a community is the client: community-oriented, population-focused care, and relationship-based care.
- ◆ Describe the contributions of at least five models of nursing practice to community health nursing practice.
- ◆ Explain the benefits of applying the eight principles of public health nursing to community health nursing.
- ◆ Identify at least five social issues that influence contemporary community health nursing care.

*“We know a great deal more about the causes of physical disease than we do about the causes of physical health.”*

—M. Scott Peck, *The Road Less Traveled*

Theory

 **When** you open the door of a senior center where you will be promoting cardiovascular fitness, advocating for exercise equipment, and suggesting changes in the on-site meal program, how might theories of community health nursing contribute to your success? When you approach your city council about the need to increase staffing of public health services, what models of community health nursing practice might support your argument? What is meant by *theories*, *models*, and *principles*, and what is their relevance to day-to-day community health nursing practice? These are the key issues explored in this chapter. First, however, we revisit some of the fundamental characteristics of community health nursing that we began to explore in Unit 1.

## WHEN THE CLIENT IS A COMMUNITY: CHARACTERISTICS OF COMMUNITY HEALTH NURSING PRACTICE

Nursing exists to address people's health care needs, and nurses fulfill this purpose through their work in various specialty areas. Specialties are characterized by the unit of care for which the specialty is responsible and by the goal of the specialty. Each specialty requires a particular area of knowledge and a set of skills for excellence in practice.

Community health nursing is a specialty in which the unit of care is a specific community or aggregate, and the nurse has responsibility to promote group health. The goal of this specialty is health improvement of the community. The skills required for excellence in community health nursing practice include epidemiology, research, teaching, community organizing, and interpersonal relational care, as well as many others.

In summary, community health nursing is characterized by community-oriented, population-focused care and is based on interpersonal relationships. In the following sections, each of these characteristics is examined in more depth.

### Community-Oriented, Population-Focused Care

As was discussed in Chapter 1, a *community* is a group of people who have some characteristics in common, are bounded by time, interact with one another, and feel a connection to one another. For example, members of an Internet-based support group for people with colitis are a community. They share similar experiences and concerns, and they often influence one another's behavior. For instance, they may recommend food choices or complementary therapies to one another. Members of a class of community health nursing students are also a community. Because they begin and end their studies in a particular month and year, they are bonded by time, and they certainly share certain values and feel a sense of connection to one another.

*Community orientation* is a process that is actively shaped by the unique experiences, knowledge, concerns, values, beliefs, and culture of a given community. For example, when an outbreak of hepatitis occurs, the community health nurse does more than simply treat infection in individuals. The nurse also

- ◆ Uses disease-investigation skills to locate possible sources of infection.

- ◆ Determines how the community's knowledge, values, beliefs, and prior experiences with infectious disease may influence its interpretation of the disease, response to the outbreak, and treatment preferences.
- ◆ Uses knowledge and suggestions gathered from the community to develop, in collaboration with other health professionals, a community-specific program to prevent future outbreaks.

A community-oriented nurse who provides education about sexually transmitted diseases to a group of students at a Catholic college includes consideration of community values regarding sexual behavior. Similarly, a community-oriented nurse who provides nutritional counseling to a community of Hispanic seniors considers the meaning of food in this culture, the types of food most commonly consumed, and the cooking methods most commonly used.

A *population* is any group of people who share at least one characteristic, such as age, gender, race, a particular risk factor, or disease. Smokers and breast cancer survivors are two populations. The concept of population may also include delineation by time (e.g., all children born in the year 2008). The nurse's place of employment commonly limits the population that the nurse serves. For example, a nurse who works for a county health department is limited professionally to caring for the population of that county.

A *population focus* implies that a nurse uses population-based skills such as epidemiology, research in community assessment, and community organizing as the basis for interventions. For example, a population-focused nurse employed by an autoworkers' union may study all cases of repetitive-use injury occurring in the auto industry in the United States in the past 5 years, develop a program for reducing repetitive-use injury, and lobby industry executives for adoption of the program.

**Community-oriented, population-focused care** employs population-based skills and is shaped by the characteristics and needs of a given community. Community health nurses provide community-oriented, population-focused care when they count and interview homeless people sleeping in a park and, based on these data, help develop a program to provide food, clothing, shelter, health care, and job training for this population.

### Relationship-Based Care

**Relationship-based care** incorporates the value of establishing and maintaining a reciprocal, caring relationship with the community. It is a necessary and feasible aspect of community health nursing practice and is foundational to caring effectively for the community's health. A reciprocal, caring relationship with the community involves listening, participatory dialogue, and critical reflection, and it may also involve sociopolitical elements of practice such as advocacy, community empowerment, and movement to action (Shields & Lindsey, 1998).

Community health nurses provide relationship-based care when they meet regularly with groups of female inmates to learn about their physical and psychosocial health care needs and the needs of their families, and then use the information gathered to advocate for this population with prison

officials and other professionals in the community. A nurse also provides relationship-based care when working with parents of children with cancer, a psychologist, and a hospital chaplain to determine the needs of each family and to facilitate formation of a self-help group. In both these examples, community health nurses are working to establish and maintain ongoing relationships with other professionals in the community and with their communities of clients.

## THEORIES AND MODELS FOR COMMUNITY HEALTH NURSING PRACTICE

A **theory** is a set of systematically interrelated concepts or hypotheses that seek to explain or predict phenomena. For example, the “big bang theory” seeks to explain the series of events that occurred during the earliest moments in the history of our universe. The evolution of theory development in nursing dominated the last half of the 20th century. The scholarly and creative efforts of these nurse leaders and researchers resulted in broad and often abstract theories explaining what nursing is and how it influences individuals, families, or communities. These early theories, also termed *grand theories* or **conceptual models** (Walker & Avant, 2005), provided a basis for building nursing knowledge. One feature separating **nursing theory** from other professional theories is the use of the nursing metaparadigm concepts: nursing, client/patient, health, and environment (Fawcett, 1989; Walker & Avant, 2005). As you read through the descriptions of the theories and models, see if you can determine which ones conform to the nursing metaparadigm and which ones can be used by nurses as well as other health care professionals.

From these early efforts came more testable theories, many from those same nurse researchers; these theories are typically referred to as middle-range theories. Although less abstract than the grand theories, the need for an even more practical approach to theory use and testing led ultimately to practice-based theories. Walker and Avant note that “the essence of practice theory was a desired goal and prescriptions for action to achieve the goal” (p. 14), clearly emphasizing the goal directiveness of nursing practice. Most significantly, the focus on practice has opened up new opportunities for generalist nurses to both understand and use nursing theories.

To more fully understand the elements inherent in a nursing theory, a pictorial representation, or **model**, is often used. These models provide a visual means to understand the relationships between, for instance, the nurse and the environment, the nurse and the client, or the stress factors experienced by the client. However complex these models, comprehension of the entire work can only be derived from reading the theorist’s descriptions of the model and the use of the theory by others. Both theories and models have been developed to describe, clarify, and guide nursing practice. Theories and models that have particular relevance to the practice of community health nursing are described here.

### Nightingale’s Theory of Environment

Florence Nightingale’s environmental theory has great significance to nursing in general and to community health nursing specifically, because it focuses on preventive care for populations. While organizing and supervising a nursing service for soldiers in the Crimean War, Nightingale kept

meticulous records. Her observations suggested that disease was more prevalent in poor environments, and that health could be promoted by providing adequate ventilation, pure water, quiet, warmth, light, and cleanliness. The crux of her theory was that poor environmental conditions are bad for health and that good environmental conditions reduce disease (Nightingale, 1859/1992).

There is no consensus of opinion on specific conditions that ensure people’s health. Some people believe that, in addition to a clean environment, social services such as public transportation, education, and health care are necessary. In thinking about services that promote the health of communities, it is useful to consider

- ◆ Why these services were created.
- ◆ Who benefits from the services.
- ◆ Who pays for the services.
- ◆ The cost to the people using the services.
- ◆ The public’s perception of the services.

For example, if ventilation in a city’s homeless shelter is inadequate, the community health nurse who plans to advocate for capital improvements to the shelter needs to consider who pays for the shelter as well as the public’s perception of the shelter.

One contemporary example of the utility of Nightingale’s theory is the work of Shaner-McRae, McRae, and Jas (2007), who sought to bring attention to the need for nurses to optimize environments for healing. Although they specifically focused on the health care setting, describing ways to manage both “upstream and downstream waste (solid, biohazard, and hazardous chemical wastes)” (p. 1), their premise can be easily applied to the home, community, or even the public health department. Controlling environmental contaminants and protecting the environment are important goals in a wide variety of settings. Nightingale’s influence on the way we approach health issues impacting our communities remains a powerful force.

### Orem’s Self-Care Model

Dorothy Orem, a nurse administrator and educator, focused on the concept of *self-care*—learned, goal-oriented actions to preserve and promote life, health, and well-being. She described people who need nursing care as those who lack ability in self-care (Orem, 2001). If a demand for self-care exceeds the client’s ability, the client experiences a self-care deficit, and nursing intervention becomes appropriate. The goal of nursing action is to help people recognize their self-care demands and limitations and increase their self-care ability. Nursing care also functions to meet clients’ self-care needs until they are able to care for themselves.

Orem further described three types of requirements that influence people’s self-care abilities:

- ◆ Universal requirements, common to all human beings, are self-care activities essential to meet physiologic and psychosocial needs.
- ◆ Developmental requirements are activities necessary to help people progress developmentally.
- ◆ Health-deviation requirements are activities needed to help people deal with a diminished level of wellness.

Although Orem’s model focused primarily on individuals, it can be applied to community health nursing. Populations and communities can be considered to have a collective set of self-care actions and requirements that affect the well-being of the total group. If an aggregate’s demands for self-care exceed its ability, the aggregate experiences a self-care deficit, and community health nursing intervention is indicated. According to this interpretation, the goal of community health nursing is to promote a community’s collective independence and self-care ability.

For example, a riverside community that ingests large quantities of fish contaminated with heavy metals might have self-care deficits related to the lack of awareness that eating local fish is dangerous and that some subpopulations, such as pregnant women and young children, are especially vulnerable. The community health nurse should help the community become aware of the risk and identify other food sources. The nurse should also help the community lobby government and industry to reduce pollution and clean up the river.

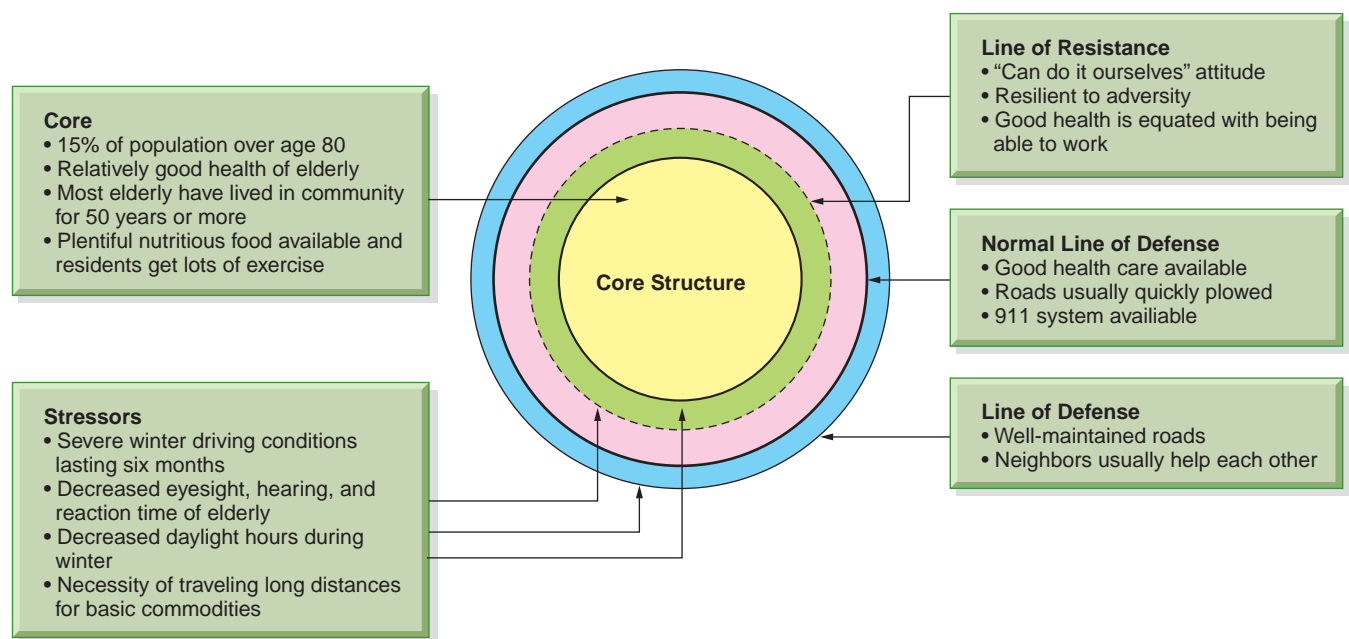

Three specific theories have been derived from the original model: the self-care deficit theory, the theory of self-care, and the theory of nursing system (Gast & Montgomery, 2005). The applicability of the self-care deficit theory to public health nursing was demonstrated in a study of adherence to latent tuberculosis therapy among Latino immigrants (Ailinger, Moore, Nguyen, & Lasus, 2006), and in a pilot study of mother’s knowledge of childhood immunizations (Wilson, Baker, Nordstrom, & Legwand, 2008). The theory of self-care was utilized to identify self-care behaviors of school-aged children with heart disease (Fan, 2008). Clearly the model and the derived theories have shown applicability to public health practice directed at improving health outcomes in the community setting.

### Neuman’s Health Care Systems Model

Betty Neuman, a leader in mental health nursing and nursing education, proposed a systems model (Neuman, 1982; Neuman & Fawcett, 2002) that can be adapted to view clients as aggregates. In this model, people are seen as open systems that constantly and reciprocally interact with their environments. Each system is greater than the sum of its parts, and wellness exists when the parts of the system interact in harmony with each other and with the system’s environment. Four sets of variables, or influences, make up each system’s “whole.” These are physiologic, psychological, sociocultural, and developmental variables. Given these variables, each system has a unique response to stressors and to those tension-producing stimuli that may cause disequilibrium or illness.

A system’s response to stressors may be envisioned as a series of concentric circles (Fig. 14.1). In the center is a core of basic survival abilities, such as a community’s ability to make the best use of its natural resources. Surrounding this core are three boundaries. The innermost boundary is a flexible line of resistance that encompasses internal defenses, such as a community’s collective sense of responsibility for raising healthy children. The second boundary is the system’s normal line of defense, such as a community’s police force or voluntary fire brigade. The third boundary is a dynamic, flexible line of defense, a buffer that prevents stressors from invading the system’s normal line of defense. An example is regular maintenance of a community’s roads and bridges.

In Neuman’s model, stressors can originate from the internal environment or the external environment. Examples of internal stressors include a high proportion of low-income residents or an inadequate system of water purification.

**FIGURE 14.1** Neuman’s health care systems model applied to a rural county regarding traffic safety issues concerning the elderly by D. Block, from Allender, J., & Spradley, B. (2001). *Community health nursing: Concepts and Practice* (5th ed.). Philadelphia: Lippincott, with permission.

External stressors might include natural disasters, war, or a downturn in the global economy. The role of community health nursing, then, is to assist communities in remaining stable within their environments. The applicability of the Neuman model to community health nursing was clearly demonstrated in a comprehensive literature review of published studies between 1983 and 2005 (Skalski, DiGerolamo, & Gigliotti, 2006). This review yielded 13 studies dealing with stressors in client populations; the vast majority were pertinent to community health nursing practice (i.e., spousal alcoholism, long-term cancer survivors, informal caregivers of head-injured adults, and telephone counseling).

### Rogers' Model of the Science of Unitary Beings

Not typically linked with community health nursing practice, Martha Rogers (1915–1994) established the first visiting nursing service in Arizona in the mid 1940s; it was one of the first in the nation (Tomasson, 1994). A nursing administrator and long-time nurse educator, Rogers is responsible for modern nursing's emphasis on the whole person (Hemphill & Muth Quillin, 2005). In 1970, she developed a nursing conceptual model based on systems theory. Her model emphasized that the whole is greater than the sum of its parts; that is, focusing on the parts of a community, such as its health care or housing, does not provide an adequate picture of its totality.

Rogers also incorporated developmental theory into her model by describing the development of “unitary” persons or systems according to three principles: (1) life proceeds in one direction along a rhythmic spiral, (2) energy fields follow a certain wave pattern and organization, and (3) human and environmental energy fields interact simultaneously and mutually, leading to completeness and unity (Rogers, 1990). Using this model, the community health nurse can focus on community–environment interaction; the community functions interdependently with others and with the environment. The goal of community health nursing is to promote holistic and healthful community–environment interaction.

Even after her death, Rogers continues to garner a strong following. Talley, Rushing, and Gee (2005) utilized Rogers' model as a framework in the creation a profile of a small rural community in a southern state. This profile was used to exemplify the link between the model and community assessment, providing a comprehensive and thoughtful view of community needs and a clear basis for nursing interventions.

### King

Imogene King (1923–2007), nursing scholar and educator, was one of the early nurse theorists to provide a conceptual model of nursing (Messmer & Palmer, 2008). Her groundbreaking work *Toward a Theory for Nursing* (1970) and the subsequent *A Theory for Nursing: Systems, Concepts, Process* (1981) were designed to “promote conceptual learning in undergraduate and graduate nursing programs” (1981, p. vii). From the original general systems model, which demonstrated the interrelationship between social, interpersonal, and personal systems (Killeen & King, 2007), King formulated the *theory of goal attainment*. The theory focuses on the personal and interpersonal systems of the

model. The basis of the theory is that, in any nurse–client encounter, each comes to the situation with her own goals and expectations. Optimal success at goal achievement is only possible when the nurse and the client work together to set goals, thus recognizing the expectations of both parties rather than the preeminence of one over the other. For instance, a community health nurse may have planned to speak to a teen mother about birth control on a home visit. The teen, however has nearly run out of formula and has exhausted all her cash. In this instance, the teen's priorities are to locate formula or the resources to obtain formula, while the nurse may be concerned that the teen has resumed sexual activity and may become pregnant again. The priority would clearly be the formula, but the nurse can also provide birth control information within that context after the teen is aware that a solution to the formula issue can be found. King's theory is a reminder of the importance of the reciprocal relationship between the nurse and the client. Negotiation is a skill inherent in the theory; only through recognition of the perceived needs and goals of the client can the community health nurse help maintain or improve the client's health and well-being. The principles of public health nursing discussed later in this chapter (ANA, 2007) also emphasize the need to treat the client as an equal partner—a strong reminder of King's legacy to nursing practice.

### Parse's Human Becoming Theory

Rosemarie Rizzo Parse developed her theory, initially called the “man-living-health” theory, in 1981. In 1992, she changed the name to “Human Becoming Theory” to better reflect all people. The theory posits quality of life from each person's own perspective as the goal of nursing practice. The theory is structured around three themes (Parse, 1981, 1998):

*Meaning.* People coparticipate in creating what is real for them through self-expression by living their values in their own chosen way.

*Rhythmicity.* The unity of life encompasses apparent opposites in rhythmic patterns of relating. While living moment-to-moment, one shows and does not show the self, creating both opportunities and limitations that emerge as moving with and moving apart from others.

*Transcendence.* Moving beyond the moment and forging a unique personal path for oneself in the midst of ambiguity and continuous change.

These three themes apply effectively to the community. The nurse must know what the community means to its inhabitants, identify and be aware of the rhythmicity of the people as attempts are made to create positive health changes in the community, and realize the transcendence that occurs when people work in the presence of ambiguity and continuous change, characteristics inherent in a community. Use of this model as a guide enhances the ability of community members to work together to accomplish identified goals.

### Pender's Health Promotion Model

As we have noted throughout this text, health promotion is a priority in community health nursing practice. Pender defined health promotion as actions that are directed toward

increasing the level of well-being and self-actualization in individuals or groups (Pender, Murdaugh, & Parsons, 2006). It is a proactive set of behaviors in which people act on their environment rather than react to stressors arising from the environment.

Pender's *health promotion model* seeks to explain this proactive behavior. The model, based on social learning theory, stresses cognitive processes that help regulate behavior such as perceptions people have that directly influence their motivation to begin or continue health-promoting behaviors. These include, for example, perceptions of control of health, health status, benefits of health-promoting behaviors, and barriers to engaging in health-promoting behaviors.

Five types of modifying factors influence people's perceptions about pursuing health-promoting behaviors:

- ◆ Demographic factors, such as age and race
- ◆ Biologic characteristics, such as height and weight
- ◆ Interpersonal influences, such as the expectations of others
- ◆ Situational factors, such as availability of healthful foods
- ◆ Behavioral factors, such as stress-coping patterns

Using Pender's model, a community health nurse might interview the residents of a low-income housing project to determine their perceptions about improving health and safety. Research of demographic, situational, and other factors that might influence the residents' motivation and ability to change their circumstances could then be conducted. Pender's model is being increasingly used as a framework in studies of health promotion in diverse populations: preventing farm accidents in children (Conway, McClune, & Nosel, 2007), self-efficacy and health-promoting behaviors in older adults in Iran (Morowatisharifabad, Ghofranipour, Heidarnia, Ruchi, & Ehrampoush, 2006), adolescent health-promoting behavior (Srof & Velsor-Friedrich, 2006), and health-promoting behaviors of low-income elderly Korean women (Shin, Kang, Park, Cho, & Heitkemper, 2008). Pender's model is further discussed in relation to client education in Chapter 11.

### Roy's Adaptation Model

Sister Callista Roy's model describes people as open and adaptive systems that experience stimuli, develop coping mechanisms, and produce responses. These responses, which may be adaptive or maladaptive, provide feedback that influences the amount and type of stimuli that can be handled in the future (Andrews & Roy, 1991; Roy & Andrews, 1999).

Roy describes two response processes. In the *regulator* process, stimuli from the internal and external environments are received, and this combination of information is then processed to produce a response. In the *cognator* process, perceptions, learning, judgment, and emotion are considered in formulating a response to stimuli. For example, a regulator process might begin with a community's desire to keep adolescents from smoking (internal stimulus) and new state regulations prohibiting the sale of tobacco products to minors (external stimulus). These combined stimuli lead to a city ordinance that prevents the sale of cigarettes to minors

(coping mechanism), resulting in reduced levels of smoking (response) among this population. A cognator process might begin with the stimulus of heavy rainfall in a riverside community. Residents' perceptions of the amount of rainfall, memories of past floods, insights about preventing or managing floods, and the level of anxiety all contribute to their plans for evacuation, sandbagging, and soliciting county or state assistance.

In applying Roy's model to community health nursing, it is important to remember that communities are made up of many parts and are influenced by many variables. The community's collective adaptation level is constantly changing. The community health nurse must assess a community's coping mechanisms and help its members use these collective abilities in adapting to challenges. For example, if a community is doing nothing to respond to the increased number of teen pregnancies, nursing actions can be designed to encourage more healthful coping patterns and adaptive responses. Roy's model has been utilized in a number of studies with direct applicability to community health: bulimia nervosa (Hannon-Engel, 2008), self-concept of children with HIV/AIDS in the United States and Kenya (Waweru, Reynolds, & Buckner, 2008), and as the basis for developing a new conceptual framework explaining the coping processes of Taiwanese families following the hip fracture of an elderly family member (Li & Shyu, 2007).

### Salmon's Construct for Public Health Nursing

Marla Salmon, a leader in public health nursing administration, nursing education, and public health policy in the United States, proposed a model to guide community health nursing practice. In *Construct for Public Health Nursing*, Salmon (1982) described public health as an organized societal effort to protect, promote, and restore the health of people, and public health nursing as focused on achieving and maintaining public health.

The model describes three practice priorities. Not surprisingly, these are prevention of disease and poor health, protection against disease and external agents, and promotion of health. There are three general categories of nursing intervention:

- ◆ Education directed toward voluntary change in the attitudes and behavior of the subjects
- ◆ Engineering directed at managing risk-related variables
- ◆ Enforcement directed at mandatory regulation to achieve better health

The scope of practice spans individual, family, community, and global care. Interventions target determinants in four categories: human/biologic, environmental, medical/technologic/organizational, and social. Using Salmon's approach, a community health nurse attempting to reduce the transmission of tuberculosis would use education, engineering, and enforcement in working with the population of affected individuals and families. The nurse would also collaborate with the client community on a variety of interventions, from medications to teaching to social support, to prevent further disease in the community and to promote global health.

A decade later, Salmon’s editorial entitled *Public Health Nursing: The Opportunity of a Century* again stressed the importance of the central functions of public health nursing practice: “assessment, surveillance, policy, and health promotion and disease and injury prevention activities” (1993, p. 1674). In the revised *Public Health Nursing: Scope and Standards of Practice* (ANA, 2007) the Salmon model is cited as an exemplar of an ecological approach to public health nursing interventions.

### Minnesota Wheel—The Public Health Interventions Model

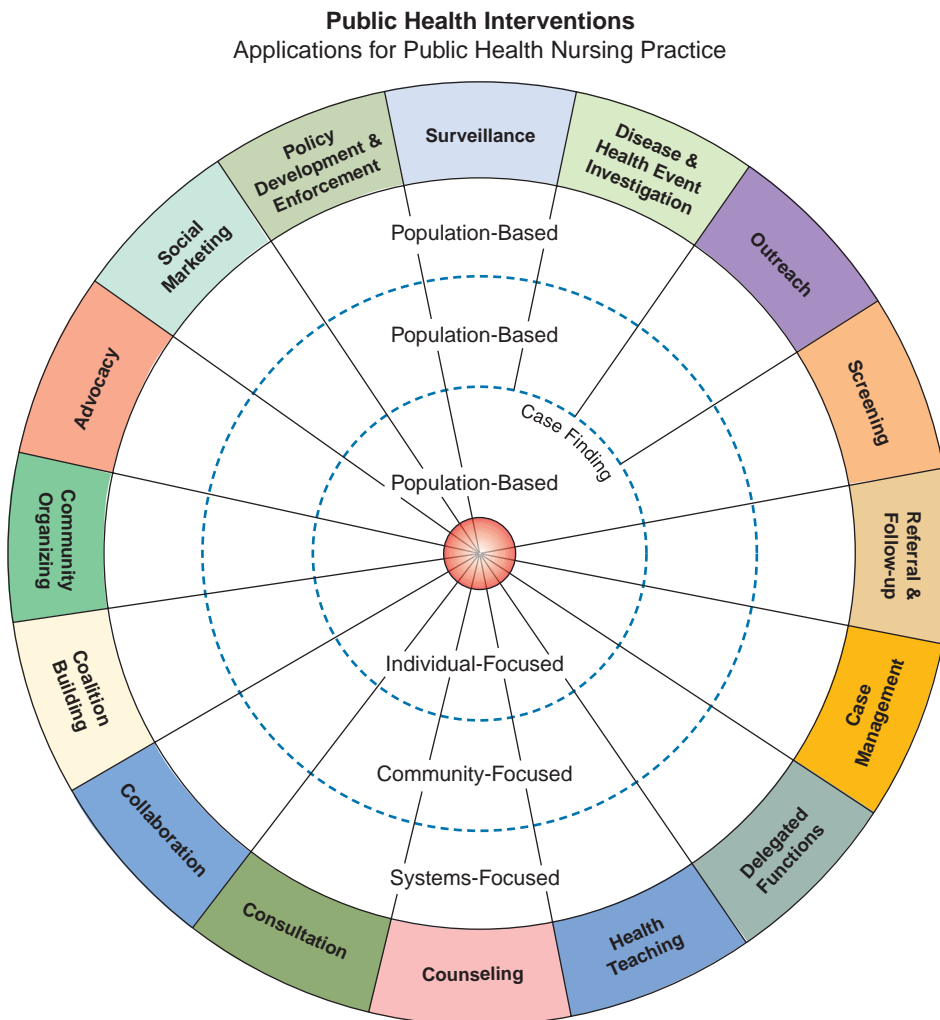

The Minnesota Department of Health, Division of Community Health Services, Public Health Nursing Section, has devised a model that depicts public health interventions and applications for public health practice. In the form of a wheel, the model shows 17 different interventions within three levels of public health practice: population-based community-focused practice, systems-focused practice, and individual-focused practice. The “Minnesota Wheel” (2001) is depicted in Figure 14.2.

The intervention wheel was first proposed in 1998 (Keller, Strohschein, Lia-Hoagberg, & Schaffer) as a practice model for population-based public health nursing. It is currently used in a

variety of venues including public health practice, nursing education, and management. Keller and colleagues emphasize that “use of the Wheel has empowered nurses to explain in a better way how their practice contributes to the improvement of population health (Keller, Strohschein, Lia-Hoagberg, & Schaffer, 2004, p. 454). The wheel is useful for community health nurses because it visually depicts the comprehensive list of interventions nurses must consider in the scope of practice. Saewyc, Solsvig, and Edinburgh (2007) utilized the Minnesota Wheel in an evaluation of “a coalition formed to address a growing issue of young Hmong girls in a Midwest state running away from home, being truant from school, and experiencing subsequent sexual exploitation” (p. 69). The outcomes of the task force were assessed relative to best practices identified in the model. This example shows just one of the many ways the model can assist both the novice nurse and the expert practitioner, as well as other public health disciplines.

### Public Health Nursing Practice Model

The need for a model that could blend public health nursing practice and the principles of public health, and could be applicable to both the generalist nurse and nurses working in specific programs, was the impetus for development of the Public Health Nursing Practice Model (Smith & Bazini-

**FIGURE 14.2** The Minnesota Wheel. (Source: Minnesota Department of Health, Division of Community Health Services, Public Health Nursing Section.)

Barakat, 2003). The model was created by Los Angeles County, Department of Health Services (LAC-DHS), Public Health Nursing with input from the California Conference of Local Health Department Nursing Directors (CCLHNDN) Southern Region and other public health nurse leaders. Referred to as the LAC PHN Practice Model, it is described as integrating the Public Health Nursing Standards of Practice, the 10 Essential Public Health Services, the 10 Leading Health Indicators from *Healthy People 2010*, and the Minnesota Public Health Nursing Interventions Model. “The LAC PHN Practice Model provides a conceptual framework that assists in clarifying the role of the public health nurse and presents a guide for public health practice applicable to all public health disciplines” (Smith & Bazini-Barakat, p. 42).

As described by Smith and Bazini-Barakat (2003), the principles of population-based practice are included in the LAC PHN Practice Model. The public health nurse integrates assessment, policy development, and assurance into her work. The three levels of population-based practice—individuals and families, community, and systems—are addressed, with the nursing process applied throughout the model. Seventeen interventions, as first presented in the Minnesota Public Health Nursing Model, are also incorporated into the LAC PHN Practice Model. The LAC PHN Practice Model promotes the concepts of an interdisciplinary public health team working together, with an emphasis on primary prevention. It also recognizes the importance of active participation of the individual, family, and community. See Figure 30.2 for a depiction of the LAC PHN Model.

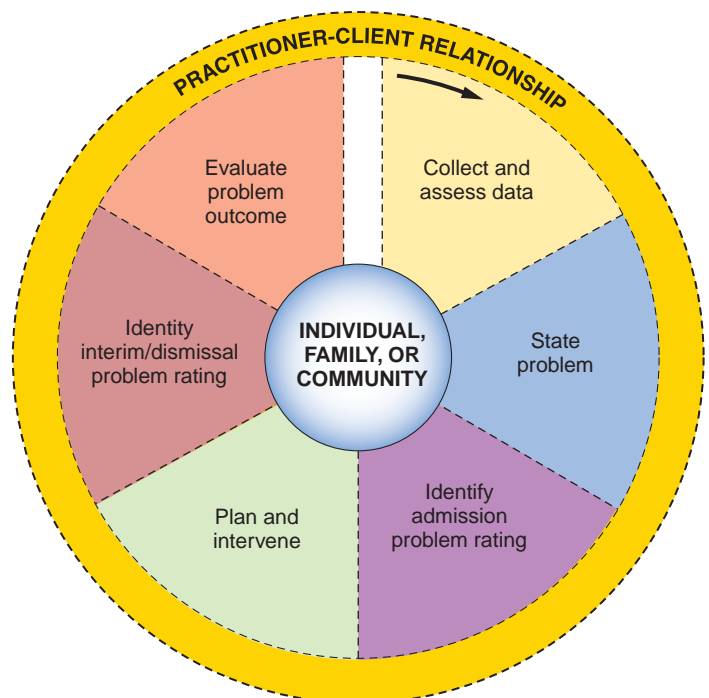

### Omaha System

The Omaha System was developed and refined during four research projects conducted between 1975 and 1992 in the Omaha Visiting Nursing Association. It was designed to increase the effectiveness and efficiency of nursing practice in the agency (Bowles & Naylor, 1996; Martin, Leak, & Aden,

1997). The system is now finding increasing utility in facilitating evidence-based practice, documentation, and information management (Martin, 2005), all of which are critical to contemporary public health care systems. It is a comprehensive system, including the following components (Martin, 2005):

- ◆ Problem classification scheme. Offers nurses a holistic, comprehensive method for identifying clients’ health-related concerns. It includes domains, problems, modifiers, and signs/symptoms. Problems can be identified at the individual, family, or community level.
- ◆ Intervention scheme. Provides a framework for documenting plans and interventions in the client record in the areas of health teaching, guidance, and counseling; treatments and procedures; case management; and surveillance
- ◆ Problem rating scale for outcomes. Consists of a Likert-type scale that is a systematic and recurring method used to document the progress of clients in the record and in case conferences during their time of service in the agency. It is used in conjunction with any problem in the Problem Classification Scheme. Central to problem rating is quantifying outcomes in three dimensions: knowledge (what the client knows), behavior (what the client does), and status (how the client is).

The Omaha System is based on universal principles of nursing practice. The model was judged to be consistent with the Nightingale model of environmental health (Zurakowki, 2005). Citing some variations in language use, Gast and Montgomery (2005) found that Orem’s model of self-care was also consistent with the premises of the Omaha System. The *Omaha System model of the problem solving process* (Fig. 14.3) shows the interrelationship between the practitioner and the client in addressing health problems. The model guides the nurse through the six steps in the

**FIGURE 14.3** Omaha System Model of the Problem Solving Process. From Martin, K.S. (2005). *The Omaha System: A Key to Practice, Documentation, and Information Management*, 2nd ed. St. Louis: Elsevier, with permission.

process: (1) collecting and assessing data, (2) stating the problem, (3) identifying the problem rating on admission, (4) planning and actual interventions, (5) identification of interim or dismissal problem rating, and finally, (6) evaluating problem outcome. The model is applicable to individuals, families, and communities, and provides a mechanism to evaluate both individual and group change over time. Of particular concern to many public health departments is tangibly demonstrating what changes have resulted following interventions with clients.

The system is now available in a Web-based format. This automated version of the model is currently being used in home care agencies, public health departments, and residential long-term care, as well as in schools and universities (Martin, 2005). The Omaha System website provides links to a wide variety of resources for those interested in the system (see Internet Resources). For students and practicing nurses, case studies are available that demonstrate the use of the system with a variety of client types. An extensive list of references is continually updated to provide the most up-to-date evidence regarding the system and its impact on nursing practice.

## PRINCIPLES OF PUBLIC HEALTH NURSING

The word **principle** can be defined variably as rule of conduct, a quality that produces a specific effect, or even the method of operation of a thing (Webster's, 2004). Whatever the definition, there are universals in practice that can guide public health nursing practice in a way that can help achieve the most beneficial outcomes. The goals of community health nursing, to promote and protect the health of communities, are facilitated by adhering to the eight principles of public health nursing summarized in Display 14.1 (ANA, 2007).

### Principle 1: Focus on the Community

The first principle reminds us that the ultimate responsibility of public health nursing is to direct services to the population as a whole. Even though public health nurses may intervene to address individual, family, or group needs, the entire community is the client.

### Principle 2: Give Priority to Community Needs

The second principle deals with the ethical obligation of the community health nurse to give priority to the needs and preferences of the whole community over those of one individual. This means that the nurse must consider interventions that will lead to the greatest good for the most people. For example, programs that make mammograms for early detection of breast cancer available to all women regardless of income level are given priority over those that provide bone marrow transplantation for women with advanced metastatic breast cancer.

### Principle 3: Work in Partnership With the People

The third principle requires the community health nurse to work in partnership with the community. The nurse and the community each bring their own values, beliefs, and expertise to the partnership. Policy development and assurance are more likely to be accepted and applied if there is mutual consideration of and respect for these elements. Developed poli-

#### DISPLAY 14.1

## PRINCIPLES OF PUBLIC HEALTH NURSING

1. **Focus on the Community.** The client or unit of care is the population.
2. **Give Priority to Community Needs.** The primary obligation is to achieve the greatest good for the greatest number of people or the population as a whole.
3. **Work in Partnership With the People.** The processes used by public health nurses include working with the client as an equal partner.
4. **Focus on Primary Prevention.** Primary prevention is the priority in selecting appropriate activities.
5. **Promote a Healthful Environment.** Public health nursing focuses on strategies that create healthy environmental, social, and economic conditions in which populations may thrive.
6. **Target All Who Might Benefit.** A public health nurse is obligated to actively identify and reach out to all who might benefit from a specific activity or service.
7. **Promote Optimum Allocation of Resources.** Optimal use of available resources to assure the best overall improvement in the health of the population is a key element of the practice.
8. **Collaborate with Others in the Community.** Collaboration with a variety of other professions, populations, organizations, and other stakeholder groups is the most effective way to promote and protect the health of the people.

Adapted from American Nurses Association. (2007). *Public health nursing: Scope and standards of practice*. (pp. 7–9). Silver Spring, MD: Nursesbooks.org.

cies need to be communicated in language that reflects an understanding of the community. For these reasons, an essential part of establishing a partnership with a community is getting to know the members and groups within that community.

### Principle 4: Focus on Primary Prevention

The fourth principle of public health nursing underscores the importance of primary prevention in promoting the health of people. Most fields of medicine, including acute care nursing, are primarily concerned with illness, and with efforts to prevent complications from and reoccurrence of the illness. In contrast, community health nursing has an obligation to prevent health problems and to promote a higher level of wellness. Community health nurses take initiative to seek out high-risk groups, potential health problems, and situations that contribute to health problems. They then institute preventive programs. For example, if community assessment revealed a large number of new mothers with postpartum depression, community health nurses would address secondary prevention by establishing mental health programs. Equally as important, they would attend to primary prevention by working to change the conditions in the community that increase the risk for postpartum depression.

### Principle 5: Promote a Healthful Environment

The fifth principle recognizes the importance of ensuring that people live in conditions conducive to health. Therefore, it is aligned with Nightingale's environmental theory of health. People are less likely to be healthy if they live in a community with high unemployment, crowded housing, and dirty air, or where it is difficult to obtain inexpensive, healthful food. They are also less likely to be healthy if the community's norms include acceptance or even encouragement of activities such as smoking, binge drinking, drug use, or unsafe sex. To change these conditions requires commitment, perseverance, patience, resourcefulness, and a long-range view.

### Principle 6: Target All Who Might Benefit

The sixth principle involves outreach strategies to meet the obligation to serve all people who might benefit from an intervention. This tenet requires that the nurse examine policies or programs to determine whether they are accessible and acceptable to the entire population in need and advocate for change if necessary.

In one community, families with young children had a high (80%) rate of compliance with regulations requiring the use of infant and toddler car seats, but assessment revealed that more than 90% of the seats were being used incorrectly. For example, the harness straps were too loose, the seats were not properly installed, or the model used had been recalled because of safety problems. A coalition of community health nurses and law enforcement officials implemented a summer-long, monthly car seat checkup service in the parking lot of a local mall and advertised the service in a media campaign. In evaluating the program, the coalition acknowledged that the campaign had not affected the transport of children born after the intervention period had expired, nor residents who were out of town for the summer, nor had it increased the knowledge of car seat safety among expectant parents or the community in general.

The questions in Display 14.2 can help the nurse evaluate a planned program's success in reaching people who might benefit. These questions should guide the design, implementation, and evaluation of outreach strategies.

#### DISPLAY 14.2

#### DETERMINING WHETHER PROGRAMS SERVE INTENDED POPULATIONS

- Is the service offered in a manner that encourages utilization?
  - Are the services located conveniently?
  - Do the hours of the service fit with the work or school life of the people?
  - Are the services offered in a manner that is respectful of the values, beliefs, mores, and traditions of the people?
  - What kind of marketing strategies have been used to inform the people of the service?
- What is the satisfaction level of users of the service?
- Why are some people not using services?

### Principle 7: Promote Optimum Allocation of Resources

The seventh principle addresses resource-allocation decisions. In most communities, the available resources are not sufficient to meet all the needs of all the people. The nurse must ensure that the community is using limited resources in ways that lead to the greatest improvement in health. To promote optimum allocation of resources, the nurse must

- ◆ Know the latest research on the effectiveness of various programs in addressing needs
- ◆ Collect information about the short- and long-term costs of programs
- ◆ Evaluate existing programs and policies for ways to improve or discontinue them
- ◆ Communicate this information to community decision makers, so that they can make resource-allocation decisions that are most likely to improve the community's health

### Principle 8: Collaborate with Others in the Community

The eighth principle underscores the importance of collaboration with other nurses, health care providers, social workers, educators, spiritual leaders, business leaders, and government officials within the community. This interdisciplinary collaboration is essential to establish and maintain effective programs. Programs that are planned and implemented in isolation can lead to fragmentation, gaps, and overlaps in health services. For example, without collaboration, a well-child clinic may be started in a community that already has a strong developmental screening program but does not have community prenatal services. Without collaboration, programs may also fail to be effective. For instance, a Saturday-morning cardiovascular fitness program designed without consultation with spiritual leaders may be totally ineffective in a devout Jewish community, where members devote Saturdays to religious observances.

### SOCIETAL INFLUENCES ON COMMUNITY-ORIENTED, POPULATION-FOCUSED NURSING

Society is constantly changing. The community health nurse needs to stay abreast of these changes for several reasons.

Social changes influence a community's health. Community health nurses need to continually adapt their strategies to respond to changing conditions. For example, increased international air travel means increased levels of communicable disease in a small city with a new international airport. Community health nurses in this city must be proactive in developing strategies to control the spread of communicable disease.

Social changes affect the availability of resources necessary to ensure that effective intervention strategies are available. For example, a downturn in the stock market may prompt closure of a community business that once generously supported local community services.

Contemporary community health nurses must be especially aware of the mutual interaction between nursing and technology. The term **technology** refers to the application of science to change processes of production or industry. Ideally,

technologic innovations lead to improvements in processes for creating products or services. The 20th century was filled with technologic innovations that simultaneously disrupted old patterns of production and created new opportunities to increase production. Two technologic changes that are highly relevant to contemporary community health nursing are communication technology and genetic engineering.

## Communication Technology

Changes in communication technology present new opportunities and challenges for community-oriented, population-focused care. Because of advances in satellite and telecommunications technology, communication is possible anywhere in the world where resources are available to purchase equipment and services. This means that a community health nurse, whether working in the Australian outback or at a public health clinic in Anchorage, Alaska, can contact clients, consultants, and agencies worldwide, if resources are available to take advantage of the technologies.

In addition, Internet technology has made it possible to access local, state, national, and international data for community assessment, planning, and evaluation. Nurses who require data for a new intervention strategy, for example, can search the Internet for information from consumer groups, researchers, and other experts worldwide. To keep apprised of emerging issues and trends in public health, the nurse can join numerous Internet-based electronic discussion groups or listservs (electronic discussions distributed by way of e-mail). The challenge to the nurse is to manage the volume of information and to weigh its worth.

Health care consumers face similar opportunities and challenges. Most diseases and disabilities can be researched online; information is available on the Internet, and consumers are increasingly searching the Net for health-related data. Certainly, the validity and reliability of information on the Internet vary widely. Research is needed to understand how people decide what information to use from the Internet, how they use it, and how its use affects their health. As health educators, community health nurses can provide guidelines to help people decide how to use health information found on the Internet (Display 14.3). Additionally, community health nurses need to

participate in studies to determine whether regulation of health information on the Internet is feasible and desirable.

At the same time, community health nurses need to be actively involved in creating their own Internet sites to provide health information specific to their targeted communities. Such sites can include interactive chat sessions, listserv discussions, and asynchronous communications in which community health nurses interact with community members to improve their health (Goldsmith, 2001).

The Internet is a superb vehicle for rapidly tracing the international spread of infectious diseases. For example, the World Health Organization has developed an Internet site for countries to report epidemiologic and laboratory data on influenza. The Centers for Disease Control and Prevention (CDC) offers current data on communicable diseases through the online publication, *Morbidity and Mortality Weekly Report*.

With so much technology at our finger tips, we often forget that not everyone has access to, or regularly uses the internet. A study by Rains (2008) supported the notion that younger, more educated individuals living in urban areas utilize the Internet at much higher rates than do other groups. Access to broadband (rather than dial-up connections) is one likely explanation. The public health nurse must be vigilant, so that access issues do not impede access to health information for the many poor and elderly clients who are less likely to have access to computers.

## Genetics, Genomics, and Genetic Engineering

**Genetics**, the science of heredity and **genomics**, the study of the entire genome, are terms that have gained increased attention from nurses over the past decade. An outgrowth of this knowledge is **genetic engineering**, which can be defined as gene manipulation in a laboratory setting. The development of the field was made possible by the discovery of certain enzymes that can “cut” DNA from two or more different sources into pieces that can be recombined in a test tube. Gene manipulation also required the development of methods for inserting these recombinant DNA molecules into cells by the use of so-called *vectors* such as viruses.

Genetic engineering allows scientists to alter the herbicide-, pest-, and stress-resistance of crops and to increase the nutrition and attractiveness of the foods we eat. Genetic engineering also allows scientists to develop new kinds of medicines and to cure diseases by replacing absent or faulty genes. Mapping of the DNA sequence that makes up the “genetic blueprint” of human beings has provided new opportunities for protecting human health (Ellsworth & Manolio, 1999; Jenkins & Calzone, 2007). In addition to increasing understanding of the contribution of genetic material to health and disease, genetic research has created new opportunities for early identification, prevention, and treatment of people at risk for disease. For example, techniques for DNA screening of newborns allows early detection of risk for certain diseases and disabilities, thereby permitting early intervention. Genetic counseling, previously only available to a limited population, is being used increasingly by women in the preconception and prenatal periods (Dolan, Biermann, & Damus, 2007).

Despite the enthusiasm of many groups, especially commercial concerns, genetic engineering has generated much controversy. The controversy emerges from a number of different concerns. One concern is the inability to know

### DISPLAY 14.3

#### DETERMINING WORTH OF HEALTH INFORMATION ON THE INTERNET

- What are the credentials and affiliation of the author?
- Is it easy to determine who is the publisher or sponsor of the web site? Evaluate how the publisher or sponsor might gain economically through your use of the information.
- Is the date of publication of the web site included? Is the information current?
- Are both sides of an issue described? Does the author discuss pros and cons of information presented?
- What references are included to substantiate the information in the article?

for certain the long-term consequences of genetic alteration of foods or organisms such as bacteria, insects, or human beings. For example, the release of a genetically altered weed or insect could be catastrophic if that weed or insect reproduces prolifically and damages the ecosystem. Fears of negative effects of engineered gene transfers between species in genetically engineered food include allergic reactions, spread of diseases across crop species, and emergence of new diseases because of unpredictable mutations in the genetic code.

The Human Genome Project has opened dramatic possibilities for health and well-being, as well as creating ethical challenges in the near future. The potential scientific capacity to alter methods of human reproduction raises concerns about creating unintended consequences for the human race. Another source of concern is that science is “playing God.” For some people, the possibility of being able to select the gender, intelligence, or eye color of a child raises concerns about interfering with nature and creates conflict with religious or ethical views. In addition, genetic screening could be used to deny rights and opportunities to people. For example, someone who is found to carry a gene that increases the risk for heart disease might be denied health insurance coverage. Another source of concern is the distrust many people have of government, large commercial enterprises, and the scientific community. Some people believe that they are not being told the truth about scientific or other issues. Because genetic alteration of food or humans can affect the survival of individuals, groups, or society as a whole, this distrust results in some strong opposition to any type of genetic engineering.

In dealing with these concerns, it is the community health nurse’s responsibility to be aware of the latest scientific information when educating communities, so that the decisions made best fit the community’s value system. Advocating for the highest scientific rigor in genetic engineering research is another important role of community health nurses. Community health nurses need to advocate for research that not only maps DNA but also identifies interventions that can change the outcome for people at risk for genetic disorders. Nurses need to balance what is good for the community as a whole against potential costs to people at risk, advocating for policies and regulations that ensure such a balance. Despite growing evidence of the need to establish essential nursing competencies in this area, Jenkins and Calzone (2007) note that “the relevance of genetics and genomics to nursing practice is not fully appreciated and many nurses still consider it a subspecialty that is not relevant to the entire profession” (p. 11).

## Global Economy

Hundreds of years ago, the economies of communities were largely local. If drought led to a reduction in crop yield in one region, only that region and perhaps its closest neighbors would be affected. Since World War II, however, there has been a consistent trend toward international trade, investment, travel, and ownership of information and ideas (Moller, 1999). This increasingly **global economy** is evidenced by the creation of the European Economic Community and passage of the North American Free Trade Agreement. It has contributed to a strong economy for many developed nations, including the United States, but has also

led to increased instability of all economies as problems in markets in distant countries affect markets worldwide.

This interrelationship was made clear after the terrorist attacks in the United States on September 11, 2001. Key markets in the world experienced downturns, as did the economies of the United States and other nations. The United States and other countries are still experiencing the effects of that day, compounded by the effects of the “war on terrorism.” The toll worldwide—a dramatic increase in refugees and poverty, and the long-term expense of infrastructure repair and redevelopment—is further evidence that national economies are interrelated. Added to this stress on world economic health is the rising cost of fuels, predominately oil. As world economies grow, so too does their need for oil. Fueled by increasing demand and limited growth in production capacity, the price of a barrel of oil is no longer a discussion only on Wall Street, but on Main Street as well.

A global economy also permits rich countries in need of skilled workers to recruit them from developing countries, causing a shortage of skilled labor in those countries that need it most. In countries able to recruit labor, the presence of new immigrant groups may be seen as a threat to the local culture or economy, causing an increase in ethnic, racial, and religious tensions. Even people with jobs that pay well may react negatively because they see their world changing and their own future as more uncertain. At the same time, when citizens in developing nations perceive their country or its citizens as suffering unjustly because of unfair economic changes, there may be an increase in nationalism and even international terrorism.

More recently, the national economy has been impacted by a major decline in U.S. home values, precipitated by imprudent and possibly illegal lending practices by some residential mortgage lenders. The result has been thousands of home mortgage foreclosures, as families found they were unable to afford the escalating costs of mortgages with adjustable interest rates. With rising foreclosures, others who were continuing to pay their mortgages on time found their homes’ values decreasing at an alarming rate, due in part to the large inventory of foreclosed houses in their neighborhoods. Fear that the housing market could decline further has kept many prospective buyers out of the market. The resulting impact on available and affordable rental properties is felt most by those with limited incomes. As more and more people compete for limited rental housing options, the prices rise accordingly. The impact on the international community of the U.S. housing decline is just starting to be realized.

Finally, the economic trends of the late 20th century have contributed to greater worldwide disparities in wealth, health, and *relative poverty*, a measurement of an individual’s income against the average for the society in which that individual lives. In the United States, economic disparity has been fueled by increased demand for skilled workers and decreased demand for unskilled laborers. When the demand for skilled workers (e.g., software engineers) exceeds the supply, these workers can demand increased wages, resulting ultimately in increased costs for housing, health care, products, and services, even for those unskilled laborers whose wages have decreased proportionately.

Reducing income disparity and its numerous effects is a challenge for all people who work in service to humanity. Community health nurses have an obligation to read the latest

research, so that they can better understand the relationship of poverty to health. At the same time, they need to advocate for policies that will reduce adverse effects of poverty and income disparities.

## Migration

**Migration** is the act of moving from one region or country to another, either temporarily, seasonally, or permanently. Throughout history, people have migrated from place to place to seek improved opportunities or to escape intolerable conditions in their home countries. In the late 20th century and the early years of the 21st century, a dramatic increase occurred in the number of *refugees* who migrated from their homes to escape invasion, oppression, or persecution. We also saw an increased reliance on migrant farm workers, people who move from one region to another seasonally, following the crops.

The health care needs of migrants and migrant refugees are enormous. Environmental factors are a primary reason for compromised health, and include inadequate waste disposal, crowded and often unsanitary living conditions, lack of access to healthful foods, and air pollution from an increased concentration of vehicles used for moving refugees. The potential detriments to health associated with migration require that community health nurses ensure that surveillance systems able to detect emerging health problems are in place; programs to prevent health problems and treat existing conditions also need to be developed.

## Terrorism and Bioterrorism

Terrorism is one way in which a small number of people who perceive that they have been unfairly treated can exert influence on a larger group or nation. Groups wishing to harm other countries need sophisticated skills and coordination for most conventional weapons. Terrorists may also use unconventional weapons when highly motivated such as flying planes into buildings, strapping bombs to their bodies, or hiding bombs in their shoes.

Some methods of bioterrorism may be even cheaper and easier to use. **Bioterrorism** is the use of living organisms, such as bacteria, viruses, or other organic materials, to harm or intimidate others, in order to achieve political ends. Some of the possible biologic agents used include *Bacillus anthracis*, smallpox virus, *Brucella*, and botulinum toxin (see Chapter 17).

Because of escalating concerns about bioterrorism, public health workers increasingly recognize the need for skills in dealing with a bioterrorist attack. They need to do the following (CDC, 2008):

- ◆ Ensure that adequate surveillance systems are in place for early detection.
- ◆ Educate emergency and other health personnel about symptoms, treatment, and prevention of further spread.
- ◆ Establish coordinated response plans with health and law-enforcement officials.

Perhaps more importantly, community health nurses need to be involved in primary prevention of bioterrorism through advocating for the elimination of biologic weapons

and addressing the root causes of terrorism, such as poverty, hunger, poor housing, limited educational opportunities, lack of clean water, and inadequate or no health care.

## Climate Changes

Climate changes can be considered societal changes because they may be influenced by economics. Since the Industrial Revolution, increased amounts of carbon dioxide, methane, and nitrous oxide created by manufacturing industries, automobile emissions, and consumer products have been introduced into the earth's atmosphere. These increases have contributed to climate changes that are expected to affect sea level; the production of food, fiber, and medicines; and the spread of infectious diseases. Conversely, significant increases in fuel efficiency and efforts to reduce pollution could avoid millions of deaths around the world. Population-focused nurses need to educate the public about the potential dangers of continuing to contaminate the environment and to advocate for changes in public policy that reduce air and water contaminants. Chapter 9 explores health-related environmental issues in detail.

## Summary

Community health nursing is a community-oriented, population-focused nursing specialty that is based on interpersonal relationships. The unit of care is the community or population rather than the individual, and the goal is to promote healthy communities.

Theories and models of community health nursing aid the nurse in understanding the rationale behind community-oriented care. Florence Nightingale's environmental theory emphasizes the importance of improving environmental conditions to promote health. Orem's self-care model provides a framework, within which the community health nurse can promote a community's collective independence and self-care ability. Neuman's health care systems model describes the nurse's role as one of assisting clients to remain stable within their environment, whereas Rogers' model of the science of unitary man focuses on client–environment interaction and holistic health. King's Theory of Goal Attainment reminds us to work in partnership with clients to achieve the best health outcomes. Parse's Human Becoming Theory posits quality of life from each person's own perspective as the goal of nursing practice. Pender's model focuses on the promotion of health behaviors in people; the goal of nursing is to enhance the likelihood that people will engage in health-promoting behaviors by assessing and influencing perceptual and modifying factors. Roy's adaptation model describes the nurse's goal as one that promotes healthful coping mechanisms and adaptive responses to stressors. Salmon's construct for public health nursing prescribes education, engineering, and enforcement with individuals, families, communities, and nations. Finally, the models used in public health nursing practice, the Minnesota Intervention "Wheel," the Los Angeles County–Public Health Nursing Practice Model, and the Omaha System Model of the Problem Solving Process provide a mechanism for public health nurses to assess, plan, intervene, and evaluate the care they provide in their communities.

The eight principles of public health nursing applied to community health nursing provide a framework within which

the nurse works to promote and protect the health of populations. They emphasize the primacy of prevention, the need for outreach, and the importance of working in collaboration for the greatest good of the greatest number of people.

Nurses need to anticipate and adapt to societal changes in order to fulfill their mission of promoting the health of all people. Contemporary societal influences on community health nursing include communication technology, genetic engineering, the global economy, migration, terrorism, and climate changes. ■

### ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Interview a community health nursing director to determine what population-focused programs are offered in your locality. Explore nursing's role in the assessment, development, implementation, and evaluation of these programs. Discuss with the director how community health nurses might expand their population-focused interventions.
2. Describe a situation in community health nursing practice in which the use of an educational intervention would be most appropriate. Do the same with engineering and enforcement interventions. Discuss what made you match each situation with that intervention.
3. Assume you have been asked to make a home visit to a 75-year-old man, living alone, whose wife recently died. In addition to assessing his individual needs, what factors should you consider for assessment and intervention that would indicate an aggregate- or community-focused approach?
4. Select one of the societal influences on community or population. How would the theories or models for community health nursing practice that were discussed in this chapter guide your practice concerning that societal issue? Choose three models or theories to discuss.
5. Explore one of the societal influences on community or population using the Internet. Using the information in Display 14.3, try to determine the worth of the information available on several Internet sites.

# 15

## Community as Client: Applying the Nursing Process

### LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Describe the characteristics of a healthy community.
- ◆ Describe the meaning of community as client.
- ◆ Articulate three specific considerations of each of the three dimensions of the community as client.
- ◆ Explain methods the community health nurse might use to interact with the community.
- ◆ Discuss methods of community needs assessment.
- ◆ Compare and contrast five types of community needs assessment.
- ◆ Delineate five sources of community data.
- ◆ Describe the role of the community health nurse as a catalyst for community development.

*“A community needs a soul if it is to become a true home for human beings. You, the people, must get it this soul.”*

—Pope John Paul II (1920–2005)

### KEY TERMS

Assets assessment  
Coalition  
Community as client  
Community development

Windshield survey

 **Although** community health nursing practice involves the care of individuals, families, and groups, the care of communities is vital to promoting health and preventing disease. The terms community health nurse and public health nurse (PHN) will be used synonymously in this chapter as both roles require specialized knowledge and skills to work with populations. The American Public Health Association (APHA) (1996) defines public health nursing as “the practice of promoting and protecting the health of populations using knowledge from nursing, social, and public health sciences” (p. 1).

The term community has been well defined in the nursing literature. A community is a collection of people interacting with one another because of geography, common interests, characteristics, or goals. These interactions include social institutions, such as schools, government agencies, and

social services. The concept of **community as client** refers to a group or population of people as the focus of nursing service (Anderson & McFarlane, 2004). Understanding the concept of the community as client is a prerequisite for effective service at every level of community nursing practice, as described in Chapter 1. It is this population-focused practice that distinguishes community health nursing from other nursing specialties (APHA, 2003; Williams, 1977). The Quad Council of Public Health Nursing Organizations, building on the work of the Council on Linkages Between Academia and Public Health Practice (COL) developed a list of “Core Competencies for Public Health Nurses.” These competencies help clarify the role of the community health nurse within the context of community as client (Quad Council, 2003). See Display 15.1.

## DISPLAY 15.1

## QUAD COUNCIL CORE COMPETENCIES OF PUBLIC HEALTH NURSING

- Analytic Assessment Skills.** Define a problem, select and define relevant variables, identify sources of appropriate data and information, identify gaps in data, partner with community to assess meaning of data, make relevant inferences from data, interpret risk and benefits for community, recognize overall public health issues and ethical, scientific, economic, and political implications.
- Policy Development and Program Planning Skills.** Collect and interpret relevant information regarding a specific issue; write policy statements; identify, interpret, and implement policies, laws, and regulations specific to programs; determine feasibility and expected outcomes of policy options; decide on appropriate course of action; develop action plan to implement policy; translate policies into organizational structures and programs, including monitoring and evaluation components to determine effectiveness and quality.
- Communication Skills.** Communicate effectively; solicit individual and organizational input; serve as advocate for public health programs and resources; lead and participate in groups to address specific needs and issues; use the media, technology, and community networks to disseminate information; effectively present information to professional and lay audiences; listen to others in an unbiased manner, respecting others’ viewpoints; promote expression of diverse perspectives and opinions.
- Cultural Competency Skills.** Interact professionally and effectively with persons from diverse cultures, socioeconomic, educational, and racial/ethnic backgrounds, as well as with persons of different lifestyle preferences and ages; utilize culturally, socially, and behaviorally appropriate methods of delivering public health services; appreciate the importance of a diverse public health workforce.
- Community Dimensions of Practice Skills.** Establish and maintain linkages with key stakeholders; build partnerships in the community through the use of team building, leadership, conflict resolution, and negotiation; collaborate with community partners in promoting population health; identify operations of public and private community organizations; engage effectively with the community; develop, implement, and evaluate community public health assessments; understand government’s role in the delivery of community health services.
- Basic Public Health Sciences Skills.** Identify individual and organizational responsibilities related to essential public health services and core functions; define, assess, and understand the health status of populations, determinants of health and illness, factors that contribute to disease prevention, health promotion, and the use of health services; understand the historical development of public health; apply basic public health sciences (e.g., social and behavioral sciences, epidemiology and biostatistics, environmental health, prevention of infectious and chronic diseases, injuries); identify and retrieve current relevant scientific evidence and understand the limitations of research; develop a lifelong commitment to critical thinking.
- Financial Planning and Management Skills.** Develop and present a budget; manage programs within budget constraints; monitor program performance; determine budget priorities; prepare proposals for external funding sources; apply basic human relations skills in managing organizations, motivating personnel, and resolving conflicts; manage collection, retrieval, and use of data for decision making; negotiate and develop contracts and other documents for population-based services; conduct cost–benefit, cost-effectiveness, and cost–utility studies.
- Leadership and Systems Thinking.** Create a culture of ethical standards within communities and organizations; help create key values and shared vision and use these principles to guide actions; identify internal and external issues that could impact essential public health service delivery; facilitate collaboration with internal and external groups to facilitate participation of key stakeholders; promote organizational and team learning; contribute to development, implementation, and monitoring of organizational performance standards; use legal and political system to effect change.

## WHAT IS A HEALTHY COMMUNITY?

What is a healthy community? Just as health for an individual is relative and will change, all communities exist in a relative state of health. A community's health can be seen within the context of health being more than the absence of disease, and “includes those elements that enable people to maintain a high quality of life and productivity” (USDHHS, 2001). A key vision for healthy communities is presented in *Healthy People 2010*, the national health promotion and disease prevention agenda published by the U.S. Department of Health and Human Services (USDHHS). *Healthy People 2010* presents two overarching goals for the health of the nation: to increase quality and years of healthy life and to eliminate health disparities (USDHHS, 2000). “These two goals are supported by specific objectives in 28 focus areas. Each objective was developed with a target to be achieved by the year 2010” (§ 2). (See Chapter 1 describing *Healthy People 2010*.) These objectives and targets provide guidelines for communities to follow to promote the health of their members USDHHS, n.d. “Motivating individuals to act on just one of the indicators can have a profound effect on increasing the quality and years of healthy life and on eliminating health disparities—for the individual, as well as the community overall” (USDHHS, 2001, ¶ 4).

## DIMENSIONS OF THE COMMUNITY AS CLIENT

The health of a community can be characterized through a number of perspectives. One such view is by examining three dimensions: status, structure, and process (Shuster & Goepfinger, 2004).

*Status* is the most common measure of the health of a community. It typically comprises morbidity and mortality data identifying the physical, emotional, and social determinants of health. Physical and social indices include vital statistics, leading causes of death and illness, suicide rates, and rates of drug and alcohol addiction. Social determinants can be identified by crime rates and functional ability level, or by high school dropout rates or average income levels.

*Structure* of a community refers to its services and resources. Adequacy and appropriateness of health services can be determined by examining patterns of use, number and types of health and social services, and quality measures. Classification as a medically underserved area is indicative of a lack of sufficient health care providers (e.g., nurses, physicians, dentists). Demographic data, such as socioeconomic and racial distribution, age, gender, and educational level, are also important indicators of community structure. These measures provide key information and correlate to health status.

*Process* reflects the community's ability to function effectively. In a classic work, Cottrell (1976) describes *community competency* as a key component to the process dimension. Just as nurses assess the strengths and limitations of clients when working with individuals, the community health nurse must assess the strengths and limitations of the community when working with the community as client. Strengths must be enhanced and limitations addressed to achieve agreed-upon goals. Characteristics of a competent community follow. A competent community can:

- ◆ Collaborate effectively in identifying community needs and problems

- ◆ Achieve a working consensus on goals and priorities
- ◆ Agree on ways and means to implement the agreed-upon goals
- ◆ Collaborate effectively to take the required actions.

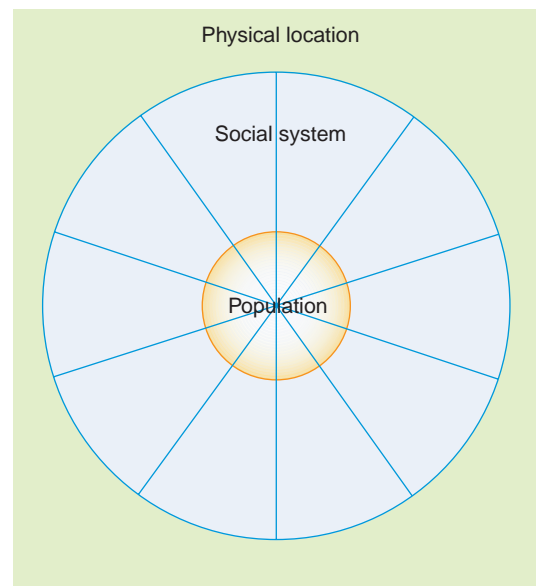

These characteristics will be discussed in more detail later in the discussion on “Planning to Meet the Health Needs of the Community.” See Chapter 1 for more information on healthy communities.

Addressing community health by examining the process in addition to the structure and status dimensions provides a broader view into the complexities of community health and community actions for change. It is key to examine not only the individual components of the community, but also the sum of all the parts—the *whole*—including interactions among all the constituents (Schulte, 2000).

Another perspective identifies the community as having three features: a location, a population, and a social system. Figure 15.1 presents a visual interpretation of this perspective. Each of these features has several components that need to be addressed and represents further information that must be collected and analyzed when assessing the health of a community. These are detailed in Tables 15.1, 15.2, and 15.3.

### Location

Every physical community carries out its daily existence in a specific geographic location. The health of a community is affected by location, because placement of health services, geographic features, climate, plants, animals, and the human-made environment are intrinsic to geographic location. The location of a community places it in an environment that offers resources and also poses threats (Skelly, et al., 2002; Neuman & Fawcett, 2001). The healthy

**FIGURE 15.1** Three features of a community. The community has (1) a physical location, represented here by the square boundary; (2) a population, shown here by the central circle; and (3) a social system, divided here into subsystems.

community is one that makes wise use of its resources and is prepared to meet threats and dangers. In assessing the health of any community, it is necessary to collect information not only about variables specific to location but also about relationships between the community and its location. Do groups cooperate to identify threats? Do health agencies cooperate to prepare for an emergency such as a flood or earthquake? Does the community make certain that its members are given available information about resources and dangers? Table 15.1 describes the location perspective of the Community Profile Inventory, including the six **location variables**: community boundaries, location of health services, geographic features, climate, flora and fauna, and the human-made environment.

### Community Boundaries

To talk about the community in any sense, one must first describe its boundaries (Tatalovich, Wilson, Milam, Jerrett, & McConnell, 2006). Measurements of wellness and illness within a community depend on defining the outer geographic limits of the unit under consideration (Chappell, Funk, & Allan, 2006). Nurses need to be clear, for example, that a target community of the elderly includes a description of age and location (e.g., all persons age 65 and older in a given city or county). Some communities are distinctly separate, such as an isolated rural town, whereas others are closely situated to one another, such as the suburbs of a large metropolis. Therefore, it is important for the

**TABLE 15.1 Community Profile Inventory: Location Perspective**

Location Variables	Community Health Implications	Community Assessment Questions	Information Sources
Boundary of community	Community boundaries serve as basis for measuring incidence of wellness and illness, and for determining spread of disease.	Where is the community located? What is its boundary? Is it a part of a larger community? What smaller communities does it include?	(For all—various Internet sites) Atlas State maps County maps City maps Telephone book City directory Public library
Location of health services	Use of health services depends on availability and accessibility.	Where are the major health institutions located? What necessary health institutions are outside the community? Where are they?	Telephone book Chamber of commerce State health department County or local health departments Maps Public library
Geographic features	Injury, death, and destruction may be caused by floods, earthquakes, volcanoes, tornadoes, or hurricanes. Recreational opportunities at lakes, seashore, mountains promote health and fitness.	What major landforms are in or near the community? What geographic features pose possible threats? What geographic features offer opportunities for healthful activities?	Atlas Chamber of commerce Maps State health department Public library
Climate	Extremes of heat and cold affect health and illness. Extremes of temperature and precipitation may tax community's coping ability.	What are the average temperature and precipitation? What are the extremes? What climatic features affect health and fitness? Is the community prepared to cope with emergencies?	Weather atlas Chamber of commerce State health department Maps Local government Weather bureau Public library
Flora and fauna	Poisonous plants and disease-carrying animals can affect community health. Plants and animals offer resources as well as dangers.	What plants and animals pose possible threats to health?	State health department Poison control center Police department Emergency rooms Encyclopedia Public library
Human-made environment	All human influences on environment (housing, dams, farming, type of industry, chemical waste, air pollution, and so forth) can influence levels of community wellness.	What are the major industries? How have air, land, and water been affected by humans? What is the quality of housing? Do highways allow access to health institutions?	Chamber of commerce Local government City directory State health department University research reports Public library

nurse to know the nature of each location and explicitly define its boundaries.

### **Location of Health Services**

If the members of a town must travel 200 miles to the nearest clinic or dental office, the health of the community will be affected. When assessing a community, the community health nurse needs to identify the major health centers and know where they are located (Schulte, 2000). For example, an alcoholism treatment center for indigent alcoholics was located 30 miles outside one city. This location presented transportation problems and profoundly affected the willingness of clients to voluntarily seek treatment and the length of time they remained at the center. If a well-baby clinic is located on the edge of a high-crime district, parents may be deterred from using it. It is often enlightening to plot the major health institutions, both inside and outside the community, on a map that shows their proximity and relationship to the community as a whole.

### **Geographic Features**

Communities have been constructed in every conceivable physical environment, and environment certainly can affect the health of a community (see Chapter 9). A healthy community is one that takes into consideration the geography of its location, identifies possible problems and likely resources, and responds in an adaptive fashion (Neuman & Fawcett, 2001). For example, both Anchorage, Alaska, and San Francisco, California, are located on a geologic fault line and subject to major earthquakes. In such places, the health of the community is determined, in part, by its preparedness for an earthquake and its ability to cope and respond quickly when such a crisis occurs. In Ontario, Canada, a series of lakes called the Lac la Croix is a valuable food resource for Ojibway Indian communities because they depend on fish from the lakes for their livelihood. Over the years, acid rain generated from coal-burning power plants in the United States and Canada has begun to affect the lakes and the fish, thus contaminating a major food supply of the Ojibway communities. In another example, naturally occurring high levels of arsenic are found in the ground and surface water and are linked to diarrheal illness among the people living in the Kanker District of India (Pandey, Sharma, Roy, Roy, & Pandey, 2006). Although this is not a human-made hazard that can be controlled by compliance with environmental regulations, it must be addressed in order to prevent disease.

### **Climate**

The climate also has a direct influence on the health of a community (Dixon, 2002; Knowlton et al., 2007). When Buffalo, New York, is blanketed with deep winter snows, members of the community sometimes are immobilized for days. Deaths from coronary occlusion increase as people attempt to shovel their sidewalks and uncover their cars. Falls in the elderly have been associated with colder climate (Stevens, Thomas, & Sogolow, 2007). The intense summer heat of a location such as Phoenix, Arizona, can create many health problems (e.g., heat stroke, heat exhaustion). Asthma

and other lung diseases are exacerbated in the Central San Joaquin Valley of California because the area is surrounded by mountains that create an air inversion, trapping vehicle and agricultural by-products in what can be described as a “large bowl” and causing smog during many months of the year. In Costa Rica, higher asthma prevalence has been linked to the warm, humid, tropical weather and the presence of mites and cockroach allergens (Soto-Quiros, Soto-Martinez, & Hanson, 2002). Skin cancer incidence is associated with unprotected sun exposure, which increases the risk for people who live in warm, sunny regions (Saraiya, Glanz, Briss, Nichols, & White, 2003).

A healthy community encourages physical activity among its members, but the climate affects this activity. Although long, cold winters can restrict activity, one community, St. Paul, Minnesota, holds an annual Winter Carnival. Sporting events, parades, ice sailing, dogsledding, a treasure hunt, and hot air balloon races bring thousands of Minnesotans outdoors at a time when they might otherwise be confined by the weather.

### **Flora and Fauna**

Plant and animal populations in a community are often determined by location. The way a community responds to these populations, whether wild or domesticated, can affect the health of the community. The asthma study, mentioned earlier, not only dealt with climate, but also with the preponderance of tropical plants and animals and the high exposure to mites and cockroaches (Soto-Quiros et al., 2002). Poison oak, ivy, and sumac can be found across the United States, and these plants produce an allergic contact dermatitis in many people who come in contact with it (Gladman, 2006). In the Sierra foothill communities of central California, black widow and tarantula spiders, scorpions, and rattlesnakes are resident populations that pose potential health threats. The poison from a single bite may cause injury or death (Diaz, 2005). In the south-central Midwest, the bite of the brown recluse spider injects a toxin that can lead to necrotic skin ulcers as well as systemic symptoms (Rhoads, 2007). In the Northeast and Midatlantic states, increased deer populations—and consequently deer ticks—bring with them an increased incidence of Lyme disease.

The community health nurse needs to know about the major sources of danger from plants and animals affecting the community under study. Are there community agencies that provide educational information about these dangers? Does the populace understand their significance? Are emergency services, such as a poison control center, available to community members?

### **Human-Made Environment**

Every community is located in the midst of an environment created and transformed by human ingenuity. People build houses and factories, dump wastes into streams or vacant lots, fill the air with gases, and build dams to control streams. All of these human alterations of the environment have important implications for community health (Sattler & Lipscomb, 2003). A community health nurse might improve the health of a community by working for

legislation to prevent disposal of waste chemicals into water or landfills. Such legislation might have prevented the disaster at Love Canal in New York state, where groundwater contaminated with toxic wastes continued to seep into residential areas for many years, severely affecting the community's health and spurring community activism that led to the creation of the federal Superfund program to clean up areas with hazardous wastes (Brown & Clapp, 2002).

## Population

When one considers the community as the client, examining the health status of the total population in a given community is a critical component. Population consists not of a specialized aggregate, but of all the diverse people who live within the boundaries of the community.

The health of any community is greatly influenced by the attributes of its population. Various features of the population suggest health needs and provide a basis for health planning (Oleske, 2001; Hutchings, Raine, Brady, Wildman, & Rowan, 2004). A healthy community has leaders who are aware of the population's characteristics, know its various needs, and respond to those needs. Community health nurses can better understand any community by knowing about its **population variables**: size, density, composition, rate of growth or decline, cultural characteristics, social class structure, and mobility. Table 15.2 presents the population perspective section of the Community Profile Inventory.

### Size

The town of Dover, Delaware, with approximately 35,000 people, and the city of Los Angeles, California, with around 4 million people, have radically different health problems. If a single case of *Salmonella* poisoning occurred in Dover, health officials would probably quickly learn of it. It would be relatively easy to trace the course, check the few restaurants in town, and interview people about sanitation practices. However, many cases might occur in Los Angeles without the health department's knowledge. Moreover, once the cases were discovered, tracing the source of contamination might involve a long and complicated search. This is only one small way in which population size can affect the health of a community. The size of a community also influences the presence of inadequate housing, the heterogeneity of the population, and almost every conceivable aspect of health needs and services. Knowing a community's size provides community health nurses with important information for planning. See Chapter 29 for issues related to rural and urban health of populations.

### Density

In some communities, thousands of people are crowded into high-rise apartment buildings. In others, such as farm communities, people live at great distances from one another. The full impact of living in high-density communities is being researched, and some research has already shown that crowding affects individual and community health. Motor vehicle exhaust from highways has been

shown to be associated with higher risk of asthma and reduced lung function in children, as well as higher pulmonary and cardiac mortality in adults (Brugge, Durant, & Rioux, 2007). Fine particulate matter in urban areas is linked to higher rates of hospital admissions (Dominici et al., 2006). When compared with rural populations, urban populations in Ireland have a higher incidence of lung cancer and respiratory disease, thought to be associated with higher air pollution levels (O'Reilly, O'Reilly, Rosato, & Connolly, 2007). A Michigan study found that urban residents had higher risk of mortality when compared with rural residents, even when health and sociodemographic variables were controlled (House et al., 2000).

A low-density community, however, may have problems. When people are spread out, health care provision can become difficult. There may not be enough resources in the form of taxes to support public health services. Rural communities often suffer from inadequate distribution of health care personnel, including private physicians and community health nurses. A large national survey indicated that rural residents reported fewer visits with their health care provider than those living in urban areas (Larson & Fleishman, 2003). A Canadian study found that "rural residents are increasingly less likely to receive personal care assistance" (Forbes & Janzen, 2004, p. 227). Other rural health risks include greater rates of injuries from traffic accidents (Tiesman, Zwerling, Peek-Asa, Sprince, & Cavanaugh, 2007) and illnesses related to agricultural pesticide exposure (Calvert et al., 2004).

A healthy community takes into consideration the density of its population. It organizes to meet the differing needs created by its density levels (e.g., it recognizes differences in density between the inner city and the suburbs and allocates services accordingly). See Chapter 29 for more on health risks specific to rural and urban areas.

### Composition

Communities differ in the types of people who live within their boundaries. A retirement community in Florida whose members are mostly older than age 65 has one set of interests and concerns, whereas a city with a large number of women in their childbearing years will have another set of concerns. A healthy community is one that takes full account of its constituents and provides for their differences. Age, sex, educational level, occupation, and many other demographic variables affect health concerns (Smedley, Stith, & Nelson, 2003). In communities with a high proportion of low-income families, considerations must be made to accommodate the needs of the poor (Kumanyika & Grier, 2006). Occupation can also affect health. For example, in a town where 75% of the workers are employed in a textile mill, the community lives with the threat of brown lung disease, which is caused by cotton dust. In areas where tobacco is the main source of income and a large proportion of the population is engaged in its production, green tobacco sickness—or acute nicotine poisoning—is a concern because workers can absorb nicotine through the skin, and precautions must be taken to prevent this from happening (McKnight & Spiller, 2005). Understanding a community's composition is an important early step in determining its level of health.

TABLE 15.2 Community Profile Inventory: Population Perspective			
Population Variables	Community Health Implications	Community Assessment Questions	Information Sources
Size	The number of people influences number and size of health care institutions. Size affects homogeneity of the population and its needs.	What is the population of the community? Is it an urban, suburban, or rural community?	(For all—various Internet sites) State health department Census data Maps City or town officials Chamber of commerce
Density	Increased density may increase stress. High and low density often affect the availability of health services.	What is the density of the population per square mile?	Census data State health department
Composition	Composition of the population often determines types of health needs.	What is the age composition of the community? What is the sex composition of the community? What is the marital status of community members? What occupations are represented and in what percentages?	Census data State health department Chamber of Commerce U.S. Department of Labor Statistics
Rate of growth or decline	Rapidly growing communities may place excessive demands on health services. Marked decline in population may signal a poorly functioning community.	How has population size changed over the past two decades? What are the health implications of this change?	Census data State health department
Cultural differences	Health needs vary among sub-cultural and ethnic populations. Utilization of health services varies with culture. Health practices and extent of knowledge are affected by culture.	What is the ethnic breakdown of population? What racial groups are represented? What subcultural populations exist in the community? Do any of the subcultural groups have unique health needs and practices? Are different ethnic and cultural groups included in health planning?	Census data State health department Social and cultural research reports Human rights commission City government Health planning boards
Social class	Class differences influence the utilization of health services. Class composition influences cost of public health services.	What percentage of the population falls into each social class? What do class differences suggest for health needs and services?	State health department Census data Sociological reports
Mobility	Mobility of the population affects continuity of care. Mobility affects availability of service to highly mobile populations.	How frequently do members move into and out of the community? How frequently do members move within the community? Are there any specific populations, such as migrant workers, that are highly mobile? How does the pattern of mobility affect the health of the community? Is the community organized to meet the health needs of mobile groups?	State health department Census data Health agencies serving migrant workers Farm labor offices Program serving transients and the homeless

TABLE 15.2 **Community Profile Inventory: Population Perspective** (Continued)

Population Variables	Community Health Implications	Community Assessment Questions	Information Sources
Poverty Level	Economic disparities may lead to health disparities.	What percentage of the population is below federal poverty levels? How many children qualify for free or reduced cost school lunch?	Census data State data Local data (schools)
Education level	Education disparities may lead to health disparities.	What percentage of the population has less than high school education? What is the literacy rate?	State data Local data (schools)
Unemployment rate	Health insurance is often tied to employment. Lack of regular income can be a family stressor. Both can lead to health disparities.	What is the rate of unemployment? How variable is this rate?	U.S. Department of Labor State data Local data
Population by age	A high proportion of children and elderly can overburden health care and social systems.	What is the dependency ratio? Has this rate changed dramatically? What is the trend?	Census data State data Local data
Health status	Community members' status relative to the 10 Leading Health Indicators can impact overall community health.	What is the rate of obesity/overweight? What are the rates of tobacco use and substance abuse? What is the immunization rate? What are rates of injury and violence? What are the STD and HIV/AIDS rates?	State data Local data CDC data Vital Statistics—Numbers of births, deaths, marriages, and infant mortality rate. (Compare local to state data; state to national data.)
Environmental health status	Poor environmental health (e.g. presence of coliform bacteria in well water, toxic chemicals or poor air quality) can lead to increased incidence of communicable or chronic diseases.	What are rates of communicable or chronic diseases (e.g., <i>E. coli</i> infections, asthma)? What is the Toxic Release Inventory?	CDC data State data Local data

### Rate of Growth or Decline

Community populations change over time. Some grow rapidly. The unparalleled recent growth of Las Vegas, Nevada, as a popular place to live has placed extreme demands on the environment, along with the provision of health care and other services. Other populations may experience a decline because of economic change, for example those areas of the United States where steel manufacturing has declined (Aepfel, 2007). Any significant fluctuation in population size can affect the health of the community. As people leave to find new employment or better living conditions, consumption of goods and services drops. Community morale may suffer, and community leadership may decline. Even a stable community can have problems (e.g., members may resist needed change because they notice little fluctuation in their population;

commercial and residential properties may be abandoned or left vacant).

### Cultural Characteristics

A community may be composed of a single cultural group, such as Ojibway Indians on their reservation in Wisconsin, or it may be made up of many cultures or subcultures. For instance, if a city has a large Hispanic population, along with a group of Native Americans living in the inner city and a cluster of Vietnamese refugees, the cultural differences among these members will influence the health of the community. These differences can create conflicting or competing demands for resources and services or create intergroup hostility. A healthy community is aware of such cultural differences and acts to promote understanding among cultural subgroups (Spector, 2009).

### Social Class and Educational Level

**Social class** refers to the ranking of groups within society by income, education, occupation, prestige, or a combination of these factors. There is no absolute agreement on income levels or other criteria to designate social class categories (upper, middle, lower), other than the government formula used to compute poverty level (U.S. Department of Health & Human Services, 2007). Although class distinctions are not clearly defined, class rankings based on occupation, education, and wealth (income plus assets) seem to correlate with many different social patterns and are used frequently in research (Cargan, 2007). Occupational level, in particular, has historically and consistently proven to be a reliable measure, with surprisingly similar rankings among all societies for which data exist (Adcock & Brown, 1957). This classic research has shown that people with higher occupational levels generally have higher incomes and education, exert greater political influence, and are more highly esteemed by others.

*Healthy People 2010* identified the relationship between education, income, and health status:

“Inequalities in income and education underlie many health disparities in the United States . . . in general, population groups that suffer the worst health status also are those that have the highest poverty rates and the least education. Disparities in income and education levels are associated with differences in the occurrence of illness and death, including heart disease, diabetes, obesity, elevated blood lead level, and low birth weight. Higher incomes permit increased access to medical care, enable people to afford better housing and live in safer neighborhoods, and increase the opportunity to engage in health-promoting behaviors” (USDHHS, 2000, p.12).

Typically, health promotion and preventive health services are most needed by low-income groups and people with fewer years of education, although a good number of community residents will benefit from community health efforts (Clark, 2002).

It is generally known that different social classes have different health problems, as well as a variety of resources for coping with illness and diverse ways of using health services. A healthy community recognizes these differences and creates health care services to meet these varied needs.

### Mobility

Americans are a mobile population; between 2002 and 2003, more than 40 million residents moved (Population Reference Bureau, 2005). People move to go to college, take a new job, join other family members or friends, or seek a new climate after retirement. This mobility has a direct effect on the health of communities (Dong et al., 2005). If the population turnover is extensive, continuity of services may suffer. Leadership for improving the health of the community may change so frequently that concerted action becomes difficult. High turnover may necessitate special attention to health education about local conditions.

Population groups may arrive and depart in seasonal swings; fluctuations in the number of migrant farm workers, tourists, or college students can affect a community. Border

health issues are of special concern, as people continually move across borders, bringing with them health issues such as communicable diseases (National Latino Research Center, 2004). Immigrants and refugees may represent a significant population subgroup in many areas of a country, and public health officials must meet their unique needs. The community health nurse also needs to identify those populations that are seasonally mobile. These subgroups present special health needs and place an added burden on a community (e.g., migrant workers). If a town of 3,000 people has an annual influx of 10,000 students who disappear in the summer, residents must prepare to meet this population instability. The small towns of the San Juan Islands in Puget Sound, Washington, can command such high prices for accommodations in the summer that some low-income, year-round residents camp in tents during those months because they are unable to pay the high rents. Thus, the lives of many families are disrupted each year. A healthy community neither ignores nor overreacts to this kind of mobility. Rather, it identifies the nature of the population change, determines the needs created by such change, and organizes to meet those needs.

### Social System

In addition to location and population, every community has a third feature—a social system. The various parts of a community’s social system that interact and influence the health of a community are called **social system variables**. These variables include health, family, economic, educational, religious, welfare, political, recreational, legal, and communication. Whether assessing a community’s health, developing new services for the mentally ill within the community, or promoting the health of the elderly, the community health nurse needs to understand the community as a social system. A community health nurse working in a tiny village in Alaska needs to understand and work with the social system of that village no less than a nurse practicing in New York City. Table 15.3 guides the nurse in assessing a community’s social system variables.

### The Concept of a Social System

A social system is an abstract concept and can be more readily understood by first considering the people who make up the community’s population. Each person enacts multiple roles, such as parent, spouse, employee, citizen, church member, and political volunteer. People in certain roles tend to interact more closely with others in related roles, such as a nursing supervisor with a staff nurse or a customer with a sales clerk. The patterns and communication that emerge from these interactions form the basis of organizations. Some organizations are informal (e.g., an extended family group). Other organizations, such as a city police department or a software business, are more formal. However, all organizations are constructed from roles that are enacted by individual citizens. Organizations, in turn, interact with one another, forming linkages. For example, a medical equipment company and a laboratory establish contracts (linkages) with a home care agency. When a group of organizations are linked and have similar functions, such as all those providing social services, they form

**TABLE 15.3 Community Profile Inventory: Social System Perspective**

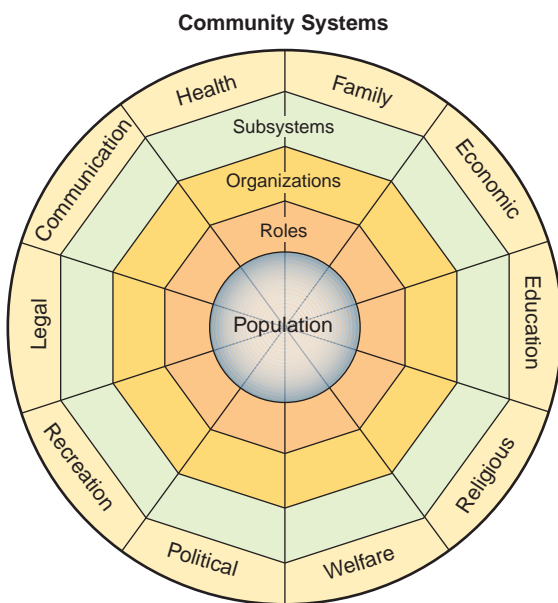

Social System Variables	Community Health Implications	Community Assessment Questions	Information Sources
Health system Family system Economic system Educational system Religious system Welfare system Political system Recreational system Legal system Communication system	Each system must fulfill its functions for a healthy community. Collaboration among the systems to identify goals and problems affects health of community. Undue influence of one system on another may lower the health of the community. Agreement on the means to achieve community goals affects community health. Communication among organizations in each system affects community health.	What are the functions of each major system? What are the major subsystems of each system? What are the major organizations in each subsystem? How well do the various organizations function? Are the subsystems in each major system in conflict? Is there adequate communication among the major systems? Is there agreement on community goals? Are there mechanisms for resolving conflict? Do any parts of the total system dominate the others? What community needs are not being met?	(For all—various Internet sites) Chamber of Commerce Telephone book City directory Organizational literature Officials in organizations Community self-study Community survey Local library Key informants

a community system or subsystem (Fig. 15.2). The various community systems have a profound influence on one another. Because this interaction among parts determines the health of the whole, it is the total social system that concerns community health nurses.

### The Health Care Delivery System as Part of the Social System

Although community health nurses must examine all the systems in a community and must understand how they interact, the health system is of particular importance. The major function of the health system is to promote the health of the community. Community assessment asks not only whether, but also how well, the system is functioning. What is the level of health promotion carried out by the health system of a community? To answer this question, one that can be applied to any system, the PHN needs a clear notion about the subsystems, organizations, and roles that make up the system. Any evidence of inadequate functioning becomes a warning signal for more careful assessment. For example, a high rate of teenage pregnancies in a city may signal inadequate functioning of several systems (e.g., family, educational, religious, health), so a closer look is in order. What community values influence sexual behavior among adolescents? What sex education programs are available to this population? Does the health system provide information and counseling?

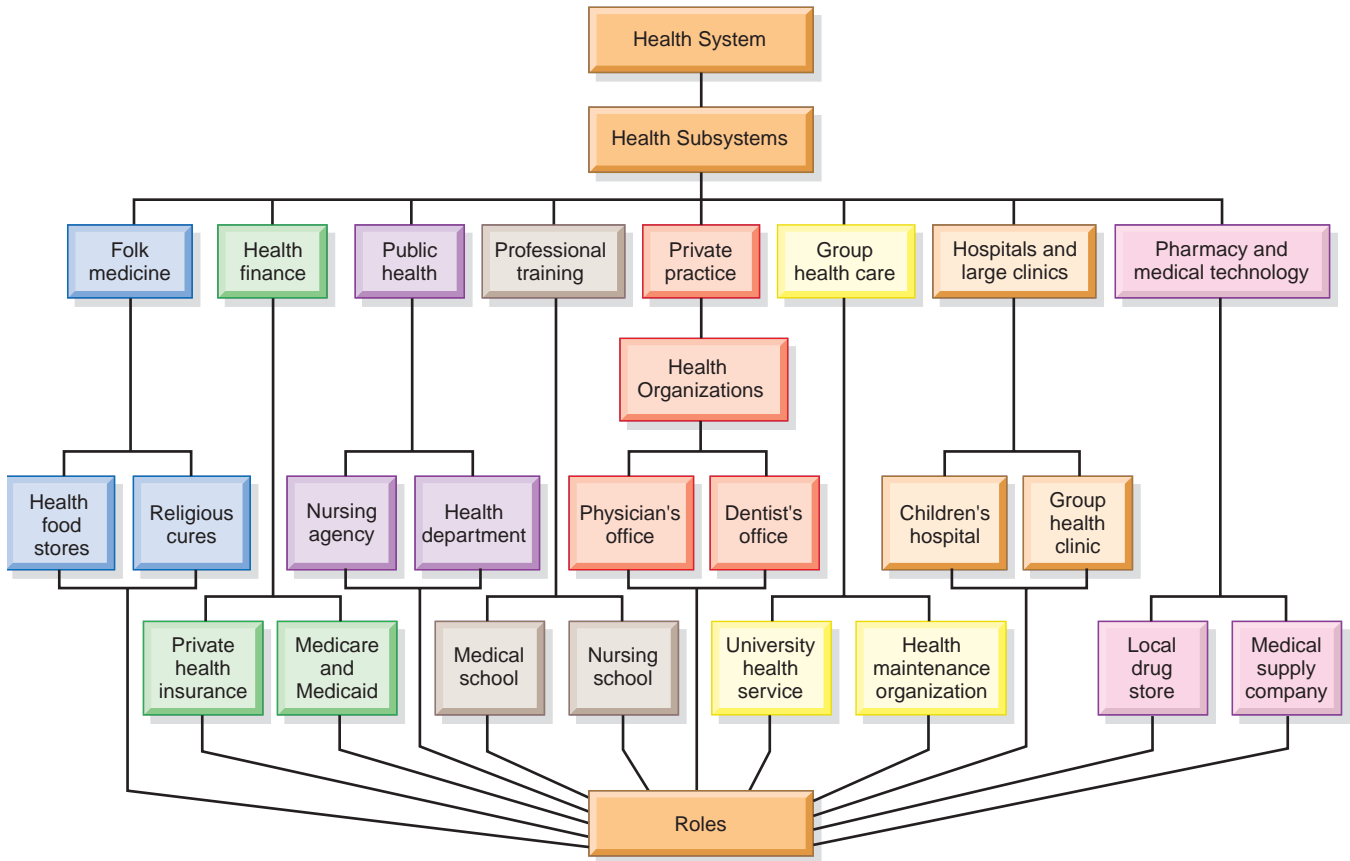

The components of the health system, described in Figure 15.3, include eight major subsystems—each with one or more organizations. Although the community health nurse must be aware of all the systems in a community, the health system is of central importance.

**FIGURE 15.2** The community as a social system. Each of the 10 major systems of a community includes a number of subsystems that are made up of organizations. Members of the community occupy roles in these organizations.

### THE NURSING PROCESS FOR THE COMMUNITY AS CLIENT

Consisting of a systematic, purposeful set of interpersonal actions, the nursing process provides a structure for change that remains a viable tool employed by the community health

**FIGURE 15.3** Components of the health system. This figure shows some representative types of organizations for each of the major subsystems. In turn, each of these organizations also has members with many different roles, and the health of the entire system depends, in part, on how well these roles are carried out.

nurse. This chapter examines the use of the nursing process as applied at the aggregate or community level. Five components—assessment, diagnosis, planning, implementation, and evaluation—give direction to the dynamics for solving problems, managing nursing actions, and improving the health of communities and community health nursing practice.

### NURSING PROCESS CHARACTERISTICS APPLIED TO COMMUNITY AS CLIENT

Three characteristics support the use of the nursing process in community health nursing. First, the nursing process is a problem-solving process that addresses community health problems at every aggregate level with the goals of preventing illness and promoting public health. Second, it is a management process that requires situational analysis, decision making, planning, organization, direction, and control of services, as well as outcome evaluation. As a management tool, the nursing process addresses all aggregate levels. Third, it is a process for implementing changes that improve the function of various health-related systems and the ways that people behave within those systems.

The nursing process provides a framework or structure on which community health nursing actions are based. Application of the process varies with each situation, but the

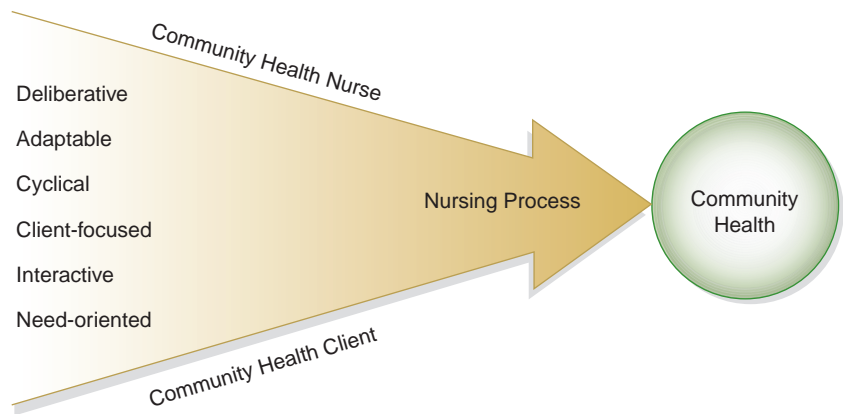

nature of the process remains the same. Certain characteristics of that process are important for community health nurses to emphasize in their practices (Fig. 15.4).

#### Deliberative

The nursing process is deliberative—purposefully, rationally, and carefully thought out. It requires the use of sound judgment that is based on adequate information. Community health nurses often practice in situations that demand the ability to think independently and make difficult decisions. Furthermore, thoughtful, deliberative problem solving is a necessary skill for working with the community health team to address the needs and problems of aggregates in the community. The nursing process is a decision-making tool to facilitate these determinations.

#### Adaptable

The nursing process is adaptable. Its dynamic nature enables the community health nurse to adjust appropriately to each situation and to be flexible in applying the process to aggregate health needs. Furthermore, its flexibility is a reminder to the nurse that each client group and each community situation is unique. The nursing process must be applied specifically to the

**FIGURE 15.4** Nursing process characteristics emphasized in community health.

individual situation and group of people. Based on assessment and sound planning, the nurse adapts and tailors services to meet the identified needs of each community client group.

### Cyclic

The nursing process is cyclic and is in constant progression. Steps are repeated over and over in the nurse–aggregate client relationship. The nurse engages in continual interaction, data collection, analysis, intervention, and evaluation. As interactions between nurse and client group continue, various steps in the process overlap with one another and are used simultaneously. The cyclic nature of the nursing process enables the nurse to engage in a constant information feedback loop: The information gathered and lessons learned at each step of the process promote greater understanding of the group being served, the most effective way to provide quality services, and the best methods of raising this group’s level of health.

### Client-focused

The nursing process is client-focused; it is used for and with clients. Community health nurses use the nursing process for the express purpose of addressing the health of populations. They are helping aggregate clients, directly or indirectly, to achieve and maintain health. Clients as total systems—whether groups, populations, or communities—are the PHN’s target of the nursing process.

### Interactive

The nursing process is interactive, in that nurse and clients are engaged in a process of ongoing interpersonal communication. Giving and receiving accurate information is necessary to promote understanding between nurse and clients and to foster effective use of the nursing process. Furthermore, because of the movement toward informed use of medical care, demands for clients’ rights and the concept of self-care have gained emphasis. Client groups and community health nurses have increasingly joined forces to assume responsibility for promoting community health. The nurse–aggregate client relationship can and should be a partnership, a shared experience by professionals (nurses and others) and client groups (Chrisman, 2007; Schulte, 2000).

### Need-oriented

The nursing process is need-oriented. A long association with problem solving has tended to limit the focus of the nursing process to the correction of existing problems. Although problem solving is certainly an appropriate use of the nursing process, the community health nurse can also use the nursing process to anticipate client needs and prevent problems. The nurse should think of nursing diagnoses as ranging from health problem identification to primary prevention and health promotion opportunities. This focus is needed if the goals of community health—to protect, promote, and restore the people’s health—are to be realized.

### Interacting with the Community

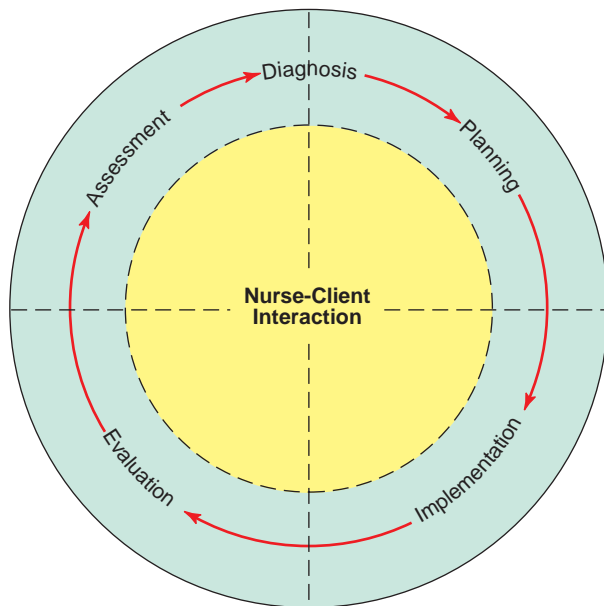

All steps of the nursing process depend on **interaction**, reciprocal exchange and influence among people. Although nurse–client interaction is often an implied or assumed element in the process, it is an essential first consideration for community health nursing (see Chapter 10 for more details). Listening to a group of elderly people, teaching a class of expectant mothers, lobbying in the legislature for the poor, working with parents to set up a dental screening program for children—all these involve relationships, and relationships require interaction. Mutual give and take between nurse and clients—whether a family, a group of mothers on a Native American reservation, or a population of school children—is an expected and much needed skill that should be integrated throughout the nursing process (Fig. 15.5).

### Need for Communication

When a community health nurse initially contacts a group of community leaders, for example, any information the nurse may have in advance can give only partial clues to that group’s needs and wants. Unless everyone involved talks and listens, the steps of the nursing process will go awry.

### Interaction Requires Communication

Through open, honest sharing, the nurse (and others on the health team) will begin to develop trust and establish lines of effective communication. For instance, the nurse explains

**FIGURE 15.5** Nursing process components. Nurse–client interaction, a preamble structure, forms the core of the process. As a nurse and client maintain a reciprocal exchange of information and trust through interaction, they can effectively assess client needs, diagnose needs, and plan, implement, and evaluate care.

who he is and why he is there. The nurse encourages the group members to talk about themselves. Nurse and group members together discuss their relationship and clarify the desired nature of that alliance (Badger, Gagan, & McNiece, 2001). Does the group want help to identify and work on its health needs? Would its members like this nurse to continue regular contacts? What will their respective roles be? Effective communication, as a part of interaction, is essential to develop understanding and facilitate a free exchange of information between nurse and client.

### Interaction Is Reciprocal

Sharing of information, ideas, feelings, concerns, and self goes both ways. Nurses must avoid the temptation either to do all the talking or merely to listen while a few group members monopolize the conversation (Stone, 2002). A dynamic exchange must exist between two systems. The community health nurse (and other collaborating health professionals) represents one system and the client group represents the other. Health care professionals tend to prioritize based on their own perspective and many times neglect to take the clients' wishes into account. Whether the client is a parent group, a homeless population, or an entire community, this exchange involves a two-way sharing between the nurse and client group. The key elements of interaction are mutuality and cooperation.

Consider the following example: A dozen junior high school boys, most of whom were on the football team, met for several weeks with the school nurse to discuss physical fitness, nutrition, and other health topics. After their agreed-upon goals had been accomplished, the nurse wondered whether further meetings were needed. The nurse raised the

question and offered several topics for possible future sessions, such as the use of steroids and other drugs and injury prevention. The boys were not interested in these suggestions, but, after more discussion, they decided that they wanted help with talking to girls. Renewed interaction was a necessary first step in reapplying the nursing process and redefining the goals for the group.

### Interaction Paves the Way for a Helping Relationship

As nurse and client interact, each learns about the other. A test period occurs before trust can be fully established. For the school nurse, establishing interaction was more difficult at the time of the initial contact with the boys. They had been reluctant to talk and felt embarrassed to discuss personal subjects with an adult they did not know. Nonetheless, their interests in bodybuilding and personal appearance were strong enough to attract them to these optional sessions. Interaction began with a friendly exchange on nonthreatening topics and gradually deepened as the boys seemed ready to discuss personal subjects. Eventually, it was relatively simple to talk about a new “problem” (and start the nursing process over again), because a helping relationship had already been developed. The nurse had a track record. The boys trusted, respected, and liked the nurse, so they were happy to interact around a newly stated need.

### Aggregate Application

As noted in earlier chapters, community health practice focuses largely on the health of population groups; therefore, interaction goes beyond the one-on-one with individual patients. The challenge that the community health nurse faces is a one-to-aggregate approach. A group of parents concerned about teenage alcoholism, handicapped people needing access ramps, and a neighborhood's elderly population frightened by muggings and thefts are all aggregates or clients with different concerns and opinions. As defined in Chapter 1, an aggregate refers to a mass or grouping of distinct individuals who are considered as a whole and who are loosely associated with one another. Each person in an aggregate is influenced by the thoughts and behavior of other group members. Nursing interaction with an aggregate client demands an understanding of group behavior, group dynamics, and group-level decision-making. It requires interpersonal communication at the group level. Interaction is more complex with an aggregate than with an individual, but it also can be challenging and rewarding. Once community health nurses acquire an understanding of aggregate behavior, they can capitalize on the potential of group influence to make a far-reaching impact on the health of the total community. Chapter 10 examines communication and interaction with groups more closely.

### Forming Partnerships and Building Coalitions

Another important consideration in community-level nursing practice requires teamwork. The job of planning for the health of an entire community or a community subsystem requires that the nurse collaborate with other professionals. Usually, the nurse is part of an organized team, separate

from the agency that employs the nurse. The team is brought together with the goal of improving the health of the community. Each group member brings expertise and a particular view of the problem. These interprofessional work groups are often formed as either partnerships or coalitions.

**Partnerships** are agreements between people (and agencies) that support a joint purpose (Zahner, Kaiser, & Kapelke-Dale, 2005). A partnership can be large (e.g., a multinational corporation and several high schools; a city government and the county jail system), or it can be a more modest endeavor (e.g., a group of senior citizens and a preschool program; a Girl Scout troop and a community recycling program). Community-wide partnerships require more planning and coordination than do small partnerships. For example, because of increased student enrollment, a college may need two additional temporary and part-time faculty members who can teach the community health nursing course. The county public health department is interested in more new graduate nurses coming to work in the agency. The nursing program and the health department form a partnership and design a plan to solve both problems. The health department selects two staff nurses who have master's degrees and are qualified to teach undergraduate clinical laboratories in community health nursing one day a week for two semesters. The benefits for everyone are numerous. The nursing program solves a temporary staffing problem; the nurses from the health department share their expertise with students, enhancing their practice and the students' learning experience; and the health department successfully introduces a pool of students who may be potential staff members to the agency and the services that it provides for the community.

A **coalition** is an alliance of individuals or groups that work together to influence the outcomes of a specific problem (Green, Daniel, & Novick, 2001; Seng et al., 2005). Coalitions are an effective means to achieve a collaborative and coordinated approach to solving community problems (Chrisman, 2007). Steps to coalition building include defining goals and objectives, conducting a community assessment, identifying key players or leaders, and identifying potential coalition members. Once these steps have been accomplished, the leader needs to keep the coalition active. This is best done by knowing and staying in touch with the coalition members, running effective meetings, and keeping every participant involved.

Sound public health practice depends on pooling resources—including people—in ways that will best serve the public. Whether health service is aimed at families, groups, subpopulations, populations, or communities, the consumers of that service are equally important members of the team. In planning for a community's health, the community (represented by appropriate individuals and agencies) must be involved (Badger, Gagan, & McNiece, 2001). Community health nurses cannot lose sight of the need for client involvement at all levels and in all stages of community health practice.

## Types of Community Needs Assessment

After considering the importance of community partnerships and coalitions, the community health nurse is ready to determine the community's needs. Assessment is the key initial step of the nursing process. Assessment for nurses means collecting and evaluating information about a community's health status to discover existing or potential needs

and assets as a basis for planning future action (Heinemann & Zeiss, 2002).

Several models or frameworks can be used for assessment. Three such models are Assessment Protocol for Excellence in Public Health (APEXPH), Planned Approach to Community Health (PATCH), and Mobilizing for Action through Planning and Partnerships (MAPP). All three of these models have been developed through partnerships involved in meeting *Healthy People 2010* goals (Kalos, Kent, & Gates, 2005; Lenihan, 2005). *Healthy People 2010* also provides a *Tool Kit* for health planning in local communities (see Internet Resources at end of chapter). These are all valuable resources that provide specific guidelines focusing on local-level strategies to improve the health of communities.

Assessment involves two major activities. The first is collection of pertinent data, and the second is analysis and interpretation of data. These actions overlap and are repeated constantly throughout the assessment phase of the nursing process. While assessing a community's ability to enhance its health, the nurse may simultaneously collect data on community lifestyle behaviors and interpret previously collected data on morbidity and mortality.

**Community needs assessment** is the process of determining the real or perceived needs of a defined community. In some situations, an extensive community study may be the first priority; in others, all that is needed is a study of one system or even one organization. At other times, community health nurses may need to perform a cursory examination or "windshield survey" to familiarize themselves with an entire community without going into any depth (Laraia, 2006).

### Familiarization or Windshield Survey

A familiarization assessment is a common starting place in evaluation of a community. **Familiarization assessment** involves studying data already available on a community, then gathering a certain amount of firsthand data in order to gain a working knowledge of the community. Such an approach may utilize a **windshield survey**—an activity often used by nursing students in community health courses and by new staff members in community health agencies. Nurses drive (or walk) around the community of interest; find health, social, and governmental services; obtain literature; introduce themselves and explain that they are working in the area; and generally become familiar with the community and its residents. This type of assessment is needed whenever the community health nurse works with families, groups, organizations, or populations. The windshield survey provides a knowledge of the context in which these aggregates live and may enable the nurse to better connect clients with community resources (Table 15.4). See an example in From the Case Files I.

### Problem-Oriented Assessment

A second type of community assessment, **problem-oriented assessment**, begins with a single problem and assesses the community in terms of that problem. Suppose that Jean, the nurse who explored services available for the Angelo family's deaf child in From the Case Files I, had discovered that there

Ask people willing to talk: How long have you lived here? Has the area changed? As you talk, ask if there is an “old-timer” who knows the history of the area.</li> <li>2. Demographics—What sorts of people do you see? Young? Old? Homeless? Alone? Families? What races do you see? Is the population homogeneous?</li> <li>3. Ethnicity—Do you note indicators of different ethnic groups (e.g., restaurants, festivals)? What signs do you see of different cultural groups?</li> <li>4. Values and Beliefs—Are there churches, mosques, temples? Does it appear homogeneous? Are the lawns cared for? With flowers? Gardens? Signs of art? Culture? Heritage? Historical markers?</li> </ol> <p><b>II. Subsystems</b></p> <ol style="list-style-type: none"> <li>1. Physical Environment—How does the community look? What do you note about air quality, flora, housing, zoning, space, green areas, animals, people, human-made structures, natural beauty, water, climate? Can you find or develop a map of the area? What is the size (e.g., square miles, blocks)?</li> <li>2. Health and Social Services—Evidence of acute or chronic conditions? Shelters? “Traditional” healers (e.g., <i>curanderos</i>, herbalists)? Are there clinics, hospitals, practitioners’ offices, public health services, home health agencies, emergency centers, nursing homes, social service facilities, mental health services? Are there resources outside the community but accessible to them?</li> <li>3. Economy—Is it a “thriving” community or does it feel “seedy”? Are there industries, stores, places for employment? Where do people shop? Are there signs that food stamps are used/accepted? What is the unemployment rate?</li> <li>4. Transportation and Safety—How do people get around? What type of private and public transportation is available? Do you see buses, bicycles, taxis? Are there sidewalks, bike trails? Is getting around in the community possible for people with disabilities? What types of protective services are there (e.g., fire, police, sanitation)? Is air quality monitored? What types of crimes are committed? Do people feel safe?</li> <li>5. Politics and Government—Are there signs of political activity (e.g., posters, meetings)? What party affiliation predominates? What is the governmental jurisdiction of the community (e.g., elected mayor, city council with single member districts)? Are people involved in decision making in their local governmental unit?</li> <li>6. Communication—Are there “common areas” where people gather? What newspapers do you see in the stands? Do people have TVs and radios? What do they watch/listen to? What are the formal and informal means of communication?</li> <li>7. Education—Are there schools in the area? How do they look? Are there libraries? Is there a local board of education? How does it function? What is the reputation of the school(s)? What are major educational issues? What are the dropout rates? Are extracurricular activities available? Are they used? Is there a school health service? A school nurse?</li> <li>8. Recreation—Where do children play? What are the major forms of recreation? Who participates? What facilities for recreation do you see?</li> </ol> <p><b>III. Perceptions</b></p> <ol style="list-style-type: none"> <li>1. The Residents—How do people feel about the community? What do they identify as its strengths? Problems? Ask several people from different groups (e.g., old, young, field worker, factory worker, professional, minister, housewife) and keep track of who gives what answer.</li> <li>2. Your Perceptions—General statements about the “health” of this community. What are its strengths? What problems or potential problems can you identify?</li> </ol>		

Note: Supplement your impressions with information from the census, police records, school statistics, chamber of commerce data, health department reports, and so on to confirm or refute your conclusions. Tables, graphs, and maps are helpful and will aid in your analysis.

\*This survey form was renamed “Learning about the Community on Foot” to underscore the necessity of walking around the community. Also, when one of the authors (Elizabeth T. Anderson) used it in rural Mexico, the area being assessed was not accessible by automobile. For ease of citation and referral, we will continue to use “windshield survey” as its title.

## From the Case Files I

### The Angelo Family and a Familiarization Assessment

A community health nurse named Jean visited the Angelo family on the outskirts of Philadelphia. During the initial visit, she gathered information, learning that the family was Italian American and that there were four children, ranging in age from 13 to 3. The father had been out of work for 6 months; the mother worked on weekends as a maid in a motel; the oldest boy had been in trouble with the juvenile authorities; a younger child was deaf; and their house appeared rundown. Jean assessed this family, trying to determine its coping ability and its level of health. Furthermore, because community health nursing is population focused, her concern was not only for the Angelo family but also for the population of families with similar problems that this family represented.

However, the nurse's assessment was almost impossible without further knowledge of the community. Was theirs an Italian-American neighborhood with specific cultural influences? What was the extent of unemployment in this city? What were the services for the deaf? Were all the houses in this part of town old and in need of repair? Once the nurse began working with the family, familiarity with the community became even more imperative. She discovered that, as a result of the Angelos' low income, family conflicts were intense. The family members seldom got out; they made almost no use of the community's recreational system. Before she could help them make use of it, however, the nurse had to find out what resources were available. As she familiarized herself with the community, she discovered Friends of the Deaf, which sponsored a group for parents of deaf children. The nurse could now help Mr. and Mrs. Angelo become part of that group. A quick survey of the religious system in the community revealed two job-transition support groups, one of which would welcome Mr. Angelo. In the meantime, the nurse chose to find out about the welfare system and how this family and other similar families could benefit from its services. Even her own attitude changed as she studied the community. For instance, she discovered that a strike had closed down the plant where Mr. Angelo worked for 20 years, and so could view his and others' unemployment from a broader perspective. Using a familiarization assessment helped this nurse to enhance her practice.

Whatever role nurses play in community health promotion, they will want to be making a continuous study, an ongoing assessment. Whether nurses become client advocates, work with the local government, or operate from a nursing agency serving the elderly, a familiarization assessment is prerequisite for their work.

were none. Confronted with this problem—one family with one deaf child—she could make a problem-oriented community assessment. Her first step would be to discover the incidence of childhood deafness, both in the community and in the state. Second, she might begin interviewing officials in the schools and health institutions to find out what had been done in the past to assist deaf children. She could check the local library or the Internet to locate available resources on the subject of deafness. Are there interpreters available for people who use sign language? How do hospitals and courts approach deafness? Are there any clubs or other organizations for deaf people? Are there school programs for the deaf, and, if so, where are they located?

The problem-oriented assessment is commonly used when familiarization is not sufficient and a comprehensive assessment is too expensive. This type of assessment is responsive to a particular need. The data collected will be useful in any kind of planning for a community response to the specific problem.

### Community Subsystem Assessment

In **community subsystem assessment**, the community health nurse focuses on a single dimension of community

life. For example, the nurse might decide to survey churches and religious organizations to discover their roles in the community. What kinds of needs do the leaders in these organizations believe exist? What services do these organizations offer? To what extent are services coordinated within the religious system and between it and other systems in the community?

Community subsystem assessment can be a useful way for a team to conduct a more thorough community assessment. If five members of a nursing agency divide up the ten systems in the community and each person does an assessment of two systems, they could then share their findings to create a more comprehensive picture of the community and its needs.

### Comprehensive Assessment

**Comprehensive assessment** seeks to discover all relevant community health information. It begins with a review of existing studies and all the data presently available on the community. A survey compiles all the demographic information on the population, such as its size, density, and composition. **Key informants** are interviewed in every major system—education, health, religious, economic, and others.

Key informants are experts in one particular area of the community or they may know the community as a whole. Examples of key informants would be a school nurse, a religious leader, key cultural leaders, the local police chief or fire captain, a mail carrier, or a local city council person. Then, more detailed surveys and intensive interviews are performed to yield information on organizations and the various roles in each organization. A comprehensive assessment describes not only the systems of a community but also how power is distributed throughout the system, how decisions are made, and how change occurs (Blewett, Casey, & Call, 2004; Gandelman, Desantis, & Rietmeijer, 2006).

Because comprehensive assessment is an expensive, time-consuming process, it is not often undertaken. Performing a more focused study, based on prior knowledge of needs, is often a better and less costly strategy. Nevertheless, knowing how to conduct a comprehensive assessment is an important skill when designing smaller, more focused assessments.

### Community Assets Assessment

The final form of assessment presented here is **assets assessment**, which focuses on the strengths and capacities of a community rather than its problems (Sharpe, Greaney, Lee, & Royce, 2000). The type of assessment depends on variables such as the needs that exist, the goals to be achieved, and the resources available for carrying out the study (Pan, Littlefield, Valladolid, Tapping, & West, 2005). Although it is difficult to determine the type of assessment needed in advance, the decision will be facilitated by understanding several different types of community assessment. Based on a classic model developed by McKnight and Kretzmann in the 1980s (Kretzman & McKnight, 1993), the assets assessment provides a framework with which to conduct a complete functional community assessment and serves as a guide to the community for the nurse, as well as the foundation for community development. The previously mentioned methods are needs-oriented and deficit-based—in other words, they are *pathology* models, in which the assessment is performed in response to needs, barriers, weaknesses, problems, or perceived scarcity in the community. This may result in a fragmented approach to solutions for the community's problems rather than an approach focused on the community's possibilities, strengths, and assets. The assets assessment also provides the community the ability to “identify a variety and richness of skills, talents, knowledge, and experience of people” and “provides a base upon which to build new approaches and enterprises” (p. 4).

Assets assessment begins with what is present in the community (Davis, Cook, & Cohen, 2005). The capacities and skills of community members are identified, with a focus on creating or rebuilding relationships among local residents, associations, and institutions to multiply power and effectiveness. This approach requires that the assessor look for the positive, or see the glass as half full. The nurse can then become a partner in community intervention efforts, rather than merely a provider of services. Assets assessment has three levels:

1. Specific skills, talents, interests, and experiences of individual community members such as individual businesses, cultural groups, and professionals living in the community.
2. Local citizen associations, organizations, and institutions controlled largely by the community such as libraries, social service agencies, voluntary agencies, schools, and police.
3. Local institutions originating outside the community controlled largely outside the community such as welfare and public capital expenditures (p. 14).

The key, however, is linking these assets together to enhance the community from within. The community health nurse's role is to assist with those linkages.

## COMMUNITY ASSESSMENT METHODS

Community health needs may be assessed using a variety of methods. Regardless of the assessment method used, data must be collected. Data collection in community health requires the exercise of sound professional judgment, effective communication techniques, and special investigative skills. Four important methods are discussed here: surveys, descriptive epidemiologic studies, community forums or town meetings, and focus groups.

### Surveys

A **survey** is an assessment method in which a series of questions is used to collect data for analysis of a specific group or area. Surveys are commonly used to provide a broad range of data that will be helpful when used with other sources or if other sources are not available. To plan and conduct community health surveys, the goal should be to determine the variables (selected environmental, socioeconomic, and behavioral conditions or needs) that affect a community's ability to control disease and promote wellness. The nurse may choose to conduct a survey to determine such things as health care use patterns and needs, immunization levels, demographic characteristics, or health beliefs and practices. The survey method involves three phases that are needed to ensure an adequate design and appropriate collection of data (Polit & Beck, 2007).

### Descriptive Epidemiologic Studies

A second assessment method is a **descriptive epidemiologic study**, which examines the amount and distribution of a disease or health condition in a population by person (Who is affected?), by place (Where does the condition occur?), and by time (When do the cases occur?). In addition to their value in assessing the health status of a population, descriptive epidemiologic studies are useful for suggesting which individuals are at greatest risk and where and when the condition might occur. They are also useful for health planning purposes and for suggesting hypotheses concerning disease etiology. Their design and use are detailed in Chapter 7.

The choice of assessment method varies depending on the reasons for data collection, the goals and objectives of the study, and the available resources. It also varies according to the theoretical framework or philosophical approach through which the nurse views the community. In other words, the community health nurse's theoretical basis for approaching community assessment influences the purposes for conducting

the assessment and the selection of methodology. For example, Neuman's health care systems model forms the basis for the "community-as-partner" assessment model developed by Anderson and McFarlane (2004, p. 85). Additional resources on methodologies for assessing community health are available in the list of References and Selected Readings at the end of this chapter.

## Community Forums or Town Hall Meetings

The community forum or town hall meeting is a qualitative assessment method designed to obtain community opinions. It takes place in the neighborhood of the people involved, perhaps in a school gymnasium or an auditorium. The participants are selected to participate by invitation from the group organizing the forum. Members come from within the community and represent all segments of the community that are involved with the issue. For instance, if a community is contemplating building a swimming pool, the people invited to the community forum might include potential users of the pool (residents of the community who do not have pools and special groups such as the Girl Scouts, elders, and disabled citizens), community planners, health and safety personnel, and other key people with vested interests. They are asked to give their views on the pool: Where should it be located? Who will use it? How will the cost of building and maintaining it be assumed? What are the drawbacks to having the pool? Any other pertinent issues the participants may raise are included. This method is relatively inexpensive, and results are quickly obtained. A drawback of this method is that only the most vocal community members, or those with the greatest vested interests in the issue, may be heard. This format does not provide a representative voice to others in the community who also may be affected by the proposed decision.

This method is used to elicit public opinion on a variety of issues, including health care concerns, political views, and feelings about issues in the public eye, such as gangs. Frequently, local cable television channels air important city government or school board meetings. Local news programs may hold town meetings, soliciting public opinion on regional issues. Other methods of opinion gathering include e-mailing (e.g., to a television news program) to support a particular view, Web-based survey sites (e.g., Survey Monkey), and using a toll-free phone number set up especially for text messaging a Yes or No vote on an issue. Now commonplace, chat rooms are available for a host of topics and interests. Electronic town meetings are designed to elicit grassroots opinions from local community members, and have been utilized by many entities, including the Minnesota Senate (2006). Even presidential debates are available over the Internet, with citizens sending in e-mail questions for candidate responses in real time (Gough, 2007).

## Focus Groups

This fourth assessment method, focus groups, is similar to the community forum or town hall meeting in that it is designed to obtain grassroots opinion. However, it has some differences. First, only a small group of participants, usually 5 to 15 people (Polit & Beck, 2007), is present. The members chosen for the group are homogeneous with respect to specific demographic variables. For example, a focus group may consist of

female community health nurses, young women in their first pregnancy, or retired businessmen. Leadership skills are used in conjunction with the small group process to promote a supportive atmosphere and to accomplish set goals. The interviewer guides the discussion according to a predetermined set of questions or topics.

Major advantages of focus groups are their efficiency and low cost, similar to the community forum or town hall meeting format. A focus group can be organized to be representative of an aggregate, to capture community interest groups, or to sample for diversity among different population groups. One example is a research study involving Hmong youths and adults. Eight focus groups were held to determine perceptions of healthy diet and exercise among parents and children (Pham, Harrison, & Kagawa-Singer, 2007). Whatever the purpose, however, some people may be uncomfortable expressing their views in a group situation (Polit & Beck, 2007).

## SOURCES OF COMMUNITY DATA

The community health nurse can look in many places for data to enhance and complete a community assessment. Data sources can be primary or secondary, and they can be from international, national, state, or local sources. Websites for many primary and secondary data sources are included at the end of this chapter.

### Primary and Secondary Sources

Community health nurses make use of many sources in data collection. Community members, including formal leaders, informal leaders, and community members, can frequently offer the most accurate insights and comprehensive information. Information gathered by talking to people provides primary data, because the data are obtained directly from the community. Secondary sources of data include people who know the community well and the records such people create in the performance of their jobs. Specific examples are health team members, client records, community health (vital) statistics, census bureau data, reference books, research reports, and community health nurses. Because secondary data may not totally describe the community and do not necessarily reflect community self-perceptions, they may need augmentation or further validation through focus groups, surveys, and other primary data collection methods.

### International Sources

International data are collected by several agencies, including the World Health Organization (WHO) and its six regional offices and health organizations, such as the Pan-American Health Organization. In addition, the United Nations and global specialty organizations that focus on certain populations or health problems, such as the United Nations Children's Fund, are major sources of international health-related data (WHO, 2008a). The WHO publishes an annual report of their activity, and international statistics for diseases and illness trends can be found on the Internet (WHO, 2008b). Information from these official sources can give the nurse in the local community information about immigrant and refugee populations he serves. More information on international health agencies can be found in Chapter 16.

## National Sources

Community health nurses can access a wealth of official and nonofficial sources of national data (see Chapter 6 for more information). Official sources develop documents based on data compiled by the government. The following are the major official agencies:

- ◆ **U.S. Department of Health and Human Services, (USDHHS).** This is the main agency from which data can be retrieved, and its agency, the National Center for Health Statistics (NCHS), was specifically established for the collection and dissemination of health-related data. This agency is the nation's principal health statistics agency, compiling data from many sources. These data provide information for many functions, including health status for various populations and subgroups, identification of disparities, monitoring trends, identifying health problems, and supporting research.
 

USDHHS also published *Healthy People 2010* (USDHHS, 2000), which was designed to focus America's attention on the major national health problems, including realistic goals for national, state, and local agencies to work toward over one decade.
- ◆ **U.S. Bureau of the Census.** This agency undertakes a major survey of American families every 10 years, gathering data on health, socioeconomic, and environmental conditions. This information is available on the Web or on a CD-ROM, allowing numerous variables to be viewed in combination, for easier development of a community profile.
- ◆ **National Institutes of Health (NIH).** This system of 27 Institutes and Centers, a part of the USDHHS, focuses on improving the health of the nation. An emphasis is placed on discovery of new cures or treatments and preventing disease. Employees of these agencies prevent, diagnose, and treat diseases and conduct research and disseminate research findings (NIH, 2007).

Nonofficial agencies have data sources generated from research they conduct that focuses on the population, disease, or condition they were developed to serve. Each agency collects data at the national level; however, the more accessible arm for services function at state and local levels. Examples of these agencies are the American Cancer Society (ACS), the American Association of Retired Persons (AARP), Mothers Against Drunk Drivers (MADD), and Students Against Drunk Drivers (SADD). Information from such national sources allows community health assessment teams to compare local data with national and state statistics and trends—a very valuable function.

## State and Local Sources

For nurses, the most significant state source of assessment data comes from the state health department. This official agency is responsible for collecting state vital statistics and morbidity data. The Behavioral Health Surveillance System

(BRFSS) is the world's largest telephone health survey that monitors health risk at the state level (Centers for Disease Control & Prevention [CDC], 2007). Supported by the CDC, the information is used at various levels to identify risk and prevent disease. As a resource to local health departments, the state health department provides invaluable support services and it is the main source of health-related data on the state level. Nonofficial agencies have state chapters or headquarters and compile their information at the state level. Local nonofficial agency chapters have documents of compiled state and national data on the population, disease, or condition they address.

Many sources of information may be obtained at the local level. Some key sources are the local visitor's bureau, city Chamber of Commerce, city planner's office, health department, hospitals, social service agencies, county extension office, school districts, universities or colleges, libraries, clergy, business and service organizations, and community leaders and key informants. Some of these sources compile their own statistics, but all have views of the community particular to their discipline, interest, or knowledge base. Some agencies at the local level develop city or county directories. These are updated periodically and are valuable resources for community health assessment teams and community health nurses. More detailed information on national, state, and local health agencies can be found in Chapter 6.

## DATA ANALYSIS AND DIAGNOSIS

This stage of assessment requires analysis of the information gathered, so that inferences or conclusions may be made about its meaning. Such inferences must be validated to determine their accuracy, after which a nursing diagnosis can be formed.

### The Analysis Process

First, the data must be validated: Are they accurate? Several validation procedures may be used:

1. Data can be rechecked by the community assessment team.
2. Data can be rechecked by others.
3. Subjective and objective data can be compared.
4. Community members can consider the findings and verify them.

Validated data are then separated into categories such as physical, social, and environmental data. In many instances, data spreadsheets are used to provide a structure for data organization. Next, each category is examined to determine its significance. At this point, there may be a need to search for additional information to clarify the meaning of the data. Only then can inferences be made and a tentative conclusion about the meaning of the data be reached (Anderson & McFarlane, 2004; Gandelman, Desantis, & Rietmeijer, 2006).

Some computer programs are designed to analyze community assessment data. For large, complex, or ongoing community assessment plans, this may be the best method. For smaller, one-time assessments, the paper-and-pencil method may be sufficient and less unwieldy. Some commu-

nities may hire an outside professional assessment service. These teams often use the latest technology when analyzing data. Not all communities can afford such a service, and if key leaders become familiar with assessment, analysis, and diagnostic processes, an investment in a computer program may be worthwhile. Geographic information systems (GIS) technology is proving very useful in community assessment. These tools are becoming more user friendly and cost effective, and have been used to pinpoint incidences of various diseases, display environmental risks, note the location of health care facilities, and determine accurate community boundaries (Faruque, Lofton, Doddato, & Mangum, 2003; Choi, Afzal, & Sattler, 2006). Regardless of the analysis method used, data interpretation remains a critical phase of the process.

In data interpretation, the ever-present danger exists of making inaccurate assumptions and diagnoses. The importance of validation cannot be overemphasized. Before making a diagnosis, all assumptions must be validated: Are they sound? Community members should participate actively in validation efforts by clarifying perceptions, explaining the circumstances surrounding the situation, and acting as sounding boards for testing assumptions. Other resources, such as the health team members and community leaders, are used to explore and confirm inferences. Data collection, data interpretation, and nursing diagnosis are sequential activities, with validation serving as the bridges between them (Table 15.5). When performed thoroughly, these steps lead to accurate diagnoses.

### Community Diagnosis Formation

The next step of the nursing process, after analysis, is the development of the community diagnosis. “Community diagnoses clarify who gets the care (the community as opposed to the individual), provide a statement identifying problems faced by who is getting care (i.e., the community), and identify the factors contributing to the identified problem” (Shuster & Goepfinger, 2004, p. 360). Various taxonomies and classification systems are used in nursing

to describe specific nursing problems and each one has its limitations when dealing with community-level diagnoses. The North American Nursing Diagnosis Association (NANDA) is much more oriented to nursing diagnoses of individuals and families than to community-level problems. Nursing Outcomes Classification (NOC) is also generally individual-oriented. The Omaha System, originally designed by the Omaha Visiting Nurse Association, is again primarily used in nursing diagnoses of individuals, families, and small groups, although some community health applications have been developed (Omaha System, 2005; Mantas & Hasman, 2001).

This chapter discusses nursing diagnosis as characterized by Neufeld and Harrison (1996), based on the classic work of Munding and Jauron (1975). These authors proposed the use of nursing diagnoses in the community by substituting the term *client*, *family*, *group*, or *aggregate* for the word *patient*. Their definition of a nursing diagnosis is (Neufeld & Harrison, 1996, p. 221):

The statement of a [client’s] response which is actually or potentially unhealthful and which nursing intervention can help to change in the direction of health. It should also identify essential factors related to the unhealthful response.

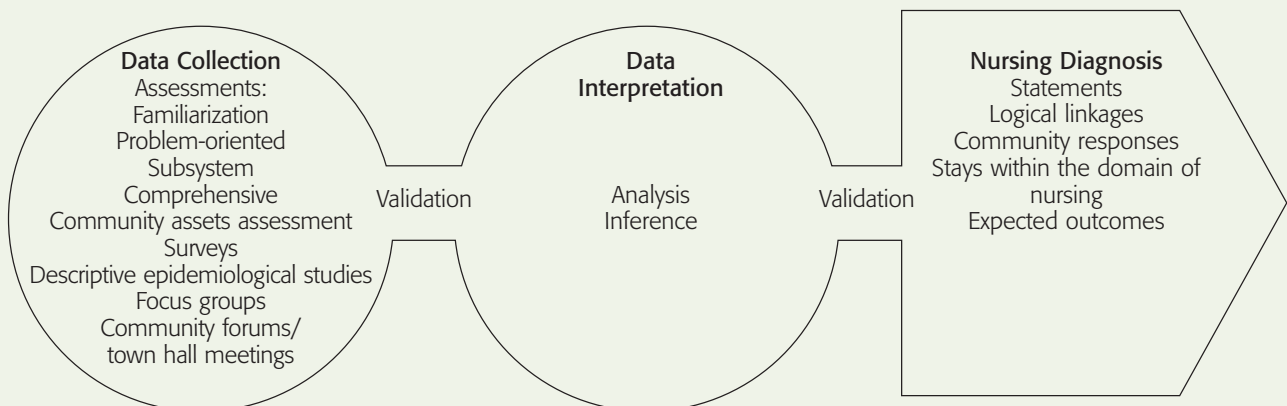

Neufeld and Harrison built on this work to form a wellness diagnosis by using the phrase *healthful response* instead of *unhealthful response*. Their definition of a wellness diagnosis is (p. 221):

The statement of a client’s [community’s] healthful response which nursing intervention can support or strengthen. It should also identify the essential factors related to the healthful response.

Stolte (1996) developed a manual for nursing wellness diagnosis. By substituting the term *community* for client, family, group, or aggregate, the nursing or wellness diagnosis can be applied to the community as a whole. These diagnoses identify the conclusion the nurse draws from interpretation of collected data and describe a community’s healthy or

**TABLE 15.5 Assessment and Diagnosis Phases of the Nursing Process**

Interpretation of data leads to diagnosis of a community’s needs, the community responses, and expected outcomes.

unhealthy responses that can be influenced or changed by nursing interventions. Change comes about through collaboration with other community and health team members.

In community health, nurses do not limit their focus to problems; they consider the community as a total system and look for evidence of all kinds of responses that may influence the community's level of wellness. Responses encompass the whole health–illness continuum, from specific deficits, such as a lack of senior centers or day care programs, to opportunities for maximizing a community's health, such as promoting improvement of police protection or the safety of the roadways. The statement of community response—the diagnosis—can focus on a wide range of topics.

## Community Diagnoses

Data have been gathered from a variety of sources and have been validated by several means. The data have been recorded, tabulated, analyzed, and synthesized, so that patterns and trends can be seen. The use of charts, graphs, and tables assists in visualizing the synthesized data. The community assessment team should present their findings to peers and colleagues, and use their expertise to assist in the formulation of the community diagnoses.

Continuing with the nursing process format, nursing diagnoses for the community are developed. **Community diagnoses** refer to nursing diagnoses about a community's ineffective coping ability and potential for enhanced coping. The statements about the community should include the strengths of the community and possible sources for community solutions, as well as the community's weaknesses or problem areas. Using the standard nursing diagnosis format, community-level diagnoses can be developed (Carpenito-Moyet, 2007). These diagnoses are used as tools as the community begins to plan, intervene, and evaluate outcomes. Diagnostic categories for individuals (e.g., knowledge deficit of senior services, high risk for injury or falls) can often be applied at the community level. Community-level nursing diagnoses should portray a community focus, include the community response, and identify any related factors that have potential for change through community health nursing. These may also include wellness diagnoses, which indicate maintenance or potential change responses (due to growth and development), when no deficit is present. Community nursing diagnoses must also include statements that are narrow enough to guide interventions, have logical linkages between community responses and related factors, and include factors within the domain of community health nursing intervention (Neufeld & Harrison, 1996).

Examples of wellness and deficit community nursing diagnoses and several diagnoses for a specific community follow:

1. *Wellness nursing diagnosis for an assisted living community of elders.* The senior residents of an assisted living center (*community focus*) have the potential for achieving optimal functioning related to (*host factors*) their expressed interest in exercise, diet, and meaningful activities and to (*environmental factors*) their access to exercise opportunities, nutritional information, and social outlets.
2. *Deficit community nursing diagnosis for a rural farm-worker community.* The inhabitants of (*name of the*

*town*) in (*name of the state*) are at risk for illness and injury related to (*host factors*) exposure to pesticides, lack of motivation to add or use safety devices on farm machinery, lack of safety knowledge, choice to take unnecessary risks (*environmental factors*), lack of family income to purchase newer equipment and long hours of work that lead to stress and exhaustion.

### 3. *Community diagnoses for Anytown, Kansas.*

Anytown, Kansas, is experiencing an increase in crime, a problem compounded by the small size of the police force and an influx of many new community members. The community has worked together constructively in the past, communicates well, and has strong recreational outlets for community members. The community:

- Has expressed vulnerability and feels overwhelmed related to threats to community safety
- Has failed to meet its own expectations related to inadequate law enforcement services
- Has expressed difficulty in meeting the demands of change related to an influx of new community members
- Has a successful history of coping with a previous crisis of teenage pregnancy
- Has positive communication among community members
- Has a well-developed program for recreation and relaxation

Such diagnoses can guide communities toward maximizing or improving their health as they plan, implement, and evaluate changes to be measured by established outcome criteria. **Outcome criteria** are measurable standards that community members use to measure success as they work toward improving the health of their community. Outcome-based or evidence-based nursing practice applies to aggregates in the community as well as to patients in acute-care settings.

The nursing diagnosis changes over time because it reflects changes in the health status of the community; therefore, diagnoses need to be periodically reevaluated and redefined. The changing diagnosis can be a useful means of moving a community toward improved health because it gives community members a clear standard against which to measure progress.

## PLANNING TO MEET THE HEALTH NEEDS OF THE COMMUNITY

**Planning** is the logical decision-making process used to design an orderly, detailed series of actions for accomplishing specific goals and objectives. Planning for community health is based on assessment of the community and the nursing diagnoses formulated, but assessment and diagnosis alone do not prescribe the specific actions necessary to meet clients' needs. Knowing that a group of mothers at the well-child clinic need emotional support does not tell the nurse what further action is indicated. A diagnosis of culture shock (adjustment deficit to a contrasting culture) for a family newly arrived from Cuba does not reveal what action to take. The nurse must systematically develop an appropriate plan (see Levels of Prevention Pyramid).

## LEVELS OF PREVENTION PYRAMID

**SITUATION:** Desire to reduce the incidence of child abuse in a given community by 50% within 2 years.

**GOAL:** Using the three levels of prevention, negative health conditions are avoided, or promptly diagnosed and treated, and the fullest possible potential is restored.

Tertiary Prevention		
Rehabilitation	Health Promotion & Education	Primary Prevention
<ul style="list-style-type: none"> <li>Establish rehabilitation programs for abused children, including safe home placement, physical and emotional treatment, and self-esteem building</li> <li>Rebuild the family unit if appropriate or possible</li> </ul>	<ul style="list-style-type: none"> <li>Provide family life education programs for families</li> <li>Develop resources to support health promotion programs</li> </ul>	<ul style="list-style-type: none"> <li>If unable or inappropriate to rehabilitate the abuser or family, keep abuser away from victim through incarceration or court order</li> </ul>
Secondary Prevention		
Early Diagnosis	Prompt Treatment

## Tools to Assist with Planning

Planning for community health care provision and programs can be enhanced by using various tools, including operational definitions of objectives and activities, conceptual frameworks, and models (Epstein et al., 2002; Kalos, Kent, & Gates, 2005). Such tools help to identify target population characteristics, clarify program goals, specify nursing interventions, and anticipate client outcomes. Tools that assist with planning also enable the nurse to test ideas and adjust solutions before actual implementation. Finally, the use of standardized tools enhances the planning process and promotes effectiveness of services, as well as professional standards of practice.

In addition to using tools, a systematic approach to planning guides the community health nurse to list needs in order of priority, establish goals and objectives, and record

the plan. As they do in the rest of the nursing process, community health nurses collaborate with clients and other appropriate professionals throughout each of these planning activities.

## The Health Planning Process

The health planning process is a four-stage system used to design new health-related programs or services in the community. It is often used by health educators when designing educational programs, or by administrators in community health agencies when initiating new services, and it can be used by other people who are not nurses when developing services. The nursing process is similar to the health planning process (Table 15.6). Each model helps to promote service effectiveness in addition to maintaining standards of practice. Community health

Health Planning Process	Nursing Process
<b>1. ASSESSMENT STAGE</b> Determine data needed and collect data. Interpret data and identify needs. Set goals based on needs.	<b>1. ASSESSMENT</b> Formulate nursing diagnoses.
<b>2. ANALYSIS AND DESIGN</b> Analyze findings and set specific objectives. Design alternative interventions. Analyze and compare pros and cons of various solutions.	<b>2. DIAGNOSIS</b> Formulate nursing diagnoses.
Create a plan.	<b>3. PLANNING</b> List needs in order of priority. Establish goals and objectives. Write an action plan.
<b>3. IMPLEMENTATION STAGE</b> Describe how to operationalize the plan. Design a method for monitoring progress.	<b>4. IMPLEMENTATION</b>
<b>4. EVALUATION STAGE</b> Examine costs and benefits of proposed solution. Judge the potential outputs, outcomes, and impact of plan. Modify to achieve the best plan. Present plan to sponsoring group or agency. Obtain acceptance (and funding).	<b>5. EVALUATION</b>

nurses familiar with both the health planning process and the nursing process should be able to work collaboratively with community health professionals using either model.

### Setting Priorities

**Priority setting** involves assigning rank or importance to the identified needs to determine the order in which goals should be addressed. There are numerous ways to set priorities in the planning process. The WHO (1976) and later, Shuster and Goeppinger (2004) identified useful criteria that

can guide ranking problems for order of action. They are presented here as a combination of criteria:

1. Significance of the problem or the number of people affected in the community
2. Level of community awareness of the problem
3. Community motivation to act on the problem (or, Is this important to the community?)
4. Nurse and partnership's ability to reduce risk and/or influence the solution
5. Cost of risk reduction in terms of financial, social, and ethical capital
6. Ability to identify a specific target population for an intervention
7. Availability of expertise to solve the problem within the partnership, coalition, or community
8. Severity of the outcome if left unresolved or the consequences of inaction
9. Speed with which the problem can be resolved

For example, a community assessment revealed that a group of elderly residents living within a specific zip code were fearful of crime, but also identified the lack of public transportation as issues to be addressed. Using the above criteria, the community health nurse working in this community identified that 85% of residents of the community had fears about crime but did not see transportation as an issue. The residents saw crime as an important concern and were also motivated to act on the crime issue, but were not willing to explore the transportation issue at the current time. The nurse, along with the community coalition partners, would be better able to influence the crime problem by helping to form Town Watch groups and getting the local police district to provide increased patrols during evening hours when robberies were more likely to occur. However, the partners had little influence to extend the hours of operation on buses or influence the creation of new bus routes. Members of the coalition included the local police chief, and chamber of commerce director. If the crime problem was left unchecked, more people could be adversely affected, including businesses, because people would not be willing to leave their homes to shop or might even be forced to move away. Finally, these initiatives could be put in place rather quickly and inexpensively after the formation and training of volunteer Town Watch groups. There certainly are no adverse social, economic, or ethical consequences attached to addressing this problem. Therefore, it would seem that the crime issue would take priority over the transportation issue. It is important to remember that each community diagnosis is examined separately and then compared. Priorities for action are discussed, ranked, and then prioritized for action. Criteria for prioritizing health problems in the community include:

- ◆ Numbers of community members affected by the problem
- ◆ Community awareness of the problem
- ◆ Ability of team to reduce risk or influence the problem
- ◆ Cost of risk reduction (social, economic, and ethical)
- ◆ Ability to clearly identify a target or risk population

- ◆ Availability of expertise
- ◆ Consequences of inaction
- ◆ Speed of resolution (WHO 1976; Shuster & Goepinger, 2004)

## Establishing Goals and Objectives

Goals and objectives are crucial to planning and should be feasible and specific (Anderson, Guthrie, & Schirle, 2002). The diagnosis that identifies needs must be translated into goals to give focus and meaning to the nursing plan. **Goals** are broad statements of desired outcomes. **Objectives** are specific statements of desired outcomes, phrased in behavioral terms that can be measured. Target dates for expected completion of each objective are also stated. Objectives are the stepping-stones to help one reach the end results of the larger goal. For the elderly group concerned about crime in the neighborhood, the need, the goal, and the objectives were defined as follows:

- ◆ *Need:* The group of elderly people has altered coping ability related to their fear of crime.
- ◆ *Goal:* Within 6 months, this group of elderly people will be free to walk the streets of their neighborhood without experiencing any incidents of criminal assault.
- ◆ *Objectives:*
  1. By the end of the first month, a safety committee (composed of senior citizens, nurses, police, and other appropriate community members) will be established to study the crime patterns in the neighborhood.
  2. The safety committee will develop strategies for crime reduction and elder protection, which will be presented to the city council for approval by the end of the third month.
  3. Safety strategies, such as increased police surveillance, Town Watch patrols, and escort services, will be implemented by the end of the fifth month.
  4. By the end of the sixth month, nursing assessment will determine that senior citizens feel free to walk about the neighborhood.
  5. By the sixth month, there will be no reported incidents of criminal assault.

Development of objectives depends on a careful analysis of all the ways in which one could accomplish the larger goal. One should first select the course of action that is best suited to meet the goal and then build objectives. For the group of elderly people, other alternatives, such as staying indoors or always walking in pairs, were considered and rejected. The ultimate choice was to find a way to make their environment safe and enjoyable.

Some rules of thumb are helpful when writing objectives. First, each objective should state a single idea. When more than one idea is expressed—as in an objective to both obtain equipment and learn procedures—it is more difficult to measure the completion of the objective. Second, each objective should describe *one* specific behavior that can be measured. For instance, the fourth objective from the list states that the seniors will report feeling free to walk outdoors within 6 months. It describes a behavior that can be

measured at some point in time. One can more readily evaluate objectives that include specifics—such as what will be done, who will do it, and when it will be accomplished. Then it is clear to everyone involved exactly what has to be done and within what time frame. Writing measurable objectives makes a tremendous difference in the success of planning. (See Chapter 11 for more information on writing behavioral objectives.)

Planning means thinking ahead. The nurse looks ahead toward the desired end and then decides what intermediate actions are necessary to meet that goal. Sometimes, an objective itself describes the intermediate actions. At other times, an objective may be further broken down into several activities. For example, the second objective states that the safety committee will be charged with developing strategies, presenting them to the city council, and gaining their approval. Good planning requires this kind of detail.

Making decisions is an important part of planning. Decisions must be made during the process of establishing priorities. Decisions are necessary for selecting goals and for choosing the best course of action from many possible courses. Further decision making is involved in selecting objectives and taking action to accomplish the objectives.

To facilitate planning and decision making, the community health nurse involves other people. Clients must be included at every step because they are the ones for whom the planning is being done. Without their insight and cooperation, the plan may not succeed. Additionally, the involvement of other nurses may be important. Team meetings, nurse-supervisor conferences, and nurse-expert consultant sessions are all useful resources for planning. In addition, you may wish to confer with members of other health and professional disciplines (e.g., teachers, social workers, mental health professionals, city planners). Interdisciplinary team conferences are valuable for gaining a broader perspective and enlisting wider support for the evolving plan.

## IMPLEMENTING PLANS FOR PROMOTING THE HEALTH OF THE COMMUNITY

**Implementation** is putting the plan into action. The activities delineated in the plan are carried out by the nurse, other professionals, or clients. Implementation is often referred to as the action phase of the nursing process. In community health nursing, implementation includes not just nursing action or nursing intervention but collaboration with clients and perhaps other professionals. When bringing about change in a community organization, “implementation involves preparing a timeline for completion of each program objective, obtaining the necessary funding, collaborating with agencies outside the community as needed, recruiting additional community volunteers needed for program implementation, and actually putting into action the interventions designed during the planning phase” (Anderson, Guthrie, & Schirle, 2002, p. 44). Certainly, the nurse’s professional expertise and judgment provide a necessary resource to the client group. The nurse is also a catalyst and facilitator in planning and activating the action plan. However, a primary goal in community health is to help people

learn to help themselves in achieving their optimal level of health. To realize this goal, the nurse must constantly involve clients in the deliberative process and encourage their sense of responsibility and autonomy. Other health team members may also participate in carrying out the plan. All are partners in implementation.

## Preparation

The actual course of implementation, outlined in the plan, should be fairly easy to follow if goals, expected outcomes, and planned actions have been designed carefully. Professionals and clients should have a clear idea of *who, what, why, when, where, and how*. Who will be involved in carrying out the plan? What are each person's responsibilities? Do all understand why and how to do their parts? Do they know when and where activities will occur? As implementation begins, nurses should review these questions for themselves, as well as for clients. This is the time to clarify any doubtful areas, thereby facilitating a smooth implementation phase.

Even the best planning may require adjustments. For example, some nurses who planned a health fair for seniors discovered that the target group would not have transportation to the site because the volunteering bus company had withdrawn its offer. To smoothly implement the plan, the nurses arranged for volunteers from local churches to pick up the seniors, bring them to the health fair, and deliver them afterward to their homes. Implementation requires flexibility and adaptation to unanticipated events.

## Activities or Actions

The process of implementation requires a series of nursing actions or activities:

1. The nurse applies appropriate theories, such as systems theory or change theory, to the actions being performed.
2. The nurse helps to facilitate an environment that is conducive to carrying out the plan (e.g., a quiet room in which to hold a group teaching session or solicitation of support from local officials for an environmental cleanup project).
3. The nurse and other health team members prepare clients to receive services by assessing their knowledge, understanding, and attitudes and by carefully interpreting the plan to clients. This interaction nurtures open communication and trust between nurse and clients. Professionals and clients (or representatives if the aggregate is large) form a contractual agreement about the content of the plan and how it is to be carried out.
4. The plan is carried out, or modified and then carried out, by professionals and clients. Modification requires constant observation and interchange during implementation, because these actions determine the success of the plan and the nature of needed changes.
5. The nurse and the team monitor and document the progress of the implementation phase by process evaluation, which measures the ongoing achievement of planned actions.

## EVALUATING IMPLEMENTED COMMUNITY HEALTH PLAN

Evaluation is usually seen as the final step, but since the nursing process is cyclic in nature, the nurse is constantly evaluating throughout the entire process. For instance, in the assessment phase, the nurse must evaluate whether the collected data are sufficient and appropriate to beginning planning. Evaluation methods must be addressed “in the planning phase, when goals and measurable objectives are established” and interventions are identified (Shuster & Groeppinger, 2004, p. 369). **Evaluation** refers to measuring and judging the effectiveness of goal or outcome attainment. Too often, emphasis is placed primarily on assessing client needs and on planning and implementing service. The nursing process is really not complete until evaluation takes place. Actually, if you look at the nursing process as cyclical instead of linear, then the evaluation guides the next assessment (Tembreull & Schaffer, 2005). How effective was the service? Were client needs truly met? How has health status changed? Professional practitioners owe it to their clients, themselves, and other health service providers to fully and effectively evaluate a program (see From the Case Files II).

As stated earlier, evaluation is an act of appraisal in which one judges value in relation to a standard and a set of criteria. Evaluation requires a stated purpose, specific standards and criteria by which to judge, and judgment skills.

## Types of Evaluations

To determine the success of their planning and intervention, community health nurses use two main types of evaluation: formative and summative evaluation. The focus of *formative* evaluation is on process during the actual interventions. *Summative* evaluation focuses on the outcome of the interventions: Did you meet your goals? In formative evaluation, performance standards are developed and used to determine what is and is not working throughout the process (Anderson, Guthrie, & Schirle, 2002). They could include the physical and organizational structure of the agency, as well as resources that provide a foundation for any interventions. Formative evaluation essentially looks at the step-by-step process of program implementation. Could I do anything better or differently to increase my desired outcome? An example would occur when looking at the poor attendance at two sessions of an evening health-promotion class for senior citizens. The nurse identifies the reason for poor attendance as being seniors' reluctance to attend an evening class because they either don't drive at night or fear coming out in the dark. The class is rescheduled for mid-morning, and the attendance dramatically increases.

Summative evaluation examines outcomes of the interventions. The *effect*, or degree to which an outcome objective has been met, informs the agency or program leader of the program's impact on clients' health. As an example, one manufacturing company had an 80% adherence rate for employees who were supposed to wear proper protective devices (goggles, safety shoes, and hard hats) in the plant. Noncompliance on the part of some workers was a concern to union representatives, the health and safety team, and the company management. They were concerned that 20% of their

## From the Case Files II

### Evaluating Outcomes of a Home Care Postpartum Program

#### Scenario

As a nurse working as the liaison between Capitol City Hospital and its home health agency, you are given the job of reviewing your early postpartum discharge program. Your program has been in effect for 18 months. Client satisfaction is high. The program has increased revenue for the hospital as many clients choose to deliver at Capitol City Hospital because of the early discharge program.

The protocol for your early discharge program includes a postpartum home visit by an RN from the home health agency. These visits are provided as a service to the client. In some cases, visits are billable to insurance companies. Medicaid authorizes payment for one postpartum visit.

You have gathered the following information about the early discharge program:

- I. Protocol: Standard is one visit within 48 hours after discharge which includes:
  - A. Education
    1. Newborn care
    2. Breast-feeding
    3. Warning signs warranting follow-up (mother and baby)
      - Infection
      - Hemorrhage
    4. Comfort
    5. Parenting
    6. Sexuality
      - Resumption of sexual activity
      - Contraception
    7. Community resources
    8. Nutrition
    9. Well and sick baby care
  - B. Assessment
    1. Infant: Jaundice (heel stick performed if necessary)  
Mother: Hemorrhage, perineal lacerations, hematomas  
Both: Nutrition
      - Weight
      - Hydration
      - Breast-feeding
    2. Elimination
- II. Cost:
  - A. Fully reimbursed by some insurance companies
  - B. All mother/baby dyads receive postpartum visits, regardless of insurance coverage
  - C. Optional or additional methods of reimbursement have not been explored by the agency
  - D. Agency makes money on reimbursed visits, loses money on non-reimbursed, but additional revenue generated by clients choosing the hospital because of the positive public perception. The program is thought to balance out cost of nonreimbursed visits.

**Outcomes.** Outcomes of postpartum early discharge with accompanying home visit (as compared to traditional length of postpartum stay)

- I. Positive
  - A. Higher percentage of successful (at least 2 months) breast-feeding
  - B. Higher rate of immunization compliance
  - C. Fewer inappropriate emergency room visits
  - D. High client satisfaction
  - E. Lower levels of maternal stress reported to pediatricians
- II. Negative
  - A. Higher incidence in jaundice in babies whose mothers participated in the early discharge program

### Questions

1. What, if any, additional information do you need to make a recommendation regarding the program?
  - How will you obtain this information?
2. As the nurse making a recommendation for the continuation or termination of the postpartum early discharge program, what are your recommendations?
  - Should the program be abandoned?
  - Should the program be maintained?
3. What, if any, alterations would you make in the following areas:
  - Funding
  - Protocol
    - Client education
    - Assessment
    - Timing of visit
4. Outcome measurements are critical to demonstrate the efficacy of this program.
  - What will you evaluate?
  - How often?
  - Why?

employees were at risk for injury that would cause pain, suffering, loss of work time, disruption to the manufacturing process, and reduced profitability. The occupational health nurse along with the safety officer began a month-long safety campaign that included safety mini-classes, posters, and incentives for departments with 100% safety equipment adherence. Three months after the program, 95% of the employees were adhering to the safety regulations. This 15% increase was attributed to the effect of the safety program. See Chapter 12 for more on program evaluation.

The *impact* of a program determines how close it comes to attaining its goals. In the earlier example, the objective of the safety campaign was to increase safety equipment use, and use was significantly increased as a result of the program. However, if the goal of the program had been to decrease accidents and save the company money, the result could be determined only with additional information. Were there fewer injuries caused by accidents? Were there fewer days lost to injuries? Did the company save money as the direct result of employee safety adherence? Depending on the answers to these questions, the overall goal of the program may or may not have been met, even though the objective of the program was met. The full impact of the program cannot be determined without additional data. See Chapter 12 for more on program evaluation.

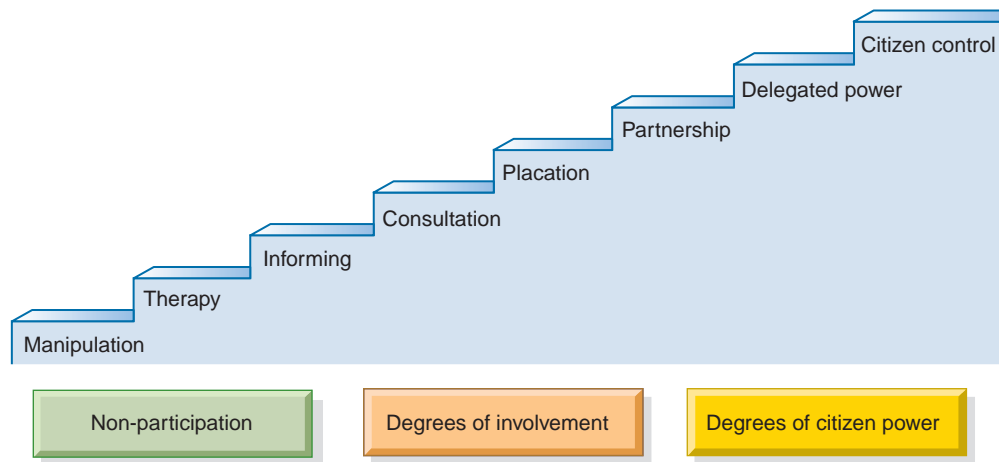

## Community Development Theory

An outcome of effective community level nursing practice is community development. **Community development** is the process of collaborating with community members to assess their collective needs and desires for positive change and to address these needs through problem-solving, the use of community experts, and resource development (Seng et al., 2005; Fawcett et al., 2000; Green, 2000; Green, Daniel, & Novick, 2001). A community development perspective assumes that community members participate in all aspects of change—assessment, planning, development, delivery of services, and evaluation. With

this approach, the focus is on healthful community changes generated from within the community, as a partnership between health care providers and inhabitants, rather than a commodity dispensed by health care providers (McLennan & Lavis, 2006; Tembreull & Schaffer, 2005; Zahner, Kaiser, & Kapelke-Dale, 2005). Chapter 11 details community change theory.

The outcomes are more positive when community members have a sense of ownership in the health programs and services that address their needs (Sharpe, Greaney, Lee, & Royce, 2000; Timmons et al., 2007). This enhances empowerment among members of the community and enables them to more effectively control and participate in transforming their environment and their personal circumstances. This implies that health care agency infrastructures are appropriate additions to services that are planned and delivered in an acceptable manner to the community (see Fig. 15.6, Arnstein's Ladder). See Chapter 13.

When applying community development theory, the agent of change (often the community health nurse) is considered a partner rather than an authority figure responsible for the community's health. To achieve acceptance as a partner, the nurse must listen and learn from the community members, because they are the experts with respect to their health care needs, culture, and values (Timmons et al., 2007; Kreuter, Lezin, & Young, 2000; Pan et al., 2005). They have mastered adaptation to the community, and they have first-hand knowledge of prevention methods and interventions that are appropriate to their lifestyles. For example, a study was conducted with 690 women from 18 impoverished inner-city neighborhoods in five cities. Women who were considered by peers to be opinion leaders conducted human immunodeficiency virus (HIV) risk-reduction workshops and community HIV prevention events. There was evidence that significant changes in health behaviors to prevent HIV infection occurred among the women who attended these events (Sikkema et al., 2000). The principles of community-based participatory research also

**FIGURE 15.6** Arnstein's Ladder—Eight steps of citizen participation. Adapted from Arnstein, S.R. (July 1969). A ladder of citizen participation. *Journal of the American Institute of Planners*, 217–224.

involve this type of partnership (see Chapters 13 and 25 for more information on this subject). Members of the community are engaged as co-researchers, and time is spent building trust and developing collaborative relationships with community members, stakeholders, and neighborhood health care providers. The expertise of community members is valued and can be useful in designing recruitment strategies, as well as in data analysis (Savage et al., 2006). This experience can enrich the community as a whole, as well as the actual participants.

The outcomes of the services provided by any organization can be benchmarked against those of other groups. *Benchmarking* involves comparing an organization's outcomes against those of a similar organization or an organization that is known for its excellence in a particular area of client care (Nolan & Mock, 2000; Wojner, 2001). Information from this comparison can be used to identify an organization's areas of weakness and to focus attention on specific outcomes. The establishment of *best practice* activities entails “continuous, collaborative, and systematic processes for measuring and examining internal programs' strengths and weaknesses” (Lewis & Latney, 2002, p. 24).

From a global perspective, the Conference on Primary Health Care held at Alma-Ata in 1978 concluded that people have little control over their own health care services and that the emphasis should be on health problems identified by the members of the community in their attempts to attain a state of wellness (WHO, 1998). Since that time, the WHO, along with other agencies and groups, has been providing leadership in the use of community development methods to improve global health, based on the following concepts (Community Development Society, 2007):

- ◆ Promote active, representative participation to influence decisions affecting community members' daily lives
- ◆ Engage community members in economic, social, political, environmental, psychological, and other issues that impact them

- ◆ Interest them in learning more about alternative courses of action
- ◆ Incorporate diverse cultures, ethnic and racial groups, and varied interests in the process of community development
- ◆ Refrain from supporting efforts that are likely to adversely affect disadvantaged members of the community
- ◆ Actively work to build leadership capacity of community leaders and groups, and individuals
- ◆ Work toward long-term sustainability and community well-being

## Summary

Characteristics of healthy communities include those elements that enable people to maintain a high quality of life and productivity by increasing health and decreasing disease and disparities in health and health care delivery. The effectiveness of community health nursing practice depends on how well the nursing process is used as a tool to enhance aggregate health. The nursing process involves appropriate application of a systematic series of actions with the goal of helping clients achieve their optimal level of health. The components of this process are assessment, diagnosis, planning, implementation, and evaluation.

The concept of community as client refers to a group or population of people as the focus of nursing service. The community's health is reflected in its status (e.g., morbidity and mortality rates, crime rates, educational and economic levels), structure (availability, use and quality of services and resources), and processes (how well it functions in regard to its strengths and limitations). The dimensions of a community's health may be seen in regard to its location (e.g., climate, vegetation, boundaries), population (e.g., diversity or homogeneity, old, young, pregnant, addicted, or academic members), and social systems (e.g., schools, businesses, communications, health care, and religious organizations, among others).

Interaction is deeply integrated in the nursing process. Because nurse and clients must first establish a relationship of reciprocal influence and exchange before any change can take place, interaction could be considered the most essential step in the process. Effective communication is inherent in assessing needs and establishing trust between nurse and clients as partners in the nursing process. The first steps in interacting involve understanding group behaviors and dynamics, followed by interpersonal communication at the group level in the form of listening, teaching, building trust, seeking client involvement, sharing, and collaborating to build partnerships and teams.

Assessment for community health nurses means collecting and evaluating information about a community's health status to discover existing or potential needs and assets as a basis for planning future action. Assessment involves two major activities. The first is collection of pertinent data, and the second is analysis and interpretation of that data.

Community health nurses may use various assessment methods to determine a community's needs. They include *familiarization assessments*, such as windshield surveys, which involves studying data already available on a community; *problem-oriented assessment*, which focuses on a single problem and looks at the community in terms of that problem; *community subsystem assessment*, by which the community health nurse focuses on a single dimension of community life; a complicated and time-consuming *comprehensive assessment*, to discover *all* relevant community health information; or an *assets assessment* that focuses on the strengths of a community as opposed to its deficits.

Community data may be provided by surveys, descriptive epidemiologic studies, community forums or town meetings, focus groups, and primary and secondary sources, such people who are familiar with the community and its character and history, websites, government departments and agencies that compile statistics, such as the Bureau of the Census, the county health department and others. Sources can include national international, state, county, and local agencies, as well as business and social organizations.

Using the nursing process in the community would not be complete without looking at the role of the community health nurse as a catalyst for community development. Community development theory is the foundation that supports citizen empowerment and use of key players in the community to plan for the health and safety of that community. ■

lation, and social system variables you would want to assess? Name some of the sources from which you might collect the data.

4. Discuss under what circumstances you might choose to conduct a problem-oriented community health assessment. What method would you consider using to conduct this assessment, and how would you carry it out?
5. Interview someone from your state or local health department who has recently conducted a community needs assessment survey. Analyze the process used, and compare it with the steps for conducting a survey described in this chapter.
6. Use the Internet to contribute your ideas in response to a health-related survey taken by a television show, newspaper, or magazine, or share your opinions in a health-related chat room.

## Global Health and International Community Health Nursing

### LEARNING OBJECTIVES

*Upon mastery of this chapter, you should be able to:*

- ◆ Describe a context and framework for delivering community based nursing within the context of international community health nursing.
- ◆ Describe the major health care conditions currently affecting the world's populations and the types and preparation of health care workers addressing them.
- ◆ Describe the community health nursing interventions and strategies commonly used within an international context.
- ◆ Recognize the factors that influence populations' perceptions of health and health status and their receptivity to community health nursing programs.
- ◆ Describe the personal and professional perceptions and biases you bring to providing community health nursing interventions within an international context.
- ◆ Identify the major international, national, regional, and local organizational structures and organizations that affect the ways in which community health nursing is practiced.
- ◆ Locate relevant resources as a basis for planning the assessment, implementation, and evaluation of community health nursing within an international context.

*“Our country is the world—our countrymen are mankind.”*

—William Lloyd Garrison, American abolitionist (1805–1879)

### KEY TERMS

Community health worker (CHW)  
Control  
Disability-adjusted life year (DALY)  
Elimination  
Era of Chronic, Long-Term Health Conditions  
Era of Infectious Diseases  
Era of Social Health Conditions  
Eradication  
Global burden of disease (GBD)  
Global nursing  
Health for All  
Integrated Management of Childhood Illness (MCI)  
Multilateral agencies  
Oral rehydration therapy (ORT)  
Pluralistic health care systems  
Primary Health Care (PHC)  
Universal Imperatives of Care  
World Bank (WB)  
World Health Assembly (WHA)  
World Health Organization (WHO)  
World Health Organization Collaborating Centers

Let us suppose that you have completed your schooling and are ready to embark on a career in global community health nursing. **Global nursing** can range from providing clinical services to policy making at an international level. Perhaps you engaged in several years of successful clinical practice and are interested in pursuing an international opportunity to practice nursing in another country. You undertake a search of the World Wide Web, you talk to professional colleagues, and you read articles in nursing and other professional and popular journals.

You quickly realize that researching health care is a rather awesome undertaking, and the search for health care opportunities within a global context is even more of a challenge. You also learn that health care is complex, and that it affects and is affected by multiple factors that have to do with geography, history, politics, culture, religion, and a nation's wealth. You also learn that some countries' data are difficult to access, and you realize this may be because a country has been involved in a long, protracted civil war, or has experienced continuous cycles of disasters or financial collapse.

In your search, you also find that people's conception of health, wellness, and illness varies from culture to culture, and that the ways in which they view nurses and other health care providers is affected by their culture and belief systems. You will also notice patterns across countries and regions regarding who lives, who dies, the way people function on a day-to-day basis, the health care decisions they make, and the cost of the care they receive (Display 16.1).

In your search, you also will learn a great deal about the health care providers that countries look to for nursing care and medical treatment. You will notice a disparity between the health status and health conditions of people in a country, as well as the kind of health care providers educated and practicing in that country. You may become sensitized to the difference between your kind of nursing education and that of the nurses in countries different from your own. The ways in which one is recruited and educated do vary from country to country, as does legislation regarding licensure and entry to practice.

You will come across hundreds of references to international, national, and regional agencies that work in health care internationally. These references will be organized according to international agencies, national governments, churches, and nongovernmental organizations, including those with religious affiliations and universities.

Finally, you will see that the ways in which community health nursing is practiced in an international context are influenced by all these factors and by your own orientation, values, cultural beliefs, and education. These factors and issues constitute a global framework for community health nursing, and they are the foci of this chapter.

This chapter begins with a framework you can use to organize your thinking and around which you can structure

your search as you expand your repertoire of knowledge and understanding. Those of us who work abroad need this kind of framework in which to place our searches, professional dialogues, and readings. We also need a way of thinking about the regions of the world or countries in which we would like to practice and about the kinds of community health nursing interventions a country may need, given the elements described here.

## A FRAMEWORK FOR GLOBAL COMMUNITY HEALTH NURSING

### The Three P's

To guide your thinking, consider a global framework bounded by a context and including three parts, the three "P's." These are: the population, the provider, and the procedure. In community health nursing, we speak about populations rather than about patients. The provider refers to the health care team which may include a community health nurse, a physician, a midwife, an "injector" (someone who is trained to only give injections), or a community health worker (CHW). The procedure refers to the interventions health care providers implement for or with populations.

### Three Eras of Health Conditions

In this global framework, alongside the three P's, think about three *eras* of health and health conditions. During our ancestors' time, people easily contracted the plague, tuberculosis, puerperal fever, and other infectious diseases. Entire populations were sometimes eliminated through these infections. During this first era, families had many children, as they knew that most children would die before adulthood and without any form of social security, children were their parents' only source of livelihood. This is referred to as the **Era of Infectious Diseases**. With the advent of antibiotics, it became usual for people to survive common infections. Children began to survive much longer than did their parents, but often they suffered from chronic, long-term illnesses such as heart disease, cancer, and debilitating arthritis (Cox, 2005). This is referred to as the **Era of Chronic, Long-Term Health Conditions**. Despite changes and advances in health care, people continued to produce large families because of the cost or absence of birth control measures, persistent religious beliefs that influenced families regarding birth, and the intent of countries—such as Romania (before 1989)—to increase their populations for financial reasons. More recently, a new array of health conditions is affecting world populations, including addictions and obesity, and social conditions such as prostitution and deviant behavior. These are examples from the **Era of Social Health Conditions**. The popular press has exposed many of these conditions through documentaries on the effects of methamphetamine on entire communities, the obesity epidemic sweeping countries throughout the world, and the slave trade of young children (Medical News Today, 2005).

### Continuing Emerging Health Conditions

Today, the communities of the world are experiencing all three eras of health conditions. In one community, a population may be dealing simultaneously with avian (bird) influenza, heart

#### DISPLAY 16.1

#### DEFINITION OF HEALTH

Health is a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity.

Source: World Health Organization Constitution

disease, cancer, and adolescent prostitution. Most of these health conditions have been present for many years, some for thousands of years. Twenty-five years ago, public health specialists believed that infectious diseases would soon play a minor role in health. However, they are still the world’s leading cause of death, and some of the newly identified infectious agents have developed into public health challenges that confront countries worldwide (WHO, 1998b). This chapter examines the context in which these conditions occur, the health care providers who work with them, and the ways in which interventions are applied through the work of many sponsoring global health organizations.

### Universal Imperatives of Care

In addition to the three P’s and the three eras of health conditions, community health nurses need to consider the current status of health in the community of interest. The **Universal Imperatives of Care** is one useful paradigm. These imperatives include: mortality, morbidity, daily functioning, decision-making, and cost. This paradigm underscores the notion of *first things first*. That is, one must be alive and well before interventions focus on functioning or decision-making (Fig. 16.1).

#### Mortality

A government’s first priority is to keep its population alive and free from illness. This is critical if a country is to survive, protect itself, and feed its population. In this regard, community health nurses may be frustrated that the disabled are going without community resources, or programs are not created to help couples make informed decisions about abortion and birth control. However, when countries are poor, they will focus on mortality and the evidence-based interventions that will ensure the survival of the people (Farrell, 2006). When mortality is a priority, the physician will be the valued health care provider.

#### Morbidity

When people are not dying, a country will focus on its population morbidity—the conditions that make people sick—and will look to physicians and nurses for assistance. Sicknes derives

from infectious diseases, long-term chronic health conditions, and the social conditions (discussed in upcoming sections).

#### Daily Functioning

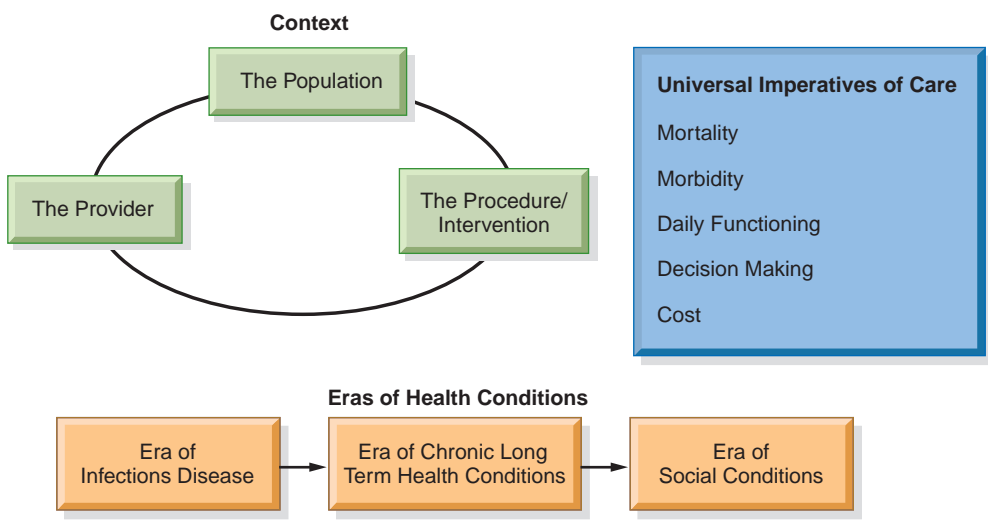

In many countries, the ability to care for oneself—to bathe, secure food, and carry out other activities of daily living—are the purview of social services and social workers, or, for the elderly, of nursing homes. However, in some countries, social workers are not part of the health care team and these functions are left entirely to the family. This is not because the government is negligent. It is because the universal imperatives in a country with constrained resources must focus on the necessities first.

#### Decision-Making

In order to choose, one needs options. In countries where there is only one health care delivery provider, there are no options. As countries have expanded to include privatization, and as people increasingly have access to the World Wide Web, they have generally evolved in their decision-making processes about the providers they will use and the sources of their health information.

#### Cost

In many countries in the past, the state provided all health care, and all costs were the burden of the community. Increasingly, these health services are being rationed, restricted, or placed under insurance schemes. Nations are forced to weigh the cost of managing some health conditions over others. Most of the time, they opt for those that can be addressed with the least input and the maximum benefit. This is, in part, the reason that the Era of Social Conditions is not being addressed in many countries. The interventions that will reduce the incidence of these conditions are largely unknown, and the knowledge and research needed to access them are well beyond many countries’ resources, thus encouraging these countries to work increasingly with the international community. Many countries do not have the resources to support the necessary research and programming to address the issues that may involve them and their border countries.

**FIGURE 16.1** Framework for global community health nursing (M. Farrell, 2006).

## THE CONTEXT

### A Context of Interdependency

The context of community health nursing suggests considering one planet of interdependent nations. This interdependence relates to virtually all areas of life, including health. As systems theory suggests, what happens in one country affects many others in important ways (Friedman, 2005). For example, air travel can transport health problems from a country halfway around the world to new communities in less than a day.

Human immunodeficiency virus/acquired immunodeficiency disease (HIV/AIDS) began in Africa and is now pandemic because communicable diseases know no geographic boundaries. In New York, in the fall of 1999, 61 severe cases and seven deaths were reported from a mysterious viral illness later identified as the West Nile virus, which had not previously been reported in the United States. Researchers now speculate that the virus may have traveled to the United States in smuggled exotic birds. The virus was closely related genetically to strains found in the Middle East (Centers for Disease Control and Prevention [CDC], 2000). Within two years, 3,737 cases of West Nile Virus and 214 deaths had occurred in 39 states. Evidence of infections in birds, humans, mosquitoes, and other animals has been documented in 43 states and the District of Columbia (CDC, 2002a).

The globalization of food commodities and food safety also affects health. For example, researchers suggest that a causal relationship exists between ongoing outbreaks in Europe of bovine spongiform encephalopathy, or *mad cow disease*, and the human disease called new variant Creutzfeldt-Jakob disease (vCJD). Of the worldwide total of 153 vCJD cases, 143 of these have occurred in the United Kingdom. Cattle are considered the only source of the disease (CDC, 2006). Global health issues become everyone's issues when they spread within or beyond one's borders, when we commit resources to a country in need, when we make a personal commitment to improve the health of a population beyond our shores, and when we import or export food.

The community health nurse works with populations that live in particular parts of the world. These localities are unique, with their own geography and environment, history, cultural traditions, religion, and ideas about health, wellness, disease, and death. Each of these elements constitutes entire disciplines of study and require years of interacting with people to understand the ways in which they affect health care in a particular country.

### Geography and Environment

The environment in which people live includes air, climate, soil, and water, and each of these may undergo changes that turn natural elements into hazardous ones. Humans are exposed to pollutants in two basic ways: by exposure to the source or by release of the pollutant into air or water.

When people use streams and rivers to dispose of body wastes and then use the same body of water for cleaning and washing their clothes, they expose themselves to infections from those waters. When people in villages build their homes around sources of water, they also invite mosquitoes that carry malaria, for instance. In this environment, community health nurses' interventions might include teaching people

the steps to preventing malaria, such as placing netting around a bed during the night, cleaning pools of stagnant water around the home, and covering the body with light cotton clothes (Heymann, 2004).

People throughout the world are affected by the impact of major developments that may occur in their communities over which they have no control. Governmental authorities may build a dam, create a waterway, or move populations to clear land for crops (Reuters News Service, 2006). For example, populations in Ethiopia were moved from one part of the country to another as colonial rulers developed crops for their own use. In the process, they displaced farmers to other areas to grow crops about which they knew little and which were not appropriate for the soil and weather conditions.

Environmental experts have focused on these and other issues, such as the effects on communities when climate changes occur or when weather conditions affect entire regions. The Tsunami in Asia and Hurricane Katrina in the United States are recent examples, sweeping away entire communities (National Geographic News, 2005). Most recently, former United States Vice President Al Gore has brought the world's attention to global warming through his provocative and moving film, *An Inconvenient Truth*, in which he examines the ways in which our current habits and beliefs are affecting the world's temperature and environmental conditions (Bender, David, Chilcott, & Burns, 2006).

Sometimes change is intentional and is made in the interests of survival and daily functioning. For example, when governments address energy concerns for transportation and industry, they may move to nuclear sources of that energy—clearly as an effort to secure a local resource, but also with some risk. The people of Chernobyl found their beloved home a wasteland when the nuclear plant disaster polluted the region with caesium and iodine (*Chernobyl Accident: Information and Issue Briefs*, March 2006). In a follow-up meeting in the Netherlands, representatives spoke of the population's fears and actions, including possessing machines that would measure the radioactivity near their homes. This accident prompted the discussion at this meeting of disaster-preparedness strategies to evacuate entire cities of people after a nuclear environmental accident.

### Classification of Environmental Hazards

The Organization for Economic Co-operation and Development (OECD), World Health Organization (WHO), and others have classified the environmental hazards affecting communities that include the impact of local climate changes on weather patterns and agriculture (OECD, 2006). The Blumenthal Classification lists classes of environmental hazards. They include: infectious agents (e.g., bacteria and viruses), respiratory fibrotic agents (e.g., coal dust), asphyxiates (e.g., carbon monoxide), poison (e.g., pesticides), physical agents (e.g., noise), psychological agents (stressful synergisms such as crowding combined with noise), mutagens (e.g., dioxin), teratogens (e.g., cadmium), and carcinogens (e.g., cigarette smoke).

### Contamination of Water Sources

In places such as Peru, Egypt, Bangladesh, India, Indonesia, and Thailand, raw sewage is released into rivers that are used for drinking and bathing. Such practices often result in

## DISPLAY 16.2

## ENVIRONMENTAL HAZARDS THAT KILL CHILDREN

1. Inadequate drinking water and sanitation
2. Indoor air pollution and accidents
3. Injuries and poisonings

These are just three of the causes of the approximately 3 million deaths suffered annually by children younger than 5 years of age as a result of environmental hazards. Research suggests that more than 40% of the global burden of disease due to environmental risk factors may fall on such young children, who constitute only about 10% of the world's population.

(World Health Organization [2002, March 3], Environmental hazards kill at least 3 million children aged under 5 every year. *Press Release WHO/12*. Geneva: WHO.)

diarrheal diseases, including cholera. In 1991, a cholera outbreak was identified at the port of Chancoy in Peru; it rapidly spread along the coast, over the Andes, and into the Amazon basin, resulting in 400,000 reported cases and 4,000 reported deaths in 13 countries (Whaley & Hashim, 1995). The International Center for Diarrhea Disease Control (ICDDR) in Bangladesh specializes in those illnesses, including cholera, that result from these practices, for which residents know of no alternative.

Five million people die annually from illnesses linked to unsafe drinking water, poor household hygiene, and improper human and animal waste disposal. Every 8 seconds, a child dies of a water-related disease. Half of the population in the poor countries of the world suffers from one or more of the five main diseases associated with water and sanitation—diarrhea, ascariasis, hookworm, schistosomiasis, and trachoma—and one-fourth of the world's population is without proper access to water and sanitation (WHO, 1996) (see Display 16.2).

Water-related diseases arise from the ingestion of pathogens in contaminated water or food and from insects or other water-associated vectors. However, overall progress in reaching people deprived of adequate water and sanitation services has been poor since 1990 (Jamison et al., 2006).

### The Ozone Layer

As the challenge of a depleted ozone layer is addressed, the incidence of cataracts and cancer (especially melanoma and basal cell carcinoma) is reduced. It is believed that human activities are contributing to the depletion of the ozone layer; these activities include the use of chlorofluorocarbons (CFCs) (used in the manufacture of air conditioners, refrigerators, aerosol propellants, and other products) and methyl bromides (found in pesticides and herbicides). Efforts are underway to phase out CFCs in 13 countries, including the United States (The Ozone Hole, 2006).

### History

If you have tea with a group of health care providers in Moscow, the conversation inevitably turns to the devastating

effects of the major historical event that faced that country—World War II. Despite the fact that this war occurred over 60 years ago, it remains in the collective memory of the Soviet people, their leaders, and many others in Eastern Europe, as 20 million Russians died along with thousands of people in other countries. That war, and the war that involved Bosnia–Herzegovina and Serbia, will affect people for decades to come and will influence the ways in which the health care systems of these countries will partner and collaborate with each other in the future.

Throughout the past century, countries throughout the world have been colonized, and they continue in their relationships with former or current colonizing countries. These political relationships also affect the ways in which community health nurses might be recruited and practice. For example, given a country's history, health care providers with particular nationalities or religious backgrounds might not be acceptable to a country. While people in one country might consider these biases unacceptable, they remain as policy in other places, determining whether or not care providers of a particular nationality are allowed to enter and work in a country. These biases are often unexpected and may be puzzling. At first glance, one may wonder why Italy might want to support a disaster preparedness program in Ethiopia. But a review of the historical relationship between Italy and Ethiopia reveals a relationship that preceded the program initiative.

Community health nurses are involved in designing and implementing projects in collaboration with international governmental organizations and non-governmental organizations. The historical context of a country is paramount as people are selected for international positions and projects, for interventions that a community is willing to adopt, and organizations are chosen to intervene in a region.

### Language

Often a language connection exists between countries, and this linkage prompts health officials to seek nurses who speak the same language. For example, common history and language often connect Mozambique, Portugal, and Brazil, which are all Portuguese-speaking countries. Many people from Mozambique immigrated to Portugal during the 1970s, and the shared historical past affects current perceptions about the two countries' relationship with each other. Knowing that a shared language exists among countries may suggest ways of gathering existing health-related teaching and learning materials and can reduce the costs of production and language validation.

A country's political orientation and practices affect the ways in which community health nurses are educated and function daily. For example, in some countries, nurses and midwives were not exposed to the emerging knowledge and practices concerning the HIV/AIDS epidemic. This happened, in part, because countries whose economies depended on tourism were fearful that high numbers of HIV-infected people would frighten away tourists. Consequently, national health policies and announcements denied the presence of the virus, and nurses and midwives were not protected as they collected blood samples, administered injections, and delivered babies.

## Cultural and Religious Context

The culture and religion of a community represent the frame within which people understand who they are, why they are on the earth, and what their purposes are in life (Spector, 2004). Culture and religion influence the knowledge, attitudes, and practices of people about what they think will kill them or make them sick, will help them function or make decisions, or will affect their financial status. People in different cultures manage these in ways that may seem peculiar, ill-advised, immoral, or even criminal to someone outside the society. For example, Illyes, (1969) in the classic book *People of the Puszta*, discusses the cultural practice of suicide in a part of Hungary, the Puszta, where people are characterized as “dirt poor.” Yet, suicide is not a socially accepted option for people in other cultures. In the Philippines, some prostitutes see their activities as their daily work, not as a moral act. Efforts to dismantle the country’s prostitution business have met with negative reactions from the prostitutes themselves, as this is their way of feeding their children and caring for their families (The Official Website of the Republic of the Philippines, 2006).

Community health nurses will face their own beliefs when confronting female circumcision, the use of nonlicensed personnel to carry out medical treatments, and the use of Western interventions used simultaneously with local treatments. For example, in Chad, clients in a Chadian hospital received Western style medical treatment and nursing care through the interventions of French physicians and nurses while lines snaked around the grounds of the hospital to the offices of the two Chinese acupuncturists.

Cultural issues are of concern when individuals and groups of a particular background from one country are often fiercely committed to “helping” their homeland. Here, both donors and recipients need to understand each other and their reasons for entering collaborative relationships. When this is thought through, the results can be most positive. In this regard, Armenian communities benefited enormously from the fundraising efforts of American community health nurses and physicians who knew well the Armenian communities in Boston, parts of Canada, and Los Angeles (Armenia Fund USA, 2006).

## Women and Culture

Women in most societies are viewed in ways that require close scrutiny. They are seen as Madonnas, superheroes, warriors, nurturers, slaves, income producers, objects of sexual desire, concubines, negotiators, angels of mercy, and assistants. Although these characterizations may be repulsive to some, to others, women in their communities have played these roles for so long that they are considered immutable and acceptable. In many countries, nurses are exclusively women and experience these projections as they carry out their daily work. In some places, women have no or little voice and are viewed as weak or ineffectual, despite their physiological hardiness and ability to survive above their male counterparts (Valadian & Farrell, 1995).

Community health nurses may perceive themselves as excellent practitioners with excellent theoretical and clinical backgrounds, and expect to be respected for these qualities. Yet, in another country, their nursing notes may be torn up

(who will read them?), their projects taken over by others (a nurse can’t possibly lead a project), and their research may be published under someone else’s name (anyone can write hypotheses, so what makes these so special?). In some countries, women (and nurses) are not expected to argue with authority, assume a team leadership role, or attend important meetings at high levels (Valadian & Farrell, 1995).

These are challenging situations, some of which become teachable moments. Some may be events that alter the duration of one’s assignment, or provide an opportunity to reframe interactions with others of differing persuasions, beliefs, and practices. Community health nurses need to determine their own position on these issues and come to terms with being placed in subservient positions or in roles that detract from their level of academic preparation, expectations for learning and developing, an ultimately, their sense of self.

## Armed Conflict, Uprisings, Wars, and Humanitarian Emergencies

An armed conflict is defined as major if the number of deaths has reached 1,000. Increasingly, conflicts are internal rather than between states. In their quest for economic and political power, the combatants target the lives and livelihoods of civilians associated with opposing factions. Typically, armed conflicts and uprisings initially cause governments and agencies to place a high priority on health care, but their ability to sustain health care is reduced as time goes on. Countries engaged in armed conflict form internal factions, including those supporting the government and those in conflict against them. Most conflicts occur between states for economic and political power, and approximately 90% of those affected by such conflicts are civilians of all ages (Toole, Waldman, & Zwi, 2001). Sometimes, outside nations support a country’s factions, and fighting escalates and continues until the supporting powers win, lose interest, change their political orientation, or exhaust their source of finance. In this regard, community health nurses need to be aware of those involved in the immediate situation and of those who are influencing the situation from abroad. In turn, funding and sustaining nursing projects may depend ultimately on the local population and on those external sources of support.

Countries that have longstanding conflicts suffer as current health care needs are unaddressed, and the long-term health status of an entire country may be affected—sometimes for decades. For example, Mozambique has endured a national conflict for over two decades. Entire generations of young people have had no formal education and are prepared only to fight. Countries in conflict deflect resources to the battlefield, and those fighting receive whatever resources are available. These conflicts are extremely complex social phenomena, for which the most rooted causes are inequity, cultural and religious intolerance, and ethnic discrimination (Mulli, 1996). The health infrastructure during conflicts and uprisings becomes vulnerable because of the instability. Often, opposing factions raid hospitals and clinics. During the 1989 Romanian uprising, health providers told of instances in which the underground secret police feigned injury, transported themselves in rigged ambulances, and entered the emergency room areas of the capitol’s major hospitals, all in an effort to kill or wound the hospitals’ health care providers.

Between the end of World War II and the end of the Cold War, most conflicts occurred in developing countries in Africa, the Middle East, Asia, and Latin America. After the dissolution of the Soviet Union, major conflicts occurred in the emerging European states, most recently in Yugoslavia (Glenny, 1992; Hall, 1994; Samary, 1995). Wars in other areas of the world also were reignited, such as that between Eritrea and Ethiopia (Global Issues, 2000). We now see similar situations in Iraq (Drum, 2005).

The community interventions that nurses develop are informed by the situation and the layers of conflict that have occurred in the past and those that may be continuing (see From the Case Files I). During national conflicts, health services become disorganized and experience decreased resources. Outside help is needed in these instances, and international help is often available. For example, during the Romanian uprising, members of WHO/EURO's International Disaster Preparedness Team, along with the country's health officials, established an Interim Ministry of Health and identified key areas that required attention. Members of the team, including the Regional Nursing Advisor, met with NATO and COMECON ambassadors in the capitol and communicated the health needs of the population. They remained in Romania and established a WHO office, participating with groups, universities, and organizations to assist the country during this difficult period.

During wars, epidemics are almost inevitable. As conflict goes on, the health care needs of the combatants often take priority over those of civilians; consequently, thousands of children may be injured, orphaned, and at risk for disease. Additionally, conflict disrupts food cultivation, harvest, and distribution, leaving populations at risk for malnutrition and setting the stage for disease. Refugees from such events have special health and social needs. Often refugee camps are developed by international organizations on the fringe of such conflicts to temporarily assist refugees with shelter, food, and the rudiments of health care. Such camps place a strain on the resources of neighboring countries, as illustrated during the recent war in Sudan (United States Fund for UNICEF, 2006).

All of these factors can lead to complex humanitarian emergencies. The Centers for Disease Control (CDC) describes complex humanitarian emergencies as situations that involve large civilian populations, and factors related to war or civil strife, shortage of necessities such as food, and the dislocation of local populations. These situations and these factors result in mortality beyond that expected under

normal circumstances (Burkholder & Toole, 1995; United Nations High Commissioner for Refugees [UNHCR], 2006).

Recovery after war is a long-term project. Any post war recovery effort must deal with the disabled, the mentally ill, prisoners, widows, orphans, abandoned children, homeless and displaced persons, refugees, and the unemployed (Mulli, 1996; Siegel & Watson, 2006). These issues are complex; for example, in some African countries, if a family loses its land and its members cannot plant and harvest crops, the family dies. During the long conflict in that region, many women lost their husbands and their land. They required care from others who had very little to offer them.

In these environments, populations are displaced and people find themselves living in war zones that are strewn with the remnants of the war (Farrell, 1992a; Farrell 1992b; UNHCR, 2006). Land mines have continued to injure or kill long after hostilities have ceased. This issue received international attention from Princess Diana of Wales, who made their removal one of her major projects before her untimely death (The Work Continues, 2006).

## Health Care Systems

Countries throughout the world have developed health care systems that they organize and structure in particular ways. When community health nurses find themselves in locations different from their own, they notice differences immediately, and their ability to focus on these differences, and even to document them, is critical. The capacity to reflect on one's consciousness is an essential skill as one considers the ways in which people expect to govern others, to provide people with what they need, determine who gets served and who does not, establish lines of authority and communication, and establish payment systems for health care services.

Important questions arise as one delivers community health nursing services within a country's health care system. For example, if a client has to wait 6 months for an elective operation, what does she do in the meantime? If a government provides all prenatal and obstetrical services, but will not instruct couples on birth control, how do couples manage, and how do health authorities deal with prevalent practices that result in an abortion rate that is three times the birth rate (Farrell, M. et al., 1994) or that allow *under the table* reimbursement for these services? If a ministry of health is administered in a centrally governed model of decision making, how do

### From the Case Files I

During the war in Yugoslavia, Bosnians and Serbs worked with the European Regional Office of the World Health Organization (WHO/EURO) in Copenhagen, Denmark, to develop interventions for women and children's health. WHO/EURO developed the training program to be held in Denmark, but was not certain that the roads between Sarajevo and the coast would be open and safe for travel, as snipers continued to operate out of the mountains surrounding Sarajevo and along the roads to the country's borders. The workshop the nurses, physicians, and midwives attended in Copenhagen included both Bosnians and Serbs in the breakout sessions, but the facilitator had to ensure separate dining spaces, as the workshops occurred during the latter part of the war—a time during which communications were difficult and awkward.

*WHO Regional Advisor*

decisions get made that require local—rather than district or national—answers? If a local nursing group is interested in developing community health nursing standards of practice, and yet all nursing actions are reviewed by only a medical board of physicians, on what are the nursing standards based?

**Pluralistic health care systems** are found in many countries. They often consist of traditional healing systems, lay practices, household remedies, transitional health workers, and practitioners of Western medicine (Kloos, 1994; Carr, 2004). Traditional healing may be all that is available to populations in most rural areas and in some cities.

Western medicine was introduced to other countries during colonial times, and systems were operated either by colonial administrations or by missions. After independence, health systems tended to vary in their development. Some continue their colonial practices; others followed tax-financed government insurance or socialist health care systems (Carr, 2004).

During the second half of the 20th century, curative health care expanded rapidly in urban areas, and the level of health care was raised in those areas. In the late 1970s, many countries adopted the primary health care (PHC) approach as they sought to serve their urban and rural populations. Four major types of health care systems are currently operational throughout the world. These systems are: entrepreneurial, welfare-oriented, comprehensive, and socialist systems.

- ◆ *Entrepreneurial health care systems.* A country's health care system is based, in part, on its political economy. An entrepreneurial health system is typically found in industrialized countries with free-market economies; abundant resources, large amounts of money allocated to health care, and decentralized governments. These countries operate from a highly individualistic perspective. For example, the health care system in the United States is typical of the entrepreneurial system.
- ◆ *Welfare-oriented health care systems.* Statutory programs drive these systems that support the cost of health care for all, or almost all, of the population through their "national health insurance." In these, half of the health-related expenditures are covered by government sources, but most physicians and dentists remain in private practice. Western Europe, Japan, and Australia subscribe to welfare-oriented health care systems.
- ◆ *Comprehensive health care systems.* These systems are a step away from the welfare-oriented types in that substantial modifications exist in delivery and financing that result in universal entitlements. These systems abandon the separate and complex sources of financing found in the previous two systems. The Scandinavian countries, Great Britain, and New Zealand use a comprehensive health care delivery system.
- ◆ *Socialist health care systems.* These systems came about through social revolutions that abolished free-market economies and replaced them with socialism, in which the health care system is also socialized. The first overthrow of capitalism was in Russia in 1917, followed by Eastern Europe, Albania, Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, Romania, Yugoslavia, and later China. In these

systems, health services are viewed as a social entitlement and a government responsibility. They emphasize prevention engage in central planning for health resources and services with one central health authority, prioritize special groups such as industrial workers and children, and base health care work on scientific principles. Nonscientific and cultist practices are not permitted. Some of these countries are now in the process of democratization and are attempting to redesign their health care systems.

The four health systems described above apply to industrialized countries. Roemer (1993) applies the same typology to transitional and very poor countries. (Countries that are in the process of development are referred to as "transitional.") Such countries and their health care systems are moving effectively toward economic and social development. The global median gross national product (GNP) of these countries is \$1,500 per capita. (It should be noted that some might object to this classification system that considers being financially poor synonymous with being socially underdeveloped. This suggests a bias in thinking and a Western perspective that determines what is developed and what needs developing.)

Very poor countries are even less economically developed and have lower per-capita GNPs than do the industrialized or transitional countries. Examples of very poor countries are Ethiopia, Kenya, Ghana, Myanmar, Sri Lanka, Mozambique, and China. Other countries that do not easily fit into the health care system matrix are the oil-rich developing countries. In just a few years, the wealth in such countries exploded upward, from low levels typical of Africa and some Asian countries to levels equal to or greater than those of highly industrialized countries. Examples are Gabon, Libya, Saudi Arabia, and Kuwait. The governments of these countries use their income to extend and improve health services for the general population. Entrepreneurial or socialist systems are not found in these countries. Gabon and Libya are classified as welfare-oriented because they have different schemes of social insurance for health services for a large percentage of the population. Saudi Arabia and Kuwait are universal and comprehensive systems that use government funding to provide complete health services to everyone.

### **Trends Affecting Health Care Systems**

Health care systems are affected by major social influences such as urbanization, industrialization, education, government structure, international trade, and demographic changes. Many national health systems have undergone major changes during the 1980s and 1990s. Specifically, these health care systems have changed the way they organize and are managed. For example, in England, health services were traditionally led by health care professionals. In the mid 1980s, the emerging view was that one did not have to be a health provider to manage the health services of the country. Increasingly, health care administrators who were not from the health service ranks assumed these positions, and the composition of health teams changed among its leadership ranks.

Health care systems also expanded their resources and added personnel, facilities, and equipment. Meanwhile, populations grew, migrated, and became more educated. They demanded more and better health care services. Over

the past decade, hospitals worldwide have shifted to outpatient services and home care, expanding the roles and positions of community health nurses. For example, hospitals in Denmark benefited from a surgical procedure for hip replacement that would allow a patient to be discharged from hospital to home in a much shorter time period than previously experienced. This meant that home care had to be ready to accept the patient within an abbreviated time frame, thus requiring innovations in discharge planning and teaching protocols. In addition to these advances, the PHC movement supported efforts to reduce the number of hospital buildings and to increase community based nursing services (Carr, 2004). Technological advances occurred to support this move, and ways of thinking about health promotion emerged with a variety of quality measures and, more recently, evidence-based practices that support nursing interventions on an outpatient basis and at lowered costs.

Most importantly, people have begun to educate themselves through the Internet and World Wide Web. Ministries of health are training community care workers in communication, observation, and technical skills for telemedicine systems that link remote areas to academic and health centers. For example, the PHC Center in Almaty, SSR is now connected through the Internet, even though it began as a relatively isolated Center in what was referred to Alma Ata. Now groups with relatively rare health care conditions can receive support and information from others in parts of the world formerly unknown to them.

## THE POPULATION

The populations that community health nurses serve are complex and include their concerns, values, beliefs, physical symptoms, and health history. As described earlier, the framework that provides some boundaries for considering these issues focuses on the three eras of health conditions and the universal imperatives of care.

### Era of Infectious Diseases

Infectious diseases and conditions have killed people, made them sick, altered their daily functioning, influenced their decision making, and affected the costs of care. Thus, these infections and infectious processes involve all the universal imperatives of care, but do so differently, depending on a variety of factors (Carr, 2004). These factors include the climate, geography, and other conditions infectious organisms need to survive and thrive, and the populations the infectious agents invade—often infants and children. Thus, it is not surprising that 98% of all deaths in children younger than 15 years of age are in those countries in which infectious diseases are rampant. Eighty-three percent of deaths of those aged 15 to 59 years are in these countries as well. The probability of death before age 15 ranges from 22% in sub-Saharan Africa to only 1.1% in countries with established market economies. Five of the 10 leading causes of death are communicable, perinatal, and nutritional maladies that largely affect children. Most of these are preventable. The major preventive measure, immunization, is described here, followed by brief descriptions of the major infectious diseases. See Display 16.3 for a ranked listing of the leading causes of death worldwide.

### Immunization

The WHO estimates that 3 million more lives could be saved each year with immunizations. One of the most cost effective interventions available has been developed through the WHO Expanded Program on Immunization (EPI) (Reingold & Phares, 2001). Vaccines are one of the most cost-effective interventions found in public health. Today, almost three-fourths of the world's children are being reached with essential vaccines, but many barriers make it difficult to maintain high levels of immunization in low- and middle-income countries. In sub-Saharan Africa, for example, only one-half of the children have access to basic immunization against common diseases (WHO, 2002i).

Barriers persist and include limited finances, lack of trained health care workers, physical obstacles to reaching remote areas, and civil wars; these factors have prompted the development of an interagency vaccine initiative entitled the Global Alliance for Vaccine and Immunizations. This initiative seeks to protect every child against vaccine-preventable diseases (Reingold & Phares, 2001). Strategies include funding, research, development, distribution of vaccines, and program sustainability. These approaches are expected to result in more immunized children and to move newer vaccines into developing countries more quickly.

### Maternal and Perinatal Morbidity and Mortality

The WHO estimates that 500,000 women die yearly from complications of pregnancy and childbirth. Ninety-nine

percent of these deaths are in economically poor countries. Pregnant women living in parts of Africa face a one in 16 risk of death because they do not receive needed prenatal care. In comparison, the risk in Europe and North America is one in 4,000 (WHO, 1999g). The death of a mother profoundly affects the well-being of the entire family.

Early pregnancy, high fertility, and close child spacing are common in developing countries, and are known to be major determinants of poor health for mothers and children. Poverty, illiteracy, poor nutrition, low weight gain, maternal age (younger than 20 or older than 34 years of age), infections, smoke in the home, smoking, and poor health care are some of the major determinants associated with high health risks to mothers and children in the poorest nations of the world.

Prevention strategies include better general health for women through poverty alleviation, education, family planning guidance, prenatal care including food supplementation, immunization, local and regional care with referrals for complications, training of traditional birth attendants (TBAs), and effective postpartum care (Walsh, Feifer, Measham, & Gertler, 1993; WHO, 2001b; Carr, 2004).

### Measles

Measles is a vaccine-preventable communicable disease. In 2000, the number of measles deaths was 800,000 (WHO/EIP, 2006). The largest number of deaths occurred in Africa and in Southeast Asia (WHO, 2006). The intervention considered to have the greatest impact in reducing measles is the **Integrated Management of Childhood Illness (MCI)**. This intervention promotes wide immunization coverage, rapid referral of serious cases, prompt recognition of secondary conditions, improved nutrition including breastfeeding, and vitamin A supplementation (WHO, 1998c). A WHO/UNICEF Measles Mortality Reduction and Regional Elimination Strategic Plan sought a 50% reduction in measles mortality worldwide by 2005—hoping eventually to eradicate the disease (WHO, 2002d).

### Poliomyelitis

In 1988, there were 35,000 annual cases of poliomyelitis (polio) in the world (WHO, 1999e). By 1991, polio was eliminated from the Western hemisphere. Polio is now almost eliminated worldwide, even in densely populated and war-torn countries. Since the inception of the Global Polio Eradication initiative, cases have fallen by 99.8% to only 483 (in 2001), and the number of polio-infected countries dropped from 125 to 10. These 10 polio-endemic countries are classified as areas of high-intensity or low-intensity transmission. India, Pakistan/Afghanistan, and Nigeria/Niger are the areas with high-intensity transmission, and together they accounted for 85% of new polio cases in 2001. All have large populations, low immunization rates, poor sanitation, and a wide distribution of the wild virus. Somalia, Sudan, Ethiopia, Angola, and Egypt are areas with low-intensity transmission; they have lower-density populations and smaller focal areas of wild poliovirus. Global priorities for polio eradication include closing the funding gap, maintaining access and political commitment to the initiative, implementing the *polio endgame* strategies including laboratory containment, certifying polio eradication, and developing of a post

certification polio immunization policy. The estimated cost of eradication is \$1 billion (WHO, 2002f).

### Diarrheal Diseases

Diarrhea is defined as the passage of more than three stools during a 24-hour period for individuals older than 3 months of age. The incidence of diarrheal diseases is somewhat elusive because it depends on the definition of diarrhea used, the frequency of surveillance, and the population. Sometimes public health professionals use the term *diarrhea* to mean dysentery, although the latter is usually characterized by the presence of blood in the stool, with or without looseness or specified frequency.

Among other causes, a host of enteric pathogens can result in diarrhea; these pathogens are most significant in countries where there is poverty, poor personal and domestic hygiene, infected water, low maternal education, and lower occupational status. These factors have been associated with diarrheal morbidity and mortality (Martines, Phillips, & Feachem, 1993; Heymann, 2004).

The risk is highest among infants who are not breastfed. In 2000, an estimated 1.3 million children younger than 5 years of age in developing countries died from diarrheal diseases caused by unsafe water supply, lack of sanitation, and poor hygiene (WHO, 2002).

Reductions in mortality rates have occurred; in some areas as many as 90% fewer deaths have been reported. This was largely the result of the promotion of **oral rehydration therapy (ORT)**, a simple treatment that mothers may administer to their children in order to replace lost fluid and electrolytes (Kosek, Bern, & Guerrant, 2003), (Display 16.4). Actions need to prevent diarrheal disease include community programs that promote personal and domestic hygiene, water supply and sanitation facility improvements, breast-feeding promotion and improved weaning practices, and immunizations for cholera and measles (Schlein, 2002d, 2007).

Countries have the possibility to reduce deaths and illness from 20% to 80% simply by improving water and sanitation (WHO, 1996; Carr, 2004). No single type of intervention has greater overall impact on national development and public health than does the provision of safe drinking water and proper disposal of human excreta.

#### DISPLAY 16.4

#### HOW TO PREPARE HOMEMADE ORAL REHYDRATION SOLUTION (ORS)

If ORS sachets are available: dilute one sachet in 1 L of safe water.

Otherwise, use 1 L of safe water and add

Salt—1/2 small teaspoon (3.5 g)

Sugar—4 big spoons (40 g)

In addition, try to compensate for loss of potassium (e.g., eat bananas or drink green coconut water).

World Health Organization. (2003). First steps for managing an outbreak of acute diarrhea. WHO Global Task Force on Cholera. Global health security: Epidemic alert and response, Box 2. Geneva: WHO.

### Acute Respiratory Tract Infections

The most common illness in the world and a leading cause of mortality is acute respiratory tract infection (ARI). Three million deaths annually are attributed to ARI among children younger than 5 years of age, usually from pneumonia. Risk factors include low birth weight, poverty, crowding, lower educational levels, poor nutrition, inadequate childcare practices, and a lack of health education about ARI. Additional risk factors include smoking and indoor and outdoor air pollution. Indoor air pollution is 20 times higher in villages in poor areas than in homes in those countries of the world where two packs of cigarettes are smoked per day (Stansfield & Shepard, 1993; Schlein, 2002g, 2007). The source of pollution is largely indoor cookstoves that use organic fuel (Ezzati, Utzinger, Cairncross, Cohen, & Singer, 2005). A threat to the reduction of pneumonia, however, is the increase in drug-resistant organisms. Measures to better control ARI include: immunizations, birth spacing, and improvement in nutrition and living conditions (including use of smokeless cooking stoves). A global commitment to reduce ARI was realized by a resolution at the World Summit for Children in 1990 that called for a one-third reduction in deaths from the condition. This goal has been difficult to achieve because of the varying clinical symptoms and causative organisms of pneumonia (see Levels of Prevention Pyramid).

### Human Immunodeficiency Virus Infection and Acquired Immunodeficiency Syndrome

An estimated 42 million people worldwide are living with the human immunodeficiency virus infection (HIV) and acquired immunodeficiency syndrome (AIDS). Almost 95% of these people live in developing or transitional countries where health care, resources, and drugs are scarce (WHO/Food and Agriculture Organization, 2003). Asia and Eastern Europe are experiencing epidemic rates of HIV/AIDS cases. Russia reported a 15-fold increase in just 3 years, and HIV is beginning to spread among high-risk populations in some Middle Eastern countries (WHO, 2001c). The pandemic could claim an additional 68 million lives by 2020—55 million of them in Africa (Fleshman, 2002). It is predicted that life expectancy in those countries is likely to decline by as much as 27%.

The virus attacks young adults in productive age groups, requiring older people to care for and support their terminally ill adult children and, later, their orphaned grandchildren. Often these elders are themselves impoverished and in poor health, and are left without caregivers when they require assistance in their later years. The HIV/AIDS epidemic threatens to upset and destabilize entire societies in Africa. Reduced productivity of adult workers and early death are counterproductive to economic and social development (WHO, 2002i).

Recently, an expanded global response to the pandemic offered 12 essential interventions to reduce HIV transmission: mass media campaigns, public sector condom promotion and distribution, condom social marketing, voluntary counseling and testing programs, prevention of mother-to-child transmission, school-based programs, programs for out-of-school youth, workplace programs, treatment of sexually transmitted infections, peer counseling for sex workers, outreach to men

who have sex with men, and harm reduction programs for injection drug users. It is estimated that if these interventions were enacted by 2005, 29 million new HIV infections among adults could be prevented by 2010. The estimated cost for the large-scale prevention program is \$27 billion (WHO, 2002c).

There is also hope regarding treatment. In 2002, the International AIDS Society launched new international guidelines to treat AIDS in resource-poor areas. Simplified and less expensive antiretroviral therapy has become available, and is expected to extend life expectancy and productivity of those persons living with AIDS (WHO, 2002b). Other research has demonstrated the effectiveness of circumcision for adult males in decreasing the spread of HIV (The Boston Globe, 2006), and the importance of protecting HIV-positive patients from malaria, as they become “super-contagious” and are more likely to spread HIV after contracting malaria (International Herald Tribune, 2006, p. 2).

### Tuberculosis

Tuberculosis (TB) is an infectious disease caused by the tubercle bacillus. The disease has been known for hundreds of years and was commonly referred to as *consumption*. The tubercle bacillus has become resistant to the medications used to treat it, and currently a worldwide TB epidemic is underway. Two million die from TB each year, accounting for more than one-quarter of all preventable adult deaths in developing countries. Someone in the world is newly infected with TB every second. More than 8 million people around the world become sick with the condition each year; of these, 2 million cases occur in sub-Saharan Africa, 3 million in Southeast Asia, a 250,000 in Eastern Europe. Tuberculosis is one of the illnesses that disproportionately affect poor people around the world (Carr, 2004).

### Tuberculosis and Human Immunodeficiency Virus

Tuberculosis alone is a pernicious illness. When TB and HIV occur in one individual, the combination is lethal, with each speeding the other’s progress. Tuberculosis is the leading cause of death among people who are HIV-positive. Poorly managed TB programs are threatening to make TB incurable, and the movement of people through travel and relocation is helping to spread the disease. In the United States, almost 40% of TB cases are among foreign-born people (WHO, 2002e).

### Malaria

Malaria is a disease caused by the presence of the protozoan parasite *Plasmodium* in human red blood cells; the parasite is usually transmitted to humans by the bite of an infected female mosquito. “Humans are the only important reservoir of human malaria” (Heymann, 2004, p. 325). Fifty percent of the world population lives in malaria endemic areas. During the 1990s, 200 million new cases were diagnosed yearly, and 2 million deaths were reported from the disease (Kaneko, 1998). Over 1 million deaths occur per year due to malaria (Heymann, 2004). In 2003, it was reported that sub-Saharan Africa accounted for 90% of the deaths due to malaria (WHO, 2003).

## LEVELS OF PREVENTION PYRAMID

**SITUATION:** Prevent acute respiratory tract infections (ARIs) in children in developing countries.

**GOAL:** Using the three levels of prevention, negative health conditions are avoided or promptly diagnosed and treated, and the fullest possible potential is restored.

<b>Tertiary Prevention</b>	
<b>Rehabilitation</b>	<b>Primary Prevention</b>
<ul style="list-style-type: none"> <li>▪ Restore child to optimal level of functioning through the recovery period</li> </ul>	<p style="text-align: center;"><i>Health Promotion &amp; Education</i></p> <ul style="list-style-type: none"> <li>▪ Continue to promote educational programs and individual teaching regarding practices that promote health and prevent diseases among family members</li> </ul> <p style="text-align: center;"><i>Health Protection</i></p> <ul style="list-style-type: none"> <li>▪ Educate on the prevention of recurrence and spread of disease</li> </ul>
<b>Secondary Prevention</b>	
<b>Early Diagnosis</b>	<b>Prompt Treatment</b>
<ul style="list-style-type: none"> <li>▪ Get a prompt diagnosis of an acute ARI</li> </ul>	<ul style="list-style-type: none"> <li>▪ Collaborate with families to combine the best of folk and home remedies with established Western medical practices</li> <li>▪ Treat early with antibiotics (if indicated and available)</li> <li>▪ Provide culturally appropriate symptomatic care</li> <li>▪ Teach caregiver signs and symptoms of complications</li> </ul>
<b>Primary Prevention</b>	
<b>Health Promotion &amp; Education</b>	<b>Health Protection</b>
<ul style="list-style-type: none"> <li>▪ Promote general health education among community members</li> <li>▪ Good prenatal care</li> <li>▪ Advocate breast-feeding, child spacing, and adequate nutrition</li> <li>▪ Teach good hygiene and child care practices</li> <li>▪ Teach when to seek medical attention</li> <li>▪ Eliminate poverty and household crowding</li> </ul>	<ul style="list-style-type: none"> <li>▪ Administer appropriate immunizations</li> <li>▪ Eliminate indoor contaminants such as smoke from cookstoves without chimneys and cigarette, cigar, or pipe smoking</li> <li>▪ Ventilate rooms to eliminate indoor smoke and allow fresh air in</li> </ul>

The global disease burden from malaria is estimated to be greater than 300 million acute illnesses and 1 million deaths per year. Ninety percent of the world's malaria cases occur in Africa, south of the Sahara. Malaria and the deaths it causes mainly affect two vulnerable groups—young children and pregnant women.

Malaria is resistant to multidrug therapy, and the mosquito, its tenacious vector, persists. Malaria is highly endemic in some areas, and its eradication depends on pesticides such as DDT. In addition, human and economic resources are not available to fully implement a malaria program. Perhaps the major contributors to lack of success have been failure to

integrate the malaria eradication effort into basic health services, inadequate efforts to exploit the effective involvement of communities, and the absence of political will.

Health authorities who have reduced their expectations and are now focusing on programs of control, joined the WHO in a control strategy (Trigg & Kondrachine, 1998). This strategy includes the following elements (Jamison, Mosley, Measham, & Bobadilla, 1993; Heymann, 2004):

1. Early case finding and treatment
2. Reduction of contact with mosquitoes
3. Destruction of adult mosquitoes and larvae
4. Source detection
5. Destruction of malaria parasites
6. Community education programs

The WHO, UNICEF, UNDP, and the World Bank have partnered to launch an initiative entitled the Roll Back Malaria Program (RBM) the goal of which is to halve the incidence of malaria-related deaths throughout the world by 2010. The RBM initiative focuses on four major actions (WHO, 2002a):

1. Prompt access to treatment
2. Use of insecticide-treated bed nets
3. Prevention and control of malaria in pregnant women
4. Malaria epidemic and emergency response

The CDC, based in Atlanta, Georgia, continues work on developing an antimalaria vaccine using recombinant gene techniques. India and Kenya also have vaccine studies under way (WHO, 1999f).

Decreased effectiveness of antimalaria drugs due to development of drug resistance, particularly for the parasite of the most deadly form of the disease (*Plasmodium falciparum*), has brought attention to the need for new antimalaria medications. This problem is most acute on the Thai-Myanmar border in Southeast Asia, but it is also widespread in Africa. The WHO Tropical Disease Research Program (TDR), the Swiss Medicines for Malaria Venture (MMV), and Shin Poong Pharmaceuticals, Co. Ltd. in Seoul, Korea have collaborated in developing and producing a new combination antimalaria medicine, pyronaridine-artesunate, which is proving effective and affordable. One component of this medicine is a natural plant, *Artemisia annua*, whose antimalarial properties were first discovered centuries ago by the Chinese (WHO, 2002j).

Illustrating the spillover effect of disease from an endemic country to a nonendemic country are statistics on malaria in the United Kingdom. In 1996, 2,500 cases of malaria were reported—the largest number of cases in over 25 years (Bradley, Warhurst, Blaze, Smith, & Williams, 1998). Researchers found that 46% of the infected people had traveled to West or Central Africa on oil-related business (Nathwani & Spiteri, 1997). This spike in cases has declined due to community health education efforts.

### River Blindness (*Onchocerciasis*)

Onchocerciasis or River Blindness destroys vision and causes significant damage to other tissues. This centuries-old infection is transmitted by the bites of black flies that appear near rivers. Hundreds of thousands were affected by this condition, which has now been eliminated. Officials announced its eradication in Ouagadougou, Burkina Faso, on December 6, 2002. A 30-year effort was required to eliminate this

scourge as a public health threat in West Africa. When the program began, 10% of the infected population in high-impact areas was blind, and 30% had severe visual handicaps that caused loss of livelihood and autonomy (WHO, 2002k).

Health authorities carried out massive aerial spraying of *larvicide* to eliminate the vector, the black fly, in an area of 1.3 million square kilometers with a population of 30 million people. In 1991, the program delivered Ivermectin, the medication used to treat river blindness, to at least 80% of those living in endemic areas to maintain coverage for 10 to 15 years (Miri, 1998). The evidence of the elimination of the condition was the return of people to fertile areas formerly left unoccupied because of the debilitating disease. The resulting economic benefits are now dramatically enhancing the well-being of the population.

### Leprosy

Leprosy is a chronic granulomatous infection caused by *Mycobacterium leprae* (Hansen's bacillus). It affects various parts of the body including the skin (*Stedman's Medical Dictionary*, 1995). Leprosy is curable, and in the last two decades of the 20th century, the prevalence of leprosy was reduced by 90%; today, it is found mainly in Africa, Asia, and Latin America, with 70% of the world's registered leprosy patients living in India (WHO, 2003a). People with leprosy have had access to free effective drug treatment since 1995. The global health community has set a goal of leprosy elimination by 2005. Communities can help others meet this goal through proper diagnosis and treatment and provision of care without stigma or isolation. Interventions require that communities make political commitments, integrate the treatment protocols into the everyday practices of the PHC systems, and change in the image of leprosy, so that people with the condition will more readily present themselves for treatment (WHO, 2003b).

### Guinea Worm Disease (*Dracunculiasis*)

Dracunculiasis or Guinea Worm Disease is a parasitic disease that is transmitted to humans when a person drinks water containing a worm's intermediate host, a water flea that can ingest and harbor guinea worm larvae. Once in a human body, the larvae migrate through the tissue and the mature adult worm attempts to emerge, usually from the lower leg. Farmers are the most commonly affected. Although there is no cure, once the larvae are ingested, the eradication strategy includes interruption of transmission, surveillance, health education, and certification.

It is expected that Guinea Worm Disease will be completely eradicated soon. It is prevalent in 17 countries, 16 of which are in Africa. Cases decreased from 1 million to 80,000 between 1989 and 1997, demonstrating great promise for eradication. Interruption of transmission includes measures such as protecting drinking water by keeping infected persons out of it, filtering drinking water, and chemically treating water to eliminate the intermediate host. Geographical Information Systems (GIS) monitor guinea worm cases. There is interagency collaboration for the Dracunculiasis Eradication Program; the estimated cost to reach the ultimate goal of eradication is \$40 million (WHO, 1998a). In 2000, over 75,000 cases were reported by WHO (2006b).

## Era of Infectious Disease and the Universal Imperatives of Care

The infectious diseases and processes carry the potential for death, illness, and compromised functioning. When addressed promptly, some diseases, such as measles, can be prevented. When left unmanaged, they can result in sickness and lifelong consequences to daily functioning. Some of these conditions involve decision making. For example, when national governments do not provide clear national policies or funding for immunization programs, entire populations are at risk for the consequences of diphtheria, pertussis, typhoid, measles, and polio. When families and communities insist on living in areas with infectious agents, or do not clear their land as needed, they expose their members to the ravages of malaria. When community health programs do not include sanitation and the building of latrines, the result is diarrheal diseases that affect an entire community (Carr, 2004).

### *Eradication, Elimination, and Control of Communicable Diseases*

The primary global health goals related to communicable disease are eradication, elimination, and worldwide control. **Eradication** means interruption of person-to-person transmission and limitation of the reservoir of infection so that no further preventive efforts are required; it indicates a status whereby no further cases of a disease occur anywhere. At times, the term **elimination** is used when a disease has been interrupted in a defined geographic area. In 1991, WHO defined elimination as a reduction of prevalence to less than one case per 1 million population in a given area. In contrast, the term **control** indicates that a specific disease has ceased to be a public health threat. Control programs are aimed at reducing the incidence and prevalence of communicable and some noncommunicable conditions.

Although eradication is always the desired effect, extensive funding and much international cooperation are usually required to achieve such a goal (see What Do You Think?). The successful eradication of smallpox from the world in 1977 came about because of the leadership of the WHO, and it was a tremendous accomplishment in public health. In 1967, smallpox was endemic in 31 countries, with 10 to 15 million individuals infected. Remarkably, within 10 years, there were no cases in the world (Whaley & Hashim, 1995). Clearly, if global eradication programs are to be successful, collaboration and partnerships are essential. Certification of river blindness elimination has now joined the growing list of global public health accomplishments (WHO, 2002k). These programs are dependent on commitment from involved governments, international bodies, NGOs, and the affected communities themselves. Global eradication and elimination programs that are close to meeting the goal include poliomyelitis and Guinea Worm Disease. Eradication programs for leprosy and measles are continuing. Additional major efforts have increased to reduce, control, and prevent malaria, tuberculosis, HIV/AIDS, diarrheal diseases, and respiratory infections. Unfortunately, international terrorism threatens to reintroduce smallpox through acts of bioterrorism; smallpox vaccination programs have had to be reestablished to protect health workers and the populations at risk (Connolly, 2003).

## What Do You Think?

Imagine today's world without any international cooperation related to communicable disease knowledge or control. What would be some of the health, social, and economic consequences of such inaction?

### *New and Emerging Infectious Diseases and Conditions*

Despite the advances made, new and emerging diseases, conditions, and syndromes have appeared in parts of the world. Health authorities thought that some of these were under control. Since 1973, a number of previously unknown diseases have emerged, among them Ebola hemorrhagic fever, Lassa fever, Hantavirus, Lyme disease, Legionnaires' disease, and toxic shock syndrome (see Table 16.1). Most recently, severe acute respiratory syndrome (SARS), an atypical pneumonia thought to be caused by a coronavirus, has been recognized (WHO, 2003e). SARS has been reported to have a mortality rate of up to 15%, and up to 50% for seniors and infants.

The development of antimicrobial-resistant organisms, mainly as a result of the overuse and misuse of antibiotics, has fueled a resurgence of some diseases that were under control, such as TB. Anti-TB medications are no longer effective in up to 20% of patients in some parts of the world. Two leading antimalaria medicines have become ineffective in many Asian countries, and a third is effective in only half of the world. The easy availability of global air travel and subsequent rapid transmission of microbes pose real health threats (Howard, Scott, Packard, & Jones, 2003).

Another factor related to emergence of new and recycling conditions is urbanization, which serves to concentrate large numbers of people in small geographic areas. With urbanization, deforestation continues, and the two phenomena may permit the infestation of microbes into human populations, as humans who move into the cleared forests may encounter previously unknown pathogens. Changes in agricultural practices, such as new dams and irrigation schemes, also present potential transmission scenarios (Shannon, 2001). The ability of microbes to change and adapt rapidly is a persistent threat as well.

### *Era of Chronic Long-term Health Conditions*

Despite the programs of control, many infectious diseases persist. But populations now survive and also experience chronic, long-term conditions. These conditions affect mortality and morbidity, daily functioning, decision-making, and cost. Thus, the longevity that has resulted from meeting the challenges of the Era of Infectious Diseases compounds the more recent emergence of chronic diseases in the many countries. For countries in development, an interesting transition occurs. As infectious diseases decrease, life expectancy lengthens and the population experiences the degenerative diseases seen in developed countries. The concept of epidemiologic transition explains the replacement of

**TABLE 16.1 Examples of Emerging Pathogens Identified Since 1973**

Year	Microbe	Disease
1973	Rotavirus	Major cause of infantile diarrhea globally
1976	<i>Cryptosporidium parvum</i>	Acute and chronic diarrhea
1977	Ebola virus	Ebola hemorrhagic fever
1977	<i>Legionella pneumophila</i>	Legionnaires' disease
1977	Hantaan virus	Hemorrhagic fever with renal syndrome
1977	<i>Campylobacter jejuni</i>	Enteric diseases distributed globally
1980	Human T-lymphotropic virus 1 (HTLV-1)	T-cell lymphoma-leukemia
1981	Toxin producing strains of <i>Staphylococcus aureus</i>	Toxic shock syndrome
1982	<i>Escherichia coli</i> 0157:H7	Hemorrhagic colitis; hemolytic uremic syndrome
1982	HTLV-II	Hairy cell leukemia
1982	<i>Borrelia burgdorferi</i>	Lyme disease
1983	HIV	AIDS
1983	<i>Helicobacter pylori</i>	Peptic ulcer disease
1988	Hepatitis E	Enterically transmitted non-A, non-B hepatitis
1990	Guanarito virus	Venezuelan hemorrhagic fever
1991	<i>Encephalitozoon hellem</i>	Conjunctivitis, disseminated disease
1992	<i>Vibrio cholerae</i> 0139	New strain associated with epidemic cholera
1992	<i>Bartonella henselae</i>	Cat-scratch disease; bacillary angiomatosis
1994	Sabia virus	Brazilian hemorrhagic fever
1995	Hepatitis G virus	Parenterally transmitted non-A, non-B hepatitis
1995	Human herpesvirus-8	Associated with Kaposi sarcoma in AIDS patients
1996	TSE-causing agent	New variant Creutzfeldt-Jakob disease
1997	Avian influenza (Type A [H5N1])	Influenza
1999	Nipah virus	Influenza-like symptoms, high fever, myalgia; may progress to encephalitis, convulsions, coma; 50% mortality rate
2002	SARS	Severe acute respiratory syndrome

(World Health Organization. [1998d]. Examples of pathogens recognized since 1973. *WHO Fact Sheet No. 97, 4*. Geneva: WHO; World Health Organization. [2001]. Nipah virus. *WHO Fact Sheet*, 262, 1–2. infectious disease morbidity and mortality with that of chronic disease. How people in remote areas will manage their heart disease or cope with the stigma of a disability is yet to be understood. Formerly, those with disabilities or compromised activities of daily living were cared for by the family, and were often hidden from the community. This was often due to religious and cultural beliefs and lack of knowledge.

As families change their composition, the care of those who require daily assistance will also have to change. It will require a change in the response of the health care system in terms of provision of care, planning, and allocation of resources. Addressing these concerns is considered a cost-effective investment in a nation's human capital (McQueen, McKenna, & Sleet, 2001).

## Era of Social Health Conditions

The WHO researchers suggest that dramatic changes in health-related needs will occur within the next 20 years. There is evidence that noncommunicable diseases are rapidly replacing infectious diseases as the major causes of disability and premature death. Noncommunicable diseases are expected to account for seven of every 10 deaths in developing countries, compared with fewer than five of every 10 today (Display 16.5).

## Mental Health Conditions

The burden of mental illness was previously unseen. Now recognized, it accounts for almost 11% of disease burden worldwide. Unipolar major depression is expected to be a

leading cause of disability-adjust life years (DALYS) by 2020 (WHO, 2002h).

### Tobacco

Tobacco is expected to develop into the single largest killer and to cause the greatest burden of disease in the 21st century, with deaths increasing from 4.9 million to 10 million per year by the late 2020s (WHO, 2002g). The WHO has predicted that tobacco will be the leading cause of disease burden in the world by the year 2030, accounting for one in eight deaths, with 70% of them in poor countries (WHO, 1999a). With a decline of tobacco use in Western countries, the tobacco industry has aggressively marketed in low- and middle-income countries (Kickbusch & Buse, 2001). As a result, the prevalence of smoking among adult men is high and troublesome. For example, more than 50% of men in Bangladesh, China, Japan, Korea, Russia, Indonesia, and Vietnam smoke tobacco (McQueen, McKenna, & Sleet, 2001).

The aim of WHO's Tobacco Free Initiative is to prevent and control the global spread of tobacco use in the 21st century. By 2003, 171 member states completed a groundbreaking public health treaty to control tobacco supply and consumption (WHO, 2003c). The treaty's signatory parties agreed to implement comprehensive tobacco control programs and strategies. Some of its central control components are tobacco taxation and pricing, health warning labels, restriction of advertising and promotion, holding the tobacco industry liable for tobacco-related costs, financial support for national tobacco control programs, and funding for treatment programs. This legally binding treaty and international effort represents an important step in global public health and is expected to reduce the impact of tobacco use in the decades to come.

### Global Burden of Disease (GBD)

If a member of your family dies, what does it cost? What does it cost if you miss a month of work or school due to an illness? What does it cost a country when the majority of adults smoke a package of cigarettes a day or when adults eat beetle nut several times a day? These questions

are often irritating and are sometimes considered in poor taste. Yet governments and community members do ask these questions—as they must carry the financial burden for them. But how does one go about putting a value on a life? Or, a value on the cost of a disability? To capture these concerns, WHO coined the term: the *global burden of disease (GBD)*.

WHO's GBD numerically verified numerous long-held assumptions about disparities in the burden of disease worldwide, especially in regard to children, through landmark studies by Murray and colleagues that revealed startling statistics:

- ◆ 98% of all child and deaths (younger than 15 years) are in the developing world.
- ◆ 83% of deaths between ages 15 and 19 are in the developing world (Murray & Lopez, 1997).

In addition to causes of mortality, the GBD study quantified the burden of disease with a measure that could be used for cost-effectiveness analysis. To compare across conditions and risk factors, researchers developed a measure called the **disability-adjusted life year (DALY)**, which are the combination of years of life lost due to premature mortality and years of life lived with disability adjusted for the severity of disability. The GBD study ranked the leading causes of DALYs in 1990 and projected changes by the year 2020 (see Table 16.2). Chronic disease, unipolar major depression, and accidents were expected to be the three top DALYs by that time, replacing respiratory infections, diarrheal diseases, and perinatal disorders.

Within the first 10 years of this period, changes in the rankings were evident. The three leading causes of DALYs in 2001 were acute respiratory infections, HIV/AIDS, and conditions related to the perinatal period (WHO, 2003d). The GBD study grouped diseases and injuries into three clusters: Group 1 represents communicable diseases, maternal causes, conditions arising in the perinatal period, and nutritional conditions; Group 2 lists noncommunicable diseases; and Group 3 lists all types of injuries (see Table 16.3).

The information obtained from the GBD and its analysis guides current decisions related to investments in health, research, human resource development, and physical infrastructure. Reassessment of global and regional information on diseases and injuries is expected to occur every 3 to 5 years.

### PROVIDERS OF HEALTH CARE

The implications for community health nursing concerning the three eras of health conditions are many. The health provider most appropriate when death is a common occurrence, as it was during the Era of Infectious Diseases, is a physician. This category of health worker is best suited for saving lives and for delivering the medical interventions that keep people alive. Nursing and nursing personnel are health care providers who have traditionally served populations that experience long-term chronic illnesses. Nursing personnel worldwide serve populations in nursing homes, long-term care facilities, and in community-based programs for the elderly and disabled. The nursing services in Slovenia and Germany are excellent examples of this kind of practice in Europe.

**TABLE 16.2 Seventeen Leading Causes of Disability-adjusted Life Years (DALYs) in the World in 1990 and Projected to 2020**

Disease or Injury	Rank: 1990	Rank: 2020
Lower respiratory tract infections	1	6
Diarrheal diseases	2	9
Conditions arising during the perinatal period	3	11
Unipolar major depression	4	2
Ischemic heart disease	5	1
Cerebrovascular disease	6	4
Tuberculosis	7	7
Measles	8	25
Road traffic accidents	9	3
Congenital anomalies	10	13
Malaria	11	24
Chronic obstructive pulmonary disease	12	5
Falls	13	19
Iron deficiency anemia	14	39
Protein-energy malnutrition	14	37
War	16	8
Self-inflicted injuries	17	14
Violence	19	12
Human immunodeficiency virus (HIV) infection	28	10
Trachea, bronchus, and lung cancers	33	15

(Murray, C.J. & Lopez, A.D. [1996]. Evidence-based health policy—Lessons from the Global Burden of Disease Study. *Science*, 274, 740–743.)

The caregiver needed for the Era of Social Conditions is evolving. For example, community health nurses and primary care physicians are developing new competencies for HIV/AIDS prevention among adolescent prostitutes, but a host of other interventions that require collaboration with other social service and educational personnel is needed. In addition, some communities, because of their former political persuasion and cultural beliefs, have not created networks and other mechanisms to address their emerging social health conditions. For example, during the earthquake in Armenia, international workers recognized the need for social supports for those whose homes and community had been destroyed. At that time, these social structures, as they existed in North America, were not available to that population. In Mizoram, India, the burgeoning drug trade from

**TABLE 16.3 Distribution of Death by Specific Causes in 1990**

Group 1	Group 2	Group 3
Infectious and parasitic diseases	Malignant neoplasms	Unintentional injuries
Respiratory infections	Other neoplasms	Intentional injuries
Maternal disorders	Diabetes mellitus	
Perinatal disorders	Endocrine disorders	
Nutritional deficiencies	Neuropsychiatric disorders	
	Sense organ disorders	
	Cardiovascular disorders	
	Respiratory disorders	
	Digestive disorders	
	Genitourinary disorders	
	Skin disorders	
	Musculoskeletal disorders	
	Congenital anomalies	
	Oral disorders	

(Murray, C.J. & Lopez, A.D. [1996]. Evidence-based health policy—Lessons from the Global Burden of Disease Study. *Science*, 274, 740–743.)

Myanmar has had a profound impact on this Christian, family-centered, close-knit community in the northeast part of India (Segor, 2006).

In the future, community health care will be increasingly collaborative, and experienced as participatory partnerships with clear shifts in ownership and leadership. Formerly, international workers and consultants went to a country as outsiders and delivered their ideas, programs, and projects. The philosophy, beliefs, practices, and values of this dominant group of outsiders prevailed, and the recipient groups were considered a success to the extent that they adopted the dominant groups ways of being, living, and caring for their health.

In the future, partnerships that are sensitive to the dynamics of power and oppression, and which honor the need for local groups to be in control of their own projects and the resources that are used to implement them, will prevail. Freire's (1970) advocacy for using *generative themes* that support education and critical consciousness are being adopted as collaborative projects demonstrate innovative ways of learning and conducting research. For example, in many countries, local experts and community members are forming partnerships with outside consultants and are insisting on striking changes in responsibility, authority, and ownership of data and innovations. In these emerging models, the community becomes the initiator of action.

### Health Providers at District Levels

In earlier forms of primary health care (PHC), the locus of decision-making was at the village level. However, after many years of effort, the WHO and other organizations realized that the power to sustain change required more than village-level involvement. Thus, the move to the district

level of implementation is currently being practiced in many places.

Regardless of level, however, the essential point is the adage: Think globally, act locally. Specifically, this means that expertise is needed from those at international, national, regional, and district levels; but the ways in which communities interpret the issues and their solutions belongs to them. In local areas, communities adopt the health centers or organizations created to address community concerns. For example, in one Greek community, a local mayor sat through a week of deliberations on ways to bring PHC to his island. He heard the comments of members of the local community, its health workers, and an international WHO PHC team. Ultimately, the mayor realized that rooms for health providers would be needed, and he declared the community's full support to provide these rooms to further the work of the health center. In this way, his community was fully active and responsible for its own health status.

### Community Health Workers

In some countries, particularly those in which professional health providers are scarce, the community identifies a local, respected, responsible person most often called the **community health worker (CHW)**. This person is selected from the village and is approved by the committee to serve the village people in health matters. CHWs usually provide 1 to 2 hours of health service per day, for which they may or may not be compensated by the community.

The CHW is trained in the fundamentals of promoting health and preventing and treating the most common health care conditions (Lewin et al., 2004). This includes basic first aid, advice and assistance on simple treatments, and health teaching on personal hygiene, safe water supplies, safe disposal of human waste and refuse, and nutrition. Community health nurses often serve as consultants to the CHW and, in some places, are expected to supervise their work and provide ongoing education. These CHWs have demonstrated their effectiveness in controlling communicable diseases, for example, in the malaria control programs in Ethiopia (Gebreyesus et al., 2000).

### Village Midwife

The village midwife receives training in obstetrics and child-care. This person provides basic antenatal, intrapartum, and postnatal care and makes referrals as required (McInerney, 2004). In India, the village midwife is referred to as a trained *dais*. These are most often older women who may have had training from professional nurses and who are expected to call on professionals when needed. However, they often make their own decisions even though they have a referral source to professionals. Many times, adverse effects occur because cultural practices take precedence over knowledge-based practices that require collaborative decision-making.

In some countries, traditional health practitioners receive formal training and return to their villages to continue their services with new knowledge and skills to enhance their effectiveness. Countries such as Bangladesh implemented programs to train workers who would practice in ways similar to the “barefoot doctors” of China (Valentine, 2005). The Ministry of Health in Bangladesh was challenged in its efforts

during the 1980s, as women would not leave their homes for training and, if they did, would rarely allow themselves to be posted in a village other than their own. This is because women are viewed as wayward if they are not with their families in their home environments. This issue also occurred in Indonesia, when community health nurses were placed in villages away from home. They did not have the respect of the local community, were not seen as experts, and were considered to be in dubious moral standing. This cultural barrier presents challenges to nursing education programs that focus on community- rather than hospital-based experiences.

## Community Health Nurses

### Background and Age at Entry to Nursing Education

When community health nurses join their colleagues in a country other than their own, they often assume that “a nurse is a nurse, is a nurse.” Nothing could be further from the truth. The ways in which women and men are socialized, recruited into, advanced through, and graduated from nursing school varies considerable from country to country. So does the age at entry, the exposure that nursing students have to the social and behavioral sciences, the theoretical and clinical applications studied, and the kind and extent of supervision they receive. For example, in some countries, young people begin their study of nursing at age 15, studying nursing in programs designed, sequenced, and financed by the government. These graduates are expected to practice as fully experienced community health nurses by age 18.

### Curricula of Nursing Programs

The practice of controlling and designing nursing curricula at central levels carries opportunities and risks. The opportunity it provides is consistency of teaching and learning and the possibility to produce teaching learning materials in a uniform way, and in the language of the country. The risks are that local conditions are not included, and care practices essential for a region of a country may not be addressed. For example, during the earthquake in Armenia, nurse leaders requested that content related to earthquakes and disaster preparedness be added to the curriculum. Authorities refused, showing the consulting team and local nurse leaders the detailed content and hours developed for the curriculum designed in Moscow. No opportunities, at that time, were possible for this content to be added, despite the fact that 25,000 people had lost their lives in the natural disaster.

Nursing educational programs may be based in a hospital, technical school, or university. Specialty areas may be introduced as part of the basic curriculum, as is the practice in Denmark where midwifery is a basic program offered and is seen as a discipline different from nursing. This design differs from other countries in which nursing is the basic preparation upon which mental health, midwifery, and other areas are built and considered as advanced practice.

### Development of Nursing Programs Globally

Nursing is a discipline that takes many forms and often requires champions to support its contributions. Nursing education's development history has been checkered, in part,

because of this need for champions. The reasons are many. Modern nursing was launched by Florence Nightingale, who began her work during the war in the Crimea, within the context of a military hospital system (see Chapter 2). Since that time, nurses—who are predominately women—have had to demonstrate the difference between curing and caring, between a hierarchy of disciplines under physicians—who are predominately men at the top of the hierarchy—and a horizontal organizational structure that recognizes nursing and other health care disciplines as equal contributors to the health care team.

### **Forces That Support Nursing Development**

In many places, nursing has yet to distinguish itself with its own body of research, knowledge, managerial practices, standards of practice, and ethical tenets. However, it appears that nursing has thrived as a respected discipline in countries where women, in general, are respected and where those in leadership positions understand the value of the caring process and are willing to champion nursing at all levels, including at the national level. For example, Turkey stands out as a country with a cadre of doctorally prepared nurses who were able to secure their education abroad thanks to Dr. Ihsan Dogramaci, an international figure, pediatrician, and child health specialist (2006). Dr. Dogramaci sponsored nurses in Turkey, so that they were able to pursue higher education through the doctoral level of preparation. Nursing has developed in unusual ways in other countries as well. For example, conversations with Portuguese nurses reveal that many of the leaders of nursing in that country came from wealthy families and were committed to a contemporary view of nursing practice.

In Indonesia, many types of nursing personnel had proliferated, and 25 categories of nursing personnel practiced in the country until the mid-1980s. The WHO worked diligently with the Ministry of Health to introduce PHC nursing, a transformation that was clearly a challenge in a country peppered with hundreds of islands, where providing community learning experiences requires time and financial resources to travel to clinical sites. This situation is exacerbated by the limited availability of qualified faculty and the nature of the clinical experiences available in remote locations.

A major challenge to community health nurses who have undergone theory and clinical experiences as learners is working with nurses who have not had community health experience. As is well understood, functioning well in a fully equipped hospital is different from working in a community or village where resources are not easily available. Exploring these differences is an essential part of one's own needs assessment as one embarks on an experience with a team from locations other than one's own.

## **THE PROCEDURES/INTERVENTIONS**

Community health nurses consider the population as their patient or client. A population might refer to all those living in a catchment area, in a neighborhood, village, a district, or city. Countries might refer to their populations at national, regional, or international levels. Regardless of location or level, community health nurses practice within the context of some kind of health care system or organization.

Nurses and midwives constitute 80% of the qualified work force in most national health care systems, and they represent a powerful force for bringing health care to all populations. Nurses provide the spectrum of PHC services and conduct health research (International Council of Nurses [ICN], 1999).

The interventions that community health nurses provide depend on the context in which they are working, and on the population, its health status, and the health conditions it presents. These interventions also depend on how nursing is practiced in a country and on the organizations in which community health nurses are employed or with which they are collaborating.

The key issue here is that community health nurses need to know the mission of the agencies with which they are working and the kinds of services and resources their employing organizations provide. This section describes selected organizations that provide interventions to address community health care issues and the ways in which community health nurses work within them.

Providing an intervention that “works” constitutes an achievement. Providing an intervention in community health constitutes a remarkable achievement. This is because interventions are complex, often costly, and involve considerable knowledge, planning, and expert execution and evaluation skills. This section also focuses on the interventions community health nurses provide in a context different from their own within the context of a sponsoring organization.

As noted, the first step is to understand who is involved, the roles they play, and the contributions they are able to bring to the issue. Again, knowing the context in which one is working, and understanding the population and their health status and health conditions are also critical elements (and have been addressed earlier). A second, but often-overlooked step, is to understand the reasons the interventions are being delivered, and one's reasons for being involved. Specifically, what does the donor agency believe is its mission, and why now, why here? What do the recipients have to say? Do they see themselves as recipients of donations or as partners and collaborators? How do they see the intervention? Did they identify the need and ask for assistance? Have the recipients been involved in identifying the issue, in planning strategies for the intervention? Are they committed to the issue and to the outcome? What is their level of involvement in the issue?

Questions you need to ask yourself are: Why are you there? What motivates you and what is your commitment? How does this fit with the scope of the work you will be undertaking, and will your time commitment see the project through, and if not, what effect will your leaving have on its success?

## **Criteria for Support of Interventions**

Most donor groups want to know if the recipient unit, a village health center, a district hospital, a regional health office, has the capacity to manage projects, and if they are able to sustain the project after external funds are no longer available. Some organizations want to know if the project and its principles and practices might be applied to other areas in the country or throughout the world. These questions address three critical criteria that organizations use to determine

funding. These are: sustainability, absorptive capacity, and transferability.

An example of these criteria was made clear in a project the WHO was asked to develop in several African countries. The donor indicated that no project under \$5 million would be supported, as the paperwork and administration of the project would not be worth the cost of resources. The office of the Maternal Child Health Section in the country's Ministry of Health included a full-time staff member and one half-time staff member. These two staff members worked with no computer, no typewriter, and no bookkeeping staff. Clearly, the criteria of sustainability and absorptive capacity could not be met, as they would not have any way of managing the many written papers and financial accounting documents required for a \$5 million dollar international project. In addition, the unique situation of a project developed for this Ministry of Health would have to be tailored to such an extent that its transferability, or use in another country, would be minimal.

When considering a project's funding, questions need to be asked about gender, political, and cultural issues. For example, if an organization plans to support the elimination of the practice of female circumcision, how will that be seen by the population? If a donor agency insists on a democratic process of decision-making, how do leaders implement this process when they have no background or skills in the democratic process, and their positions are tied to their ability to make decisions without team input? How do community health workers implement sanitation programs that place farm animals in places segregated from humans when villagers see their cows as sacred and want to have them in the family compound? How does the community health nurse reduce the fever of a newly delivered woman when the village midwife, the dais, insists "you sponge her only on day three"?

These and many other questions challenge the underlying assumptions about the process of change and the unplanned effects a well-intentioned intervention is designed to deliver. Yet another question relates to the way community health services are organized. Many communities throughout the world have adopted a form of organization that is presented here.

The most commonly involved organizations that provide health-related interventions and support are described here. An overall umbrella agency is the United Nations (UN). Most people know of the UN's work in peacekeeping. This body also focuses on working conditions through the International Labor Organization (ILO), educational issues through the United Nations Educational Scientific and Cultural Organization (UNESCO) and health issues, specifically, through WHO and UNICEF.

## The World Health Organization (WHO)

The leading global agency that focuses specifically on health is the **World Health Organization (WHO)**. The organization has regional offices in six parts of the world with its headquarters in Geneva, Switzerland. The six regional offices include: WHO Regional Office for Americas (PAHO), WHO Regional Office for the Eastern Mediterranean (EMRO), WHO Regional Office for Europe (EURO), WHO Regional Office for Southeast Asia (SEARO), WHO Regional Office for Africa (AFRO), and WHO Regional Office for the Western Pacific (WPRO). The WHO established special offices in

Addis Ababa, Ethiopia, to work with the new African Union (formerly the Organization of African Unity), and in Moscow to work with Eastern European countries and the newly independent states of Central Asia. These regional offices recruit and place community health nurses in their many projects throughout their regions.

## The WHO, Its History and Its Work

The WHO began in 1945. It developed its own charter, although it has been closely associated with the UN since its inception. It is responsible for its own programs, funded by regular and extra budgetary funds, and also for health-related initiatives sponsored and funded by UN agencies and other international bodies. The WHO carries out its work through the policies it creates with its member states throughout the world. It does this initially at its annual May meeting, the World Health Assembly.

## The World Health Assembly

**The World Health Assembly (WHA)** is the highest governing body within the WHO and includes 193 member countries. Representatives from each of the world's regions attend this Assembly and bring the policies and recommendations to their respective regional offices for implementation and expression at regional and local levels. Staff members at the regional offices then work with their member countries through their annual September Regional Committee Meeting held each year after the World Health Assembly.

The WHO provides technical support and advises member states on strategies to meet their health care needs. The WHO serves as a catalyst to mobilize the resources of national governments, financial institutions and endowments, and bilateral partners for health development (WHO, 2002m). The WHO is not the organization of choice when vehicles, equipment, and medicines are required; the WHO can help a member state determine the drugs that are essential, and will assist in developing health policy, project plans, and programs.

The WHO employs many types of professionals, including nurses. However, the organization does not focus on professional issues to support the development of particular health-related practitioners, such as nurses, midwives, social workers, or physicians. Nurses interested in these types of issues should explore opportunities with the ICN or nursing organizations at national or state levels. In the United States, these would include the American Association of Colleges of Nursing, the American Nurses Association, or National Council of State Boards of Nursing.

The WHO does focus on the interventions these health professionals deliver, and for these, considerable effort is expended on developing nursing, midwifery, social work, and physician-related knowledge and skills that are basic to the interventions they deliver. However, the WHO works closely with the ICN and with national nursing organizations on policies and programming issues.

## WHO Collaborating Centers

The WHO uses a 5-year planning cycle that is divided into 2-year cycles of projects, documentation, publications, and the development of information systems. Community health

nurses are employed at the international level in Geneva, and they hold regional level positions as Regional Nursing Advisors. However, one or two Regional Nursing Advisors cannot possibly carry out the work of a region that might be the home to thousands of nursing personnel. To address this issue, WHO has developed a network of **World Health Organization Collaborating Centers** in nursing and other fields. These Centers focus on specific areas of expertise and carry out the work of the member countries in these areas. For example, the Collaborating Center network in nursing of the European Region has focused on primary health care and information systems, and the network in the United States has worked through universities in their respective areas of excellence. In the United States, early pioneer universities included the University of Illinois, the University of Pennsylvania, the University of Texas, the University of Alabama, and the University of California. Student nurses in these universities have the opportunity to participate in the research, nursing projects, and other international activities their universities sponsor, both in the United States and in their partnering countries. Sometimes these collaborating centers represent the WHO and their countries at national and international meetings. They provide critical services that are recognized by, but cannot be funded or staffed by the WHO. They also bring credibility to projects, as they come from the communities they represent, and they know the issues and interventions that have the greatest chances of succeeding.

### WHO and Its Collaborators

The WHO works closely with national governments, its collaborating center network, its universities, research centers, and nongovernmental organizations. Experts from member countries are recruited throughout the year to deliberate on global health and health-related issues. For example, during the Chernobyl disaster, WHO/EURO called five internationally recognized nuclear experts to an emergency meeting to examine the issues and assist the member countries with next-step actions to protect their populations, livestock, and agricultural industries. Historically, the WHO has collaborated with centers of excellence throughout the world, including the CDC in the United States.

### WHO As a Multilateral Agency

The WHO and other UN agencies are sometimes referred to as *multinational* or **multilateral agencies**. They support development efforts of governments and organizations in countries throughout the world. The WHO regional offices also collaborate with each other to address issues on which they can partner and provide resources. For example, during the civil wars in Africa, Chad, Angola, and Mozambique, WHO/AFRO and WHO/EURO collaborated to develop projects on rehabilitation for the countries with no medical schools and no comprehensive programs for the disabled. The WHO intervenes through its own staff's efforts and through those of its partnerships. In another example, the WHO's Health Promoting Schools is a collaborative effort with UNESCO and UNICEF. Still another example is the Human Reproduction Program, a global research program on reproductive health. It collaborates with two programs of the UN as well as the WB. Similarly, the WHO has joined with several other organizations to fight

#### DISPLAY 16.6

#### HEALTH PROMOTION

Health is created and lived by people within the settings of their everyday life; where they learn, work, play and love. Health is created by caring for oneself and others, by being able to make decisions and have control over one's life circumstances; and by ensuring that the society one lives in creates conditions that allow the attainment of health by all its members.

World Health Organization. (1997). Promoting health through schools: Report of a WHO expert committee on comprehensive school health education and promotion. *WHO Technical Report Series, 180*, 5. Geneva: WHO.

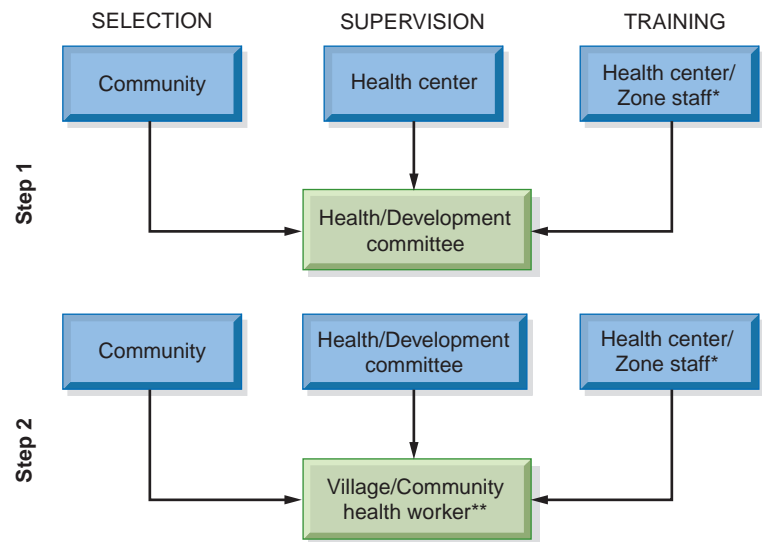

hunger and improve food standards, and has collaborated in a *Solar Alert Campaign* to alert people about the harmful effects of solar radiation (WHO, 1999d) (Display 16.6).

### Health for All: A Primary Health Care Initiative

In its earlier years, the WHO personnel watched as hospitals and costly health establishments were built throughout the world. One of the world's leading economists, Dr. Brian Abel Smith, noted that countries could not afford to erect costly buildings, nor could they add numbers of health professional to their cadres of personnel. Rather, he suggested that the health personnel available work with the population to manage their health care needs. His major assertion is that health care needs and wants may expand infinitely, but resources do not, and all must manage with the resources currently available. Many health leaders throughout the world recognized the trends emerging and believed that a major change in thinking and practice was needed. They met together in Alma Ata, Kazakhstan, in the former Soviet Union and created a sweeping set of declarations that became the *Declaration of Alma-Ata* (see Chapter 1) or **Health for All**. The world body of 134 countries called on all members to reframe their expectations and implement primary health care (PHC). In Europe, the 32 member countries developed its 38 Regional Targets for Health. In the United States, health care professionals launched *Healthy People 2000*. Since then, the 2000 year mark has passed, and *Healthy People 2010* is now the blueprint for the future (United States Department of Health and Human Services, 2000).

**Primary Health Care (PHC)** is sometimes called a philosophy, a movement, a way of thinking, a way of working, a setting for health services, or a set of principles. Making it operational at the national level, however, meant that communities would focus on health care services at the local level rather than building large, tertiary hospitals that cater exclusively to urban, financially secure populations. This also meant that the education of health care providers would be located at this level with a de-emphasis on high-cost medical interventions and technology available only to a few members of the population.

Health for All emphasizes PHC that is affordable, culturally acceptable, appropriate, accessible, and delivered through partnerships between national health services system

**FIGURE 16.2** Community-based primary care.

\*Nurse, sanitarian, midwife, health education assistant

\*\*Assistant midwife, traditional birth attendant, traditional practitioner

and local communities. The communities take the leading responsibility for identifying their own priority health concerns and planning and implementing their own PHC service. These PHC services include prevention, health promotion, and curative and rehabilitative care provided by the people themselves (WHO, 1998e). (See Figure 16.2 for an illustration of the organizational pattern of community-based PHC.)

### Functions of Public Health Care

Article VII of the *Declaration of Alma-Ata* lists the eight basic elements of PHC (*Primary Health Care*, 1978).

1. Education concerning prevailing health problems and the methods of preventing and controlling them
2. Promotion of food supply and proper nutrition
3. An adequate supply of safe water and basic sanitation
4. Maternal and child health, including family planning
5. Immunization against major infectious diseases
6. Prevention and control of locally endemic diseases
7. Appropriate treatment of common diseases and injuries
8. Provision of essential drugs

Public health care also involves related sectors concerned with national and community development, including agriculture, animal husbandry, food, industry, education, housing, public works, and communication (Article VI, section 4).

### Deterrents to Public Health Care

Fostering a PHC approach is one thing, implementing it is another. Initially, there were political reactions from professional groups who saw their incomes being funneled to the local level in a health care system. Universities and teaching institutions did not know how to educate professionals for PHC. Textbooks were based on education for treating

diseases and assumed the back-up of well-equipped hospital environments. Nursing faculty adopted community health nursing textbooks from North America but continued to teach students as if PHC did not exist. Faculty was virtually nonexistent in rural areas and, if they were available, clients were not. Stationing young women in villages without supervision was seen in some countries as ill-advised, and clients refused to appear at these health centers. Inadequate supervision and follow-up led to misapplication of theory learned, and those in rural areas were not prepared for the situations they faced daily. Health care workers did not understand their responsibilities for maintaining, restocking, and securing medical supplies on a regular basis, and many had no knowledge of community-based principles of case finding, record keeping, community monitoring of immunizations, prenatal care, disease prevention, health promotion, and basic measures to ensure community sanitation.

In many places, referral systems to nearby hospitals were not effective, and health care workers were reluctant to place themselves in responsible positions without back-up and accessible secondary and tertiary facilities.

Natural environmental phenomena such as rain, floods, and poor or absent communication facilities periodically isolated areas and prevented transport of patients to nearby facilities. Other problems arose when expensive drugs were dispensed in place of less expensive generic brands (or in some cases were given first to the family and friends of the health care workers) and when health centers failed to refer patients back to the referring CHW (see Evidence-Based Practice).

### Achievements of Public Health Care

A renewal took place in 1994 regarding the strategy of Health for All by WHO members and acknowledged significant global accomplishments. The worldwide infant mortality rate decreased from 90 per 1000 live births in 1975, to 59 per 1000 in 1995—a 34% decrease. Immunization coverage for children

## EVIDENCE-BASED PRACTICE

### The Uferi Project

Despite an increasing number of high-technology assessments or interventions in developed countries, many villages throughout the world continue to rely on the creativity of nurses and the most basic of health care principles. This study of tropical leg ulcer treatment demonstrated one way in which village health workers can be taught by nurses to improve health in the community in an effective and economical manner.

Painful, debilitating leg ulcers are not uncommon for children in many developing countries. A group of five schoolchildren in the village of Chiba, in the Democratic Republic of Congo, requested treatment for such leg ulcers. Their request triggered a successful treatment project in 1996 that continues today.

Tropical leg ulcers primarily affect school age children and are painful and often debilitating. There is no causative organism for these ulcers: rather, they are caused by poor nutrition and lack of sanitation. Because they are more frequent in times of food scarcity, improved nutrition may not be available. Left untreated, tropical ulcers progress to open, weeping sores, 2 to 3 inches in diameter, that attract flies, eventually exposing tendons and bones. Such ulcers can remain for months or years. If healing occurs, it is often the site for future breakdown. These ulcers can lead to septicemia, osteomyelitis, or even death.

A house-to-house survey was conducted in the village to determine the underlying causes of the ulcers. Open-ended questions regarding overall health as well as the leg ulcers were included. The survey revealed an even higher incidence of ulcer than was initially projected.

Tissue biopsies were performed to diagnose the cases. If no causative organisms were found, the diagnosis of “tropical leg ulcers” was made. The design of the treatment plan included cost, availability of material, and sustainability for the project. The researcher served as a consultant to the village health workers who implemented the treatment. Pictures were designed for teaching children and mothers, and captions were translated into Swahili. Volunteers in the United States prepared bandages (made from sheets), washcloths, and bars of soap, and raised money for antibiotic ointments that were subsequently sent to Africa.

Word of mouth alerted the villagers about the project. Parents and children were invited to a teaching session to learn about causes of the ulcers and intervention. Each affected child was given supplies and an identification number. Once treatment began, a patient's response to treatment was tracked. The treatment consisted of cleaning the ulcers with a traditional tea made from guava leaves, applying antibiotic ointment to the most severe ulcers, and covering

them with bandages. The traditional antiseptic solution made from guava tea has been reported to be effective in several nations, was readily available, and had no cost because villagers could make it themselves from local resources.

Mothers were taught to wash their hands and the wound with soap, apply the antiseptic solution, and cover each wound with a dressing and bandages. Each patient was given a replacement dressing for use while the other was washed and dried in the sun for “sterilization.”

The sores responded rapidly to treatment. The ulcers were dubbed “uferi” after a local political party that had the same characteristics of “emerging and flourishing overnight.” Many patients saw dramatic improvement in 1 week. A review of the records 6 months later revealed that volunteer health workers treated more than 600 uferi that had successfully healed. Eight failures were attributed to patients’ lack of compliance.

News of the successful treatment traveled for several hundred miles and into the neighboring Zambia. Volunteer caregiver health care workers became consultants to neighboring communities. The development of self-esteem and leadership skills was a side benefit of the Uferi project. Both the treatment and the community leadership of health care workers continue today despite recent civil war and political difficulties. This is an excellent example of operationalization of the Primary Health Care model supported by the World Health Organization.

1. Do you think the results of the Uferi project would be the same if a nurse had conducted the intervention rather than the village health care worker? Why or why not?
2. How does the village health care worker fit into the Primary Health Care scheme? What were the advantages of the village health care workers in the Uferi project?
3. What factors do you think might affect a mother's compliance with the treatment of tropical leg ulcers?
4. If you were the nurse researcher, how would you go about determining indigenous, effective treatment interventions?
5. Could something like the Uferi project work in the United States?
6. Why do you think the health care workers developed increased self-esteem and leadership skills because of this project?

#### Reference:

Kirkpatrick, S.M. (2000). The Congo children's weeping sores. *Reflections on Nursing Leadership*, 26(2). 10–16,45.

younger than 1 year of age rose from 20% to 80% between 1980 and 1990. Access to safe drinking water in developing countries increased from 38% to 66%, and adequate improved sanitation moved from 32% to 38% between the mid-1970s and 1990.

Future action regarding PHC calls for strengthened collaboration among governmental agencies and NGOs in both the public and private sectors. Only then will the world have a realistic chance of achieving all the goals set out in the *Declaration of Alma-Ata* (1978) (Display 16.7).

## DISPLAY 16.7

**WHO'S TEN GOALS  
TOWARD HEALTH FOR ALL**

- To increase the span of healthy life for all people in such a way that health disparities between social groups are reduced.
- To ensure universal access to an agreed upon set of essential health-care services of acceptable quality, comprising at least the eight essential elements of primary health care.
- To ensure survival and healthy development of children.
- To improve the health and well being of women.
- To ensure healthy population development.
- To eradicate, eliminate, or control major diseases constituting global health problems.
- To reduce avoidable disabilities through appropriate preventive and rehabilitative measures.
- To ensure continued improvements in nutritional status for all population groups.
- To enable universal access to safe and healthy environments and living conditions.
- To enable all people to adopt and maintain healthy lifestyles and health behavior.

Lanza, R. (1996). *One world: The health and survival of the human species in the 21st century*. Santa Fe, NM: Health Press.

**The Way Forward**

One of the greatest achievements of WHO has been the eradication of smallpox. In 1967, when smallpox was endemic in 31 countries, 13 million cases were estimated worldwide. It is projected that 20 million people would have died in the next two decades if smallpox had not been eradicated. The WHO, with Dr. D.A. Henderson of Johns Hopkins University, is credited with eliminating smallpox (Henig, 1997). The WHO's other accomplishments include reduction of malaria, standardization of data-collection systems, adoption of international standards for the control and reporting of morbidity and mortality, and publication of classic works for the prevention and management of disease (Whaley & Hashim, 1995). In addition, the WHO has been credited with preventing hundreds of millions of cases of tropical diseases. As the 21st century begins, new eradication/elimination programs are under way for polio, leprosy, Guinea Worm Disease, and measles. Other initiatives include:

1. Reducing transmission and incidence of HIV/AIDS
2. Launching the *Roll Back Malaria* program
3. Stopping the transmission of tuberculosis
4. Increasing access to essential pharmaceuticals
5. Improving the poor quality of some pharmaceuticals
6. Preventing and treating iron deficiency
7. Reducing maternal morbidity and mortality
8. Promoting healthful lifestyles for all age groups, including elders

Dr. Gro Harlem Brundtland, former Director General of WHO, characterized the 20th century as one encompassing

the biggest social transformations of history. Living conditions, she noted, have dramatically improved for the large majority of human beings, and she identified health as the key to improving the productivity of people and nations. She noted the persistence of excess mortality and morbidity that disproportionately affect poor people, and underscored the need to focus on those interventions that can achieve the greatest health gains possible using available resources (Newsday, 2001).

**International Governmental Organizations with National Governments**

Sometimes, the WHO is the first to describe a health-related situation requiring international support. It then contacts other groups or organizations with the requisite expertise, assembling members of its international disaster-preparedness teams from governmental organizations that represent various nations. Organizations such as church-related groups, universities, researchers, and governments provide international assistance.

Countries throughout the world are structured to fund within-country health issues and to contribute to the international agenda. The United States contributes internationally through its United States Agency for International Development (USAID). Some other countries' international arms include Denmark's DANIDA and Italy's Italian Cooperation. The European Union (EU) is an organization that provides funding for many health-related projects.

**United States Agency for International Development**

The United States Agency for International Development (USAID) is an independent, bilateral agency of the executive branch that is under the guidance of the Secretary of State. It works to enhance long-term and equitable economic growth and to advance U. S. foreign policy by supporting countries in their efforts to recover from disaster, escape poverty, and engage in democratic reforms. The Agency provides support to developing countries for economic development, agriculture and trade, global health, democracy, conflict prevention, and humanitarian assistance and does this through its collaboration with many governmental and private agencies to implement its programs (Natsios, 2002). This agency also hires nurses and other health care providers, and often provides workshops to brief grant writers on the interventions currently under exploration.

**American International Health Alliance**

The USAID often collaborates with other organizations to implement its programs. The American International Health Alliance (AIHA) is one of these, and operates under a cooperative agreement with USAID. It establishes and manages hospital partnerships between health care institutions in the United States and their counterparts in central and Eastern Europe and in the newly independent states of Central Asia. The AIHA is reportedly the U.S. hospital sector's most coordinated response to health care issues in those areas. In 2002, AIHA managed more than 90 partnerships in 21 countries (AIHA, 2002).

## DISPLAY 16.8

## WORLD BANK

The fight against poverty is not a fight for glory. It is about equity and social justice, about the environment and resources we all share, and about peace and security. It is a fight for a better life for all of us and for our children who will live in this very interconnected world.

James D. Wolfensohn, 1999

## World Bank

The **World Bank (WB)** is an agency that focuses on economic development, and it includes a health component. It partners with countries, the WHO, and other organizations to address poverty, build capacity, transfer knowledge, provide resources, and forge partnerships in the public and private sectors (Display 16.8).

## Nongovernmental Organizations

Countries throughout the world provide interventions through formal governmental organizations and through nongovernmental organizations (NGOs). These organizations are not under government sponsorship or control. In the United States, they are designated as private voluntary organizations (PVOs) that focus on humanitarian and professional issues related to global health. Examples of PVOs are the Global Health Council, the Center for International Health and Cooperation, CARE, the Carter Center, and the International Council of Nurses (ICN).

These organizations contribute in their particular areas of expertise and work with other international organizations, research centers, and universities. Some focus on children, such as Save the Children; some on medically focused interventions, such as Doctors Without Borders; and some on logistics and supplies, such as Direct Relief International.

## Global Health Council

The Global Health Council (GHC), (formerly known as the National Council for International Health), is the world's largest membership alliance dedicated to saving lives by improving health throughout the world. The GHC advocates for needed policies and resources, builds networks and alliances among those working to improve health, and shares innovative ideas, knowledge, and best practices in health (Global Health Council, 1999b).

The GHC's membership includes hundreds of private and public organizations around the world, as well as several thousand professionals involved in global health. It is staffed by a multidisciplinary, cross-cultural board of directors, health professionals, student interns, volunteers, and members (GHC, 1999b).

## Center for International Health and Cooperation

The Center for International Health and Cooperation (CIHC), founded in 1992, promotes healing and peace in countries

shattered by war, regional conflicts, and ethnic violence. Its belief is that health and other basic humanitarian actions often provide the only common ground for initiating dialogue and cooperation among warring parties (CIHC, 2002).

## CARE

The Cooperative for American Remittances to Europe (CARE) was founded in 1945, when 22 American organizations joined together to rush life-saving *care packages* from individual American citizens, churches, clubs, and businesses to survivors of World War II. Millions of CARE packages followed in the next two decades. In the 1950s, CARE expanded its program to developing nations, using surplus American food to feed the hungry. In the 1960s, it pioneered PHC. Now renamed the Cooperative for Assistance and Relief Everywhere, CARE is affiliated with an international confederation of 11 member organizations. CARE intervenes by responding to famines and disasters worldwide with emergency food, supplies, and rehabilitative efforts. It delivers programs in education, health, population, water and sanitation, agriculture, environmental preservation, economic development, and community building (CARE, 2002).

## The Carter Center

Former United States President, Jimmy Carter, and his wife Roselyn, founded the Carter Center in 1986. The Carter Center intervenes in disease prevention and agriculture throughout the world. The particularly successful interventions include the Guinea Worm Disease eradication program in Africa and parts of Asia in the areas served by the Carter Center, and the program to eradicate River Blindness, which has been eliminated in Africa and Latin America. Its Trachoma Control Program continues to fight blindness in Africa and Yemen.

The Carter Center also sponsors the Ethiopia Public Health Training Initiative, designed to strengthen teaching capacities of faculty members at five major universities of Ethiopia. Staff members of the Carter Center collaborate with Ethiopians to develop curriculum materials specifically created to meet the learning needs of rural and urban health center team personnel (Carter Center, 2002).

## International Council of Nurses

As noted earlier, the ICN represents the global interests and concerns of the nursing profession. ICN's mission is to maintain the role of nursing in health care through its global voice (Vance, 1999). Its current membership includes nursing organizations from 120 countries and 1.5 million nurses.

## National Governments Working Alone

Individual nations have considerable experience working across agencies and organizations, and they have traditions that they honor as they intervene. For example, the Federal Republic of Germany has one of the largest voluntary sectors in the world and is known for its work with the International Red Cross. The Finnish Nursing Organization has an outstanding international reputation for its work during the Armenian earthquake and in other international efforts throughout Europe. The Danish Nurses Organization has

provided funds, leadership, and expertise to numerous projects in collaboration with the WHO and with the ICN.

At times, however, governments facing a crisis or disaster prefer to operate alone, without international assistance. This position must be respected and, because of this expectation, international organizations will not appear in a country until a formal request is received from representatives of the country in crisis. Furthermore, some countries are more receptive to certain kinds of assistance than others. Some countries do not welcome foreign professionals, as they believe they have enough of their own. They may prefer help in the form of equipment, transport, medications, or vital supplies, such as water and food. Those in disaster preparedness are well aware of what some refer to as the “second disaster,” when well-intentioned groups send in truckloads of used clothing and articles that are useless in some environments. At times, governments would prefer to work alone, but do not have the resources to do so, nor can their authorities provide the personnel to sort the kinds of contributions donors provide during emergencies.

### Organizations with Religious Affiliations

Many organizations are sponsored by religious groups, some of which include a religiously oriented agenda along with their interventions. Some, however, do not. Often, the work of these groups is similar to those with a nonreligious focus, and the source of funding for a particular project may be the only overt connection to any religious group. Catholic Charities and other Christian organizations provide critical interventions, as do Moslem, Jewish, and other religiously oriented organizations. These organizations often recruit community health nurses and other health care providers for short- and long-term assignments.

## COMMUNITY HEALTH NURSING OPPORTUNITIES

Let us suppose that, after reading this chapter and some of its references, you have decided to work in a location other than your own. In all probability, you would begin your work at a local level, at a local health center in a village. You would be aware of your own issues and reasons for wanting this experience, and you would have selected the location because of some factors that draw you to it. How then might you go about preparing for the experience? In what kind of activities might you be involved? What might be the expectations and commitments you would make regarding the assignment?

Community health nurses, as shown in this chapter, carry major responsibility for managing health services in health centers, clinics, schools, workplaces, and community settings that range in population density and complexity from remote areas to major centers in large metropolitan areas. This work includes providing education, guidance, and professional supervision to other cadres of health care providers.

Before you travel, conduct your own preliminary needs assessment. You can use the logic of the thinking process developed in this chapter and move through the framework as a guide. Begin, as this chapter suggests, with a review of the context. Here you would examine the location, climate, temperatures, weather conditions, travel routes, living arrangements, languages spoken, cultural patterns, religious beliefs,

and religious holidays. Locate novels and literature from the country, as this source of data is often more revealing than many of the statistical charts and information available from official sources (Illyes, 1967; Dizdarevic, 1993; Cooke, 1967; Barzini, 1983; Rushdie, 1995; McCourt, 1999). Interacting with people from the country often provides valuable insights not available from reading materials. In all probability, you will find enclaves of people living in the United States from the country in which you plan to work. For example, Armenian communities are located in Watertown, Massachusetts and Los Angeles, California. There are many Ethiopian communities in Atlanta, Georgia; New York City, New York; and Los Angeles, California. There are groups and organizations of Albanian Americans, Polish Americans, Hungarian Americans, Romanian Americans, and Indian Americans. These groups maintain close contact with their mother country, and receive and give support to their family members and organizations in those countries.

Next, examine the population’s health status, at the regional levels (e.g., Europe, Asia, Africa) the country level (Chad, Nepal, India) and at the local level (Tete Provinces and villages in Tete Provinces, Mozambique). Here you would review the data to identify the universals of care; that is, the causes of mortality and morbidity, the level of functioning in the community, decision making (if available), and cost of health care (Farrell, Gehring, & Howe, 2000).

Then, move on to review evidence of the three eras of health conditions in the country and determine the age of the population and the health conditions they experience, given their history, location, and experiences with natural or man made disasters. Look at birth rates, death rates, infant mortality rates, and maternal mortality rates, asking: How many infants are born? How many of these die at birth, during the first month of life, during the first year of life? How long do people live? What kills them? What makes them sick? How do people function everyday? What kinds of decisions do they have to make and how do they make them? What community supports exist to help people with these processes? What is the average income per capita? What do people buy with their money?

Review the conditions that account for the three eras of health conditions as described in this chapter, and determine the prevailing health conditions that you will encounter. Review the kinds of health conditions that are reported both in the professional literature and in the popular literature and media.

Next, it’s helpful to review the organization with which you will be associated. Examine its philosophy, its mission, its ways of working, its relationship to the community of interest, and the ways in which community health nurses are considered, placed, and function. Query the nature of the health care team of which you would become a member, those to whom you report and those who would report to you. Review their scope of practice, the interventions they provide, and their ways of delivering health services.

It is helpful to identify the international governmental and NGOs working in the area and obtain their publications for review, and their addresses and contact numbers (when you arrive in the area, visit these organizations and request a briefing). Review the projects currently under way, and examine their track record for the factors that suggest ill-conceived outcomes and evidence of those that produced successful outcomes.

## PERSPECTIVES VOICES FROM THE COMMUNITY

You cannot build a strong country on the backs of sick people.

*Dr. Mohammad Akhter, Executive Director,  
American Public Health Association*

Nurses and midwives play a crucial and cost-effective role in reducing excess mortality, morbidity, and disability and in promotion of healthy lifestyles.

*Dr. Gro Harlem Brundtland, Director-General,  
World Health Organization*

Global health nurses always receive far more than they give.

*Cydne, former Peace Corps nurse*

The developing world may be poor materially, but it is rich in hope and spirit.

*Edith, missionary nurse*

Nurses working in foreign lands make a big difference through their training and support of local nurses and others. Their professional dedication to quality health care and promotion of healthful living among their patients, families, and communities serves as an effective role model and has a profound impact on the well-being of the people they work with.

*Tom, physician*

Living overseas for many years was a challenging and rewarding experience. Raising a family was not always easy, but our six children, now adults, value the exposure they had to other cultures and the many interesting friendships they made.

*Inez, spouse of a global health administrator*

Nurses play an important role ministering to the health care needs of not only the indigenous population, but also the sometimes-sizable population of expatriates and their families.

*Jennifer, teacher*

There is nothing so powerful as seeing a community that has changed through individuals taking responsibility for themselves and their own community.

*Lydia, volunteer PHN with Medical Ambassadors*

Following this review, identify and remediate gaps in your knowledge of theory and practice. Most importantly, take the time to plan, to take care of yourself and your health, as your own health status is critical to your functioning in what may be a very different context from your own.

To explore specific opportunities, contact the organization of interest (see the listing of selected organizations at the end of the chapter). Some of the larger organizations, such as the WHO, require graduate education and at least 5 years of experience, but many organizations do not. Nurses can participate in numerous smaller organizations that are involved in health programs. Among such groups seeking nurses are the U.S. Peace Corps, religious and lay organizations, and

private and governmental agencies, societies, and foundations. Health Volunteers Overseas (HVO) is an example of a private, nonprofit organization that seeks to improve health care quality and access in developing countries through education. Twelve professional organizations sponsor HVO, including the American Association of Colleges of Nursing (Health Volunteers Overseas, 2003). The GHC provides information on career opportunities in global health for community health nurses and others. It also offers career seminars and provides suggestions from global health experts for nurses interested in entering the field (Global Health Council, 1999b). University student nurses can also contact their campus Office of Global Affairs for opportunities available overseas (see Perspectives: Voices from the Community).

## Summary

Community health nursing is practiced throughout the world and can be considered within a useful, worldwide framework. This framework considers first the context within which the population, the provider, and the procedures interact.

The context reflects a location's geography, history, weather, culture, religious patterns, and belief systems. This context is a critical element that community health nurses appreciate for its influences on the populations, the providers, and the interventions they are able to deliver.

Community health nurses work with populations that vary from country to country, and to serve them appropriately requires an understanding of the ways in which the context in which they are located interacts with their health status and health histories. In this regard, an examination is required to assess the universal imperatives of care, to identify the population's current health status, and to determine the focus of nursing interventions. That is, when a population is experiencing high mortality, the interventions must be targeted to that level, and not, say, at the level of functioning.

Community health nurses also examine the population to assess the kinds of health conditions they experience, and the three eras are helpful guides in this assessment. These are: the Era of Infectious Diseases, the Era of Chronic Long Term Health Conditions, and the Era of Social Conditions. The three P's (Population, Providers, and Procedures) relate to the interventions community health nurses deliver as they serve populations and are informed by the organization with which the community health nurse works. A number of international, national, and local organizations intervene in communities. Some of these agencies are intergovernmental and multilateral, such as the United Nations and WHO; others are bilateral, such as the USAID and the Peace Corps. Many NGOs (or PVOs) also assist with global health.

The focus remains on delivering PHC to populations throughout the world. The world's communities deliver health care in different ways, depending on their political economies. The entrepreneurial, welfare-oriented, comprehensive, and socialist systems provide for the health of their citizens in unique ways.

Variations of these systems exist, depending on whether the country is considered industrialized, transitional, or very poor. The GBD study has provided important quantifiable information about morbidity and mortality in the world, as well as disability measurements. Primary global health concerns include the eradication, elimination,

or control of communicable disease, as well as immunization, maternal and perinatal morbidity and mortality, tobacco-related diseases, chronic disease, environmental illness, and malnutrition. In addition to these age-old health problems, there are new, emerging, and re-emerging diseases. Armed conflicts and political upheavals also adversely affect health; this is an important consideration because of the number of major armed conflicts occurring at any given time.

Community health nursing services are critical to the ultimate health of a community. They provide important primary, secondary, and tertiary levels of care and prevention throughout the world. In the future, community health nurses will continue as major contributors to global health. ■

### ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Identify a country or community in which you would like to practice community health nursing. Before you being a review of this community, bracket your own knowledge, attitudes, and beliefs about the country, the people, and the culture. Examine your own reasons for wanting this experience. Identify the way you might feel if you were the recipient rather than the donor of the services you plan to provide?
2. Conduct your own needs assessment using the framework provided in this chapter. Given what you have found, what would you prioritize as the major focus of a community nursing intervention for that community? Provide your rationale for your choices.
3. Given what you have found, what organizations, groups, or references would you access before you left on your assignment?
4. Based on your examination, what questions would you want to ask of the employing agency before you left on your assignment? What additional actions would you take to protect yourself and your health, given the review you conducted?
5. What sources of information appear to be most informative? What data are you seeking that is not reported? Why do you think this is the case?
6. Identify a person or a group from the community in which you plan to work. Develop an interview protocol that includes questions that address the framework developed in this chapter. What are the most appropriate questions these individuals or groups can answer?

## Being Prepared: Disasters and Terrorism

### LEARNING OBJECTIVES

*Upon mastery of this chapter, you should be able to:*

- ◆ Describe a variety of characteristics of disasters, including causation, number of casualties, scope, and intensity.
- ◆ Discuss a variety of factors contributing to a community's potential for experiencing a disaster.
- ◆ Identify the four phases of disaster management.
- ◆ Describe factors involved in disaster planning.
- ◆ Describe the role of the community health nurse in preventing, preparing for, responding to, and supporting recovery from disasters.
- ◆ Use the levels of prevention to describe the role of the community health nurse in relation to acts of chemical, biologic, or nuclear terrorism.

*“Dig a well before you are thirsty.”*

—Chinese Proverb

### KEY TERMS

Biologic warfare  
Casualty  
Chemical warfare  
Critical incident stress  
debriefing (CISD)  
Direct victims  
Disaster  
Disaster planning  
Displaced persons  
Indirect victims  
Intensity  
Man-made disaster  
Mass-casualty incident  
Moulage  
Natural disaster  
Nuclear warfare  
Post-traumatic stress  
disorder (PTSD)  
Refugee  
Resilience  
Scope  
Terrorism  
Triage

 **What** would you do if your local news station broadcast an announcement that your community was directly in the path of a hurricane that earlier in the day had caused extensive damage and loss of life in a neighboring state? What would you do if you were shopping at a local mall, suddenly heard an explosive noise followed by shouts and cries for help, then noticed that a pungent odor was filling the air? What *did* you do on the morning of September 11, 2001, when the world of each American, especially those in New York City, in Washington, D.C., and on a plane over rural Pennsylvania, changed forever? In August of 2007, were you glued to your television set as the frantic search for survivors of the I-35W bridge collapse in Minneapolis, MN, took place? When you heard news of the massive loss of life and property from the 2008 cyclone that devastated Myanmar (Burma), could you even imagine the plight of the survivors whose lives hung in the balance? Even today, the impact of the 2005 hurricanes Katrina and Rita on the Gulf Coast continues to affect the lives of the residents of those communities devastated by the storms. As distant as some of these scenarios might seem from your own life, natural disasters and terrorism are ever-present possibilities, and nurses and other health care professionals have an obligation to respond appropriately. This chapter will increase your understanding of the community health nurse's role in preparing for, responding to, and recovering from natural disasters and terrorism.

## DISASTERS

A **disaster** is any natural or man-made event that causes a level of destruction or emotional trauma exceeding the abilities of those affected to respond without community assistance. The crash of a private plane over the Pacific Ocean in which no bodies are recovered and no environmental impact is felt is not a disaster by this definition, because no specific community-based response is required or even possible. Such a tragedy may however, be felt for a lifetime by family members and friends, who need emotional support and possibly long-term financial assistance. If a plane with 150 passengers crashes over land, destroying several homes in its path, the community affected is unable to cope with the resulting injuries, deaths, and property destruction without assistance; by the definition used here, this constitutes a disaster.

The geographic distribution of disasters varies because certain types of disasters are more common in some parts of the world. For example, California is associated with earthquakes and Florida with hurricanes. Similarly, it is not surprising to hear of drought in Ethiopia or floods in India during the monsoon season. When certain types of disasters are anticipated, communities are usually better prepared for them. For instance, California has strict building codes to prevent destruction of structures in the event of earthquakes, but most California homes lack the basements and insulation that characterize homes in regions often visited by tornadoes or winter storms. Similarly, residents of Germany, Austria, and Russia are better prepared for blizzards than for heavy rain, which probably explains in part the devastation caused in some communities by floods there in 2002.

Because the local media in the United States do not typically report on disasters unless there are mass casualties, one may be unaware of the frequency and variety of both natural and technologic disasters worldwide. Here is a brief

sampling of major disasters that occurred in 2007–2008 (Infoplease, 2008; International Charter, 2008):

### May 2007

- ◆ **Russia:** Explosion killed 38 coal miners in Yubileinaya, 2 months after a similar explosion in a nearby town killed 110.

### June 2007

- ◆ **Pakistan:** More than 200 people died during severe storms in Karachi, Pakistan's biggest city.

### August 2007

- ◆ **Greece:** Over 220 separate fires ravaged the Greek countryside, threatening ancient Olympic sites around Athens. At least 59 people died in the blazes.

### September 2007

- ◆ **Sudan:** Over 20 people died, 65 people were injured, and thousands of livestock were lost by flooding in central Sudan.

### October 2007

- ◆ **California:** Wildfires burned more than 516,000 acres in southern California. Seven died, and nearly 90 people were injured. Over 500,000 people were forced to evacuate their homes; 2,000 homes were destroyed.

### November 2007

- ◆ **Bangladesh:** Cyclone killed nearly 3,500 people in southern Bangladesh; millions of people were left homeless.

### February 2008

- ◆ **U.S. South:** Violent tornadoes strike Kentucky, Tennessee, Alabama, Mississippi, and Arkansas with little warning, resulting in 54 deaths and hundreds of injured, with widespread damage reported.

### May 2008

- ◆ **China:** Earthquake struck eastern Sichuan, northwest of Chengdu. The tremor was felt throughout the region, with the death toll exceeding 65,000.

## Characteristics of Disasters

Disasters are often characterized by their cause. A **natural disaster** is caused by natural events, such as the floods in Namibia or the earthquake in China in 2008. A **man-made disaster** is caused by human activity, such as the 2007 bombings in India on a train headed to Pakistan, the bombing of the World Trade Center in New York City in 2001, the displacement of thousands of Kosovars during their war with Serbia in 1999, or the riots in Los Angeles in the early 1990s. Other man-made disasters include nuclear reactor meltdowns, industrial accidents, oil spills, construction accidents, and air, train, bus, and subway crashes.

A **casualty** is a human being who is injured or killed by or as a direct result of an accident. Although major disasters sometimes occur without any injury or loss of life, disasters are commonly characterized by the number of casualties involved. If casualties number more than two people but fewer than 100, the disaster is characterized as a *multiple-*

*casualty incident*. Although multiple-casualty incidents may strain the health care systems of small or mid-sized communities, a **mass-casualty incident**—involving 100 or more casualties—often completely overwhelms the resources of even large cities. Preparedness for mass-casualty incidents is essential for all communities.

The possibility of being prepared is another characteristic that varies with different types of disasters. For instance, the path and time of landfall of a hurricane can be tracked, so that residents in the storm's path can be evacuated and families and businesses can be protected. Communities can also minimize devastation from flooding by building reservoirs or refusing to grant building permits in flood-prone areas, and by reinforcing areas around waterways with sandbags during rainy weather. In fire-prone areas, communities can post notices to heighten awareness of fire danger and enforce regulations to cut back vegetation near structures in forested areas.

On the other hand, some disasters strike without warning. For example, the terrorist attacks in New York City caught thousands of civilians unaware. They were trapped in buildings with limited escape routes and very little time to retreat to safety. For employees in the Pentagon on 9/11, survival depended on being in the right place at the right time. The number of fires in southern California in 2007 was unanticipated and uncharacteristically large, and control was hindered by heat and high winds. Residents were barred from reentering their communities for weeks, without any knowledge of whether they would have homes when they were allowed to return.

The **scope** of a disaster is the range of its effect, either geographically or in terms of the number of victims. The collapse of a 500-unit high-rise apartment building has a greater scope than does the collapse of a bridge that occurs while only two cars are crossing.

The **intensity** of a disaster is the level of destruction and devastation it causes. For instance, an earthquake centered in

a large metropolitan area and one centered in a desert may have the same numeric rating on the Richter scale, yet have very different intensities in terms of the destruction they cause.

## Victims of Disasters

Because disasters are so variable, there is no typical victim in a disaster. Nor can anyone predict whether he will ever become a victim of a disaster. However, once disaster strikes, victims may be characterized by their level of involvement. **Direct victims** are the people who experience the event, whether fire, volcanic eruption, war, or bomb. They are the dead and the survivors, and even if they are without physical injuries, they are likely to have health effects from their experience. Some may be without shelter or food, and many experience serious psychological stress long after the event is over (Display 17.1).

Depending on the cause and characteristics of the disaster, some direct victims may become displaced persons or refugees. **Displaced persons** are forced to leave their homes to escape the effects of a disaster. Usually, displacement is a temporary condition and involves movement within the person's own country. A common example is relocation of residents of flooded areas to schools, churches, and other shelters on higher ground. Typically, the term **refugee** is reserved for people who are forced to leave their homeland because of war or persecution. For example, over 2.5 million displaced people live in camps in Darfur after fleeing ethnic cleansing by Sudanese government forces and militia. The United Nations (U.N.) estimates that an additional 2 million have been impacted by the conflict, resulting from the damage to local economies and trade (Human Rights Watch, 2008). Also of concern to the world community is the 4.5 million Iraqis believed to have been displaced by violence in their country, over 2 million of

### DISPLAY 17.1

## DIRECT AND INDIRECT VICTIMS OF A DISASTER

On September 11, 2001, almost 3,000 people died in the terrorist attacks on the World Trade Center in New York City. Although all of the employees and visitors in the two buildings were direct victims of this disaster, the entire population of Manhattan can be considered indirect victims. Hotels, businesses, and apartments for blocks surrounding the Twin Towers suffered structural damage, blown-out windows, and interiors covered with inches of powdered cement and other debris. A year after this disaster, many residents in the surrounding areas still were unable to return home.

Many rescue workers who were survivors have lasting psychological effects from their own survival experiences and from losing close friends and colleagues. In addition, many rescuers inhaled the dust in the air for days and now suffer respiratory damages, which changes their status from indirect to direct victims of the disaster.

All people working or visiting in Manhattan that day were affected by the closing of the bridges and tunnels and were stranded in New York City until transportation routes opened again, thus becoming indirect victims. Other indirect

victims included children attending school and living within sight of the Twin Towers. They received counseling in school for months, and in some cases years, after the disaster.

For 1 year after the attack, volunteer construction workers and rescue workers who lost fellow police officers, paramedics, or firefighters worked 24 hours a day. First, the efforts were geared to find survivors. Shortly after, workers knew that they were looking for the bodies or body parts of victims while removing thousands of tons of building pieces. Thousands of people involved in the recovery efforts can still be considered indirect victims.

Family members of the 2,980 deceased victims, who have been affected for a lifetime, also are indirect victims. Thousands of children lost a parent, some parents lost multiple children, and, in some cases, both spouses were lost because husband and wife worked in the World Trade Center. The ripples of tragedy extended beyond the borders of the United States, because there were hundreds of people working in the Twin Towers from many different countries whose family members remain indirect victims.

whom now live in neighboring countries, such as Jordan and Syria (United Nations Refugee Agency, 2008). Often, the displacement of refugees is permanent, with lasting impact to both the country of origin and the host country.

**Indirect victims** are the relatives and friends of direct victims. Although these people do not experience the stress of the event itself, they often undergo extreme anguish from trying to locate loved ones or accommodate their emergency needs. If bodies cannot be found or are unidentifiable, indirect victims experience even greater anguish and may not be able to accept that their loved one has died. For example, many of the mothers of young Argentines who disappeared in the 1970s still march daily in downtown Buenos Aires, demanding public acknowledgment of the murders of their daughters and sons. Family members of victims from 9/11 in New York City have worked with architects to develop a complex of buildings and a memorial that meets the expectations of most of the indirect victims and honors their loved ones. This effort, along with the Flight 93 National Memorial (Shanksville, PA) and the Pentagon Memorial Project, will help with the long healing process. They also serve as a reminder of the impact that day had on each of our lives.

## Factors Contributing to Disasters

It is useful to apply the host, agent, and environment model to understand the factors contributing to disasters, because manipulation of these factors can be instrumental in planning strategies to prevent or prepare for disasters.

### Host Factors

The *host* is the human being who experiences the disaster. Host factors that contribute to the likelihood of experiencing a disaster include age, general health, mobility, psychological factors, and even socioeconomic factors. For instance, elderly residents of a mobile home community may be unable to evacuate independently in response to a tornado warning if they no longer can drive. Impoverished residents of a low-income apartment complex in a large city may notice that their building is not compliant with city fire codes but may avoid alerting authorities for fear of being forced to move to more expensive housing.

### Agent Factors

The *agent* is the natural or technologic element that causes the disaster. For example, the high winds of a hurricane and the lava of an erupting volcano are agents, as are radiation, industrial chemicals, biologic agents, and bombs. The Station Nightclub fire and the apartment deck collapse in Chicago (both in 2003) demonstrated that the irresponsibility of contractors and inspectors and failure to adhere to safety policies, can act as agents of disaster, resulting in death and destruction.

### Environmental Factors

*Environmental factors* are those that could potentially contribute to or mitigate a disaster. Some of the most common environmental factors are a community's level of preparedness; the presence of industries that produce harmful chem-

icals or radiation; the presence of flood-prone rivers, lakes, or streams; average amount of rainfall or snowfall; average high and low temperatures; proximity to fault lines, coastal waters, or volcanoes; level of compliance with local building codes; and presence or absence of political unrest.

## Agencies and Organizations for Disaster Management

Among disaster-relief organizations, perhaps none is as famous as the Red Cross, the name commonly used when referring to the American Red Cross, the Federation of Red Cross and Red Crescent Societies, and the International Committee of the Red Cross. The American Red Cross was founded in 1881 by Clara Barton and was chartered by the U.S. Congress in 1905. It is authorized to provide disaster assistance free of charge across the country through its more than 1 million volunteers. A common misconception is that the Red Cross is supported by the federal government; this is not the case. The American Red Cross provides services solely on donations from individuals, groups, and corporations. The duties assumed by the Red Cross in the event of a disaster are to provide sheltering, food, basic health and mental health services, and distribution of emergency supplies (American Red Cross, 2008).

The Federal Emergency Management Agency (FEMA), established in 1979, is the federal agency responsible for assessing and responding to disaster events in the United States. It also provides training and guidance in all phases of disaster management. In 2003, FEMA became part of the Department of Homeland Security (DHS). The DHS was organized in 2002, and incorporates many of the nation's security, protection, and emergency response activities into a single federal department. Other agencies that fall under the DHS include: Directorate for Preparedness, Domestic Nuclear Detection Office, Federal Law Enforcement Training Center, Office of the Inspector General, and the more widely known agencies—the Transportation Security Administration (TSA), U.S. Customs and Border Protection, U.S. Immigration and Customs Enforcement (ICE), U.S. Coast Guard, and the U.S. Secret Service (DHS, 2006). Under the oversight of FEMA is the National Incident Management System (NIMS), which was developed to allow responders from different jurisdictions and disciplines to work more cohesively in response to natural disasters, emergencies, and terrorist acts. “NIMS benefits included a unified approach to incident management; standard command and management structures; and emphasis on preparedness, mutual aid and resource management” (FEMA, 2008). Nurses and other health care professionals must understand this system and are encouraged to take courses dealing with the incident command system; these courses are available free online from FEMA.

The World Health Organization's (WHO) Emergency Relief Operations provide disaster assistance internationally, and the Pan American Health Organization works to coordinate relief efforts in Latin America and the Caribbean. In addition, various international nongovernmental organizations (such as Doctors Without Borders, the International Medical Corps, and Operation Blessing), religious groups, and other volunteer agencies provide needed emergency care.

Governments often send their military personnel and equipment in response to international disasters. For example, in May 2008, the U.S. Navy attempted for 3 weeks to provide much-needed supplies to the cyclone survivors in Myanmar (Burma). With limited options, the Navy had helicopters and landing craft on standby to deliver food, water, and medical supplies to the most remote areas of the country. The military junta in Myanmar refused to allow the shipments; further risking the lives of the millions of survivors. U.S. military planes were eventually allowed to land with supplies in the country's largest city, Rangoon (Washington Post, 2008). Transport of vital supplies to the rural areas was conducted by the government, with questionable results.

When natural or man-made disasters within the United States are accompanied by civil disturbance, looting, or violent crime, the resources of local police departments may be overwhelmed. In such cases, the National Guard is often called in to restore order. This action is typically accomplished within each individual state, under the jurisdiction of the governor.

In this situation, political agendas prevented the aid so typically accepted by countries experiencing catastrophe. Fortunately, nurses from the Commissioned Corps of the U.S. Public Health Service (USPHS) were allowed to provide aid in 2004/2005 for the tsunami and earthquake victims in Indonesia, as well assist in the 2006 medicine contamination in Panama, which ultimately claimed the lives of over 100 (USPHS, 2008). Chapter 30 contains additional information about the role of the USPHS Commissioned Corps Nurses and their role in emergency preparedness.

## Phases of Disaster Management

In developing strategies to address the problem of disasters, it is helpful for the community health nurse to consider each of the four phases of disaster management: prevention, preparedness, response, and recovery. Additionally, some knowledge of the language typically used in disaster preparedness may be helpful and is included in Display 17.2.

### DISPLAY 17.2

## COMMON TERMS USED IN EMERGENCY PREPAREDNESS AND RESPONSE

**All-hazards preparation:** Preparedness for domestic terrorist attacks, major disasters, and other emergencies.

**Chain of command:** A series of command, control, executive or management positions in hierarchical order of authority.

**Credential:** A health volunteer's qualifications. Credentials are used to determine a health volunteer's emergency credentialing level (i.e., nursing license).

**Designated equivalent source:** Selected agencies that have been determined to maintain a specific item or items of credential information that is identical to the information at the primary source.

**Disaster, major (federal):** Any natural catastrophe, or regardless of cause, any fire, flood, or explosion, in any part of the United States, which in the determination of the President, causes damage of sufficient severity and magnitude to warrant major disaster assistance to supplement the efforts and available resources of states, local governments, and disaster relief organizations.

**Emergency declaration:** Refers to the State (or local) government's capacity to declare a general emergency or public health emergency, or state of disaster.

**Emergency Management Assistance Compact (EMAC):** An interstate mutual aid agreement that allows States to assist one another in responding to all types of natural and man-made disasters.

**Just-in-Time training:** Concise, targeted training, normally provided on-site after a disaster or emergency has occurred. It provides a minimum level of exposure for volunteers to select issues in disaster response. Examples could be use of self-protection equipment, documentation, mental health triage, or registration of casualties.

### Hospital Emergency Incident Command System

**(HEICS):** An emergency management system that employs a logical management structure, defined responsibilities, clear reporting channels, and a common nomenclature to help unify hospitals with other emergency responders.

**Incident Command System (ICS):** The combination of facilities, equipment, personnel, procedures, and communications operating within a common organizational structure, designed to aid in the management of resources during incidents.

### National Electronic Disease Surveillance System

**(NEDSS):** A CDC initiative promoting the use of data and information systems standards to improve disease surveillance systems at federal, state, and local levels.

**National Incident Management System (NIMS):** The single all-hazards incident management system required by Homeland Security Presidential Directive 5 that governs the management of the National Response Plan.

**Public Health Information Network (PHIN):** A framework providing the basis for information technology projects for CDC-funded programs including NEDSS, Health Alert Network (HAN), and others.

**Strategic National Stockpile:** A national cache of drugs, vaccines, and supplies that can be deployed to areas struck by disasters, including bioterrorism.

**Surge capacity:** The accommodation by the health system to a transient sudden rise in demand for health care following an incident with real or perceived adverse health effects.

Adapted from U.S. Department of Health and Human Services–HRSA. (2005). ESAR–VHP interim technical and policy guidelines, standards, and definitions (Ver. 2) (Appendix 8: ESAR–VHP Guidelines glossary of terms). Washington, DC: U.S. Government Printing Office.

### Prevention Phase

During the *prevention phase*, no disaster is expected or anticipated. The task during this phase is to identify community risk factors and to develop and implement programs to prevent disasters from occurring. Task forces typically include representatives from the community's local government, health care providers, social services providers, police and fire departments, major industries, local media, and citizens' groups. Programs developed during the prevention phase may also focus on strategies to mitigate the effects of disasters that cannot be prevented, such as earthquakes, hurricanes, and tornadoes.

The United States has strengthened this phase of disaster management since September 2001. This can be seen especially at airports, where airline passengers must now go through a more rigorous security screening before boarding the plane. Nonpassengers cannot go beyond the security area. Photographic identification is required at two or more points before boarding. Strict limits have been placed on liquids that can be in carry-on baggage. Random searches of hand-carried luggage occur, and passengers are screened with wands that detect metal. In some states, luggage is tested for radioactive material, police officials with trained dogs patrol the airport, or people are asked to remove their shoes for examination as part of the screening process. All of these measures have been initiated to prevent a disaster.

### Preparedness Phase

Disaster *preparedness* involves improving community and individual reaction and responses, so that the effects of a disaster are minimized. Disaster preparedness saves lives and minimizes injury and property damage. It includes plans for communication, evacuation, rescue, and victim care. Any plan must also address acquisition of equipment, supplies, medicine, and even food, clean water, blankets, and shelter. Semi-annual disaster drills and tests of the Emergency Broadcast System are examples of appropriate activities during the preparedness phase.

Disaster preparedness activities occur locally, regionally, and nationally. A town keeps its warning system working and tests it each month. Sections of the country coordinate larger warning systems to notify communities in the path of a tornado or hurricane, and the country has a plan to stockpile vital pharmaceuticals such as smallpox vaccine for mass immunization. The Centers for Disease Control (CDC) reports that the Strategic National Stockpile (SNS) contains enough doses of smallpox vaccine to vaccinate every person in the U.S. should biological warfare become a threat (CDC, 2007). The last case of smallpox in the United States occurred in 1949, and routine immunization was halted in 1972 (CDC, 2007). With a largely unvaccinated population, most people in the nation would need the vaccine. Having the vaccine ready is a demonstration of disaster preparedness.

### Response Phase

The *response phase* begins immediately after the onset of the disastrous event. Preparedness plans take effect immediately,

with the goals of saving lives and preventing further injury or damage. Activities during the response phase include rescue, triage, on-site stabilization, transportation of victims, and treatment at local hospitals. Response also requires recovery, identification, and refrigeration of bodies, so that notification of family members is possible and correct, even weeks after a disaster. This care of the dead is demanding and time-consuming work that is often overlooked by people unfamiliar with disaster response. Persons trained in mortuary services are an essential part of any emergency planning efforts. Supportive care, including food, water, and shelter for victims and relief workers is also an essential element of the total disaster response. The extent of care provided for animals is an additional area of concern that should be addressed in the overall plan. Many shelters will not accept pets; those that do need to be identified as soon as possible to avoid unnecessary confusion and delays in sheltering.

### Recovery Phase

During the *recovery phase*, the community takes actions to repair, rebuild, or relocate damaged homes and businesses and restore health and economic vitality to the community. Psychological recovery must also be addressed. The emotional scars from witnessing a traumatic event may last a lifetime. Both victims and relief workers should be offered mental health services to support their recovery (see Perspectives: Voices from the Community).

### Role of the Community Health Nurse

The community health nurse has a pivotal role in preventing, preparing for, responding to, and supporting recovery from a disaster. After a thorough community assessment for risk factors, the community health nurse may initiate the formation of a multidisciplinary task force to address disaster prevention and preparedness in the community.

### Preventing Disasters

Disaster prevention may be considered on three levels: primary, secondary, and tertiary. These are applied to a natural disaster in the Levels of Prevention Pyramid.

#### Primary Prevention

Primary prevention of a disaster means keeping the disaster from ever happening by taking actions that completely eliminate its occurrence. This is the first aspect of primary disaster prevention. Although it is obviously the most effective level of intervention, both in terms of promoting clients' health and containing costs, it is not always possible. Tornadoes, earthquakes, and other disasters often strike without warning, despite the use of every available technologic device for prediction and tracking.

If possible, primary prevention of disasters can be practiced in all settings: in the workplace and home with programs to reduce safety hazards, and in the community with programs to monitor risk factors, reduce pollution, and encourage nonviolent conflict resolution. Primary

## PERSPECTIVES VOICES FROM THE COMMUNITY

It was 5:00 p.m. on October 17, 1989, in Santa Cruz, CA, a day that would change my view of life forever. I had just fed my newborn son and was rocking him in a soft, comfortable chair when the house began to shake. Without even thinking or being aware of what I was doing, I jumped up with my baby in my arms and headed for the nearest doorway, as I had done so many times before in an earthquake. I stood there holding my son in one arm and braced myself against the door jamb with the other one as the house continued to shake all around us. It was not until the shaking stopped that I began to feel fear and worry as I surveyed the damage to my house.

In my kitchen, all of the cupboard doors were flung open and their contents spilled onto the floor, which was now a mess of spilled food, sticky sauces, dented tin cans, and broken glass. Tears came to my eyes as I saw my son's infant seat, where he had been seated only moments before the quake, covered with glass shards and fallen tin cans. I realized he could have been killed, and I had no control over it. I became afraid for the safety of my 10-year-old daughter, who was at dancing lessons across town. Fortunately, when I got to her, she was safe.

The next few days continued to be very stressful. We had no gas or electricity and no running water that was safe to drink. I went to the drug store in a panic to buy premixed formula to feed my son, since I could not boil the water to mix with the powdered formula. Both the drug store and the grocery store were "trashed," all of the items were thrown

off of the shelves and laying on the debris-strewn floors. The grocery store was giving away the ice cream because they had no power to keep it frozen. But who could eat ice cream?

There was something about seeing my favorite grocery store in such a disastrous condition that made me realize how little control I had over the consequences of what insurance companies call "acts of God." I couldn't just run to the grocery store for what I needed; it wouldn't be there for me. My family and I felt very unsafe as we all huddled together in the master bedroom at night. My son was in his bassinet at the foot of the bed and my daughter slept with me until she felt safe enough to return to her own room. I was attempting to regain control of my life as I cleaned up my house and waited for the water and electricity to be restored. Of all the losses, the greatest loss was the illusion of safety and the illusion that I had control over my life.

Over the next week, I experienced the loss of many services and products that made up my comfortable and safe lifestyle: homes were damaged, with their chimneys strewn across front lawns, there was no phone service for days, and a normal 10-minute drive took an hour and a half on clogged highways provided as an alternative route to highways and bridges damaged by the quake. As a community mental health nurse, I wanted to volunteer to help others who were experiencing the same feelings as I was, but I was told that they were not taking mental health volunteers from the immediate area because we, too, were victims of the disaster, and needed to care for ourselves first. I think they were right, since I had many feelings that took a long while to heal, and I have lost the illusion of control forever.

disaster prevention efforts should take into account a community's physical, psychosocial, cultural, economic, and spiritual needs. The community health nurse has a role in each of these areas. As a teacher, the community health nurse educates people at home, at work, at school, or in a faith community about safety and security focused on preventing a disaster. The community health nurse can teach community members how to protect themselves from the effects of a natural disaster. The nurse can be a part of a safety team, if working as a school nurse or occupational health nurse. If working for a health department, the nurse can determine during home visits whether a family has a personal disaster plan and help them develop one if none exists. Nursing students can work with low-income community dwelling elders to assure that they have enough food, water, and medical supplies to "shelter in place" for at least several days. There are many actions the nurse can initiate.

The second aspect of primary disaster prevention is anticipatory guidance. Disaster drills and other anticipatory exercises help relief workers experience some of the feelings of chaos and stress associated with a disaster before one occurs. It is much easier to do this when energy and

intellectual processes are at a high level of functioning. Anticipatory work can dissipate the impact of a disastrous event. The community health nurse has a role in these disaster drills through committee membership, organization of drills at the place of employment, or activism at the grass-roots level to assist in holding community-wide disaster drills on a regular basis.

### Secondary Prevention

Secondary disaster prevention focuses on the earliest possible detection and treatment. For example, a mobile home community is devastated by a tornado, and the local health department's community health nurses work with the American Red Cross to provide emergency assistance. Secondary prevention corresponds to immediate and effective response. In a post-Katrina study of the emergency planning and response by home health providers serving the poor in New Orleans during the emergency (Kirkpatrick & Bryan, 2007), the successes and challenges of these providers were identified. Agencies that provided early evacuation, identified shelters for special-needs patients outside the high risk area, implemented volunteer cascading communication systems,

## LEVELS OF PREVENTION PYRAMID

**SITUATION:** A natural disaster—tornado.

**GOAL:** By using the three levels of prevention, negative health conditions are avoided, promptly diagnosed and treated, and/or the fullest possible potential is restored.

Tertiary Prevention					
Rehabilitation	Primary Prevention				
<ul style="list-style-type: none"> <li>Remain safe during the immediate recovery period</li> <li>Accept help from others—friends, family, and community services</li> <li>Rebuild family lives through counseling and other services to reestablish stable life physically, emotionally, spiritually, and financially</li> </ul>	<table border="1"> <thead> <tr> <th>Health Promotion &amp; Education</th> <th>Health Protection</th> </tr> </thead> <tbody> <tr> <td> <ul style="list-style-type: none"> <li>Educate community members about the need to enhance planning against damage from future natural disasters, based on experiences with the current disaster</li> </ul> </td> <td> <ul style="list-style-type: none"> <li>Keep recommended immunizations current</li> <li>Community physical structures need rebuilding, with infrastructure planning and supports that improve ability to withstand natural disasters</li> </ul> </td> </tr> </tbody> </table>	Health Promotion & Education	Health Protection	<ul style="list-style-type: none"> <li>Educate community members about the need to enhance planning against damage from future natural disasters, based on experiences with the current disaster</li> </ul>	<ul style="list-style-type: none"> <li>Keep recommended immunizations current</li> <li>Community physical structures need rebuilding, with infrastructure planning and supports that improve ability to withstand natural disasters</li> </ul>
Health Promotion & Education	Health Protection				
<ul style="list-style-type: none"> <li>Educate community members about the need to enhance planning against damage from future natural disasters, based on experiences with the current disaster</li> </ul>	<ul style="list-style-type: none"> <li>Keep recommended immunizations current</li> <li>Community physical structures need rebuilding, with infrastructure planning and supports that improve ability to withstand natural disasters</li> </ul>				
Secondary Prevention					
Early Diagnosis	Prompt Treatment				
<ul style="list-style-type: none"> <li>Remain in your position of safety until a community all-clear warning signal is sounded or until rescued</li> <li>Leave a damaged building cautiously, if able and not seriously injured, and do not return until it is declared safe</li> </ul>	<ul style="list-style-type: none"> <li>Rescue individuals promptly and get appropriate care for those injured as soon as possible</li> <li>The infrastructure of the community becomes/remains intact, keeping community members safe from hazards such as live wires, broken gas lines, and fallen debris</li> </ul>				
Primary Prevention					
Health Promotion & Education	Health Protection				
<ul style="list-style-type: none"> <li>Increase community awareness</li> <li>Increase community preparation through education</li> <li>Each person is as prepared as possible both physically and emotionally</li> </ul>	<ul style="list-style-type: none"> <li>Community members know what to do and where to go, whether at home, work, school, or elsewhere in the community</li> <li>Get to safety before the impact—southwest corner of a home's basement or an interior room away from windows and under heavy furniture</li> </ul>				

conducted pre-event mock evacuation plans, and those that included volunteers in their disaster plan were most successful. Recommendations to improve response include identification of patients who may be reluctant to evacuate, the provision of adequate security at special-needs shelters and, most importantly, practice drills (Kirkpatrick & Bryan, 2007). With appropriate planning, sound and easily understood emergency response can provide optimal care and services to those impacted by the disaster.

### Tertiary Prevention

Tertiary disaster prevention involves reducing the amount and degree of disability or damage resulting from the disaster.

Although it involves rehabilitative work, it can help a community recover and reduce the risk of further disasters. In this sense, it becomes a preventive measure.

An example from September 11, 2001, comes from a nurse living in the Boston area who, after that date, began to lose a sense of hope for her future. She often found it difficult to assist her patients with their needs because of her own insecurities and fears. She and a peer responded to a request from the Logan Airport Employee Assistance Program (EAP) asking for help with crisis counseling for United Airlines survivors of 9/11. The planes used in the attacks were from American and United Airlines, and the community of employees felt like survivors because they lived while fellow employees were lost in the disaster.

Employees were in turmoil, and their ability to function was affected. “The terrorists had taken away their colleagues, friends and sense of security” (DiVitto, 2002, p. 21).

The most important interventions the nurses provided were a listening ear and validation that what the employees were feeling and experiencing was normal, and often essential, for healthy grieving. Some employees needed to talk about good times, others were quiet and sad, and others expressed a fear of flying again but did so with the support of family and friends. All demonstrated courage and an ability to continue their lives with a sense of strength and hope. Working with these employees enabled the nurse to recapture the essence and true meaning of her life (DiVitto, 2002).

### Preparing for Disasters

**Disaster planning** is essential for a community, business, or hospital. It involves thinking about details of preparation and management by all involved, including community leaders, health and safety professionals, and lay people. A disaster plan need not be lengthy. Two weeks after the April 1995 Oklahoma City bombing of the Murrah Federal Building by two American citizens, one hospital distilled its 44-page manual into a 5-page disaster response guide. Such a concise plan should still contain information on the elements discussed in this and the following section. See Display 17.3 for a summary of these elements.

### Personal Preparation

The preparation of a disaster plan for a community should be preceded by the need for all nurses to address their own personal preparedness to respond in a disaster. Display 17.4 describes the tragic outcome of one nurse’s lack of preparation when she attempted to provide nursing care at the scene of the Oklahoma City bombing.

Personal preparedness means that the nurse has read and understood workplace and community disaster plans and has developed a disaster plan for his own family. The prepared nurse also has participated in disaster drills and knows cardiopulmonary resuscitation and first aid. Finally, nurses preparing to work in disaster areas should bring

#### DISPLAY 17.4

### NURSES AT DISASTER SITES: HELP OR HINDRANCE?

On April 19, 1995, 37-year-old Rebecca Anderson, a registered nurse working in Oklahoma City, after hearing a televised report of the bombing of the Federal Building, went to the site wearing jeans and a sweat-shirt. Along with firefighters and other rescue workers in hardhats and other protective gear, she was allowed to enter the scene. Within a short time, Rebecca was struck on the back of the head by a concrete slab that fell from the building’s wreckage. She died 5 days later of massive cerebral edema. Nurses can learn the following lessons from this tragedy:

- Never enter a disaster scene unless you are directed to do so by an emergency medical technician, fire, or law enforcement official.
- Contact local hospitals and clinics to offer your help; your medical expertise is more useful in the clinical environment.
- Take courses in first aid and emergency care. Contact your local Red Cross for a list of courses.
- Contact your local health department to learn more about your community’s disaster plan and how you can contribute in the event of a disaster in your area.

copies of their nursing license and driver’s license, durable clothing, and basic equipment, such as stethoscopes, flashlights, and cellular phones. In the event of an emergency, many who are unprepared or untrained often present at the site of a disaster or at local hospitals to volunteer. These “spontaneous volunteers” can be an additional burden to those in charge (Display 17.5).

To increase understanding of and the ability to work within an emergency situation, every nurse should become familiar with the National Incident Command System (NIMS). The NIMS offers a “unified approach to incident management; standard command and management structures; and emphasis on preparedness, mutual aid, and resource management” (FEMA, 2008). In essence, it provides a common language for disaster response, to reduce confusion as much as possible. Free

#### DISPLAY 17.3

### ELEMENTS OF A DISASTER PLAN

**A disaster plan should address all of the following:**

- Chain of authority
- Lines of communication
- Routes and modes of transport
- Mobilization
- Warning
- Evacuation
- Rescue and recovery
- Triage
- Treatment
- Support of victims and families
- Care of dead bodies
- Disaster worker rehabilitation

#### DISPLAY 17.5

### SPONTANEOUS VOLUNTEERS

Volunteers represent a potential resource to a community affected by a disaster, whether of natural or man-made origin. However, individuals who respond spontaneously and without appropriate training and verifiable qualifications can easily overwhelm the capabilities of local government and other agencies.

From Warner, K., & Hanna, B. (2007, October). *Disasters happen: Do you know your role?* Presented at 21st Century Nursing Challenges, Kappa Omicron Chapter STTI, Chico, CA.

online courses are offered through FEMA (see Display 17.6). Additionally, every nurse should have up-to-date vaccinations; many biologic threats have the same initial presentations, and reducing susceptibility to common illnesses such as influenza can help with initial identification.

### Assessment for Risk Factors and Disaster History

As noted earlier in the chapter, the community health nurse is uniquely qualified to perform a community assessment for risk factors that may contribute to disasters. In addition, the nurse should review the *disaster history* of the community. Have earthquakes, tornadoes, hurricanes, floods, blizzards, riots, or other disasters occurred in the past? If so, what (if any) were the warning signs? Were they heeded? Were people warned in time? Did evacuation efforts remove all people in danger? What were the community's onsite responses, and how effective were they? What programs were put in place to rehabilitate the community?

### Establishing Authority, Communication, and Transportation

In addition to assessing for preparedness, the effective disaster plan establishes a clear chain of authority, develops lines of communication, and delineates routes of transport. Establishing a clear and flexible chain of authority is critical for successful implementation of a disaster plan. Usually, the chain is hierarchical, with, for example, the community's governmental head (e.g., mayor) initiating the plan, alerting the media to broadcast warnings, authorizing the police to begin evacuations, and so on. Within each level of the organization, the hierarchy continues. For example, at the local hospital, the hospital administrator may be responsible for alerting nurse managers to call in additional personnel. Flexibility is essential, because key authority figures may themselves be victims of the disaster. If the home of the chief of police is destroyed in an earthquake, his second-

in-command must have equal knowledge of the community's disaster plan and be able to step in without delay.

Effective communication is often a point of breakdown for communities attempting to cope with major disasters. After the terrorist attacks in Oklahoma City and New York City, phone lines were damaged and cellular sites were overwhelmed, making communication difficult. Communication was possible only through handheld radios or by way of couriers on foot. At times of heightened chaos and stress, as well as after physical damage to communication facilities and equipment, misinformation and misinterpretation can flourish, leading to delayed treatment and increased loss of life.

Again, clarity and flexibility are the watchwords for establishing lines of communication. How will warnings be communicated? What backups are available if the normal communication systems are destroyed in the disaster? How will communication between relief workers at the disaster site, hospital personnel, police, and governmental authorities be maintained? What role will local media play, both in keeping information flowing to the outside world and in broadcasting needs for assistance and supplies? Finally, how will friends and family members of victims be informed of the whereabouts or health status of their loved ones? The characteristics of effective communication during disasters are summarized in Display 17.7.

Closed or inefficient routes of transportation can also increase injury and loss of life. For example, if a single, narrow mountainous road is the only means of transporting firefighters to or evacuating residents from the scene of a forest fire, then disaster planners should propose widening the road

## DISPLAY 17.7

## EFFECTIVE COMMUNICATION DURING DISASTERS

To be effective, communication during disasters must elicit action. Communication that elicits action provides information that is

- Believable
- Current
- Unambiguous
- Authoritative
- Predictive of the probability of future events (what is going to happen next?)

Effective communication is

- Interactive—it allows for and addresses questions
- Conclusive—it eliminates room for speculation and catastrophizing
- Urgent—conveys seriousness without resorting to fear tactics
- Clear, simple, and repetitive
- Characterized by solutions and suggestions for success
- Personal—it uses people's names if possible and addresses their real and perceived needs

Finally, because rumors can hinder effective action or provoke premature action, effective communication includes rumor control. It provides suggestions for constructive activity, reducing time and energy spent on rumor generation and perpetuation.

or clearing a second road. Disaster planners must also consider what routes emergency vehicles will take when transporting disaster victims to local and outlying hospitals or health care workers to the disaster site. What if the chosen routes are inaccessible because of floodwaters, advancing fires, mountain slides, or building rubble? Are alternative routes designated?

### Mobilizing, Warning, and Evacuating

In many natural disasters, local weather service personnel, public works officials, police officers, or firefighters have the earliest information indicating an increasing potential for a disaster. These officials typically have a plan in place for providing community authorities with specific data indicating increased risk. They may also advise the mayor's office or other community leaders of their recommendations for warning or evacuating the public. Additionally, they may recommend actions the community can take to mitigate damage, such as spraying rooftops in the path of fires, sandbagging the banks of rising rivers, or imposing a curfew in times of civil unrest.

Disaster plans must specify the means of communicating warnings to the public, as well as the precise information that should be included in warnings. Planners should never assume that all citizens can be reached by radio or television or that broadcast systems will be unaffected by the disaster. Broadcast media may indeed be a primary means of communicating warnings, but alternative strategies, such as police or volunteers canvassing neighborhoods with loudspeakers, should also be in place. In multilingual communities, messages should be broadcast in multiple languages. Not only homes but also businesses must be informed. Information that should be communicated includes the nature of the disaster; the exact geographic region affected, including street names if appropriate, and the actions citizens should take to protect themselves and their property.

An evacuation plan is an essential component of the total disaster plan. The plan should cover notification of the police, local military personnel, or voluntary citizens' groups of the need to evacuate people, as well as methods of notifying and transporting the evacuees. A plan should also be made for responding to citizens who refuse to evacuate. For example, will police authorities forcibly remove an elderly citizen from his home to a shelter? Will evacuation plans include household pets? If farms or ranches are in the path of fires or floods, will animals be evacuated?

### Responding to Disasters

At the disaster site, police, firefighters, nurses, and other relief workers develop a coordinated response to rescue, triage, and treat disaster victims. One of the first obligations of relief workers is to remove victims from danger.

#### Rescue

The job of rescue typically belongs to firefighters and personnel with special training in search and rescue. Depending on the disaster agent, protective gear, heavy equipment, and special vehicles may be needed, and dogs trained to locate dead bodies may be brought in (Fig. 17.1). Usually, the immediate disaster site is not the best place for the disaster nurse, who can be far more effective in triage and treatment of victims. One of the lessons of the World Trade Center

**FIGURE 17.1** Hazardous materials suit used by the military and most fire departments. (Photo by Cynthia Tait.)

bombing was that the greatest need for medical professionals was at the local hospitals, not at the disaster site.

Rescue workers face the logistically and psychologically difficult task of determining when to cease rescue efforts. Some factors to consider include increasing danger to rescue workers, diminishing numbers of survivors, and diminishing possibilities for survival. For example, after a plane crash on a snowy mountain, rescue efforts may cease if it is deemed that anyone who might have survived the crash would subsequently have died of exposure.

#### Triage

Whereas emergency nurses daily determine which clients require priority care, the community health nurse may be at a loss as to where to start when faced with multiple victims of a disaster. Knowing the principles and practice of triage allows the nurse to offer nursing skills most effectively. **Triage** is the process of sorting multiple casualties in the event of a war or major disaster. It is required when the number of casualties exceeds immediate treatment resources. The goal of triage is to effect the greatest amount of good for the greatest number of people. Figure 17.2 shows the four basic categories of the international triage system, as well as a triage tag.

Prioritization of treatment may be very different in a mass-casualty event as opposed to an average day in a hospital emergency department. Under normal circumstances, a person presenting to a hospital emergency department with a

1. **Red:** Urgent/Critical  
Victims in this category have injuries or medical problems that will likely lead to death if not treated immediately (e.g., an unconscious victim with signs of internal bleeding).
2. **Yellow:** Delayed  
Victims in this category have injuries that will require medical attention; however, time to medical treatment is not yet critical (e.g., a conscious victim with a fractured femur).
3. **Green:** Minor/Walking Wounded  
Victims in this category have sustained minor injury or are presenting with minimal signs of illness. Prolonged delay in care most likely will not adversely effect their long-term outcome (e.g., a conscious victim with superficial cuts, scrapes, and bruises).
4. **Black:** Dead/Non-salvageable  
Victims in this category are obviously dead or have suffered mortal wounds because of which death is imminent (e.g., an unconscious victim with an open skull fracture with brain matter showing). Life-saving heroics on this group of victims will only delay medical care on more viable victims.

**FIGURE 17.2** Victim triage tag recommended by the California Fire Chiefs Association. Four basic categories are all applied when a medical system is overwhelmed with victims. (Photo by Cynthia Tait.)

myocardial infarction and showing no pulse or respirations would receive immediate treatment and have a chance of recovery. At a disaster site, a victim without a pulse or respirations would most likely be placed in the nonsalvageable category.

The term *mass casualty* refers to a number of victims that is greater than that which can be managed safely with the resources the community has to offer (such as rescue vehicles and emergency facilities available to serve disaster victims while also meeting the needs of the rest of the community). Frequently, in mass-casualty occurrences, the broader community needs to become involved, which necessitates calling in rescue vehicles, firefighters, and police officers from neighboring towns, or the use of neighboring hospitals. This adds another layer of disaster management coordination that must be considered.

## DISPLAY 17.8

## MOBILE FIELD HOSPITAL

On August 25, 2007, we attended a statewide disaster-training exercise featuring the first state-owned mobile field hospital. The tent hospital is one of three 200-bed hospitals purchased by California and prepositioned around the state in the event of a major emergency. The hospital can be deployed and onsite within 72 hours, and comes equipped for 7 days of full patient care. Used together, the hospitals can even be reconfigured into a 400- or 600-bed hospital, if needed. This is the same type of mobile field hospital used by the military, and it was modeled after the hospitals used by the Air Force and Navy. The various units within the hospital mirror services provided in any modern facility including emergency room, surgical suite, laboratory, x-ray, surgical intensive care, and even a pediatric unit. The exercise included personnel from the Medical Reserve Corps (MRC), federal Disaster Medical Assistance Team (DMAT), state Medical Assistance Team, Mental Health Response Team, Ambulance Strike Team, California Air National Guard, and the California Highway Patrol. “Victims” were provided by a local nursing program.

From Warner, K., & Hanna, B. (2007, October). *Disasters happen: Do you know your role?* Presented at 21st Century Nursing Challenges, Kappa Omicron Chapter STTI, Chico, CA.

## Immediate Treatment and Support

Disaster nurses provide treatment onsite at emergency treatment stations, at mobile field hospitals, in shelters, and at local hospitals and clinics (see Display 17.8). In addition to direct nursing care, onsite interventions might include arranging for transport once victims are stabilized and managing the procurement, distribution, and replenishment of all supplies. Disposable items might be in short supply, requiring resterilization procedures that may be unfamiliar to a nurse not accustomed to field work. These procedures may pose a challenge even to an experienced nurse because of the field environment. The nurse may also manage provision or distribution of food and beverages, including infant formulas and rehydration fluids, and arrange for adequate, accessible, and safe sanitation facilities, either onsite or in a shelter. Finally, the nurse often must also arrange for psychological and spiritual care of victims of disasters.

Some victims who seem physically uninjured may, in fact, be suffering from major injuries but be unable to relate their symptoms to a relief worker because of shock or anxiety. For instance, a father pulling debris away from his collapsed house after a tornado may be so worried about a missing child that he does not realize that he has a broken arm.

Other victims may be so emotionally traumatized by a disaster that they act out, disrupting efforts to assist them and other victims and even engaging in dangerous activities. This may cause relief workers to focus on emotional care; however, such victims must be assessed for head trauma and internal injuries, because their behavior may have a physical cause. If they are physically able, such victims may be given

a simple, repetitive task to perform, which serves as both a distraction and a means to restore, to a small extent, their sense of control over their environment.

### Care of Bodies and Notification of Families

Identification and transport of the dead to a morgue or holding facility are crucial, especially if contagion is feared. Toe tags make documentation visible and accessible. Records of deaths must be made and maintained, and family members should be notified of their loved ones' deaths as quickly and compassionately as possible. If feasible, a representative from each of the area's faith communities should be available to assist families awaiting news of missing loved ones. As stated earlier, a family's recovery from loss is often delayed when notification of relatives (indirect victims) is not possible because the victims' bodies are badly damaged or not found.

### Supporting Recovery from Disasters

Disasters do not suddenly end when the rubble is cleared and the victims' wounds are healed. Rather, recovery is a long, complex process. It often includes long-term medical treatment, physical rehabilitation, financial restitution, and psychological and spiritual support.

#### Long-term Treatment

Long-term treatment may be required for many victims of disasters, straining the local rehabilitative-care facilities and resources. Children who were victims may have to deal with lifelong disabilities or scars from their ordeal, and families may be without adequate financial support for their child's medical care. Elderly citizens who had been in excellent health but who sustained serious injuries in the disaster might suddenly find that they can no longer live independently and must move to a long-term care facility. After floods, landslides, fires, or earthquakes, extensive property damage may cause some residents or businesses to relocate rather than rebuild on land they now deem to be disaster prone. A disaster that creates numerous victims in a small community may alter the entire social fabric of that community permanently.

#### Long-term Support

Disaster victims may need funding to repair or rebuild their homes or to reopen businesses, such as stores, restaurants, and other services needed by the community. Insurance settlements, FEMA funding, and private donations may assist in financing community rehabilitation. Health care workers may be required to assist victims with necessary paperwork. Immediately after a disaster, some victims may be unable to concentrate on anything beyond fulfilling their immediate needs and those of their family.

Psychological support is often required after a disaster, both for victims and for relief workers. Some individuals may experience posttraumatic stress disorder (PTSD) (discussed later). Many victims, especially elderly persons displaced from their homes, may quietly lose their will to live and drift into apathy and malaise. Individuals whose belief in God was unshakable before the incident may now question their faith, wondering how a loving God could have let this happen, espe-

cially if they lost a loved one. These victims often require not only empathic listening but also long-term skilled spiritual counseling. In assessing a community's citizens for counseling needs after a disaster, the nurse should not forget to include children. Often, children do not have words to express their feelings or fears and may act out in ways adults find difficult to understand, unless age-appropriate psychological intervention is provided.

#### Need for Self-care

Self-care, including stress education for all relief workers after a disaster, helps to reduce anxiety and put the situation into proper perspective. **Critical incident stress debriefing (CISD)** provides relief workers with professional debriefing in small groups or individually and becomes a mechanism for emotional reconciliation. The ideal time for CISD is between 24 and 72 hours after the disaster event. CISD typically produces positive effects by

- ◆ Accelerating the healing process
- ◆ Equipping participants with positive coping mechanisms
- ◆ Clearing up misconceptions and misunderstandings
- ◆ Restoring or reinforcing group cohesiveness
- ◆ Promoting a healthy, supportive work atmosphere
- ◆ Identifying individuals who require more extensive psychological assistance.

A CISD addresses all components of the human response to trauma, including physiologic effects, emotions, and cognition. Studies show that CISD allows individuals to regain a sense of normalcy much sooner than those not involved in CISD. Self-care comes in many forms and is part of a prescription for emotional healing after a traumatic event. Self-care is not just for rescue workers but for everyone touched by trauma. Keep in mind the following self-care points (Peeke, 2002):

- ◆ *Give yourself time to heal.* You need time to adjust. Even though you want the pain to be over immediately, it is healthier to realize that this is a long-term recovery process.
- ◆ *Ask for emotional support.* Talk with family and friends around the country. It feels good to be connected with others. You listen and support one another as you share your feelings.
- ◆ *Take care of yourself;* it will improve your ability to deal with stress. Eat regularly, avoid alcohol, maintain sleep patterns, follow your exercise routine, and embrace each day as a gift.
- ◆ *Reestablish daily routines.* Getting back to your regular routine is important and gives you a sense of security and normalcy.
- ◆ *Use your time wisely.* A significant traumatic event gives you an opportunity to reprioritize how you spend your time each day. Are you living your dreams and passions? Traumatic events remind us of our fragile nature and that each moment should be savored and enjoyed.
- ◆ *Give something back.* Your life goes on. Demonstrate your gratefulness by becoming part of a global healing process. Donate to charities and give time to causes you have ignored. Seek ways to reach out to those who are in need of help.

## Psychological Consequences of Disasters

In addition to physical injury, potential loss of life, and destruction of property that can occur from a disaster, people affected by the disaster can also suffer from psychological consequences, such as acute stress disorder, depression, and PTSD. The community health and community mental health nurses, through education, screening, assessment, and referral, have an important role in the primary, secondary, and tertiary prevention of psychological disturbances due to a disaster.

### Primary Prevention

Although a disaster, by its very nature, is often unforeseen, people's ability to cope with the disaster can be determined in part by their previous level of coping and the resources available to help them. Stuart and Laraia (2005) explain that primary prevention in behavioral health care has two basic objectives:

- ◆ To help people avoid stressors or cope with them more adaptively
- ◆ To change the resources, policies, or agents of the environment so that they no longer cause stress but rather enhance people's functioning (pp. 208–209).

A community health nurse can engage in many activities to promote mental health and strengthen adaptive coping skills in individuals and the community. He can teach health education classes in positive stress adaptation, positive ways of coping, self-efficacy, and **resilience**, an important quality that enables people to cope with disaster. A definition of resilience is offered by the President's New Freedom Commission on Mental Health in their 2003 report *Achieving the Promise: Transforming Mental Health Care in America*:

Resilience means the personal and community qualities that enable us to rebound from adversity, trauma, tragedy, threats, or other stresses—and to go on with life with a sense of mastery, competence, and hope. We now understand from research that resilience is fostered by positive individual traits, such as optimism, good problem-solving skills, and treatments. Closely knit communities and neighborhoods are also resilient, providing supports for their members (p. 5).

According to Stuart and Laraia (2005), the building of competency or resilience may be the most important primary prevention strategy, since a competent person or community can make informed decisions based on availability of resources and problem-solving skills. In a phone survey of more than 2,700 New York City residents (after September 11, 2001), Bonanno, Galea, Bucciarelli, and Vlahov (2007) found that the strongest variables associated with resilience pertained to the absence of additional life stressors, pointing to the need for more research on the role of resilience in recovery from extreme incidents.

In addition to working with individuals within the community to enhance their resilience, community health nurses can contribute to primary prevention in the face of disaster by being active advocates for improving the social structure of the community, including housing, work, and economic conditions for community members. At a time when governments are reducing spending and services, it is important for the community health nurse to advocate for the resources necessary for the community to meet both the physical and psychological challenges of a disaster.

### Secondary Prevention

Despite community education and intervention, people involved in a disaster often feel anxious and overwhelmed. They are in a *mental health crisis*, defined as a state when people's usual coping mechanisms no longer are effective in the face of the overwhelming disaster (Stuart & Laraia, 2005). A crisis or disaster, an event that is out of the ordinary in magnitude and personal experience, is called an *adventitious crisis*. Examples of adventitious crises are natural disasters, such as floods, earthquakes, and fires, and national disasters such as terrorist attacks, war, riots, and airplane crashes (Varcaro-lis, Carson, & Shoemaker, 2006). When the stress of these disasters causes overwhelming anxiety, *crisis intervention* is a secondary prevention intervention that the trained community health or community mental health nurse can employ to minimize the psychological consequences of the disaster.

*Crisis intervention* is a short-term intervention, no longer than 6 weeks, designed to return an individual or community to its predisaster level of functioning and solve immediate psychological problems. Interventions are provided on several levels: environmental manipulation, general support, generic approach, and the individual approach (Stuart & Laraia, 2005). *Environmental manipulation* results in the change of a person's physical or interpersonal situation, providing situational support to relieve stress. An example of environmental manipulation is when a community health nurse coordinates the reunification of family members separated by the disaster. *General support* is defined as the caring, warmth, and concern the community health nurse conveys to the client as he delivers services (Stuart & Laraia, 2005).

The *generic approach* is an aspect of crisis intervention that is particularly well suited to the community health nurse. This approach is designed to reach high-risk individuals and large groups who have experienced the same disaster, teaching them about the expected emotional reactions to the type of disaster they have experienced and promoting adaptive responses. Grief reactions follow a known pattern, and large groups can be taught what to expect in the face of severe loss while giving individual members of the group an opportunity to express their feelings of loss. This generic approach is sometimes called *debriefing*. Individual crisis intervention is reserved for high-risk individuals who need special treatment because of the severity of their symptoms and is best provided by nurses trained in mental health treatment and crisis intervention (Stuart & Laraia, 2005).

### Tertiary Prevention

People who have experienced or witnessed a disaster and have been unable to adequately cope with its consequences can develop long-term effects, such as *acute stress disorder* or **post-traumatic stress disorder (PTSD)**. According to the fourth edition of *Diagnostic and Statistical Manual of Mental Disorders*, text revision (DSM-IV-TR) (American Psychiatric Association [APA], 2000), both acute stress disorder and PTSD can occur after any traumatic event in which a person responds with intense fear, helplessness, or horror to an actual or threatened death or serious injury to oneself or others. Both natural and man-made disasters fit into this definition (see Evidence-based Practice).

## EVIDENCE-BASED PRACTICE

### Posttraumatic Stress Disorder and Physical Health

What is the relationship between posttraumatic stress disorder (PTSD) and physical health? Researchers in the Netherlands (Dirkzwager et al., 2007) asked this question and conducted a longitudinal study of 876 survivors of a man-made disaster to look for answers.

In 2000, a fireworks depot in a residential neighborhood in Enschede, Netherlands, exploded, leaving 1,000 people injured and 23 people (including four firefighters) dead. Five hundred houses were uninhabitable and 1,000 more houses were damaged. Twelve hundred residents were left homeless and had to be relocated.

The researchers examined survivors' medical records from 1 year before until 4 years after the disaster. They also surveyed the survivors at 3 weeks and 18 months after the disaster. A self-rating scale for PTSD symptoms, a Dutch version of the Symptom Checklist-90-R, and a Dutch translation of the Short Form Health Survey-36 (RAND-36) were administered to survivors 18 months post disaster. The data were examined using multiple regression

analysis and adjusting for demographics, predisaster health status, and smoking behavior. Results showed a significant relationship between PTSD and vascular, musculoskeletal, and dermatologic problems, as recorded in the medical record and between PTSD and all self-reported physical health problems.

#### Nursing Implications

The results of this study indicate that a relationship exists between PTSD and physical problems. Nurses assessing people for PTSD should be aware of physical symptoms as well as psychological ones. Nurses assessing physical symptoms in people who have survived a disaster should be aware of the possible comorbidity of PTSD.

#### Reference:

Dirkzwager, A.J., Van der Velden, P.G., Grievink, L., & Yzermans, C.J. (2007). Disaster-related posttraumatic stress disorder and physical health. *Psychosomatic Medicine*, 69, 435–440.

The DSM IV-TR (APA, 2000) defines acute stress disorder as occurring within 1 month of the disaster and resolving within 4 weeks. A person experiencing acute distress disorder must have three symptoms of dissociation during or after the disaster:

- ◆ A subjective sense of numbing, or absence of emotional responsiveness
- ◆ A reduction of awareness of his or her surroundings (e.g., “being in a daze”)
- ◆ Derealization (a sense of unreality regarding one's environment)
- ◆ Depersonalization (sense of unreality or self-estrangement)
- ◆ Dissociative amnesia (i.e., inability to recall an important aspect of the trauma) (p. 432)

If an acute reaction to the disaster lasts longer than 4 weeks, it can develop into the more chronic disorder of PTSD. According to the DSM-IV-TR (APA, 2000), the symptoms for both acute stress disorder and PTSD include the following:

- ◆ The traumatic event is persistently reexperienced in one (or more) of the following ways:
  1. Recurrent and intrusive distressing recollections of the event, including images thoughts, or perceptions
  2. Recurrent distressing dreams of the event
  3. Acting or feeling as if the traumatic event were recurring (includes a sense of reliving the experience, illusions, hallucinations, and dissociative flashback episodes, including those which occur on awakening or while intoxicated)

4. Intense psychological distress at exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event
  5. Physiological reactivity on exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event
- ◆ Persistent avoidance of stimuli associated with the trauma and numbing of general responsiveness (not present before trauma) as indicated by three (or more) of the following:
    1. Efforts to avoid thoughts, feelings, or conversations associated with the trauma
    2. Efforts to avoid activities, places, or people that arouse recollections of the trauma
    3. Inability to recall an important aspect of the trauma
    4. Markedly diminished interest or participation in significant activities
    5. Feelings of detachment or estrangement from others
    6. Restricted range of affect (e.g., unable to have loving feelings)
    7. Sense of a foreshortened future (e.g., does not expect to have a career, marriage, children, or normal life span)
  - ◆ Persistent symptoms of increased arousal (not present before the trauma), as indicated by two (or more) of the following:
    1. Difficulty in falling or staying asleep
    2. Irritability or outburst of anger
    3. Difficulty concentrating
    4. Hypervigilance
    5. Exaggerated startle response (p. 428)

It is important for the community health nurse to be aware of the symptoms of these disorders so that he can refer the client for treatment, which should be left to the advanced practice mental health nurse and other mental health professionals.

## TERRORISM

At the start of the 21st century, the world is a global community. This is particularly evident in the increased incidence and sophistication of terrorist threats and acts around the world. Incidents occurring on U.S. soil, such as the bombing of the World Trade Center in 1993 and its destruction on September, 11, 2001, alerted us to our vulnerability and dramatically emphasized the need for increased preparedness within our communities.

The July 2005 bombings in London that struck multiple transportation system sites, which killed 56 and injured over 700; the February 2008 bombings in Baghdad by remotely controlled bombs carried by two mentally disabled women, which killed 98 and wounded 200; and the 2007 bombings in Karachi, Pakistan, which killed 136 and injured 387, all confirm that our vulnerability exists in many areas. Biologic, chemical, and nuclear terror are tragically possible.

The U.S. Federal Bureau of Investigation (FBI) defines **terrorism** as “the unlawful use of force and violence against persons or property to intimidate or coerce a government, the civilian population, or any segment thereof, in furtherance of political or social objectives” (Evans, Crutcher, Shadel, Clements, & Bronze, 2002). A terrorist is overzealous and obsessed with an idea. Terrorism and terrorist acts are not new. The term *terrorism* can be traced to 1798, and the use of terrorist tactics precedes this date. A highly organized religious sect called the *sicarii* attacked crowds of people with knives during holiday celebrations in Palestine at about the time of Christ. During the French and Indian War of 1763, British forces gave smallpox-contaminated blankets to Native Americans. During World War I, the German bioweapons program developed anthrax, glanders, cholera, and wheat fungus as weapons targeting cavalry animals. In World War II, the Japanese tested biologic weapons on Chinese prisoners.

Three major countries operated offensive bioweapons programs in recent years: the United Kingdom until 1957, the United States until 1969, and the former Soviet Union until 1990. Iraq started its bioweapons program in 1985 and continued to develop weapons until 2003. At least 17 other nations are currently suspected of operating offensive bioweapons programs (Evans et al., 2002). Bioweapons include mustard gas, sarin and VX gas, and anthrax. Terrorists typically use biologic, or chemical agents and explosives or incendiary devices to deliver the agents to their targets.

**Nuclear warfare** involves the use of nuclear devices as weapons, and can take several forms. Terrorists who gain access to nuclear power plants could cause a chain of events that lead to a meltdown of the nuclear core, thereby releasing radioactive particles for hundreds of miles around the site. Nuclear accidents have occurred, but no known terrorist attacks have yet involved the use of nuclear power plants as weapons. A terrorist attack using nuclear weapons or destruction of a nuclear plant would cause multiple and prolonged deaths with extensive damage and negative effects for decades.

**Chemical warfare** involves the use of chemicals such as explosives, nerve agents, blister agents, choking agents, and incapacitating or riot-control agents to cause confusion, debilitation, death, and destruction (Yergler, 2002). Terrorists in the Middle East, willing to sacrifice their own lives, strap bombs to themselves and detonate the explosives in or near targets. Others crash vehicles loaded with explosives into crowds of people or into a building.

The aircraft used on September 11, 2001, were huge chemical weapons because they were carrying thousands of tons of jet fuel. The success of the mission depended on the surprise of the attack, severe damage to recognizable buildings, and the deaths of many people. The collapse of the buildings was unplanned. If the planes had been low on fuel, the damage would not have been as severe. The liquid fuel burned at such a high temperature that the internal structures of the buildings were weakened (National Institute of Standards and Technology, 2006).

**Biologic warfare** involves using biologic agents to cause multiple illnesses and deaths. Typical biologic agents are anthrax, botulinum, bubonic plague, Ebola, and smallpox. These agents could be used to contaminate food, water, or air. Deliberate food and water contamination remains the easiest way to distribute biologic agents for the purpose of terrorism (Khan, Swerdlow, & Juranek, 2001). The U.S. Office of Technology Assessment has speculated that the release of 220 pounds of anthrax spores from a crop-duster over the Washington, D.C., area on a calm, clear night could kill between 1 and 3 million people (U.S. Army Chemical and Biological Defense Command, 1998).

The United States is very concerned about the possibility of biologic warfare or bioterrorism, as nations should be. The anthrax infections and deaths that occurred after September 11, 2001, added to these concerns. For years, it was not known if these incidents were committed by an organized foreign or domestic terrorist group, or a single disturbed citizen. In 2008 the investigation led to an army scientist as the cause of this terroristic act. Although charges were never filed due to the individual’s suicide, the Federal Bureau of Investigation believes that he was solely responsible for this act of domestic terrorism (FBI, 2008). Regardless of the source of terrorism, the outcomes are the same: fear, death, and destruction.

## Factors Contributing to Terrorism

Political factors are the most common contributors to terrorism. Anti-American sentiment runs high in many foreign countries, especially those that perceive the United States as a threat to their military, economic, social, or religious self-determination. Terrorist acts against American military installations abroad, in airports, in airplanes, at American embassies, and even on American soil have occurred frequently in the last decade as an expression of political unrest. The war in Iraq in 2003 was based on information about suspected bioterrorism weapons and reports that Iraq was harboring anti-Western terrorists; these two pieces of information resulted in the toppling of the Saddam Hussein political regime. However, hundreds of military lives were lost, and no weapons of mass destruction were found. As of September 2008, more than 4,000 U.S. military have lost their lives, and some 30,000 are dealing with injuries in the ongoing military campaign (Associated Press, 2008).

Within the United States, violence-prone members of militia movements, violent anti-abortion activists, racial desegregation advocates, and other radical groups have performed terrorist acts, such as the bombing of health clinics offering abortions. In 1984, members of a religious cult, the Rajneeshees, lived in Wasco County, Oregon, and followed a self-proclaimed guru exiled from India. In an attempt to reduce voter turnout in an upcoming county election, they sprinkled *Salmonella* bacteria over items on salad bars in local restaurants and in the produce sections of grocery stores. They hoped that, with a reduced voter turnout, representatives friendlier to their group would win the election. Their attack failed to affect the election and killed no one; however, 751 people became sick (Bernett, 2006; McDade & Franze, 1998). The media underreported this event because domestic terrorism was not a topic of concern at that time in U.S. history.

## Role of the Community Health Nurse

Community health nurses need to be prepared for the possibility of terrorist activity. They have a role in primary, secondary, and tertiary prevention.

### Primary Prevention

Community health nurses are in ideal situations within communities to participate in surveillance. They must look and listen within their communities for anti-group sentiments, for example, anti-religion, anti-gay, or anti-ethnic feelings. The nurse should report any untoward activities accordingly.

Nurses should be alert to signs of possible terrorist activity. Specific indicators of possible chemical or biologic terrorism include unusual numbers of dead or dying animals; unexplained serious illnesses or deaths; an unusual liquid, spray, vapor, or odor; and low-lying clouds or fog unrelated to weather. Unusual swarms of insects might also indicate the use of biologic agents for terrorism. “Many nurses currently employed have little knowledge regarding the potential pathogens that could be released or how to respond to a chemical or biologic attack” (Veenema, 2002, p. 63). Additionally, Secor-Turner and O’Boyle (2006) noted a lack of studies of nurses’ responses to bioterrorism events in a literature review of studies between 2002 and 2004. They emphasized the need for bioterrorism plans that “incorporate strategies to support nurses and address their physical, psychological, and emotional issues” (p. 414). Less subtle forms of terrorism include bombings, mass shootings, and hijackings, which are more difficult to uncover in time to prevent injury or death.

### Secondary and Tertiary Prevention

Although prevention of terrorist incidents is primarily the responsibility of the Department of Defense, the Department of Homeland Security, and public health and law enforcement agencies, community health nurses must be ready to handle the secondary and tertiary effects of such attacks. Knowing the lethal and incapacitating chemical weapons that may be used by terrorists is important. Many of the communicable disease organisms that could be used by terrorists were discussed in Chapter 8.

Realizing that terrorist attacks may result in large numbers of casualties, the community health nurse must be prepared to act safely, access information rapidly, and use

resources effectively. Specifically, the community health nurse may be called on to provide direct care to victims, to volunteer as a hospital–community liaison, to set up and administer mass immunizations, to make home visits to affected families, or to serve on committees responding to terrorist acts. Formulating, updating, and following a disaster plan is one of the most effective community-based strategies to minimize injury and mortality from terrorism.

Most community health nurses will not be on the front line of uncovering or immediately responding to terrorist activities, but their skills will be needed with groups, families, or individuals who experience a terrorist-related event. Some of the activities listed earlier in this chapter to help people deal with the aftermath of a disaster would also be appropriate if terrorism is the cause of the disaster. In addition, community health nurses may work with people who need help coping or who want to do something to help. After experiencing a traumatic event such as a terrorist attack, people do not know how to cope. We are warned to expect more attacks. We are told to be vigilant. The terror we are fighting is often our own. This is a new experience for most people, and assistance from the community health nurse can help them cope effectively. The following 10 tips were gathered from experts in many fields by Foley (2002) and are common-sense approaches to fighting anxiety:

- ◆ *Be a little afraid.* A certain level of fear is healthy if you learn to use it as positive energy. Use your pinch of anxiety to be more vigilant about your safety and that of your family, especially when you travel, and in taking care of your health.
- ◆ *Keep a courage journal.* Fear immobilizes, and courage takes action. Every time you take action, you are getting past fear. Even small steps are an opportunity to build more courage. Every time you take a courageous step—getting on a plane, opening your mail—write it down.
- ◆ *Reassure your children.* In the act of reassuring your children, you will reassure yourself.
- ◆ *Hang out with children.* Do things with your children—most young people carry a charge of positive energy that is infectious. If you do not have young children, volunteer at a school or read to children at a nearby day care center.
- ◆ *Cook something hearty, healthy, and large, and invite lots of people in to eat it.* The process of cooking is good for the soul. The aromas are good for the soul. And the chopping and dicing make you feel that you are doing something useful and concrete.
- ◆ *Give kindness to others.* We all need each other. Make a point of chatting with the woman at the checkout counter or letting a pedestrian cross the street when you are driving. Wave hello to strangers. You will be amazed how much it is true that in giving, we receive.
- ◆ *Get spiritual.* Reach out and participate in your faith community or get involved in one, if so inclined. Believing in a power greater than yourself can be comforting.
- ◆ *Laugh.* Laughter is the best medicine for fear. Spend evenings in good company—group laughter is better than laughing alone.

- ◆ *Get back to nature.* Spending interactive time with nature is a remedy for just about any soul sickness. Go to the park, take a walk, or work in your garden.
- ◆ *Find reasons to believe the sky is not falling.* All the unpleasant facts and figures get our “anxiety juices” flowing. Seek out positive people, and read literature that encourages positive thinking. Do not feed the “dark side.” Turn off the news and opt for a funny movie or an inspirational story.

Community health nurses can make major differences in grassroots efforts to bring about change, but on a day-to-day basis, the little things they say and do with peers and clients can make just as big a difference.

### Current and Future Opportunities

There are many ways in which nurses, and most especially nursing students, can prepare themselves both personally and professionally for emergency events in their own communities. Various governmental and educational programs have been developed to provide free online training covering a broad range of topics. A summary of some of those training opportunities is provided in Display 17.6. For the novice nurse, or nursing student, an important issue is your role, if any, in your local response plan. Many schools of nursing have now begun to formalize their emergency preparedness plans in coordination with local hospitals, public health departments, or faith institutions. Take some time to discuss with your faculty what role you have in the event of a local emergency. If no organized plan exists, then perhaps you can work with the nursing faculty or your local student nurses association to prepare one. Knowing your role in an emergency will give you the peace of mind of knowing where you should go and what you are expected to do. Doing a little extra work by completing some of the online courses listed will help you to feel more involved and less fearful if the unimaginable were to happen. FEMA offers four particular courses within the Incident Command System (ICS 100, ICS 200, IS700, & IS800B); these are recommended for all health care personnel. Students who are also employed at local hospitals as interns or salaried employees should find out what role they have in the hospital’s emergency plan.

Increasingly, communities are conducting emergency preparedness exercises (for example, mass casualty exercises and table-top exercises; see Display 17.9) in response to the need to prepare local resources to coordinate emergency response efforts for maximum effectiveness (Center for Public Health Preparedness, 2007). As a student, you may be asked to participate in one of these exercises as a “victim.” Take the opportunity. The knowledge you gain from this experience will enhance your understanding of the process, and you may be able to help identify gaps in services or areas in need of improvement. With your expertise in nursing, you are a much greater asset to the exercise than untrained individuals. You may be asked to have **moulage** applied to simulate injuries, and you will likely be given a brief description of your trauma (see Display 17.10). Your assigned health problem may be emotional and not physical, allowing you to utilize your understanding of behavioral health issues and crisis intervention. Whatever your capacity, the experience will provide as close to a realistic event as possible. Just as

#### DISPLAY 17.9

### WHAT IS A TABLE-TOP EXERCISE?

A table-top exercise is a drill typically used by emergency planners and responders. It is designed to allow personnel to gather in a semi-formal setting, so that they can participate in open discussions regarding their role in the event of an emergency situation. Participants typically assume their own role, but may be required to assume other key positions. A simulated disaster/emergency event is provided, called the *scenario*. This type of drill:

- Does not require complete plans and procedures.
- Allows for practice in coordinated emergency problem solving.
- Permits discussion of the decisions reached.
- Prepares personnel for larger, more costly exercises (i.e., mass casualty exercises).

Adapted from Placer County Department of Health and Human Services (2005). *Table Top Exercises: What are they? Why do we have them?* Auburn, CA.

immunizations help fight against infections, participating in an emergency preparedness drill can build your tolerance for responding appropriately in a real event.

Many organizations, both private and governmental, are seeking volunteers. As a student, you have more limited options; however, two major opportunities are available to you. Both require initial and ongoing training, but if you wish to become more active in emergency preparedness volunteer efforts, the American Red Cross and your local Medical Reserve Corps are two options. You can continue your relationship with these organizations after you receive your nursing license, and your role with them will likely evolve.

With your registered nurse license in hand, many more options are open to you. Each state is developing plans for a database of licensed health care providers who may be willing to volunteer in the event of local, state, or national emergencies. The exact criteria being developed for registration by each

#### DISPLAY 17.10

### WHAT IS MOULAGE?

Pronounced *mü-läzh*, the term *moulage* comes from the French word *mouler*, which means “to mold.” In emergency preparedness training, moulage refers to the art of applying mock injuries for use in mass-casualty exercises. These injuries can be very simple or more complex, depending on available resources and the skills of the person applying the moulage. The use of moulage typically provides a more realistic experience for personnel participating in mass casualty exercises.

Of the many online resources for information regarding equipment needed and how-to advice, one such website is Community Emergency Response Team (CERT) Los Angeles—*Moulage Information* at: <http://www.cert-la.com/education/moulage.htm>.

state may vary slightly, but as a licensed health care professional you may add your name to the registry along with your specialty training and contact information. Registration does not obligate you to any service; you agree only to be contacted if the need arises. The guidelines for these state-run databases were generated by the U.S. Department of Health and Human Services, and can be reviewed in the document *Emergency Systems for Advance Registration of Volunteer Health Professionals* (ESAR-VHP) (USDHHS Health Resources Services Administration, 2005). The professional volunteer registry in Wisconsin is named WEAVR (*Wisconsin Emergency Assistance Volunteer Registry*). Using similar guidelines, California launched its version of the registry (*California Medical Volunteers*). Mississippi has the *Volunteers in Preparedness Registry* (VIPR), and Arkansas nurses can register with the *Arkansas Volunteer Registry*. Check with your state's office of emergency preparedness and response for the link to your particular registry or information on availability.

As you progress in your career, many other high-intensity efforts are available for your involvement. At both the national and state level are Disaster Medical Assistance Teams (DMAT), groups of highly trained health professionals who can rapidly respond to emergencies within a state or nationally. The DMATs operate as part of the National Disaster Medical System (NDMS). Each DMAT has a sponsoring organization (i.e., major medical center, public health agency, nonprofit organization). Check to see if your organization has sponsored a DMAT; if so, you might want to interview one of the members to learn more about his training and experiences.

For those assuming roles in public health nursing, competencies formulated by Gebbie and Qureshi (2002, 2006) provide a sound basis for practice. The work of Gebbie and Qureshi was included in the 2007 position paper *The Role of Public Health Nurses in Emergency Preparedness and Response* (Jakeway, LaRosa, Cary, & Schoenfisch, 2008). The specific competencies can serve as an emergency preparedness guide for students and practicing public health nurses. They include the following:

1. Describe the public health role in responding to a range of likely emergencies.
2. Describe the agency's chain of command in emergency response.
3. Identify and locate the agency's emergency response plan.
4. Describe one's functional roles and responsibilities in emergency response and demonstrate those roles in regular drills.
5. Demonstrate the correct use of equipment (including personal protective equipment) and the skills required in emergency response during regular drills.
6. Demonstrate the correct use of all equipment used for emergency communication.
7. Describe communication role(s) in emergency response.
8. Identify the limits of one's own knowledge, skills, and authority, and identify key system resources for matters that exceed these limits.
9. Apply creative problem-solving skills and flexible thinking to unusual challenges within one's func-

tional responsibilities, and evaluate the effectiveness of all actions taken.

10. Recognize deviations from the norm that might indicated an emergency and describe appropriate action.
11. Participate in continuing education to maintain up-to-date knowledge in areas relevant to emergency response.
12. Participate in planning, exercising, and evaluating drills.

Many options are available to you as both a student and a practicing nurse. What is important is that you are prepared. Assuring that you understand the role you may assume in the event of a local disaster or emergency situation is critical to your own welfare as well as to your community. You decide your level of participation, but resources are available for you to become as prepared as possible.

## Healthy People 2010

The past decade of *Healthy People* has been devoted to increasing quality and years of healthy life and to eliminating health disparities (USDHHS, 2000). Formulated in the years before January 2000, many disasters, both natural and man-made, had yet to occur. The United States had not yet faced the national failures in the response to the hurricanes Katrina and Rita. We would also learn 18 months after the publication of *Healthy People 2010* that our nation was not immune from acts of terrorism. The objectives of *Healthy People 2010* do not directly address issues of emergency preparedness and response, but rather document a plan to support and strengthen the public health structure of this country. In the ensuing years, many of those objectives originally seen as less significant to the public's health received new and invigorated attention. Objective 23 deals with issues relevant to a robust public health structure at the local, state, and national levels (see Display 17.11). Those

### DISPLAY 17.11

### HEALTHY PEOPLE 2010

#### Data and Information Systems

- 23-1 Public health employee access to the Internet
- 23-2 Public health access to information and surveillance data
- 23-3 Use of geocoding in health data systems

#### Workforce

- 23-8 Competencies for public health workers
- 23-9 Training in essential public health services
- 23-10 Continuing education and training by public health agencies

#### Public Health Organizations

- 23-11 Performance standards for essential public health services
- 23-13 Access to public health laboratory services
- 23-14 Access to epidemiology services
- 23-15 Model statutes related to essential public health services

specific objectives provide the support needed to enhance public health surveillance activities, training, development of professional competencies, and performance standards for public health organizations. With enhanced funding and increased attention to the emerging needs of the coming decade, the issue of emergency preparedness is already on the list of proposed goals for *Healthy People 2020: The Road Ahead* (USDHHS, 2008).

## Summary

A disaster is any event that causes a level of destruction that exceeds the abilities of the affected community to respond without assistance. Disasters may be caused by natural or man-made/technologic events and may be classified as multiple-casualty incidents or mass-casualty incidents.

The scope of a disaster is its range of effect, and its intensity is the level of destruction it causes. Victims of disasters include direct victims (those injured or killed) and indirect victims (the loved ones of direct victims). Displaced persons are those who are forced to flee their homes because of the disaster, and refugees are those who are forced to leave their homelands, usually in response to war or political persecution.

Host factors that contribute to the likelihood of experiencing a disaster include age, general health, mobility, psychological factors, and socioeconomic factors. The disaster agent is the fire, flood, bomb, or other cause. Environmental factors are those that could potentially contribute to or mitigate a disaster.

In developing strategies to address the problem of disasters, it is helpful for the community health nurse to consider each of the four phases of disaster management: prevention, preparedness, response, and recovery.

Primary prevention of disasters means keeping the disaster from ever happening by taking actions to eliminate the possibility of its occurrence. Secondary prevention focuses on earliest possible detection and treatment. Tertiary prevention involves reducing the amount and degree of disability or damage resulting from the disaster.

In addition to assessing for preparedness, an effective disaster plan establishes a clear chain of authority, develops lines of communication, and delineates routes and modes of transport. Plans for mobilizing, warning, and evacuating people are also critical elements of the disaster plan. At the disaster site, police, firefighters, nurses, and other relief workers develop a coordinated response to rescue victims from further injury, triage victims by seriousness of injury, and treat victims on-site and in local hospitals. Care and transport of dead bodies must also be managed, as well as support for the loved ones of the injured, dead, or missing. Long-term support includes both financial assistance and physical and emotional rehabilitation.

In addition to the physical injuries resulting from disasters, people also suffer psychological trauma that can affect them for life. The importance of prevention, early crisis intervention, and ongoing treatment for those in need is evident. The community health nurse plays a key role in assessing individuals for symptoms of psychological trauma and intervening to prevent long-term consequences. Self-care, including stress education for all relief workers after a disaster, helps to lower anxiety and put the situation into perspective. CISD provides relief workers with a mechanism for emotional reconciliation and healing.

Terrorism is the unlawful use of force or violence against persons or property to intimidate or coerce a government or civilian population in the furtherance of political or social objectives. Terrorism may be nuclear, biologic, or chemical, and may involve the use of nerve agents and explosive devices. The community health nurse should be alert to signs of possible terrorist activity and prepared to address the secondary or tertiary effects of such attacks. Preparation includes knowledge of the effects of specific biologic or chemical agents and how to help people cope with the terror they personally feel.

Many opportunities are available for both student nurses and experienced community health nurses to become involved in emergency preparedness and response efforts. Agencies such as the American Red Cross and the Medical Reserve Corps are options available to students and at a higher level of involvement, once licensed. Natural and man-made disasters are a too frequent occurrence. It is the obligation of all nurses to be involved in emergency preparedness and to seek training that will enable them to provide the best possible service if the unthinkable happens. With the development of *Healthy People 2020*, ongoing efforts to help communities prepare for disasters and emergencies will require more nurses willing and able to respond to a call for action. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Think about your own community and its residents. What are some host factors that might increase its risk of experiencing a disaster? What environmental factors might be significant? In each case, identify the likely agent. What interventions could be included in a disaster plan to reduce these risk factors?
2. The nightly news on TV shows that at least 200 people have been injured in an explosion in a neighboring community. At the disaster site, victims are still being recovered from the wreckage, and local hospitals are overwhelmed with patients who have fractures, lacerations, and burns. You want to offer your assistance as a registered nurse. How should you go about volunteering your services?
3. Access one or more of the Internet sites listed in this chapter. Report on the change in statistics for disasters or terrorism since the year 2005. Have rates increased or decreased? What factors might be involved in this change?

# THE FAMILY AS CLIENT

# 18

## Theoretical Bases for Promoting Family Health

### LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Analyze changing definitions of family.
- ◆ Discuss characteristics all families have in common.
- ◆ Identify five attributes that help explain how families function as social systems.
- ◆ Discuss how a family's culture influences its values, behaviors, prescribed roles, and distribution of power.
- ◆ Compare and contrast the variety of structures that make up families.
- ◆ Describe the functions of a family.
- ◆ Identify the stages of the family life cycle and the developmental tasks of a family as it grows.
- ◆ Analyze the role of the community health nurse in promoting the health of the family unit.

*“Call it a clan, call it a network, call it a tribe, call it a family. Whatever you call it, whoever you are, you need one.”*

—Jane Howard, “Families”

### KEY TERMS

Augmented family  
Blended family  
Cohabiting couples  
Commune family  
Commuter family  
Contemporary family  
Energy exchange  
Family  
Family culture  
Family functioning  
Family health  
Family map  
Family structures  
Family system boundary  
Foster families  
Gangs  
Group-marriage family  
Group-network family  
Homeless families  
Intrarole functioning  
Kin-network  
Multigenerational families  
Nontraditional family  
Nuclear-dyad family  
Nuclear family  
Primary relationship  
Roles  
Single-adult families  
Single-parent families  
Stepfamily  
Traditional family  
Wider family

 **Community** health nurses are intimately involved with families. Whether the client is an individual within the context of the family or the family is the unit of care, the family plays a critical role in the health of its members. Health habits, such as preventive care, diet, exercise, and physical activity, are developed within the context of the family (Campbell, 2006). Health beliefs, genetic influences, and care of the ill family member all take place within the family environment.

The community health nurse is in a unique position to influence and promote family health while facing a multitude of challenges. The family is a separate entity with its own structure, functions, and needs. Throughout history, the family has been the most basic unit. Among one of the biggest controversies facing the community health nurse is defining what constitutes a family. This definition is important because how nurses define a family influences the care they give and, at the most basic level, how they interact with the family. When you hear the word *family*, what do you think of? How would you define your own family? Is your grandfather a member of your family? Your niece? Your neighbor? A friend? A family pet?

The definition of a **family** varies by organization, discipline, and individual. The World Health Organization (1976) characterized the family as “the primary social agent in the promotion of health and well-being” (p. 17). Many family theorists suggest that a family consists of two or more individuals who share a residence or live near one another; possess some common emotional bond; engage in interrelated social positions, roles, and tasks; and share cultural ties and sense of affection and belonging (Anderson & Sabatelli, 2006; Friedman, Bowden, & Jones, 2003; Hanson, Gedaly-Duff, & Kaakinen, 2005; McBride, 2006; Murray & Zentner, 2000). The common thread in the definitions is the recognition that the family itself defines who its members are (Bomar, 2004).

Today’s community health nurse needs to understand and work with many types of families, each of which has unique health problems and needs. For example, a young single mother who is homeless seeks help in caring for her sick infant. A 55-year-old grandfather provides care for his elderly mother, who was recently discharged from the hospital after a stroke. A group of parents, siblings, cousins, and children, all refugees from Laos, need instruction on the purchase and preparation of food. Why is it important for the community health nurse to understand and respect the unique characteristics, cultures, structures, and functions of each of these families? Do families as basic units of a community have characteristics that affect community health nursing service? The answer is an unqualified yes. The effectiveness of the community health nurse depends on knowing how to work with a family as a unit of care.

This chapter examines the nature of families, family functioning, and family health. It draws from various theories to strengthen the student’s understanding and appreciation of families as clients. This information will promote the effectiveness of interventions with families at the primary, secondary, and tertiary levels of preventions (see Levels of Prevention Pyramid). **Family functioning** is defined as those behaviors or activities by family members that maintain the family and meet family needs, individual member needs, and society’s views of family. The interdependence of

family members involves a set of internal relationships that influence the effectiveness of family functioning (Friedman et al., 2003). There is a complex communication pattern of functioning among family members, and the quality of the pattern contributes to the health of the family.

**Family health** is concerned with how well the family functions together as a unit. It involves not only the health of the members and how they relate to other members, but also how well they relate to and cope with the community outside the family. In fact, family health, like individual health, ranges along a continuum from wellness to illness. A family may be at one point on that continuum now and at a much different point 6 months from now. Family health refers to the health status of a given family at a given point in time (Hanson et al., 2005). It includes all the attitudes, beliefs, knowledge, and habits that families use to obtain, sustain, or regain maximum health (Fiese, 2006; McBride, 2006).

## UNIVERSAL CHARACTERISTICS OF FAMILIES

Several observations can be made about families in general. First, each family is unique, with its own distinct problems and strengths. When you approach the door of a house or push the buzzer of an apartment, you cannot assume what the family inside will be like. Consequently, you will have to gather information about each particular family to achieve nursing objectives.

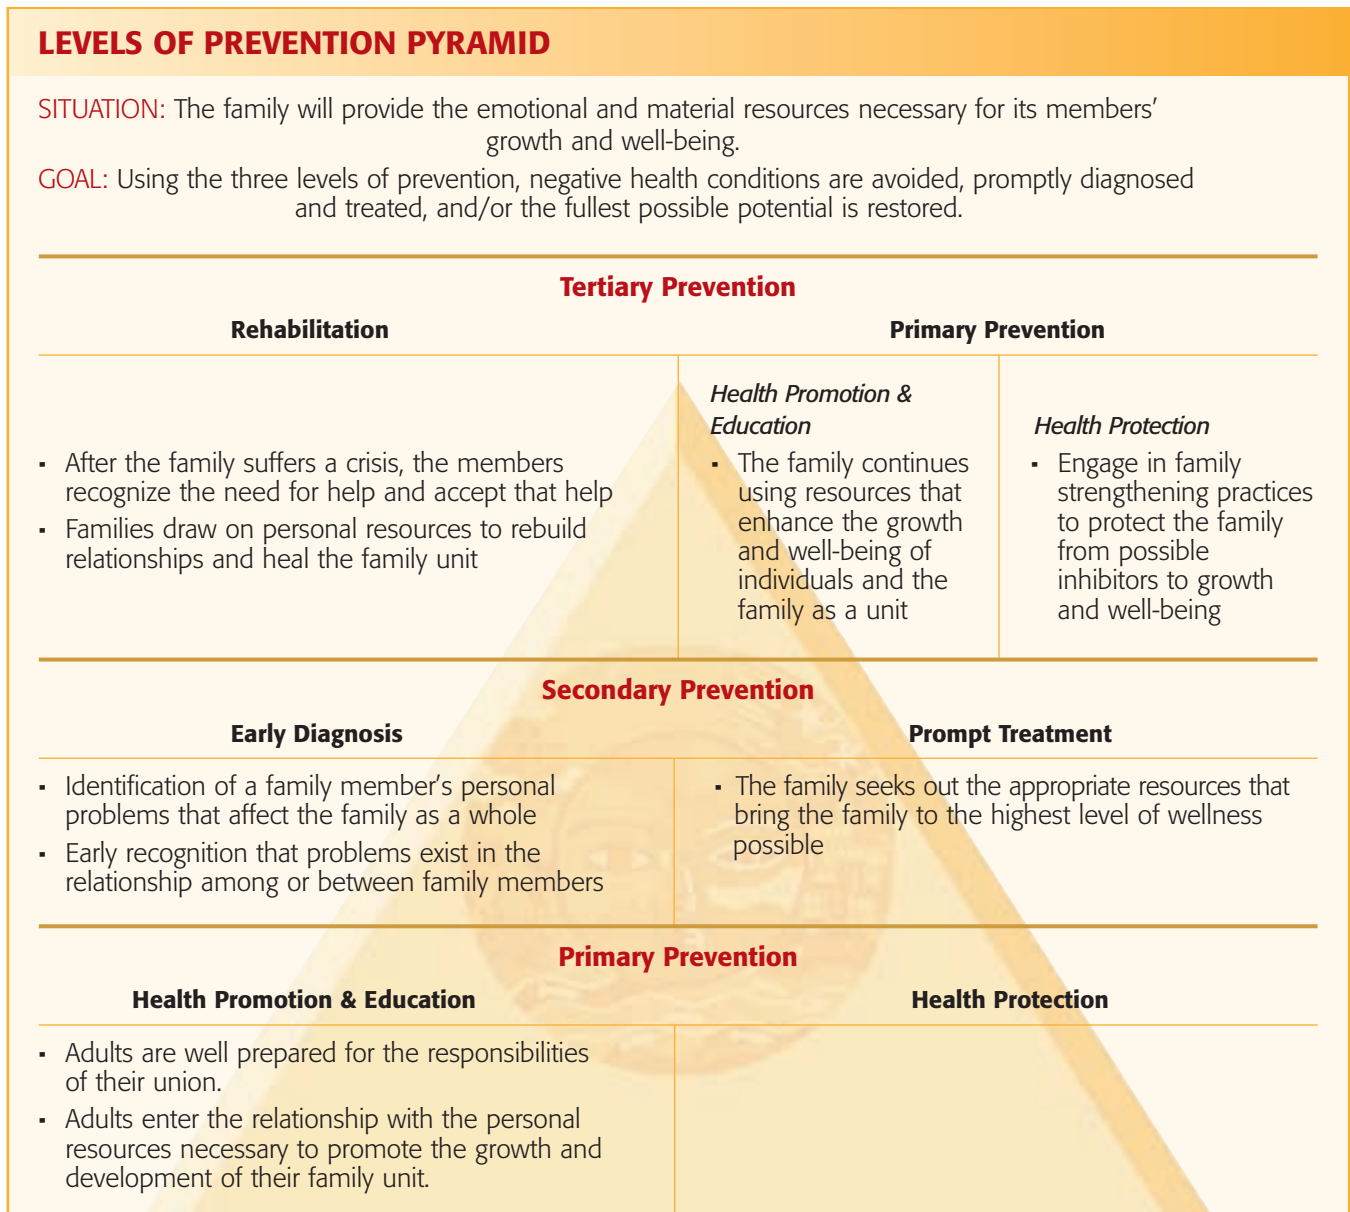

Second, every family shares some universal characteristics with every other family. These universal characteristics provide an important key to understanding each family’s uniqueness. Five of the most important family universals for community health nursing are:

1. Every family is a small social system.
2. Every family has its own cultural values and rules.
3. Every family has structure.
4. Every family has certain basic functions.
5. Every family moves through stages in its life cycle.

No matter how many families a nurse might visit or serve in the course of a year, each one will have these universal features; it is important for community health nurses to know each family’s unique manifestation of these features and their effects on family health. These five universals of family life, which provide the framework of this chapter, are based on systems theory, sociologic theories, and theories of family development. In addition to considering the universals of family life, this chapter covers the unique family features and structures that characterize our changing world.

## ATTRIBUTES OF FAMILIES AS SOCIAL SYSTEMS

Many Americans fall into the habit of viewing families merely as collections of individuals. Caused partly by the strong cultural emphasis on individualism, this error also occurs because families are often encountered through the individual members. When a community health nurse sits in a living room talking with a young mother about her new infant, it is difficult to keep in mind that all the other family members are present by way of their influence. Systems

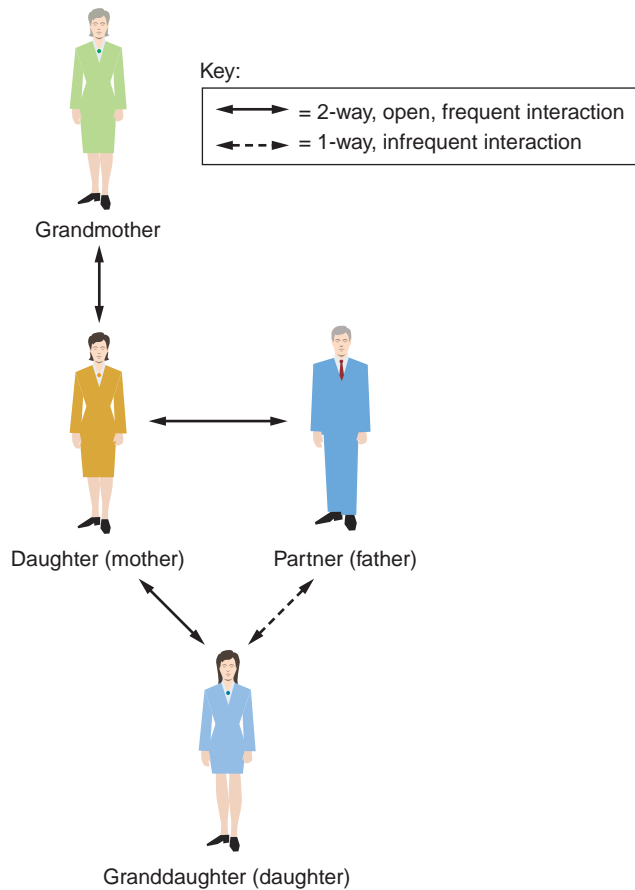

theory offers some insights about how families operate as social systems. Knowing the attributes of living systems or open systems can help strengthen understanding of family structure and function. There are five attributes of open systems that help explain how families function: (1) families are interdependent, (2) families maintain boundaries, (3) families exchange energy with their environments, (4) families are adaptive, and (5) families are goal-oriented.

### Interdependence Among Members

All the members of a family are interdependent; each member's actions affect the other members, and what affects the family system affects each family member. For example, consider the changes a father might make to reduce his risk of coronary heart disease. If he cuts back on working overtime, the family's income will be reduced. If he begins to eat different foods, food preparation and eating patterns in the

family will be altered. If he starts a new exercise program three evenings a week, this may upset other family routines. Even his ability to carry out his usual roles as husband and father may be affected if, for instance, he has less time to help his children with their homework or share household chores with his wife.

It is possible to illustrate the pattern of interactions between members using a **family map** (Fig. 18.1). This tool can reveal a great deal about the interdependence of family members. The way parents relate to each other, for instance, influences the quality of their parenting. When the interactions between them are frequent, honest, and nurturing, they have more to offer their children. Marital, parent-child, and sibling relationships all significantly influence family functioning. They determine how well the family as a system handles conflict, provides a support system for its members, copes with crises, solves daily problems, and capitalizes on its own resources.

**FIGURE 18.1** Family map. This map indicates that the mother is a key figure for family interaction. The maternal grandmother, father, and daughter communicate primarily to her, rather than directly to one another.

## Family Boundaries

Families as systems set and maintain boundaries that include some people as members while excluding others (Denham, 2005; McBride, 2006). These boundaries, which result from shared experiences and expectations, link family members together in a bond that excludes the rest of the world. Also, a greater concentration of energy exists within the family than between the family and its external environment, thereby creating a **family system boundary**.

For example, the Salazar extended family gathers for a Sunday afternoon backyard cookout. The distinctiveness of this family from all the others in the neighborhood is noticeable, as would be that of any other family. The elders in the family were born in Mexico, and they sit together reminiscing in Spanish. The food is traditional and plentiful. It is prepared and served by the women: Aunt Rosa's tamales, Cousin Teresa's tortillas, and flan for dessert from Grandma Lupe's own recipe. While the women prepare the food, some of the men play ball and others listen to Uncle Gilberto play the guitar and discuss the future of the family grape-growing business. The children gather in small groups and play loudly. Several of them, prompted by their parents, display their musical talent later in the day by singing some old favorite songs and doing some traditional Mexican dances. Because of the things they have in common, the Salazars set

and maintain boundaries that unite them and also differentiate them from others.

## Energy Exchange

Family boundaries are semipermeable; although they protect and preserve the family unit, they also allow selective linkage with the outside world. To function adequately as open systems, families exchange materials or information with their environment (Friedman et al., 2003). This process is called **energy exchange**. All normally functioning living systems engage in such an input–output relationship. This energy exchange promotes a healthy ecologic balance between the family system and the environment that is its immediate community.

A family's successful progress through its developmental stages depends on how well the family manages this energy exchange. For example, a child-bearing family needs adequate food, shelter, and emotional support, as well as information on how to accomplish its developmental tasks. The family also needs community resources, such as health care, education, and employment, all of which are forms of environmental input. In return, the family contributes to the community by working and by consuming goods and services. If a family does not have adequate income or emotional support or does not use community resources, that family does not experience a proper energy exchange with its environment. An inadequate exchange can lead to dysfunction and poor health (Neuman, 2001).

## Adaptive Behavior

Families are adaptive, equilibrium-seeking systems. In accordance with their nature, families never stay the same. They shift and change in response to internal and external forces. Internally, the family composition changes as new members are added or members leave through death or divorce. Roles and relationships change as members advance in age and experience; normative expectations change as members resolve their tensions and differing points of view. Externally, families are bombarded by influences from sources, such as school, work, peers, neighbors, religion, and government; consequently, they are forced to accommodate to new demands. Adapting to these influences may require a family to change its behaviors, its goals, and even its values. Like any system, the family needs a state of quasi-equilibrium to function (Neuman, 2001). With each new set of pressures, the family shifts and accommodates to regain balance and maintain a normal lifestyle.

Sometimes a family's capacity for adaptation may be stressed beyond its limits. At this point, the system may be in danger of disintegrating; that is, family members may leave or become dysfunctional because of unresolved stress. This is an indication that some form of intervention may be needed to help restore family equilibrium. These interventions may take the form of extended family mediation or external professional help. Community health nurses play an influential role in family equilibrium-seeking. Neuman described the major goal of nursing as keeping the individual and family client systems stable within their environments (Neuman, 2001). Chapter 19 explores the community health nurse's stabilizing interventions with families in detail.

## Goal-Directed Behavior

Families as social systems are goal directed. Families exist for a purpose—to establish and maintain a milieu that promotes the development of their members. To fulfill this purpose, a family must perform basic functions, such as providing love, security, identity, a sense of belonging; assisting with preparation for adult roles in society; and maintaining order and control. In addition to these functions, each family member engages in tasks to maintain the family as a viable unit. Duvall and Miller (1985) described specific functions and tasks for each stage of the family's development. These functions and tasks are examined in more detail later in this chapter.

## FAMILY CULTURE

**Family culture** is the acquired knowledge that family members use to interpret their experiences and to generate behaviors that influence family structure and function. The concept of family culture arises from a significant body of literature in the social and behavioral sciences. Cross-cultural comparisons and in-depth analyses demonstrate that each family has a “culture” that strongly influences its structure and function. Culture explains why families behave as they do (Leininger, 2001; Pender, Murdaugh, & Parsons, 2006; Spector, 2000). Family culture also gives the community health nurse a basis for assessing family health and designing appropriate interventions. Three aspects of family culture deserve special consideration: (1) family members share certain values that affect family behavior, (2) certain roles are prescribed and defined for family members, and (3) a family's culture determines its distribution and use of power.

## Shared Values and Their Effect on Behavior

Although families share many broad cultural values drawn from the larger society in which they live, they also develop unique variants. Every family has its own set of values and rules for operation that can be considered as family culture (Stewart & Goldfarb, 2007). Some values are explicitly stated: “Family matters must always stay within the family.” Such values may give rise to specific operating rules: “Don't tell anyone about our problems.”

Like all cultural values, many family values remain outside the conscious awareness of family members. These values, often not verbalized, become powerful determinants of what the family believes, feels, thinks, and does. Family values include those beliefs transmitted by previous generations, religious influences, immediate social pressures, and the larger society. Values become an integral part of a family's life and are very difficult to change. A family that values free expression for every member engages comfortably in loud, noisy debates. Another family that values quietness, order, and control does not tolerate its members' raising their voices. One family uses birth control based on beliefs about human life and parental responsibility; another family chooses not to use birth control because the members hold a different set of values. How a family views education, health care, lifestyle, courtship, marriage, child-rearing, sex roles, or any of the myriad other issues requiring choices depends on the cultural values of that family.

## Prescribed Roles

**Roles**, the assigned or assumed parts that members play during day-to-day family living, are bestowed and defined by the family (Denham, 2005; Hanson et al., 2005; McBride, 2006). For instance, in one family the father role may be defined as an authoritative one that includes establishing rules, judging behavior, and administering punishment for violation of rules. In another family, the father role may be defined primarily as that of a loving benefactor. If there is an absence of an immediate male parent, a grandfather, uncle, friend, or mother may take over the father role. Selection of specific roles to be played in any given family varies depending on the family's structure, needs, and patterns of functioning. In a single-parent family, the parent may need to assume the roles of mother, father, and breadwinner, as well as others.

Families distribute among their members all the responsibilities and tasks necessary to conduct family living. The responsibilities of breadwinner and homemaker, with their accompanying tasks, may belong to husband and wife, respectively, or may be shared if both husband and wife hold jobs outside the home. Older children may help younger ones with homework or entertain them. This releases parents for other tasks and increases the responsibility of older children.

Family members play several roles at the same time. This **intra-role functioning** can be exceptionally taxing. A woman may play the role of wife to her husband, daughter to her mother who lives with her, and mother to each of her children. The mother role may involve taking on several additional roles and responsibilities, and varies with each child's needs. In a family in which the mother is seriously ill, many of the roles she held must be assumed by others. A single parent often takes on the roles of both father and mother but may distribute responsibilities and tasks more widely. A grandmother or a child may assume responsibility for some chores and thereby relieve the demands placed on the single parent. Among families, there is great variation in expectations for each role and in the degree of flexibility in role prescriptions. A family may place great demands on some members, but those same members may interpret the expectations placed on them and their roles differently. Confusion and conflict can develop unless roles are clarified.

Other roles of family members extend beyond the immediate family. There may be extended family members nearby who interact with the family on a regular basis or only on special occasions such as birthdays. If both parents are employed, they may have an expansive social network from work or from within the neighborhood. Friendships are often made with the parents of the children's friends, particularly if their children participate in the same activities. Many families enjoy the fellowship of organized religious or cultural groups. This fellowship can be a source of support and comfort, as well as an additional role function for the family members. Another intra-role function is that of community participant in activities separate from the family. These roles may involve local or regional politics, community improvement, volunteerism for nonprofit agencies, or any other service outside the home that the community may offer. These diverse role relationships should enrich and energize the participants. However, many people become overcommitted, creating an imbalance of role responsibilities that is draining and causes friction and stress. The

community health nurse must work with families to achieve a balance of activities and roles that promotes family health.

## Power Distribution

Power—the possession of control, authority, or influence over others—assumes different patterns in each family. In some families, power is concentrated primarily in one member; in others, it is distributed on a more egalitarian basis. The traditional *patriarchal family*, in which the father holds absolute authority over the other members, is rare in American society. However, the pattern of husband as head of the household and dominant member of the family is still frequently seen. Whether male or female, the dominant partner holds the majority of the decision-making power, particularly over more important family matters such as employment and finances. Other areas of decision making, including choices about vacations, housing, leisure activities, household purchases, and child rearing, may be shared or delegated. With changing societal influences, however, the present trend among American families is toward *egalitarian power distribution*.

Rudolf Dreikurs (1964) advocated that families form a “family council” for shared decision making and distribution of tasks. Today, many families practice joint decision making and equal participation by all members, and the community health nurse may suggest this activity for families not using such a method. Role-playing this technique can be incorporated during a home visit or as a teaching technique with an aggregate group.

Roles often influence power distribution within the family. Along with the responsibilities attached to a role, a family may assign decision-making authority. The mother role frequently includes decision making with respect to household management. Responsibility related to a son’s role, such as lawn-mowing, may be enhanced as a learning activity if he is allowed to decide when and how often he does the job.

Family power structure is also influenced by the amount of personal power residing in each member (Friedman et al., 2003). A mother or eldest son, for example, can exercise considerable influence over the family by virtue of personality and position, rather than by delegated authority. Even a child who throws temper tantrums can wield considerable power in a family.

## FAMILY STRUCTURES

Globally, families—in all their varied forms—are the basic social unit. The meaning of family among the Hmong of northern Laos may include hundreds of people who make up a clan. In Mexico, families remain close, are large, and extend into multiple generations. In Germany and Japan, families are small and tend to the needs of their elders at home. In the United States, where families come from many cultural groups, many variations coexist within communities.

For many people in the United States, the term *family* used to evoke a picture of a husband, wife, and children living under one roof, with the man as breadwinner and the woman as homemaker. In the past, this nuclear family was often seen as the norm for everyone. Changes in social values and cultural lifestyles (e.g., women working outside the home) combined with acceptance of alternative lifestyles

has changed the definition of family. Today, definitions of family include unmarried adults living together with or without children, single-parent households, divorced couples who combine households with children from previous marriages (the blended family), and homosexual couples with or without children.

It must be considered a privilege to gain entrance into a family’s home. This is a uniquely private space belonging to the family. The people who are members of this household interact, care for one another, and bond in ways that may never be fully understood by anyone outside the family. Therefore, being granted entrance into this system gives the community health nurse an opportunity to work with the family that few other professionals experience. Each type of household requires recognition and acceptance by community health nurses, who must help families achieve optimal health (see Display 18.1).

Families come in many shapes and sizes. The varying **family structures** or compositions comprise the collective characteristics of individuals who make up a family unit (age, gender, and number). A growing body of research on family structure and function shows that families have changed dramatically because of a decrease in the number of marriages, an increase in unmarried couples living together, divorce rates, and an increase in births outside of marriage (Hofferth, 2003; McBride, 2006). Family structures fall into two general categories: traditional and contemporary.

### DISPLAY 18.1

### A LOOK AT AFRICAN AMERICAN FAMILIES

Much academic attention on the African American family focuses on pathologies. However, there is information from cultural equivalent or emergent models to recognize positive, adaptive features that is not always discussed. Three family types are described as predominant models among African American families—nuclear, single-parent, and augmented families, which are described in this chapter.

African American families can reflect other dimensions that provide broader ways to describe them. The *cultural equivalent model* demonstrates that African American families share mainstream values similar to those of Whites but do not have the same access. In the *emergent model*, the family is rooted in African culture rather than American and reflects similarities that include religion, special care of children, strong kinship ties, dance, language, stability, unity, and security as a foundation of their expression. And to some degree, the *pathological model* is represented among families who experience structural problems, symptoms of stress, physical and emotional illness, and inadequate housing. However, it is felt that the pathological model is a response to societal pathologies such as racism and discrimination, and is not a model exclusive to African Americans.

Barnes, S.L. (2001). Stressors and strengths: A theoretical and practical examination of nuclear, single-parent, and augmented African American families. *Families in Society: The Journal of Contemporary Human Service*, 82(5), 449–460.

## Traditional Families

**Traditional family** structures are those that are most familiar to us. They include the **nuclear family**—husband, wife, and children living together in the same household. In nuclear families, the workload distribution between the two adults can vary. Both adults may work outside the home; one adult may work outside the home while the other stays at home and assumes primary responsibilities for the household; or partners may alternate, constantly renegotiating work and domestic responsibilities. A **nuclear-dyad family** consists of a husband and wife living together who have no children or who have grown children living outside the home. Traditional families also include **single-adult families**, in which one adult is living alone by choice or because of separation from a spouse or children or both. Separation may be the result of divorce, death, or distance from children. Some 4% of U.S. households are **multigenerational families**, in which several generations or age groups live together in the same household (Cohn, 2001). A household in which a widowed woman lives with her divorced daughter and two young grandchildren is an example of a multigenerational family, as is one in which adult children live with aging parents. Such arrangements are increasing in number, according to the 2000 U.S. Census. Sometimes, particularly in close-knit ethnic communities, families form a **kin-network**, in which several nuclear families live in the same household or near one another and share goods and services. They may own and operate a family business, sharing work and child care responsibilities, income and expenses, and even meals. Variations of this trend are increasing among all groups as children postpone leaving home because of economic conditions or educational plans or an elderly parent moves into an adult child's home to recover from a recent illness. A variation of the kin-network is the **augmented family**. This is a family group in which extended family members or nonrelatives or both live with and provide significant care to the children (Barnes, 2001).

Another variation of the traditional nuclear family is the **blended family**. In this structure, single parents marry and raise the children from each of their previous relationships together. They may be custodial parents who have the children except during planned visits with the noncustodial parent, or they may share custody, so that the children live in the blended arrangement only part-time. This family may include children from the couple's union, in addition to the children brought into this relationship.

**Single-parent families** include one adult (either father or mother) caring for a child or children as a result of a temporary relationship, a legal separation or divorce, or the death of a spouse. In single-parent families, the parent may or may not be employed. Other contemporary single-parent family situations are described in the next section.

One contemporary variant of the traditional family is the **commuter family**. Both partners in this family work, but their jobs are in different cities. The pattern is usually for one partner to live, work, and perhaps raise children in the "home" city, while the second partner lives in the other city and commutes home. Sometimes this arrangement is short-term; for example, one partner may be transferred through work, and the couple chooses not to move the rest of the family for one or several reasons (e.g., waiting until the end

of the school year, making sure the new job is secure, locating the right housing, or selling the old home). At other times, commuting may continue for years. For example, the family home may be in a town where the cost of living is reasonable, but one parent works in a financially and personally rewarding career several hundred miles away and commutes home on weekends. In other instances, one parent may be on military assignment in another country for 6 months or longer, leaving the other parent alone for months at a time. Clearly, these arrangements influence family roles and functions, challenging a family's ability to maintain healthy relationships. A traditional family in which one partner is required to travel often (e.g., for business, to care for an ill family member at a distant location) may experience similar problems and stressors. Table 18.1 lists a number of traditional family structures.

## Nontraditional or Contemporary Families

The traditional nuclear family has been a fundamental part of the European cultural heritage shared by many Americans, and reinforced by religion, education, and other influential social institutions. Variations from this pattern often were treated as deviant and abnormal, even in relatively recent studies of the family (Olson et al., 1989). Nonetheless, infants born to unwed mothers made up 26.6% of the births in 1990 and 37% in 2005 (National Center for Health Statistics [NCHS], 2007). The number of unmarried people living together continues to increase, as does the never-married population. In 1980, 20.3% of the population were never married, increasing to 22.2% in 1990 and 23.9% in 2000 (U.S. Census Bureau, 2008b). In addition, the proportion of single-parent families has continued steady over the past decade with a slight shift toward more father-headed households. Forty-eight percent of African American children, 26% of Hispanic children, and 16% of White children live in mother-headed households, while 5.8% of African American children, 4.4% White children, and 1.5% of Hispanic children live in father-headed households (U.S. Census Bureau, 2008a). There is every indication that the upward trend for unmarried family units, single-parent households, and female heads of households will continue in the 21st century and will represent important contemporary family units in American society.

Society has begun to accept nontraditional definitions of family. The concept of **wider family** was initially presented by Marciano (1991) and is defined as a family that "emerges from lifestyle, is voluntary, and independent of necessary biological or kin connections" (p. 160). "With today's wide variety of family types and structures, the most advanced definition of family may be 'the family is who the client says it is'" (Bell & Wright, 1993, p. 391).

Divorce changes family structures. Half of all marriages now end in divorce (the rate is higher for teenage marriages), and the median duration of marriages is approximately 7 years. In the United States, the divorce rate in 2005 was 5.4 per 1,000. This number has decreased slightly since 1990, but remains higher than in other industrialized nations (Germany, 4.0 per 1,000; United Kingdom, 3.9 per 1,000; Japan, 3.1 per 1,000; Italy, 1.2 per 1,000) (U.S. Census Bureau, n.d.).

Some **contemporary family** structures are becoming more common and are generally accepted by society. Other arrangements are still regarded as unacceptable. Table 18.1

TABLE 18.1 The Traditional and Nontraditional American Family

Structure	Participants	Living Arrangements
<b>TRADITIONAL</b>		
Nuclear dyad	Husband Wife	Common household
Nuclear family	Husband Wife Child(ren)	Common household
Commuter family	Husband Wife Children (sometimes)	Household divided between two cities
Single-parent family	One adult (separated, divorced, widowed) Children	Common household
Divorced family (shared custody of children)	One adult parent, children part-time	Two separate households
Blended family	Husband Wife (His and/or hers, and possibly their children)	Common household
Single adult	One adult (at times not considered a "Family")	Living alone
Multigenerational family	Any combination of the traditional family structures	Common household
Kin network	Two or more reciprocal households (related by birth or marriage)	Close geographic proximity
Augmented family	Extended family group or nonrelatives who provide significant child care	Common household or close geographic proximity
<b>NONTRADITIONAL</b>		
Unmarried single-parent family	One parent (never married) Children	Common household
Cohabiting partners	Two adults (heterosexual, homosexual, or "just friends") Children (possibly)	Common household
Commune family	Two or more monogamous couples Sharing children	Common household
Group marriage commune family	Several adults "married" to each other Sharing childrearing	Common household
Group network	Reciprocal nuclear households or single members	Close geographic proximity
Homeless families	Any combination of family members previously mentioned	The streets and shelters
Foster families	Husband and wife or single adult Natural children (possibly) Foster children	Common household
Gangs	Males and females usually of same cultural or ethnic background	Close geographic proximity (same neighborhood)
"Loose shirt" families	Parents work from home via the personal computer (word processing, e-mail, faxing, cellular telephone—"telecommuting")	Common household

lists some of the more common nontraditional and contemporary family structures.

The approach used by Scanzoni and colleagues (1989) is to consider the **primary relationship** of two or more persons interacting in a continuing manner within the greater environment. This primary relationship encompasses all the possible

family structures. In 1981, Stein suggested the idea of a "life spiral," rather than a life cycle, to describe the fluctuations of contemporary nontraditional families. The spiral more realistically depicts the fluid movement within family structures than does a cycle, which suggests continuous curvilinear movement along a path. Traditional functions and structures

of the family continue to evolve as new combinations of people live together and consider themselves a “family.”

One of the most common nontraditional family structures is the single-parent family headed by a woman. Sometimes, single women choose to adopt or have children without being married. Sometimes, an unplanned pregnancy without marriage creates this family unit. Statistics indicate that single-parent families are being headed increasingly by teenagers, some of whom become pregnant while in junior high school. Although the birth rate among teens 15 to 19 years old declined in 2005 for the 14th consecutive year, the rate of 40.4 births per 1,000 teenage women remains high (NCHS, 2007). The implications for the role of the community health nurse are greatest with this population. For example, nurses work with young teens through schools or clinics to ensure healthy pregnancies and to teach parenting skills to the youthful parents and grandparenting skills to the teen’s parents. Nurses can also ensure that the infant receives immunizations and primary health care services as needed and can provide family planning information to the new parents. On a broader scale, community health nurses collaborate with other professionals to make sure that the community has resources for all levels of prevention, with a focus on primary prevention.

Many adult couples form a family alliance outside of marriage or in a private ceremony not legally recognized as marriage. **Cohabiting couples** may range from young adults living together to an elderly couple sharing their lives outside of marriage to avoid tax penalties or inheritance issues. Cohabiting couples may be heterosexual or homosexual; they may or may not share a sexual relationship. In some instances, these couples have their own biologic or adopted children.

Another nontraditional family form is the **commune family**, a group of unrelated couples who are monogamous (married or committed to one person) but who live together and collectively rear their children. Perhaps more popular in the 1960s and 1970s, this type of family may presently exist among people with similar life-views or spiritual beliefs. A **group-marriage family** involves several adults who share a common household and consider that all are married to one another; they share everything, including sex and child rearing. Group-marriage families usually center on a patriarch who designates responsibilities and dictates to the other members some religious or social ideology. The Branch Davidians, who lived together outside of Waco, Texas, until their compound was destroyed by fire in 1993, was a tragic example of this family type. Another disturbing situation was the removal in 2008 of more than 450 children from a polygamist sect in Texas. Although the practice of polygamy is illegal in the United States, Texas officials cited concern over sexual abuse of minors as the basis for separating the children from their parents. In a ruling by the Texas Supreme Court, the children were ordered to be returned to their parents with the stipulation that they remain in Texas and the parents take parenting classes (Ayres, 2008). The ultimate resolution to this sect’s activities and others like it remains unclear.

A **group-network family** is made up of unrelated nuclear families that are bound by a common set of values, such as a religious system. These families live close to one another and share goods, services, and child-rearing responsibilities. Some commune and group-network families select one of their members, usually a man, to be their leader or head.

Many children are removed from their homes of origin because of abuse, violence, or neglect. In most communities, these children are housed with families known as **foster families**. These families take a variety of forms, but all foster families have had formal training to accept unrelated children into their homes on a temporary basis, while the children’s parents receive the help necessary to reunify the original family. Although this arrangement is not ideal, most foster families provide safe and loving homes for these children in transition. Often foster children have emotional and physical health problems, and they may never have experienced the positive structure that foster families provide. These problems, which can cause stress for everyone involved, are typically ones that the community health nurse can help to solve.

Some families, because of lack of marketable skills, negative economic changes, or chronic mental health problems including substance abuse, find themselves without permanent shelter. **Homeless families** are increasing in numbers, and their characteristics are changing. In 2005, about 41% of the counted homeless population were families with children (National Alliance to End Homelessness, 2007). This does not include families that are homeless but live with friends or relatives. The community health nurse may provide services to shelters or drop-in clinics frequented by the homeless. Because this population is increasing, it has many implications for the nurse.

A destructive form of “family” that occurs in many cities is gangs. **Gangs** are formed by young people who are searching for emotional ties and turn to one another as a substitute for an absent or dysfunctional family. Gang members consider themselves family; they rely on one another and the group for support that they do not receive from their families of origin. Obviously, gangs are a dysfunctional and destructive form of family. Typically, members are drawn into drugs and violence; frequent injury, abuse, and even death to gang members, their associates, and innocent bystanders may be the result. Nurses who serve in urban areas may be working with families and groups who are involved with gangs, and they should be prepared to deal with the issues that gangs create.

## Implications for the Community Health Nurse

The variety of family structures raises three important issues for consideration. First, community health nurses can no longer hold to a myth that idealizes the traditional nuclear family. They must be prepared to work with all types of families and accept them as valid. Unless the community health nurse can accept the full array of family lifestyles and address the special problems and needs of each, she may not be able to help the family, and may even create additional problems.

Second, the structure of an individual’s family may change several times over a lifetime. A girl may be born into a kin-network, shift to a nuclear family when her parents move, and become part of a single-parent family when her parents are divorced. As she matures, she may become a single adult living alone, then become a part of a cohabiting couple. Still later, she may marry and have children in a nuclear family. For the individual, each family form involves changes in roles, interaction patterns, socialization processes, and links with external resources. The community health nurse must learn to address clients’ needs throughout these

## DISPLAY 18.2

FACTS ABOUT FAMILIES  
IN AMERICA

- On any given night in the United States, there are 500,000 to 600,000 homeless men, women, and children (National Alliance to End Homelessness, 2007).
- Some 500,000 children go missing each year.
- More than 3 million children live with their grandparents as the primary care providers.
- Approximately 500,000 children are in foster homes.
- Almost 8% of girls between 15 and 19 years of age get pregnant each year, producing 750,000 pregnancies annually (National Center for Health Statistics, 2006).
- Ten percent of the population has significant problems related to substance abuse (Reilly, 1998).
- At least 4% of U.S. households include three generations; approximately 78,000 homes include four generations (Cohn, 2001).
- In California, gay adoptions, or “second-parent” adoptions, number 10,000 (Kravets, 2003).

life changes, equipping people with the skills needed to deal with the inevitability of changing structures.

Finally, each type of family structure creates different issues and problems that, in turn, influence a family’s ability to perform basic functions. Each particular structure determines the kind of support needed from nursing or other human service systems (Eliopoulos, 2001). A single adult living alone may lack companionship or a sense of being needed by other family members. A kin-network family provides extended family support and security but may have problems with power distribution and decision making. An unmarried couple raising a child may be parenting well but may feel isolated from married couples in the community; they may need more peer support and socialization. Variations in structure create variations in family strengths and needs, an important consideration for community health nurses. Display 18.2 lists additional facts about families in America.

## FAMILY FUNCTIONS

Families in every culture throughout history have engaged in similar functions: families have produced children, physically maintained their members, protected their health, encouraged their education or training, given emotional support and acceptance, and provided supportive and nurturing care during illness. Some societies have experimented with separation of these functions, allocating activities such as child care, socialization, or social control to a larger group. The Israeli kibbutz and Chinese commune are examples. In U.S. society, certain social institutions help perform some aspects of traditional family functions. Schools, for example, help socialize children, professionals supervise health care, and religious organizations influence values.

Six functions are typical of American families today and are essential for the maintenance and promotion of family health: (1) providing affection, (2) providing security, (3) instilling identity, (4) promoting affiliation, (5) providing socialization, and (6) establishing controls (Duvall & Miller,

1985). These tasks help promote the growth and development of family members. Understanding these functions and how well individual families provide them enables the community health nurse to work effectively with each family at its level of functioning.

## Providing Affection

The family functions to give members affection and emotional support. In Western societies, love brings couples together. In some other cultures, affection comes after marriage. Continued affection creates an atmosphere of nurturance and care for all family members, which is necessary for health, development, and survival. It is common knowledge that infants require love to thrive. Indeed, human beings of any age require love as sustenance for growth and find it most often in their families. Families, unlike many other social groups, are bound by affectionate ties, the strength of which determines family happiness and closeness. Consider how sharing of gifts on a holiday or loving concern for a sick member draws a family together.

Positive sexual identity and sexual fulfillment are also influenced by a loving atmosphere. Early studies of the family emphasized sexual access and procreation as basic family functions. It is now recognized that families exist not only to regulate the sex drive and perpetuate the species, but also to sustain life and foster human potential through a strong affectional climate.

## Providing Security and Acceptance

Families meet their members’ physical needs by providing food, shelter, clothing, health care, and other necessities; in so doing, they create a secure environment. Members need to know that these basics will be available and that the family is committed to providing them. The stability of the family unit also gives members a sense of security. The family offers a safe retreat from the competition of the outside world and provides a place in which its members are accepted for themselves. They can learn, make mistakes, and grow in a secure environment. Where else does a toddler, after repeated falls, receive the encouragement to keep trying to walk; or a child, teased by a bully, regain his courage; or a parent, feeling burned out by a job, find comfort and renewal? The dependability of the family unit promotes confidence and self-assurance among its members. This contributes to their mental and emotional health and equips them with the skills necessary to cope with the outside world.

## Instilling Identity and Satisfaction

The family functions to give members a sense of social and personal identity. Like a mirror, the family reflects back to its members a picture of who they are and how valuable they are to others. Positive reflections provide the individual with a sense of satisfaction and worth such as that experienced by a girl when her family applauds her efforts in a swim meet or by a boy whose family praises the bird house he builds in Cub Scouts. Needs fulfillment in the home determines satisfaction in the outside world; it particularly affects other interpersonal relationships and career choices. Roles learned within the family also give members a sense of identity. A

boy growing up and learning his family's expectations for the male role quickly develops a sense of the kind of person he must strive to be; often, he is expected to be strong, competitive, successful, and unemotional. As a girl grows up, she often learns what is expected of her from her mother: to defer her needs to those of the family, be flexible and nurturing, and have homemaking skills. In other families, all children may have equal expectations of achievement and success. Families influence their members' positions in society by instilling values and goals. For some families, the emphasis may be on higher education; for others, it may be to work at a skill or trade. Still other families may be influenced by religious or political affiliations. Whatever the family influence, it is certain to shape each member's identity.

### Promoting Affiliation and Companionship

The family functions to give members a sense of belonging throughout life. Because families provide associational bonds and group membership, they help satisfy their members' needs for belonging. Each person knows that she is *integral*—that she belongs—to the family. However, the quality of a family's communication influences its closeness. If communication patterns are effective, then affiliation ties are strong and needs for belonging are met. One family handles conflict over financial expenditures, for instance, by discussing differences and making compromises; this promotes affiliation. In another family, financial conflicts go unacknowledged; members keep spending selfishly and never discuss compromises.

The family, unlike other social institutions, involves permanent relationships. Long after friends from school, the old neighborhood, work, or the religious center have come and gone, the family remains. The family provides its members with affiliation and fellowship that remain unbroken by distance or time. Even if scattered across the country, family members gather to support one another and to share a holiday, wedding, graduation, or funeral. It is to the family that its members turn in times of happiness, tragedy, or need. This family affiliation remains a resource for life.

### Providing Socialization

The family functions to socialize the young. Families transmit their culture—their values, attitudes, goals, and behavior patterns—to their members. Members, socialized into a way of life that reflects and preserves the family's cultural heritage, pass that heritage on, in turn, to the next generation. Starting in infancy, children learn to control bodily functions, eat with utensils, dress themselves, manage emotions, and behave according to sociocultural prescriptions for their age and sex. Through this process, members also learn their roles in the family. Lifestyle, food preferences, relationships with other people, ideas about child rearing, and attitudes about religion, abortion, equal rights, or euthanasia are all strongly influenced by the family. Although experiences outside the family also have a strong influence, they are filtered through the perceptions acquired during early socialization.

The socialization process also influences the degree of independence experienced by growing children. Some families release their maturing members by degrees, preparing them gradually but steadily for adult roles. Other

families promote dependent roles and find release painful and difficult.

### Establishing Controls

The family functions to maintain social control. Families maintain order through establishment of social controls both within the family and between family members and outsiders. Conduct of members is controlled by the family's definition of acceptable and unacceptable behaviors. From minor etiquette rules such as keeping elbows off the table to larger issues such as standards of home cleanliness, appropriate attire, children's behavior toward adults, or a teenager's curfew, the family imposes limits. It then maintains those limits by a system of rewards for conformity and punishments for violations. Children growing up in a family quickly learn what is "right" and what is "wrong" by family standards. Gradually, family control shifts to self-control as members learn to discipline their own behaviors; later on, they adopt or modify many of the same standards to use with their own children.

Division of labor is another aspect of the family's control function. Families allocate various roles, responsibilities, and tasks to their members to ensure the provision of income, household management, child care, and other essentials. Families also regulate the use of internal and external resources. The family identifies and directs the use of internal resources, such as member abilities, financial income, or material assets. For instance, if a man has artistic skills, he may be chosen to landscape the yard; if a woman has mechanical aptitude, she may be designated to repair appliances. One family may choose to drive an old car, rather than buy a new one, in order to spend more on entertainment.

Families also determine the external resources used by their members. Some families take advantage of the religious, health, and social services available to them in the community. They seek regular medical care, encourage their children to use the public library, become involved in religious activities, or join a bowling league. Other families, either because they do not know about potential external resources or because they do not recognize those resources as having any value, limit their members' use of them.

### FAMILY LIFE CYCLE

Many of the characteristics and defined developmental stages of individual growth also apply to families. For example, it is known that families, while maintaining themselves as entities, change continuously. Families inevitably grow and develop as the individuals within them mature and adapt to the demands of successive life changes. A family's composition, set of roles, and network of interpersonal relationships change with the passage of time (Friedman et al., 2003). Family structures, too, vary with each stage of the family life cycle.

Consider the following example. The Jordans, a young married couple, concentrated on learning their respective roles of husband and wife and building a mutually satisfying marriage. With the birth of their first child, Scott, the family composition and relationships changed and role transitions occurred. The Jordans were not only husband and wife but also father, mother, and son; the family had added three new roles. Within the next 4 years, two daughters, Lisa and Tammy, were born. The introduction of each new member not

only increased family size but also significantly reorganized family living. As Duvall and Miller (1985) pointed out, no two children are ever born into precisely the same family. The children entered school; Mrs. Jordan returned to work as a florist, and soon, Scott was leaving for college. The Jordans, like every family, were moving through a predictable and sequential pattern of stages known as the *family life cycle*.

Community nurses who are knowledgeable about this cycle can provide anticipatory guidance to families. For instance, while teaching prenatal care to a pregnant teen, the nurse can help the soon-to-be mother anticipate the responsibility and costs of raising her child by helping her calculate child care needs that must be met while she finishes school. The nurse can suggest that she figure out the monthly costs of breast-feeding versus buying formula; disposable diapers versus cloth or a diaper service; and the clothing, equipment, and medical costs of infant care. When working with the middle-aged parents of a brain-injured adult son living at home, the nurse can discuss what arrangements the parents have made for their son's care after they are older and unable to provide care themselves, or after one or both of them die.

## Stages of the Family Life Cycle

There are two broad stages in the family life cycle: one of *expansion* as new members are added and roles and relationships are increased, and one of *contraction* as family members leave to start lives of their own or age and die. Within this framework of the expanding–contracting family are more specific phases, such as launching of children and retirement of parents. In some families, expansion and contraction are repeated as various members are added, return home with their children and perhaps a partner, or leave home permanently.

## Family Developmental Tasks

To progress through the stages of the life cycle, a family must carry out its basic functions and the developmental tasks associated with those functions. Unlike individual developmental tasks, which are specific to each age level, family developmental tasks are ongoing throughout the life cycle. All families, for instance, must provide for the physical needs of their members at every stage. The manner and degree to which each function is carried out varies depending on how well members accomplish individual developmental tasks and meet the demands of each particular stage. Physical maintenance, for example, is affected by the parents' ability to accept responsibility and procure the necessary resources to provide food, clothing, and shelter for their children. At early stages, children are dependent on their parents for meeting these needs; at the school, teenage, and launching stages, children may increasingly contribute to home management and family income. The responsibility for these tasks shifts from just the parents to other family members as well.

Some functions require greater emphasis at certain stages. Socialization, for example, consumes much of a family's time during the early years of child development. These same functions and their associated developmental tasks can be further broken down into actions specific to certain stages. While carrying out its function of maintaining con-

trols, a family sets clearly defined limits for children at the preschool stage: “Do not cross the street.” “You may have dessert only after you finish your vegetables.” “Bedtime is at 8 o'clock.” During the school stage, control activities may center on allocating responsibilities and division of labor within the family: “Feed the dog.” “Clean your room.” “Take out the trash.” When a family reaches the teenage stage, its control function increasingly focuses on the relationships between family members and outsiders. The family may regulate some activities by setting limits: “Be home by midnight.” In areas such as moral conduct, controls may involve family values and therefore may be more subtle. A family at this stage must recognize the need for young people to assume increasing responsibility for their own behavior and acknowledge its own diminishing control over members who are exploring independence. Duvall and Miller (1985) described these activities as “stage-critical” family developmental tasks that must be completed before moving onto the next stage. Sample community health nursing actions with the family at different stages are presented in Table 18.2.

## EMERGING FAMILY PATTERNS

Up to this point, the discussion of the family life cycle has focused primarily on the nuclear family. Because the nurse encounters many nuclear families in community health, the family life cycle provides a useful means of analyzing their growth and development. Not all families progress through the family life cycle in the same way or sequence. Because of gradual changes in American society, community health nurses face increasing numbers of adolescent unmarried mothers, gay and lesbian families, blended families, elderly couples, and individuals living alone. They need to recognize the impact that emerging diverse family patterns have on society and available resources. To be effective, nurses must equip themselves with an appropriate knowledge base to provide needed services.

## Adolescent Unmarried Parents

Teen parenthood is an important social issue, with distinct medical and nursing ramifications. Teens are still developing emotionally. They have limited parenting skills and need a tremendous amount of education and support. Even with much media attention, availability of family planning methods, and a social environment open to discussing sexuality and pregnancy, teen pregnancy rates have remained high, especially among teens of color and those in lower socioeconomic situations.

Infants born to teen mothers are at risk for low birth weight, developmental delay, and death before 1 year of age. The infant mortality rate among mothers younger than 15 years is twice as high as for women between ages 20 and 24 years, and 20% higher among teens between ages 15 and 19 years than for women in their twenties (U.S. Department of Health and Human Services, 2000). In addition, children born to teen mothers face high rates of poverty, educational underachievement, and inadequate health care.

Teen fathers are often left out of the bevy of services that communities provide for the teen mother and infant. However, paternal involvement contributes positively to the physical, social, and cognitive development of children.

Stage of Family Life Cycle	Family Position	Stage-Critical Family Developmental Tasks	Role of the Community Health Nurse
Forming a partnership	Female partner Male partner	Establishing a mutually satisfying relationship	Interact with family where they are at
Childbearing	Partner-mother Partner-father Infant child(ren)	Adjusting to pregnancy and the promise of parenthood Fitting into the kin network Having and adjusting to infants, and encouraging their development Establishing a satisfying home for both parents and infant(s)	Assist them in developing strong relationships
Preschool-age	Partner-mother Partner-father Child, siblings	Adapting to the critical needs and interests of preschool children in stimulating, growth-promoting ways Coping with energy depletion and lack of privacy as parents	Assist in preparing for family expansion through education and anticipatory guidance
School-age	Partner-mother Partner-father Child, siblings	Fitting into the community of school-age families in constructive ways Encouraging children's educational achievement	Encourage time for each other as adults in a relationship separate from parenting role
Teenage	Partner-mother Partner-father Child, siblings	Balancing freedom with responsibility as teenagers mature and emancipate themselves Establishing outside interests and careers as growing parents	Provide anticipatory guidance for the school-age children as they grow into adulthood
Launching center	Partner-mother-grandmother Partner-father-grandfather Child, sibling, aunt or uncle	Releasing young adults into work, military service, college, marriage, etc., with appropriate rituals and assistance Maintaining a supportive home base	Provide anticipatory guidance for the contracting family as children leave home
Middle-aged parents	Partner-mother-grandmother Partner-father-grandfather	Rebuilding the relationship Maintaining kin ties with older and younger generations	Prepare adults for grandparenting role
Aging family members	Widow or widower Partner-mother-grandmother Partner-father-grandfather	Adjusting to retirement Coping with bereavement and living alone Closing the family home or adapting it to aging	Assist aging adults with emotional and financial security as they approach retirement Prepare the aging adults with ways to cope with the losses of old age, including changes in space, work, health, status, and loss of friends and family members

Children with absent fathers are at increased risk for behavioral difficulties and poor academic performance. A father who is emotionally supportive of the mother and provides child care and financial support directly and indirectly affects the well-being of his child.

With so many high-risk factors for pregnant teens and their children, it is imperative that community health nurses be knowledgeable about needed services, available resources, and the accessibility of each. In addition, because of the high-risk nature of teen pregnancy, prevention should be a priority. Nurses must collaborate in caregiving with other professionals and key players in teens' lives to provide the supportive services that young families need. *Healthy People*

2010 provides a number of national objectives relative to teen pregnancy prevention, family planning, and delayed sexual activity in younger teens, along with increased male involvement in healthy choices (see Display 18.3).

### Gay and Lesbian Families

Another emerging family pattern is the gay or lesbian family. Whether the unions between two same-sex individuals are legitimate in the eyes of the law (such civil unions are legal in some states and marriages in California in 2008) or are based on strong emotional attachments without legal sanction, gay and lesbian families may include natural

## DISPLAY 18.3

**HEALTHY PEOPLE 2010:  
OBJECTIVES RELATED TO  
FAMILY PLANNING AND  
CONCEPTION**

- 9-1 Increase the proportion of pregnancies that are intended.
- 9-2 Reduce the proportion of births occurring within 24 months of a previous birth.
- 9-3 Increase the proportion of females at risk of unintended pregnancy (and their partners) who use contraception.
- 9-6 (Developmental) Increase male involvement in pregnancy prevention and family planning efforts.
- 9-7 Reduce pregnancies among adolescent females.
- 9-8 Increase the proportion of adolescents who have never engaged in sexual intercourse before age 15 years.
- 9-9 Increase the proportion of adolescents who have never engaged in sexual intercourse.
- 9-12 Reduce the proportion of married couples whose ability to conceive or maintain a pregnancy is impaired.
- 9-13 (Developmental) Increase the proportion of health insurance policies that cover contraceptive supplies and services.

*Source:* U.S. Department of Health and Human Services. (2000). *Healthy People 2010: Understanding and Improving Health* (2nd ed.). Washington, DC: U. S. Government Printing Office. Retrieved May 30, 2008 from <http://www.healthypeople.gov/Document/HTML/Volume1/09Family.htm>

children from previous heterosexual relationships, artificial insemination, or adoption (Kravets, 2003). Although the exact number of families is not known, this emerging family pattern is increasing. It is estimated that there are between 2 and 14 million children with lesbian or gay parents in the United States (Tasker, 2005).

Although much progress has been made in accepting people with values and beliefs different from those of the mainstream, pervasive homophobia and heterosexism persist (Kravets, 2003; Silvestre, 2001). Nurses must confront and set aside their own biases in order to provide nonjudgmental and comprehensive care to these emerging families.

Gay and lesbian families have all the fears and concerns regarding parenting that any family a community health nurse visits may have. In addition, they experience the stress that accompanies being stigmatized by much of society. The nurse can become a valued resource for the family. Through education and anticipatory guidance, the nurse can assist the parents to successfully navigate the growth and developmental stages of their children, as well as the varied issues faced by families. Research has shown that the psychosocial development of the children of gay or lesbian parents is the same as that of children with heterosexual parents (American Academy of Pediatrics, 2002; Tasker, 2005).

## Divorced and Blended Families

Divorce and remarriage are more frequent occurrences today than in previous generations. Divorces have gone from fewer than 20% of all marriages in the 1960s to almost 50% in 2000 (U.S. Census Bureau, 2008b). It is estimated that close to half of all children will experience living with divorced or single parents before they reach adulthood (Gunsberg & Hymowitz, 2005).

Adjusting to divorce involves a series of transitions and reorganizations for all family members. For children, it may require coping with a new geographic location and a new school, as well as adjusting to changes in the mental and physical health of family members. In addition to the normal growth and developmental changes, children of divorce may face an absent father or mother, interparental conflict, economic distress, parental adjustment, multiple life stressors, and short-term crises.

Not all divorced adults stay single. Most remarry or cohabitate with another adult who may or may not have children. This new couple may have children from their union, creating an even more complex family. Merged or blended families require considerable adjustment and relearning of roles, tasks, communication patterns, and relationships (Friedman et al., 2003).

Identifiable phases occur in divorce, remarriage, and the blending of families; each phase has its own emotional transitions and developmental issues. Table 18.3 shows the phases of a divorce, and Table 18.4 shows the phases of remarriage and blending families.

Because this emerging family pattern has become so prominent in such a short period, it is very possible that the community health nurse is familiar with this pattern or lives in such a family. Nursing skills that are needed when working with divorced or blended families include the ability to listen and be empathic, as well as a nonjudgmental attitude. The nurse can be a rich resource for the family. Support groups for adults and children are excellent resources and provide invaluable services at a time of emotional instability in the family. Peer support groups for children and adolescents and support from within the schools should be used, if available, or started if they do not exist. The community health nurse can have a significant role in community-wide planning if services are needed but unavailable.

## Older Adults

Elderly individuals are the fastest growing segment of the population. From 1950 to 2005, the population of those 65 years of age and older increased from 12 to 37 million persons (NCHS, 2007). Most elders live independently well into their 80s and maintain healthy contacts with family and friends. Others feel isolated because of chronic health problems that limit mobility, thereby reducing or eliminating the ability to interact or contribute meaningfully in society.

The community health nurse needs to understand the complex dynamics of such situations and offer support and encouragement as family members work through these problems. Often, a nurse serves an entire community of elders, in a senior apartment complex, an assisted living center, or a mobile home community, for whom maintaining wellness is the focus. Keeping physically active, eating healthy

Phase	Emotional Responses	Transitional Issues
1. Stressor leading to marital differences	Reveal the fact that the marriage has major problems	Accepting fact that marriage has major problems
2. Decision to divorce	Accepting the inability to resolve marital differences	Accepting one's own contribution to the failed marriage
3. Planning the dissolution of the family system	Negotiating viable arrangements for all members within the system	Cooperating on custody visitation, and financial issues Informing and dealing with extended family members and friends
4. Separation	Mourning loss of intact family Working on resolving attachment to spouse	Develop coparental arrangements/relationships Restructure living arrangements Adapt to living apart Realign relationship with extended family and friends Begin to rebuild own social network
5. Divorce	Continue working on emotional recovery by overcoming hurt, anger, or guilt	Giving up fantasies of reunion Staying connected with extended families Rebuild and strengthen own social network
6. Post-divorce	Separate feeling about ex-spouse from parenting role Prepare self for possibility of changes in custody as child(ren) get older, be open to their needs Risk developing a new intimate relationship	Make flexible and generous visitation arrangements for child(ren) and noncustodial parent and extended family members Deal with possibilities of changing custody arrangements as child(ren) get older Deal with child(ren)s' reaction to parents establishing relationships with new partners

Phase	Emotional Responses	Developmental Issues
1. Meeting new people	Allowing for the possibility of developing a new intimate relationship	Dealing with child(ren)s' and ex-family members' reactions to a parent "dating"
2. Entering a new relationship	Completing an "emotional recovery" from past divorce Accepting one's fears about developing a new relationship Working on feeling good about what the future may bring	Recovery from loss of marriage is adequate Discovering what you want from a new relationship Working on openness in a new relationship
3. Planning a new marriage	Accepting one's fears about the ambiguity and complexity of entering a new relationship such as: New roles and responsibilities Boundaries; space, time, and authority Affective issues: guilt, loyalty, conflicts, unresolvable past hurts	Recommitment to marriage and forming a new family unit Dealing with stepchild(ren) as custodial or noncustodial parent Planning for maintenance of coparental relationships with ex-spouses Planning to help child(ren) deal with fears, loyalty conflicts, and memberships in two systems Realignment of relationships with ex-family to include new spouse and child(ren)
4. Remarriage and blending of families	Final resolution of attachment to previous spouse Acceptance of new family unit with different boundaries	Restructuring family boundaries to allow for new spouse or stepparent Realignment of relationships to allow intermingling of systems Expanding relationships to include all new family members Sharing family memories and histories to enrich members lives

meals regularly, receiving appropriate medical care and immunizations, and establishing and maintaining social contacts are some of the tasks elders should focus on to stay healthy well into old age, and these are some of the areas in which the community health nurse can intervene as teacher, counselor, and clinician (Gavan, 2003). Reaching 100 years of age is not an unusual occurrence today, and more people will live to see advanced age in the 21st century.

## Summary

The family as the unit of service has received increasing emphasis in nursing over the years. Today, family nursing has an important place in nursing practice, particularly in community health nursing. Its significance results from recognizing that the family itself must be a focus of service, that family health and individual health strongly influence each other, and that family health affects community health. A community health nurse's effectiveness in working with families depends on an understanding of family theory and characteristics, in addition to changing family structures.

Every family on the globe is unique; its needs and strengths are different from those of every other family. At the same time, each family is alike because of certain shared universal characteristics. Five of these universals have particular significance for community health nursing: every family is a small social system, has its own cultural values and rules, has structure, has certain basic functions, and moves through stages in its life cycle.

Every family is a small social system. The members within a family are interdependent; what one does affects the others and, ultimately, influences total family health. Families, as social systems, set and maintain boundaries that unite them and preserve their autonomy, while also differentiating them from others. Because these boundaries are semipermeable, families engage in an input–output energy exchange with external resources. Families are equilibrium-seeking, adaptive systems that strive to adjust to internal and external life changes. Like other systems, families are goal directed. They exist for the purpose of promoting their members' development.

Every family has its own culture, its own set of values, and rules for operation. Family values influence member beliefs and behaviors. These same values prescribe the types of roles that each member assumes. A family's culture also determines its power distribution and decision-making patterns.

Every family has a structure that can be categorized as either traditional or nontraditional (contemporary). The most common traditional family structure is the nuclear family, consisting of husband, wife, and one or more children living together. Other traditional structures include husband and wife living as a couple alone, single-parent families, single-adult families, multigenerational families, kin-networks, and blended families. Nontraditional or contemporary family structures incorporate many family forms, not all of which are readily accepted by society. These variations include commune families, group marriages, and group networks. Unmarried single-parent families, unmarried gay or straight couples living together with or without children, and unmarried older adults living together are examples of emerging contemporary family structures. As

less typical families become more common, they receive more recognition and acceptance. These diverse family structures remind us that the nuclear family is now in the minority, that people experience many family structures during their lifetimes, and that a family's ability to perform its basic functions is influenced by its structure.

Every family has six basic functions: (1) to provide members with affection and emotional support; (2) to promote security by providing members with an accepting, stable environment in which physical needs are met; (3) to provide members with a sense of social and personal identity and influence their placement in the social order; (4) to provide members with affiliation, a sense of belonging; (5) to socialize members by teaching basic values and attitudes that determine behavior; and (6) to establish social controls to maintain order. Community health nurses use this information to assess a family's functioning. This information enables the nurse to work with the family and assist in improving the quality of its functioning.

Every family moves through stages in its life cycle. Families develop in two broad stages: a period of expansion when new members and roles are added, and a period of contraction when members leave. Some families demonstrate a spiraling pattern with repeated expansion and contraction.

Emerging family patterns influence the role of the community health nurse. The single adolescent parent in particular needs the community health nurse's knowledge of family developmental theory. Gay and lesbian families with children may also have special needs. More complex interaction patterns and living arrangements are created by divorce, remarriage, the blending of families, and the unique relationships these arrangements create. Older adults are living longer and will soon make up 20% of the population. The multiple needs of elders from age 65 to 100 years or older are more varied than those of any other population group. Today, community health nurses see many more families expressing one of these emerging family patterns. Understanding their different needs will help the nurse provide appropriate services. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Within a small group of your peers, individually define *family* and then compare each of your definitions. How similar and how different is each definition? What in each person's background contributes to the differences in the definitions? Was each of the peers in nursing? If not, how did that contribute to any differences in the definitions?
2. Analyze two families (other than your own) that you know well, one traditional and the other nontraditional (contemporary), and answer the following questions:
  - If the major breadwinner in this family became permanently disabled and unable to work or lost his or her income, how would the family most likely respond immediately and in the long term?

- What are some of this family's rules for operation and the values underlying the rules?
  - Structurally, what kind of family is this?
  - What are the strongest and weakest functions performed by this family, and why do you think this is so?
  - In what developmental stage is this family, and how does it affect their functioning?
3. Talk with the members of a blended family and discuss with each member his or her relationships with stepchildren or siblings, half-siblings, and stepparents. What problems can they identify? What problems have they overcome? What do they see as the positive elements of the union?
  4. Gay and lesbian couples often seek parenting opportunities. How do you feel about this? What makes you feel this way? What are the positive and negative aspects of a child's being raised by a homosexual couple?
  5. Use the Internet and find information at various websites on family structural patterns in other countries. Many families in developing and some industrialized countries live in clans, tribes, groups, and kin-networks. In what countries do you find such family structures? What are the benefits and drawbacks of such systems?

# Working with Families: Applying the Nursing Process

## LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Describe the components of the nursing process as they apply to enhancing family health.
- ◆ Identify the steps in a successful family health intervention.
- ◆ Describe useful activities and actions when intervening on family health visits.
- ◆ List at least six specific safety measures the community health nurse should take when traveling to a home or making a home visit.
- ◆ Describe the effect of family health on individual health.
- ◆ Describe individual and group characteristics of a healthy family.
- ◆ Identify five family health practice guidelines.
- ◆ Describe three conceptual frameworks that can be used to assess a family.
- ◆ Describe the 12 major assessment categories for families.
- ◆ List the five basic principles the community health nurse should follow when assessing family health.
- ◆ Discuss the two foci of family health visits: Education and Health Promotion.
- ◆ Describe three types of evaluations that are necessary after family health interventions.

## KEY TERMS

Conceptual Framework  
 Developmental Framework  
 Eco-map  
 Family health  
 Family nursing  
 Genogram  
 Interactional framework  
 Outcome evaluation  
 Referral  
 Resource directory  
 Strengthening  
 Structural-functional framework

*“If the family were a fruit, it would be an orange, a circle of sections, held together but separable—each segment distinct.”*

—Letty Cottin Pogrebin

 Chapter 18 explored the theoretical basis of family formation and the variety of family structures. Other chapters have stressed that families come in all sizes, consist of members of many ages and biologic relationships, and experience the world filtered through their unique cultures. There are many theoretical approaches and roles to consider when caring for families. This chapter explores the nursing process as it applies to working with families as a unit of service.

Community health nurses deliver care to families in their homes, their work settings, classrooms, clinics and outpatient departments, neighborhood centers, and homeless shelters. Although community health nursing emphasizes the family as a unit of service, a gap exists between family nursing theory, development, and practice (Friedman, Bowden, & Jones, 2003). The problem, in part, is derived from a health care system that fosters individual services, often to the exclusion of family. This is evident in many third-party payer and reimbursement policies that impose limits to the kinds of services funded, in public health agencies' tendencies to organize services around individuals, and in government requirements that agencies keep statistics for specific diseases or service categories that reflect individual rather than family or aggregate data.

The family has been the main unit of service in communities for more than a century (Schorr & Kennedy, 1999). It is with the family in mind that the bulk of health care and related services are provided in the community. Immunization programs exist for infants and children. Parks, recreational services, organized team sports, and social centers exist for the physical and emotional well-being of families. Pregnant women can attend childbirth education classes and receive medical care from their health care providers. Growing families can access parenting classes and support groups for help with developmental crises and in the management of chronic illness. Senior centers exist for the older adults in families, and myriad social and recreational activities offer senior discounts. What all these clients have in common is they are members of families.

Think about how your family has influenced you. Did family members sway your career choice or where you are attending school? What about your value system, or how you view your health? What about the friendships you've formed? What about the foods you eat; would those choices be different if you had grown up with vegetarian parents versus a parent who took you out every fall to hunt deer?

Just as each family is unique, so too are their homes and communities. Some families live in homes that look very much like yours, where you will feel comfortable almost immediately, whereas others live in places that may not feel so comfortable to you. To a novice community health nurse, it can be daunting to enter a small cluttered apartment or a sparsely furnished single room, or a home in disrepair. Families live in mobile homes, in high-rise inner-city apartments, in rural cabins, and on farm labor camps. Each home and neighborhood can bring its own set of unique challenges, as well as strengthens, to the families you are visiting.

Family-level problem-solving techniques are needed to deal with important health issues including health promotion, pregnancy and childbirth, acute life-threatening illness, chronic illness, substance abuse, and terminal illness (Chambers, 2004; Gavan, 2003; Kitzman et al., 2000; Pinelli, 2000;

Saunders, 2003). The first step is to develop family assessment skills. This is foundational to the development of a database on which to formulate nursing diagnosis, an essential step before planning, implementation, and evaluation of services can occur. This chapter focuses on the nursing process: assessing, planning, implementing, and evaluating to enhance family health.

## NURSING PROCESS COMPONENTS APPLIED TO FAMILIES AS CLIENTS

Assessing, planning, implementing, and evaluating nursing care are steps used to deliver care to clients in acute care settings and in the extensive clinic system. These same steps are used with families and aggregates in community health settings. The steps do not change, but the context and client focus are different, and external variables that have not been encountered in other contexts must now be considered.

### Working with Families in Community Health Settings

Family visits need not be limited to homes. Family members may be visited in school or at work during a lunch break, in a day care or senior center, in a group home, or myriad after-work or after-school and recreational settings. The nurse must be creative in accommodating various family schedules and routines. In general, if a visit is all right with the family, school, or employer, it should be all right with the nurse (see Perspectives: Voices from the Community). Families appreciate the individualized effort and respond more positively when nurses are willing to work with family member schedules.

When making visits in public places, such as worksites or schools, be mindful of confidentiality and respect the family's wishes. A client may agree to your visit during lunch break in a department store on a Tuesday, which is the boss's day off, or after the lunch crowd in a fast-food restaurant disperses and the client can take a break. Seek out a place for the visit where other employees or customers cannot overhear your conversation with the client.

Sometimes, visiting clients where they spend their time during the day helps to enhance family assessment. In families with a child in day care or an elderly family member in an adult day care program, your assessment of that individual's

## PERSPECTIVES VOICES FROM THE COMMUNITY

"I couldn't believe it when she [the community health nurse] said she could visit me during my lunch break. I have been so worried about Ben's hearing and with my new work hours I kept missing her—I got her notes she left in the screen door. She actually drove all the way out to my work to tell me about his hearing test at school and the teacher's classroom changes. I can't afford to lose this job—and she came here!"

*Beth, 34, Ben's mother*

ability to manage, participate, and interact in the situation can give insight into problems the family is referring to when you make a home visit. Visiting children during the school day often gives insight into health problems the parents may be concerned about. Such visits can offer the community health nurse an excellent opportunity to consult with the principle, teachers, school nurse, counselor, and school psychologist. The community health nurse may suggest a team meeting of school professionals and the parents, coordinate the meeting, and act as liaison and client advocate during the meeting.

## Working with Families Where They Live

Depending on the setting for community health nursing practice, the nurse encounters most clients in their homes and neighborhoods. Some see families in transition, who are living on the streets, in homeless shelters, or with relatives or friends. Regardless of the family's location, the client is the family; the family is the unit of service in family nursing (Friedman et al., 2003).

### The Home Visit

Working in the community and being able to visit families in their homes is a privilege. In this unique setting you are permitted into the most intimate of spaces we, as human beings, have. Our homes are our creations, our private spaces; they hold our personal treasures and our memories. To let a stranger into our home takes a certain amount of trust. To enter a client's family home also takes trust on the part of the nurse. Once the door is shut behind you, the rules change; you are in the client's world where they are the experts, and you are the guest and may feel like a stranger.

### Nursing Skills Used During Home Visits

Many skills, in addition to expert nursing skills, are needed when assessing, planning, implementing, and evaluating services in the home to families at a variety of functional levels (Tapia, 1997). Expert interviewing skills and effective communication techniques are essential for effective family intervention (see Chapter 10). The following paragraphs describe special skills required when making home visits.

#### Acute Observation Skills

The environment is new to you, and observation of environment and client are equally important. In addition to focusing on the family members' concerns and the purpose of the visit, you need to be observant about the neighborhood, travel safety, home environmental conditions, number of household members, client demeanor, and body language, as well as other nonverbal cues.

Travel in new neighborhoods and attempts to locate a family can cause distress to even the most experienced nurse. Often clients are difficult to locate because the house or apartment number is missing. The residence may be situated behind another house, or it may be a basement apartment without a number. Many anomalies in the layout of a building or a neighborhood may make it difficult for the nurse to locate a client. Addresses on referrals may have numbers transposed such as 123 Hickory instead of 132 Hickory.

Perhaps there is a North Hickory that is miles away from South Hickory, or there is a Hickory Boulevard, Drive, Road, Street, Court, Lane, or Way. There is always the chance that the address is fictitious, given by a client who, for whatever reason, prefers to remain as anonymous as possible.

## Assessment of Home Environmental Conditions

Conditions in the neighborhood and home environments reveal important assessment information that can guide planning and intervention with families. While traveling to and arriving at the family home, you have been gathering information about resources and barriers encountered by the family. This information is used during planning with the family. It is important to remember that neighborhood conditions and even the physical appearance of the apartment or house may contradict the family's values, resources, and goals. They may have little control over the neighborhood or the building they live in, especially if they are renting. For instance, the family may be a young couple with a baby who can afford \$475 in rent; the only apartment available to them for that amount is in a deteriorating low-income neighborhood with dilapidated buildings occupied by renters and owned by absentee landlords, who may own several buildings, mainly for profit. A manager who may not know the landlord and is employed through the owner's management company handles the property. Yet, when you enter the apartment, you may see a well-furnished, neat, and clean home that is opened to you with pride by the family.

In another situation, you may plan to visit an older couple who lives in their own home in an upscale suburban neighborhood. On approaching the house, however, you barely manage to squeeze through a pathway made in the living room, which is piled ceiling-high with boxes, newspapers, and furniture. This continues throughout the house and even into a back bedroom, where half the bed is covered with papers, books, and a few cats. An older woman is in the bed. The husband moves very slowly, and after showing you in, he leaves the bedroom and heads toward the backyard.

Many environmental clues in each of these situations help the nurse begin an assessment that will lead to a plan to assist each family. Most neighborhoods and homes do not present such extremes. However, if you are unprepared for the extremes, they may overwhelm you, and you may become so distracted that you cannot focus wholly on the family and incorporate these important observations into the plan.

## Assessment of Body Language and Other Nonverbal Cues

After you have knocked on the door or rung the doorbell and are in the home (see *What Do You Think?*), or even while greeting the people in the doorway, you are gathering data. Being human, you may form opinions or make judgments about the family from the initial meeting. Know that they are doing the same. Be aware of all household members; acknowledge and greet them. If some are absent, inquire about them. Make this a habit on all visits. Each family member is important and has opinions and health care needs, even if you only see certain members of the family on each visit.

Be observant of family body language and demeanor. These nonverbal cues provide information that must not be

## What Do You Think?

### HOW YOU KNOCK HELPS FAMILIES OPEN THE DOOR

At first this may seem trite, but how do you knock on the door when you visit a family? Do you use the “I don’t want to be here and if they don’t hear the knock I can quietly leave” type of knock that even Superman can’t hear? Or do you knock like, “I’m a bill collector and YOU BETTER open this door!” During this knock, the entire family is leaving through the back door! We suggest a knock that is loud enough to be heard, yet friendly and nonthreatening. If necessary, practice “your knock” until you can create this beneficial combination.

With some families, it is helpful to call toward the door as you knock or ring the bell with, “Mrs. Smith, this is Jenny from the Health Department—remember I was coming by today” or, “Ms. Jiminez, it’s the student community health nurse, Terry Guara, and I brought those pamphlets for you” or, “Hello, it’s James from the neighborhood clinic, we planned to meet today.” Using such a greeting allows the family to know who is at the door and choose to open the door if they want. It will get you into more homes than the “quiet-as-a-mouse” or “bill-collector” knocks.

overlooked. Observations such as, “You seem anxious today,” or “Did I come at a bad time? You seem distracted,” are openings that allow family members to express what is on their minds. If you are not open to body language while making a visit, you may overlook important cues and continue with your agenda, without realizing that the family is distracted by another, more pressing issue.

On a related note, it is important to be aware of your own body language. If you fidget with car keys during the entire visit, noisily chew gum, give minimal eye contact while continuously looking at your paperwork, appear rushed, or refuse to sit on any of the furniture, your behavior will tell the family a great deal about you, including how you feel about being in their home.

## PLANNING TO MEET THE HEALTH NEEDS OF FAMILIES DURING HOME VISITS

The greatest barrier to a successful family health visit is lack of planning and preparation. A visit is not successful just because the nurse enters a home or other setting where clients are present. A successful family health visit takes much planning and preparation and requires accurate documentation and follow-up. In addition, safety measures must be followed not only while traveling in the neighborhood, but also in the home.

### Components of the Family Health Visit

The structure of family health visits can be divided into four components that follow the nursing process (Display 19.1). Pre-visit preparation steps (assessment and planning) are

necessary to ensure that the actual family health visit (implementation) is complete. The documentation and planning for the next visit (evaluation) concludes the responsibilities for one visit and prepares the nurse for the next action needed.

### Pre-visit Preparation

Community health nurses design a plan for the initial family health visit based on a referral coming into the agency. A **referral** is a request for service from another agency or person. This request is formalized by use of a form or information that the originating agency has transferred to the receiving agency. Referrals may be formal, coming from complementary agencies, or they may be informal, resulting from verbal or telephone referrals from friends or relatives who believe that someone needs help. Referrals are the source of new cases for the agencies, and they need timely responses. Referrals could be from labor and delivery units, requesting service for low-birth-weight babies and teen mothers. They could be from social service agencies, requesting a home assessment for a child being returned to parents after previous removal from the home. A referral could come via a telephone call from a woman in a city 500 miles away, requesting that a nurse check on an elderly relative who lives alone in the community and has recently exhibited slurred speech. Follow-up visits are made to these families based on need and agency protocol.

Nurses must have a physical place to work, with access to a telephone and any other supportive resources deemed necessary, such as educational material (pamphlets, brochures, computer, and related website addresses to access educational information), charting tools, and other supplies required for home visits. Nurses also need a **resource directory**, which is a published list of resources for the broader community, or a nurse-made directory of resources created over years of working with people in the community. Some agencies issue a nursing bag to their nurses but if not, many community health nurses become creative and devise their own carry-all for supplies. The supplies needed depend on the type of visit; some nurses have several totes for different types of visits. Think about what basic supplies you would need to visit a new mother and her infant, or an elderly man with hypertension.

Once the nurse is prepared, contact with the family is needed. For a home visit, ideally, the referral contains a correct telephone number for the family, a relative, or a neighbor. If the referral or chart does not contain this information, the nurse makes an unannounced visit. During this visit, it is important to get a contact number for the family. When calling for the first time, introduce yourself, explain the reason for the call, and why the family was referred, what the visit consists of, and determine when a visit would be convenient for the family and the nurse. Some people become defensive or suspicious of the nurse’s intentions. For example, a new young mother may think, “What did they see me doing wrong with my baby in the hospital?” In this kind of situation, it is very important that the nurse explain that

- ◆ The visit is a service provided by the agency to all mothers.
- ◆ The visit is paid for by taxes (or donations) or by the client’s health maintenance organization (if applicable), so there is no direct charge to the family.

## DISPLAY 19.1

## GUIDELINES FOR MAKING HOME VISITS: 30 STEPS TO SUCCESS

The following guidelines can be followed to evaluate yourself after making a home visit; or it can be a tool used when you are evaluated by another nurse (peer or instructor). Rate yourself using the following scale: 0 = does not apply, 1 = unsatisfactory, 2 = satisfactory.

**Rating****Assessment**

- \_\_\_\_\_ 1. Studies referral, record, or other available data about the family.
- \_\_\_\_\_ 2. Gathers community resource information potentially appropriate to the family.
- \_\_\_\_\_ 3. Obtains appropriate supplies or educational material in anticipation of family needs.

**Planning**

- \_\_\_\_\_ 4. Contacts family to set up an appropriate time for the home visit.
- \_\_\_\_\_ 5. Ascertains correct address and directions to the family for the home visit.
- \_\_\_\_\_ 6. Formulates a written plan for nursing intervention with each family member.
- \_\_\_\_\_ 7. Organizes a chart with forms and charting tools based on the focus of the visit.
- \_\_\_\_\_ 8. Plans a route to the family's home that is the most direct, being resource efficient.

**Implementation**

- \_\_\_\_\_ 9. Travels the community with safety, locating the family home with ease.
- \_\_\_\_\_ 10. Knock on the door loudly enough to be heard and in a friendly manner.
- \_\_\_\_\_ 11. Introduces self to family members in an appropriate manner.
- \_\_\_\_\_ 12. Clearly states the reason for the visit.
- \_\_\_\_\_ 13. Allows a few moments of socialization before beginning the visit.

- \_\_\_\_\_ 14. Smiles, speaks in a pleasant, friendly tone of voice, and maintains eye contact.
- \_\_\_\_\_ 15. Uses aseptic technique when providing nursing care.
- \_\_\_\_\_ 16. Respects the dignity, privacy, safety, and comfort of family members.
- \_\_\_\_\_ 17. Listens attentively to ascertain what family members are saying or implying.
- \_\_\_\_\_ 18. Converses with family members during the home visit.
- \_\_\_\_\_ 19. Communicates accurate and meaningful information to family members.
- \_\_\_\_\_ 20. Responds to family members in a way that encourages them to continue talking.
- \_\_\_\_\_ 21. Uses appropriate words of explanation for family member understanding.
- \_\_\_\_\_ 22. Utilizes opportunities for incidental teaching.
- \_\_\_\_\_ 23. Commends progress made by individual family members.
- \_\_\_\_\_ 24. Explains nursing measures before, during, and after each procedure.
- \_\_\_\_\_ 25. Shares the results of nursing measures with family members when indicated.
- \_\_\_\_\_ 26. Closes the home visit by summarizing the main points of the visit.
- \_\_\_\_\_ 27. Makes plans for the next visit, considering family member wishes.

**Evaluation**

- \_\_\_\_\_ 28. Utilizes information gathered on the home visit to plan care for next visit.
- \_\_\_\_\_ 29. Documents home visit in an appropriate and timely manner.
- \_\_\_\_\_ 30. Completes a self-evaluation of the home visit.

- ◆ Young mothers often have lots of questions about their new babies. Having a nurse come to the home provides an opportunity for the mother to ask questions and for the nurse to show the mother things she may not know about her baby.

The nurse needs to ask explicit directions to where the family is staying. The referral may have a different address, and the family may forget to mention that they are staying elsewhere.

**Making the Visit**

On locating and meeting the family, the following guidelines for initial contact should be used (Allender, 1998):

- ◆ Introduce yourself and explain the value to the family of the nursing services provided by the agency.
- ◆ Spend the first few minutes of the visit establishing cordiality and getting acquainted (a mutual discovery or "feeling out" time).
- ◆ Use acute observational skills.
- ◆ Be sensitive to verbal and nonverbal cues.
- ◆ Be adaptable and flexible (you may be planning a prenatal visit, but the woman delivered her baby the day after you made the appointment, and now there is a newborn).
- ◆ Use your "sixth sense" as a guide regarding family responses, questions they ask, and your personal safety (trust your feelings).
- ◆ Be aware of your own personality; balance talking and listening, and be aware of your nonverbal behaviors.
- ◆ Be aware that most clients are not acutely ill and have higher levels of wellness than are generally seen in acute care settings.
- ◆ Become acquainted with all family and household members if you are making a home visit.
- ◆ Encourage each person to speak for himself.
- ◆ Be accepting and listen carefully.
- ◆ Help the family focus on issues and move toward the desired goals.

- ◆ After the body of the visit is over, review the important points, emphasizing family strengths.
- ◆ Plan with the family for the next visit.

The length and primary focus of the visit will vary depending on its purpose. As a general guide, if the visit is shorter than 20 minutes, it probably should be folded into another visit (unless you are offering a piece of very important information, providing supplies, or have come at the family's request). On the other hand, if the visit exceeds 1 hour, it should be conducted over two visits. Families have routines that are important to them, and taking a large portion of time out of their day may lead to resentment, putting future visits in jeopardy. Similarly, if nothing of value (according to the family) occurs on a visit, family members may not continue to make themselves available for future visits. This becomes a balancing act for the family and the nurse, and it is an area in which using your sixth sense and picking up on nonverbal cues is helpful (Zerwekh, 1997). In addition, home visits are an expensive way to provide community health nursing services, which are community-based. The outcome of better health for family members must be demonstrated in order to support the value of such costly services (see Evidence-Based Practice).

### Concluding and Documenting the Visit

After planning for the next visit, saying goodbye to the family members terminates the home visit. This is a good time to put away the paperwork, materials, and supplies from this visit and retrieve items needed for the next visit on your schedule. It is always safer to open your trunk in front of this home and get out what is needed for the next family's visit than to open your trunk in front of the next family's home. You do not want to give community members information about what is stored in your car's trunk while it is unattended and you are in the family's home.

Most typically, the documentation of each home visit is completed as soon as the nurse returns to the agency. Some agencies provide their nurses with laptop computers and electronic charting forms, and charting is encouraged at the end of the visit before leaving for the next one. Sometimes, time is allowed for the nurse to chart at home after the last visit of the day. For the most part, you will be expected to complete the charting by hand, using agency forms, as soon as is practically possible. Most agencies expect all charting to be completed by the end of each workday or not later than the end of the work week.

Agencies use a variety of forms that assist the nurse to document fully and succinctly. On some forms, the nurse uses code numbers, letters, or checkmarks on developmental or disease-specific care plans that are devised in a checklist format. For example, a packet of four pages may be used to document a postpartum visit and newborn assessment: two narrative forms to chart the expectations for the mother and baby, and postpartum newborn assessment forms on which head-to-toe assessment information is documented. These forms contain a place to document parent or client teaching according to expected parameters and a place for listing other professional's involvement with the family. Similar developmentally focused forms may be used in the agency for high-risk infants, high-risk children, adolescents, and older adults. Other packets of

## EVIDENCE-BASED PRACTICE

### Prenatal and Infancy Home Visits

The Nurse–Family Partnership (NFP) has a long history of providing prenatal and infancy home visits by nurses to first time at-risk mothers. The goal of this program is to prevent child abuse and neglect, children's mental health problems, and infant mortality through home visiting during the first 2 years of the child's life. Through randomized trials, the program has demonstrated positive results in various ethnic and racial groups and in a variety of living contexts.

To test the long-term effectiveness of this program, mothers enrolled in an earlier randomized trial who had received nurse visits ( $n = 191$ ) and a control group ( $n = 436$ ) were compared. By age 9 (7 years following the intervention), the nurse-visited women used welfare and food stamps for fewer months, had reduced rates of subsequent births along with increased intervals between births, and had more stable partner relationships. The children who received the nurse visits also demonstrated higher academic adjustment and a lower rate of preventable deaths prior to age 9. Both mother and child had demonstrable benefits from the nursing intervention.

#### Nursing Implications

Home visiting can be a costly effort for a community. The NFP has demonstrated that comprehensive home visiting by nurses can have a positive impact on both the mothers and the children. The cost savings in terms of reduced use of public assistance programs, reduced pregnancy rates, and delayed pregnancy can offset the operating costs of the program. In addition, the academic achievement of these children may ultimately prove beneficial to the long-term economic prospects of these at-risk children and the communities in which they live. Communities considering reducing or eliminating home visiting programs may want to consider retaining them or possibly implementing the NFP program.

forms may focus on chronic illness, such as chronic obstructive pulmonary disease, hypertension, diabetes, alcoholism, acquired immunodeficiency syndrome (AIDS), or cancer that are common in the agency client base.

### Focus of Family Health Visits

The focus of family health visits depends on the mission and resources of the agency providing the service and the needs of the families being served. Some agencies provide education, recreational activities such as summer camps, and support groups for families of people with specific health problems

such as Alzheimer's disease, asthma, diabetes, or neurologic disorders. Other agencies provide services directed toward those with special social or economic needs, such as immigrant families, people living in poverty, or the homeless. Home visits may be a part of the service being provided and are best conducted and received in the comfort and privacy of a family's home. In general, family health visits are designed to be educational, to provide anticipatory guidance, and to focus on health promotion or prevention.

### Family Education and Anticipatory Guidance

Official agencies, such as county or city health departments, distribute their services based on the broader community's needs. For example, if there is a large population of teen pregnancies and high-risk infants, the health department may contract with hospitals and private doctors' offices to provide home or clinic visits to all teens and women with high-risk pregnancies and their newborns after delivery. On these visits, the community health nurse teaches prenatal, postpartum, and newborn care, and provides anticipatory guidance (information needed in the future regarding the child and the need for regular infant health care provider visits, immunizations, and safety awareness). Another community may have a significant number of older adults who need to learn how to manage a chronic illness, enhance their nutrition, and practice safety measures to prevent injuries and falls.

### Family Promotion and Illness Prevention

All populations, regardless of age, income, culture, or nation of origin, need the fundamental protection immunization gives to protect themselves and the health of the larger community. In addition, providing the means for families to receive required immunizations is a responsibility of health departments. Usually, immunization services are not brought into the home, but the nurse can provide information about immunizations, teach the importance of following an immunization schedule, and follow up with the client during home visits.

Teaching people how to prevent illness and how to remain healthy is basic to community health nursing (see Chapter 11). Even within the limitations of chronic illnesses, family members can be taught health promotion activities to live as healthfully as possible (Denham, 2002; Pender, Murdaugh, & Parson, 2006). Health promotion activities may include screening for hypertension and elevated cholesterol, performing a physical assessment, and teaching about nutrition and safety. The American Nurses Association's 2007 *Public Health Nursing: Scope and Standards of Practice* highlights this role in the following statement: "When public health nurses partner with individuals, the focus becomes the promotion of knowledge, attitudes, beliefs, practices, and behaviors that support and enhance health, with the ultimate goal of improving the overall health of the population" (p. 7).

Such activities can occur during a family health visit; while family members are at their place of work, school, or recreation; or at self-help group meetings. Community health nurses provide health promotion services to couples during prenatal classes by teaching about the expected changes during pregnancy and providing anticipatory guidance for safe infant care. They may also screen older adults

at senior centers for hypertension or elevated cholesterol, or teach family members who attend support groups, such as Alcoholic Anonymous.

### Personal Safety on the Home Visit

As mentioned earlier in this chapter, personal safety while traveling throughout the community is essential. In addition, continuation of personal safety while on the home visit must be considered.

### Personal Safety While Traveling and in the Neighborhood

On leaving your "base of operation," such as the health department office, neighborhood clinic, homeless shelter, or campus classroom, have with you all the necessary tools to travel in the community with safety. Most importantly, leave an itinerary of your planned travels, the telephone numbers of families you will attempt to visit, and your cellular phone number. Traveling in the community takes a variety of forms and means different things to different people.

If you are traveling in an agency or private car, you need:

- ◆ A full gas tank
- ◆ A city/county map
- ◆ A cellular phone
- ◆ The family addresses
- ◆ Money for lunch or telephone calls (in case you are in an area where your cellular phone does not work)

If you are using public transportation, plan to

- ◆ Have exact change for each bus trip
- ◆ Carry a bus schedule
- ◆ Exit the bus as near as possible to your client's home
- ◆ Know where to get the bus for the return trip or to the next home visit
- ◆ Carry a cellular phone

If you are walking or riding a bicycle to a home visit, you still need to travel safely. In some neighborhoods, it is best to call ahead to the family you plan to visit, give them an approximate time of your arrival, and if necessary, ask them to watch out for your arrival. When walking in neighborhoods, walk with direction and purpose; do not look lost even if you are. Use neighborhood shopkeepers as resources for direction and information and as refuge if you feel uncomfortable or threatened. If you need to ask for directions, and you are not near any stores, look for another professional, such as a social worker, a public service employee (postal or utility worker), or an apartment manager. If you need to approach a stranger for information, select a woman. If you see a group of people that makes you feel uncomfortable, cross the street, limit eye contact, and continue to the home you are intending to visit. Always avoid walking through alleys or along buildings that open onto alleys, and stay in the middle of the sidewalk or closer to the street. It might be helpful to carry a whistle on your key ring.

It is always safest to avoid compromising situations by staying alert and using safe traveling methods whenever you are in public, no matter how "safe" the area appears. However, if an individual or group accosts you, immediately try to break

free and run to a public place while making loud noises. Yell “Fire!” This response gets more attention than “Help!” If a criminal wants your nursing bag, purse, or wallet, freely give it up; the contents are not worth your safety. Some nurses feel safer after they have attended self-defense classes, which are offered by police departments, as employee in-service programs in some agencies, and on some university campuses.

In some rough inner-city neighborhoods, professionals visiting families travel only in pairs (usually with at least one male in the pair) or with a security guard or police escort. Know whether these resources are necessary or available to you before venturing into a crime-ridden community. In some inner-city neighborhoods, community health nurses refuse to visit people living on one block or in one apartment building. Similar issues are found in rural areas known for drug manufacturing and distribution. Know and do not challenge important safety measures that are used by expert nurses and are followed for personal safety. Safety issues are unique to each community.

Another focus of concern is the perceived risk to self when making a home visit. An individual’s cognition and perception of a situation, his views on risk taking, and the time, setting, and coping process all factor into feelings of safety when traveling in a community, entering a family’s home, or conducting a home visit (Kendra & George, 2001). What one person sees as a risk, another sees as a challenge or an opportunity. Yet another may see nothing. We each perceive risks differently based on knowledge, experience, and personality.

### **Arriving at the Home**

Make sure you are at the right house, and do not go into the home until you are assured that the family you are intending to visit does live there and is home. For example, you may be planning to visit 16-year-old Jennifer and her 5-day-old infant, Marcus. However, when you knock, a 50-year-old man answers the door. Do not enter the house without asking whether Jennifer can come to the door or you can see her, even if he invites you in. Remain outside the home and go inside only after you talk to Jennifer at the door. This precaution ensures that the family members you want to visit are really home and that this is the right address.

### **Friction Between Family Members**

During a home visit, two or more family members may begin to argue or physically fight with one another. Immediately remove yourself from the home visit, let the family know that with such distraction it is not a good time to visit, and that you will return at another time. Never step in and offer to assist an adult family member when two people are physically fighting; you may be the next victim. If necessary, call 911 from your cellular phone once you are out of the house. Depending on the type of altercation, it may be appropriate to discuss the friction in the family at a later visit.

### **Family Members Under the Influence**

If the focus of the visit is on two family members and a third member is demonstrating behaviors that indicate drug or alcohol use, you must use your judgment as to the best action to take. The agency you work for or the school you

attend has guidelines you should follow. If the intoxicated person goes to another room, it might be appropriate to continue the visit and perhaps discuss your observations with the remaining family members. If the person becomes abusive, remains in the room, or interrupts the visit it is best to terminate the visit and reschedule when the family member is not under the influence or is not present. You do not want to put yourself in the middle of a situation that could deteriorate rapidly and compromise your safety.

### **The Presence of Strangers**

In some families, the coming and going of many extended family members, neighbors, and friends is common; it is the norm and is not distracting to them, but it may be to the nurse. For example, what would you do if you arrived at a home and five teenage boys were sitting on the front porch steps, so that you had to edge your way past them to the door? What if you found three men sleeping on the living room floor in the small apartment of a teenage mother and her infant, or four neighbor children riding their tricycles inside the house during a teaching visit to two young parents who do not seem fazed by the commotion? These situations may not be indicative of danger, but they can make you feel vulnerable, uncomfortable, or distracted from the purpose of the visit. Inquire about the people you observe in the periphery of the home visit; ask about their relationship to the family and whether they should be included in the visit. The family may suggest that you ignore the other people or say they are transient family members. It may be important to learn who they are and if they have unmet health care needs or their presence influences the health of the family you are visiting.

## **EFFECTS OF FAMILY HEALTH ON THE INDIVIDUALS**

The health of each family member affects the other members and contributes to the level of **family health**. For example, a woman whose husband has had a stroke may cope successfully with the resulting physical and emotional demands of his care but may have inadequate reserves for effectively meeting the needs of her children. The level at which a family functions—how well it is able to solve problems and help its members reach their potential—significantly affects the individual’s level of health (Early, 2001). A healthy family fosters individual growth and resistance to ill health and sustains members during times of crisis such as serious illness, emotional dilemmas, divorce, or death of a family member. On the other hand, a family with limited coping skills or an underdeveloped capacity for problem solving, self-management, or self-care is often unable to promote the potential of its members or assist them in times of need (Barnes, 2001; Donnelly, 2002; Reutter, 1997).

Family health standards and practices also influence each member’s health. For instance, many individuals, even as adults, adhere to cultural and family patterns of eating, exercise, and communication. Cultural (see Chapter 5) and family values influence decisions about utilizing preventative health care as well as access to services such as immunizations, regular health assessments, or family planning. Family patterns also dictate whether members participate in their own health care and how they follow through and comply

with professional advice. Individuals influence family health, and the family can either obstruct or facilitate individual health. The family becomes an important focus for community health nursing assessment and intervention.

## CHARACTERISTICS OF HEALTHY FAMILIES

How does the community health nurse determine family health status? Analysis of how basic functions are met does not give a satisfactory picture of a family's health status. More definitive criteria are needed. Although it is difficult to define a "normal" family, studies have provided some standards that characterize a healthy family (Barker, 1998; Thompson, 1998). Over the years, research on families and on family health behavior has produced a growing body of data with which to assess family health.

In looking at families over the years, researchers have found many similar characteristics. Otto (1973) identified characteristics of family unity, loyalty and interfamily cooperation, support and security, role flexibility, and constructive relationships with community. Olson, McCubbin, Barnes, and colleagues (1983) identified seven major family strengths that are important for family functioning and coping with crisis: family pride, family support, cohesion, adaptability, communication, religious orientation, and social support. Becvar and Becvar (2003) listed the following characteristics: (a) a legitimate source of authority that is supported and consistent over time, (b) a stable and consistent system of rules, (c) consistent and regular nurturing behaviors, (d) effective child-rearing practices, (e) stable and well-maintained marriages, (f) a set of agreed-upon goals toward which the family and individuals work, and (g) sufficient flexibility to change in the face of both expected and unexpected stressors. Parachin (1997) identified six signs of a healthy family: maintaining a spiritual foundation, making the family a top priority, asking for and giving respect, communicating and listening, valuing service to others, and expecting and offering acceptance. Rucibwa, Modeste, and Montgomery (2003) found significant relationships between family characteristics and sexual attitudes and behaviors among Black and Hispanic adolescent males.

Six important characteristics of healthy families that consistently emerge in the literature (Becvar & Becvar, 2003; Freidman et al., 2003; Parachin, 1997) are:

1. A facilitative process of interaction exists among family members.
2. Individual member development is enhanced.
3. Role relationships are structured effectively.
4. Active attempts are made to cope with problems.
5. There is a healthy home environment and lifestyle.
6. Regular links with the broader community are established.

### Healthy Interaction Among Members

Healthy families communicate. Their patterns of interaction are regular, varied, and supportive. Adults communicate with adults, children with children, and adults with children (Anderson & Sabatelli, 2003). These interactions are frequent and assume many forms. Healthy families use frequent verbal communication. They discuss problems, confront each other when angry, share ideas and concerns, and write or call

each other when separated. They also communicate frequently through nonverbal means, particularly those families from cultural or subcultural groups that are less verbal. There are innumerable ways to convey feelings and thoughts without words, including smiling encouragingly, embracing warmly, frowning disapprovingly, being available, withdrawing for privacy, doing an unsolicited favor, serving refreshments, and giving a gift. The family that has learned to communicate effectively has members who are sensitive to one another. They watch for cues and verify messages to ensure understanding. This kind of family recognizes and deals with conflicts as they arise. Its members have learned to share and to work collaboratively with each other.

Effective communication is necessary for a family to carry out basic functions. Family members must communicate to demonstrate affection and acceptance, to promote identity and affiliation, and to guide behavior through socialization and social controls. Just as there is a correlation between a high degree of communication and a high degree of effectiveness in organizational functioning, facilitative communication patterns within a family promote the health and development of its members. Healthy families are more likely than unhealthy families to negotiate topics for discussion, use humor, show respect for differences of opinion, and clarify the meaning of one another's communications.

### Enhancement of Individual Development

Healthy families are responsive to the needs of individual members and provide the freedom and support necessary to promote each member's growth. If a father in a healthy family loses his job, the family will work to support his ego and help him use his energy constructively to adjust and find new work. The healthy family recognizes and fosters the growing child's need for independence by increasing opportunities for the child to try new things alone. This kind of family can tolerate differences of opinion or lifestyle. Each member is accepted unconditionally, and the right to be an individual is respected. Within an appropriate framework of stability and structure, the healthy family encourages freedom and autonomy for its members (Friedman et al., 2003).

Patterns of promoting individual member development vary from one family to another depending on cultural orientation. The way in which autonomy is expressed in an Italian American family differs from its expression in a Native American family, yet each family can promote freedom and autonomy. The result is an increase in competence, self-reliance, social skills, intellectual growth, and overall capacity for self-management among family members (Wright & Leahey, 2005) (see From the Case Files).

### Effective Structuring of Relationships

Healthy families structure role relationships to meet changing family needs over time (Hanson, 2001). In a stable social context, some families establish member roles and tasks (e.g., breadwinner, primary decision-maker, homemaker) that are maintained as workable patterns throughout the life of the family. Families in rural areas, isolated communities, or religious and subcultural groups are more likely than others to retain role consistency, because they face little or no external pressure or need to change. For example, the Amish

## From the Case Files

### A Family Assessment: Meeting Hector's Needs

You are a home health nurse working in Smithville. You have been given a referral for a new client, Hector. Hector is being released from the rehabilitation unit of Metropolis Hospital. Although he lives in Smithville, Metropolis Hospital was the only facility willing to accept a Medicaid client with a severe spinal cord injury.

Hector is a 19-year-old Hispanic man who sustained major injury to his spinal cord (T4 injury) in a motorcycle accident. The injury occurred approximately 6 weeks ago. Hector has been diagnosed as paraplegic with some residual limitation of upper body strength and mobility.

Your job is to facilitate Hector's transition from the hospital to the home environment. You will be teaching Hector and his caregivers about the following:

1. Nutrition and fluid intake
2. Signs and symptoms warranting follow-up
3. Medication administration
4. Bowel and bladder care
5. Skin care
6. Activities of daily living (ADLs), self-care with sensory-motor deficits
7. Safety/injury prevention
8. Community resources
9. Rehabilitative services
10. Anticipatory guidance about grief, anger, and suicidal ideations; sexual function; fear of abandonment, role change, and social isolation; and altered family processes.

Following is a synopsis of information obtained during your initial visit with Hector and his family in their home.

**Visit One.** Hector lives in a migrant labor camp located on the outskirts of Smithville. His family has resided in the camp for 18 years. Living in the two-bedroom cabinlike home are:

- Hector
- Hector's uncle Manuel (32 years old). Manuel's job is seasonal; he has been offered a temporary job for a much higher salary, working out of state.
- Hector's brother Efran (16 years old). Efran is considering dropping out of high school in order to assist with the care of his family. His goal is to become an auto mechanic. He is fluent in both Spanish and English.
- Manuel's wife Micaela (29 years old). Micaela was a teacher in Mexico. She is extremely supportive of her family. She is concerned about the possibility of another pregnancy but does not believe in the use of birth control.
- Manuel and Micaela's children, Arturo (5 years old) and Jasmin (6 months old). Arturo begins a Head Start Program soon and will be gone for 5 hours each day. Jasmin is a healthy baby; she continues to be breast fed and is thriving at home.
- Hector's 74-year-old paternal grandmother (Abuela), who has recently arrived from Mexico and plans on assisting in Hector's care. Abuela has congestive heart failure and arthritis. She is not a legal resident of the United States and is not eligible for medical assistance.

The whereabouts of Hector's mother are unknown; she moved from their village in Mexico shortly after Efran was born. She has remarried and started another family. She has had no contact with Hector or Efran. Hector's father lives in their home village in Mexico. Although he lived in the migrant camp in Smithville for many years, he recently remarried and has two young daughters in Mexico. Hector's father is aware of Hector's injury and has no plans to return to the United States.

Your ability to speak fluent Spanish has enabled you to solicit the above information. Manuel has provided you with most of the information. He has been very involved in Hector's recovery through daily visits to the rehabilitation unit and frequent discussions with Hector's health care providers. Manuel tells you that "Hector is like a son to me . . . I have a responsibility to my older brother to watch over his son. My brother watched out for me when I was young . . . he even left school to work to help support our family." Manuel adds, "We don't have much but we will take care of Hector . . . we'll all work together."

You begin your discussion by explaining your role as home health nurse. You inform the family about the type of education and interventions you are able to provide. You ask Hector and the family to tell you what they have learned from the health care team at the rehabilitation unit and what plans have been developed by the family to address Hector's medical and psychosocial needs. As you begin the visit you notice that Hector's grandmother is sitting quietly in the corner of the room rocking Jasmin. You learn that Efran is working in the fields. Arturo is in school. Manuel, Micaela, and Abuela are participating in the home visit this morning. The conversation is as follows.

Nurse: Hector, can you tell me how you feel about being home?

(continued)

Hector (looks at Micaela): Okay, I guess.

Micaela: He's a little scared, I think. He feels like it's going to be too much for us to deal with.

Nurse (looking at Hector): There's so much happening right now, so much to think about . . .

Hector: Uh-huh.

(Hector is maintaining eye contact with Manuel and Micaela only; since this is your initial visit to the home you feel that Hector may be more comfortable in the role of observer.)

Nurse (looking at Manuel and Micaela): Do you have any questions before we begin?

Micaela: They gave us a lot of information at the hospital... I'm most afraid about if the phone doesn't work and Hector needs help. What if something happens to Hector and I can't call anyone? That's the only thing I worry about.

Abuela: If anything happens to him I'll be right here with you, "mija." We can do this, we can take care of Hector if we work together.

Manuel: There is a store with a phone only two blocks away, if you needed to you could call from there. What I want to know is how we can get Hector into school or something that will help him to be around kids his own age. His English is good enough, he even finished high school. He needs to be ready to make a future for himself.

Hector (grins and looks at Manuel): Right, uncle, that is what I want, too.

You continue the conversation by revisiting Micaela's concerns about access to a telephone in case of an emergency. You ask specific questions about her concerns and use this as an opportunity to educate the family about circumstances warranting immediate follow-up. Together you decide that Micaela will develop a list of specific concerns that you will review together at a subsequent visit planned for 2 days from today.

Today's visit consists of:

- I. Assessment
  - A. Home environment
    1. Safety
    2. ADLs
  - B. Knowledge of disease processes
  - C. Fluid volume balance
  - D. Nutritional resources of family
    1. Food availability
    2. Food preparation
  - E. Insurance and financial status
- II. Education
  - A. Medications
  - B. Warning signs and symptoms and appropriate follow-up procedures
  - C. Bowel and bladder care
  - D. Hygiene prior to and following patient care

The plan for your visit in 2 days includes:

- I. Referrals
  - A. Community resources
  - B. Educational opportunities
  - C. Support groups (Spanish speaking)
  - D. Peer group opportunities for Hector
- II. Assessment
  - A. Continuation of above
- III. Education
  - A. Continuation of above

### Questions

1. What is the social structure of this family (traditional versus nontraditional)? Be specific about the type of traditional or nontraditional family system that exists in this scenario.
2. Discuss an example of triangulation in this scenario.
3. What essential functions are present within this family system?
4. What developmental stages appear to have been achieved?
5. What steps will you take in order to empower the family to make their own decisions?
6. List the strengths of the family.
7. Prioritize Hector's issues—medical and psychosocial.
8. Prioritize issues facing the other family members.
9. Identify mutual goals for this family:
  - Immediate
  - Mid-range
  - Long-term
10. What community health nursing interventions will you utilize to achieve these mutual goals?

community in Pennsylvania has maintained marked differentiation in family roles for more than 100 years.

In a technologically advanced society such as the United States, most families must adapt their roles to changing family needs created by external forces. As women enter the workforce, family roles, relationships, and tasks change to meet the demands of the new situation. Many husbands assume more homemaking responsibilities; fathers engage in child rearing, children along with adults in their families share decision-making and a more equal distribution of power. The latter may be essential for the survival of a single-parent family, in which the children must assume adult responsibilities while the parent works to support the family (Baris et al., 2001).

Changing life cycle stages require alterations in the structure of relationships. The healthy family recognizes members' changing developmental needs and adapts parenting roles, family tasks, and controls to fit each stage (Anderson & Sabatelli, 2003). For example, household chores of increasing complexity and responsibility are assigned as children become capable of handling them. Rules of conduct relax as members learn to govern their own behavior.

### Active Coping Effort

Healthy families actively attempt to overcome life's problems and issues. When faced with change, they assume responsibility for coping and seek energetically and creatively to meet the demands of the situation (Becvar & Becvar, 2003; Olson et al., 1983). Coping skills are needed to deal with emotional tragedies such as substance abuse problems, serious illness, or death. If a family member has a substance abuse problem, the family may seek counseling and treatment opportunities involving all family members. If a family member is seriously ill, the family may ask for and accept assistance from extended family members or community health care workers. In the event of death in the family, receiving consolation and support from one another and from relatives and friends is an important step in the healing process. The healthy family recognizes the need for assistance, accepts help, and pursues opportunities to eliminate or decrease the stressors that affect it.

More frequently, healthy families cope with less dramatic, day-to-day changes. For instance, one family may cope with the increased cost of food by cutting down on meat consumption, substituting other protein foods, and eating in restaurants less frequently. Healthy families are open to innovation, support new ideas, and find ways to solve problems. One family may try to solve the problem of spending too much on transportation by cutting down on daily travel; this may cause additional problems if three members have jobs in different areas of town or need to go to school functions and meetings. Another family, responding to environmental concerns and a personal need for a healthier lifestyle, may explore and arrive at new ways to reach destinations by walking, bicycling, skating, or car-pooling to school or work. Healthy coping may go beyond finding a simple, obvious solution. Members may try to rearrange schedules to avoid frequent trips to regular destinations and plan ahead to avoid last-minute trips to stores. Healthy families actively seek and use a variety of resources to solve problems. They may discover these resources within the family or externally; they engage in self-care. For example, a professional couple, faced with the unaffordable expense of daytime baby-sitting, arranged their work

schedules so that they could share childcare during the first 2 years. Later, they joined a cooperative preschool that allowed their child to attend daily, but required parental participation only 1 day a week. In another example, a single parent of five children, who was also a full-time nursing student, was able to finance two or three family outings each year by recycling aluminum cans that everyone in the family collected.

### Healthy Environment and Lifestyle

Another sign of a healthy family is a healthy home environment and lifestyle. Healthy families create safe and hygienic living conditions for their members. For instance, a healthy family with young children "childproofs" the home by removing potential hazards such as exposed electric outlets and cleaning solvents from the child's reach. A healthy family with an older adult who is prone to falls installs lighting and handrails (Farren, 1999). A healthy home environment is one that is clean and reduces the spread of disease-causing organisms.

A healthy family lifestyle encourages appropriate balance in the lives of its members. In an ideal family, there is activity and rest sufficient for the energy needs of daily living; the diet offered is varied and nutritionally sound, physical activity maintains ideal weight while promoting cardiac health; preventative hygiene habits are taught and followed by family members; emotional and mental health are encouraged through a support network of caring others; and family members seek out and use health care services and demonstrate adherence to recommended regimens.

The emotional climate of a healthy family is positive and supportive of growth. Contributing to this healthful emotional climate is a strong sense of shared values, often combined with a strong religious orientation (Olson et al., 1983; Parachin, 1997). A healthy family demonstrates caring, encourages and accepts expression of feelings, and respects divergent ideas. Members can express their individuality in the way they dress or decorate their rooms. The home environment makes family members feel welcome and accepted.

### Regular Links with the Broader Community

Healthy families maintain dynamic ties with the broader community. They participate regularly in external groups and activities, often in a leadership capacity. They may join in local politics, participate in a church bazaar, or promote the school's paper drive to raise money for science equipment. They use external resources suited to family needs. For example, a farm family with teenagers, recognizing the importance of peer group influences on adolescents, becomes very active in the local 4-H Club. Another family, in which the father is out of work, joins a job transition support group. Healthy families also know what is going on in the world around them. They show an interest in current events and attempt to understand significant social, economic, and political issues. This ever-broadening outreach gives families knowledge of external forces that might influence their lives. It exposes them to a wider range of alternatives and a variety of contacts, which can increase options for finding resources and strengthen coping skills.

An unhealthy family has not recognized the value of establishing links with the broader community. This may be

because of knowledge deficits regarding community resources, previous negative experiences with community services, or a lack of connection with the community due to family expectations or cultural practices.

It is important for the community health nurse to assess the family's relationship with the broader community, in addition to structural and developmental variations, interaction, coping strategies, and lifestyle. With a comprehensive family assessment, the nurse has a base from which to begin a plan of care.

## FAMILY HEALTH PRACTICE GUIDELINES

**Family nursing** is a kind of nursing practice in which the family is the unit of service (Friedman et al., 2003). It is not merely a family-oriented approach, in which family concerns that affect the health of an individual are taken into account. Family nursing asks how one provides health care to a collection of people. It does not mean that nursing must relinquish the service to individuals. One of the distinct contributions of the nursing profession is its holistic approach to individual needs. Community health nurses rise to the challenge of adding a service to populations that include families.

Five principles guide and enhance family nursing practice: (1) work with the family collectively, (2) start where the family is, (3) adapt nursing interventions to the family's stage of development, (4) recognize the validity of family structural variations, and (5) emphasize family strengths.

### Work with the Family Collectively

To practice family nursing, nurses must set aside their usual focus on the individual and remind themselves that several people together have a collective personality, collective interests, and a collective set of needs. Viewing a group of people as one unit may seem less strange if one considers the way in which business organizations are perceived. For example, you may think of a particular corporation as conservative or liberal. You may hear that a women's group has taken a stand on abortion or that a government agency needs to become better organized. In each case, the group is viewed collectively as a single entity with attributes and activities in common. So it is with families. A family has its own personality, interests, and needs.

As much as possible, community health nurses want to involve all the family's members during nurse–client interactions (Wallace, Green, Jaros, Paine, & Story, 1999; Wright & Leahey, 2005). This approach reinforces the importance of each individual member's contributions to total family functioning. Nurses want to encourage everyone's participation in the work that the nurse and the family jointly agree to do. Like a coach, the nurse wants to help family members work together as a team for their collective benefit. Consider how a nurse might work collectively with the Beck family (Display 19.2).

### Start Where the Family Is

When working with families, community health nurses begin at the present, not the ideal level of functioning. To discover where a family is, the community health nurse first conducts a family assessment to ascertain the members' needs and level of health and then determines collective interests, concerns, and priorities. The accompanying description of the Kovac family illustrates this principle (Display 19.3).

#### DISPLAY 19.2

#### THE BECK FAMILY

A community health nurse had an initial contact with Mr. and Mrs. Beck and their youngest child at the well-baby clinic. The 9-month-old child was over the 95th percentile for weight and at the 40th percentile for height. The nurse also noted that both parents were obese. The nurse asked about the eating patterns in the family and of the baby in particular and suggested a home visit to determine whether the Becks were interested in family nursing. The nurse explained the purpose of home visits (to assess all family members, coping patterns, eating patterns, and food purchasing choices) and the importance of including all family members, and asked for a time that would be good for the family as a whole. The nurse explained that each person should be involved and committed to the agreed-upon goals; that, like a team of oarsmen, the family would have to pull together to accomplish the purpose of the visits. To help the Beck family improve its nutritional status, the nurse might suggest a session of brainstorming to uncover many causes of poor nutrition. More brainstorming might result in solutions and plans for action. On each visit the nurse would view the Becks as a group. Group responses and actions would be expected. Evaluation of outcomes would be based on what the family did collectively. The Becks were interested, and a home visit date was made.

### Adapt Nursing Intervention to the Family's Stage of Development

Although every family engages in the same basic functions, the tasks necessary to accomplish these functions vary with each stage of the family's development. A young family, for instance, can appropriately meet its members' affiliation needs by establishing mutually satisfying relationships and meaningful communication patterns. As the family enters later stages, bonds change with the release of some members into new families and the loss of others through death. Awareness of the family's developmental stage enables the nurse to assess the appropriateness of the family's level of functioning and to tailor interventions accordingly. Nurses are often adept at family assessment, but interventions need to be the focus (Hanson, 2001; Wright & Leahy, 2005). A nurse's work with the Ravina family illustrates this need (Display 19.4).

### Recognize the Validity of Family Structure Variations

Many families seen by community health nurses are nontraditional, such as single-parent families and unmarried couples (Baris et al., 2001; Scanzoni, 1999). Other families are organized around nontraditional patterns, for example both parents may have careers, a husband may care for children at home while his wife financially supports the family, or both parents may telecommute and work at home. Such variations in structure and organizational patterns have resulted from social and technologic changes in employment practices, welfare programs, economic conditions, gender roles,

## DISPLAY 19.3

## THE KOVAC FAMILY

Marcia Kovac brought her baby, Tiffany, to the well-child clinic once but failed to keep further appointments. Concerned that the family might be having other difficulties, Sara Villa, a community health nurse, made a home visit. The mobile home was cluttered and dirty; the baby was crying in her playpen. Marcia seemed uninterested in the nurse's visit. She listened politely but had little to say. She repeated that everything was okay and that the baby was doing fine, explaining that she was just fussy because she was teething. As they talked, Marcia's husband Henry, a delivery van driver, stopped by to pick up a sports magazine to read on his lunch hour. The three of them discussed the problems of inflation and how expensive it was to raise a child. Sara reminded them that the clinic was free and that they could at least get good health care without extra cost. They agreed without enthusiasm. After Henry left, the nurse spent the remainder of the visit discussing infant care with Marcia, particularly emphasizing regular check-ups and immunizations.

The next visit also focused on the baby, but Sara had an uncomfortable feeling that this family was not really interested in her help. After consulting her supervisor, the nurse did what she wished she had done in the first place. She asked to talk with Marcia and Henry together and

explained frankly why she had come to their home and what she could offer in the way of counseling, teaching, support, and referral to other community resources. She then asked them what problems or concerns they had. The Kovacs were more than responsive and described their financial difficulties and feelings of isolation from family and friends. They were new in the city, and both their families lived some distance away on farms. The neighbors were friendly but not close enough to confide in. They believed they would eventually overcome their problems if they just had "someone to lean on," as they put it.

Now Sara could address the Kovacs' primary needs and concerns for friends and emotional support. The nurse began to address the Kovacs' social needs first and introduced them to a young couples' group that met at the community center. Sara continued to make periodic home visits and shared additional information about community services that the Kovacs might find helpful. She praised Marcia and Henry for following up on immunizations for Tiffany. Over time, Sara saw differences in the family's interest in their relationship with the community and their connection to its services. Sara realized that before she could address the issue of Tiffany's health, she needed to address the emotional health of the parents.

status of women and minorities, birth control, incidence of divorce, and even war. Such variations in family structure and organization lead to revised patterns of family functioning. Member roles and tasks often differ dramatically from our expectations. Examples are a family with a single parent who works full-time while raising children or a dual-career marriage in which both partners have undifferentiated roles. Community health nurses, many of whom are accustomed to traditional family patterns, must learn to understand and

accept these variations in family structure and organization in order to address the needs of the families.

There are two important principles to remember. First, what is normal for one family is not necessarily normal for another. Each family is unique in its combination of structures, composition, roles, and behaviors. As long as a family carries out its functions effectively and demonstrates the characteristics of a healthy family, one must agree that its form, no matter how variant, is valid.

## DISPLAY 19.4

## THE RAVINA FAMILY

The Ravinas, a couple in their early 70s, recently moved to a retirement complex. They received nursing visits after Mrs. Ravina's stroke 3 years earlier but requested service now because Mr. Ravina was feeling "poorly" all the time. He thought that perhaps his diet and lack of activity might be the cause and hoped the nurse would have some helpful suggestions. The couple had eagerly awaited Mr. Ravina's retirement from teaching, planning to be lazy, travel, visit all their children, and do all those things they never had time to do when they were young. Now neither of them seemed to have enough energy or the capacity to enjoy their new life. The move from their home of 28 years had been difficult: they were still trying to find space in the tiny apartment for their cherished books and mementos, although they had given many of them away.

Ronald Bell, a community health nurse, recognized that the Ravinas were experiencing a situational crisis (leaving their home of 28 years), a developmental crisis

(aging and entering retirement), and perhaps some underlying health problems. Many of the Ravinas' expectations for this new life stage were unrealistic; they had not adequately prepared themselves for the adjustments that the loss of their home and retirement would demand. Through discussion Ronald was able to help the Ravinas understand their situation and express their feelings. He completed physical assessments on the Ravinas and encouraged regular follow-up with their health care provider. He also helped them join a support group of retired persons who were experiencing some of the same difficulties. Because this nurse was able to help the Ravinas through their crisis in a supportive and non-judgmental manner, he found them receptive later to discussing preparation for the inevitable loss and bereavement that would occur when one of them died. He was adapting his nursing intervention to this family's stage of development.

Second, families are constantly changing. Marriage transforms two people into a married couple without children. Adding children changes the family structure. Divorce alters the structure and roles. Remarriage with the addition of children from another family changes the family again. Children grow up and leave the home while the parents, together or singly, are left to adjust to yet another family structure. Throughout the life cycle, a family seldom stays the same for very long. Each of these changes forces a family to adapt to its circumstances. Consider the young women with a baby whose husband deserts her: she has no choice but to assume a single-parent role. Each change also creates varying degrees of stress and demands considerable adaptive energy on the family's part. Many family changes are predictable and part of the normal life-cycle growth. Some changes are not predictable or may have a less traditional structure. The nurse's responsibility is to help families cope with the changes while remaining nonjudgmental and accepting of variations in family structure. For example, homosexual unions may be difficult for some nurses to deal with, particularly if they conflict with the nurse's own set of values. Yet the nurse's responsibility remains the same—to help promote the collective health of that family. The nurse should view all families as unique groups, each with its own set of needs and whose interests can best be served through unbiased care. Consider the nurse's work with James Cutler and Brian Hoag (Display 19.5).

### DISPLAY 19.5

### JAMES CUTLER AND BRIAN HOAG

James Cutler and Brian Hoag have a 6-year monogamous relationship. A homosexual couple, they worked with an attorney to privately adopt a child. The arrangements were completed and their 2-week-old son, Adrian, arrived in their home last week. Helen Jeffers, a community health nurse, receives a referral from the county hospital where Adrian was born. The request is for an assessment of the home situation and parenting skills. The baby tested positive for cocaine with Apgar scores of 6 and 8 and had some initial difficulty sucking. Birth weight was 2,900 g. Discharge weight, at 3 days, was 2,850 g. At her first home visit Helen finds a neat and orderly two-bedroom condominium, well-equipped with baby supplies. The infant has gained 200 g and is being well cared for by two fatigued parents who had had limited contact with infants previously. James and Brian have many questions and are anxious learners. Helen plans with the couple to make weekly home visits to assess infant growth and development, provide support, and answer questions. She also suggests a neighborhood parenting class and finding a reliable babysitter, and she helps James and Brian develop an infant care work schedule. After 6 weeks of intervention, Adrian is thriving; Helen closes the case to home visits, feeling confident that the parents' goal of becoming knowledgeable and confident has been achieved.

## Empowering Families

Throughout the family visit, you must remember that the ultimate goal is to assist the family in becoming independent of your services. This is accomplished through the approach used in conducting the visit. How you structure the nurse–client relationship also influences the outcomes. Four thoughts will help to clarify your working relationship with families:

- ◆ The family functioned in a manner that worked for them before you ever met them.
- ◆ If you ever feel obliged to do something for a family, consider who did this before you were available.
- ◆ Find family strengths even in the most deprived family situation.
- ◆ If you were in a similar situation, would you manage, cope, or function as well as the members of this family?

Many families have strengths that some middle-class nurses may overlook or interpret as weaknesses. It is the nurse's job to recognize the strengths in families and to help families recognize them as well. For example, some families borrow needed items (diapers, food, clothes) from each other, whereas others do not even recognize their next-door neighbors by sight. Children from large families often learn to physically care for one another and entertain themselves, whereas in some families with only one or two children the youngsters must constantly be entertained. The members of one family may take public transportation or walk to accomplish errands.

Too often, community health nurses tend to focus their attention on family weaknesses, looking for and referring to them as *needs* or *problems*. This negative emphasis can be devastating to a family and can undermine any hope of a therapeutic relationship between nurse and client. Families need their strengths reinforced. Emphasizing a family's strengths fosters a positive self-image, promotes self-confidence, and often helps a family feel better able to address other problems.

At times, community health nurses want to help families by taking one of the members to a doctor or to the store or by bringing a supply of formula or diapers. It might be a simple task, because you will be driving by the clinic anyway or there are extra cans of formula in the agency office, but will it promote the family's independence and self-sufficiency? It is a much better gift to promote the skill of planning ahead, so that the family may meet its own transportation needs (neighbors, family members, loose change saved for the bus, or even walking) or find ways to use formula supplies wisely. For example, bottles can be filled with only the amount the baby consumes, so that ounces are not wasted at each feeding. Unused formula should be kept refrigerated, so that it does not spoil, and care should be taken to make sure that infants are not overfed. The amount of formula consumed in 24 hours by the baby can be determined to ensure that the correct quantity is being provided. After a child reaches the appropriate age, foods and fluids other than formula may be provided. A can of powdered formula may be kept on hand for emergencies, and families may wish to switch to powdered formula if they are using the more

expensive premixed or concentrated formulas. Once families learn these skills, crises will occur less frequently or will be managed more effectively.

Finally, you should always look for ways to genuinely praise families for managing in difficult situations. On a home visit, you can empower families by pointing out the positive aspects of their self-care and care giving, rather than pointing out what they do not do or have (Renpenning, Taylor, & Eisenhandler, 2003).

One helpful communication technique is **strengthening**. Verbally list the positive aspects of an otherwise negative situation in a natural and conversational manner. For example, a young woman, who is holding her baby, greets you at the door. You note that she has a dresser drawer on the floor next to her mattress for the baby to sleep in. They live in a sparsely furnished one-room apartment. She has two baby bottles and a limited assortment of baby clothes. Later during the first visit, you say, “Carlo looks so happy when you cuddle him in your arms, and you are considering his safety by letting him sleep in the dresser drawer next to your mattress. I notice you wash each bottle before making the formula, and you keep him warm in the sleeper and blanket. I think you are managing Carlo very well.” In this brief scenario, you have mentioned, in a positive way, bonding, infant health and safety, and proper infant clothing. You have not mentioned the absence of furniture, a full set of bottles, or a layette of clothing. During the remainder of the visit, you discuss the services your agency can provide and assess whether any of them would be of interest to the young mother. This strengthening technique helps the nurse approach the family positively rather than with a condescending or punitive approach. And, in the above example, you have empowered this young mother to make decisions for her family and to use you as a resource and guide (Wright & Leahey, 2005).

If there is nothing positive the nurse can honestly say, he should be able at the very least to say that the family seems to be managing as best it can. This is not to say that the nurse should ignore problems. On the contrary, assessment should explore all aspects of family functioning to determine both strength and weaknesses. The nurse needs a total picture to achieve an adequate perspective in nursing care planning and to know when the family is ready to begin work on problems. Even as the nurse becomes more aware of a family’s unhealthy behaviors, the emphasis should remain on the positive ones. Emphasizing strengths indicates to the clients they are important to the nurse.

Family strengths are traits that facilitate the ability of the family to meet the members’ needs and the demands made by systems outside the family unit. Not all traits that appear positive are necessarily strengths. Before the nurse selects a trait to emphasize, the behavior should be examined closely to determine whether it is actually facilitating family functioning. A strong work orientation may be a strength when balanced with play and relaxation, but a family obsessed by work experiences this trait as a weakness. Whether a trait is considered a strength or weakness is determined by the amount of free choice, as opposed to compulsive drive, being exercised.

Some traits a nurse may consider as possible strengths are basic family functions, family developmental tasks, and characteristics of family health. For instance, a nurse might wish to note when a family meets its members’ physical,

## DISPLAY 19.6

## THE STEVENSON FAMILY

The community health nurse, Keith Dow, made an initial home visit after referral by an outpatient physician who was concerned about possible child abuse. Alice Stevenson had brought her baby to the emergency room for treatment of a laceration on the baby’s forehead. He had fallen off the table while she was changing him, she claimed. A bruise on his arm made the physician suspicious, but Alice explained it was caused by his older brother’s rough play. The nurse opened the visit by stating that he was simply following up on the emergency room treatment and wanted to see how the baby was progressing. Keith made no mention of child abuse. He observed the mother and children closely, looking for small things to compliment Alice on (strengthening) while learning all he could about the family’s background. Because the nurse appeared approving rather than suspicious or judgmental, Alice agreed to further visits. During a later visit, Alice admitted to the nurse that she had slapped the baby and her ring cut his forehead. She could not get him to stop crying, no matter what she did; she just could not endure it any longer, she said. There had been other times when she grabbed him roughly to pull him away from things he wasn’t allowed to touch, causing bruises on his arms. Alice told the nurse that she had not planned this baby; when her husband found out she was pregnant, he had left her shortly before the baby was born. Like many abusive parents, Alice had unrealistic expectations of her children’s behavior as well as very inadequate self-esteem (Ryan, 1997; Taylor & Kemper, 1998). Realizing that Alice would be particularly vulnerable to any criticism, the nurse concentrated on her strengths. Keith complimented her on how well she managed her home and dressed the children, on maintaining her job, and on reading to her 3-year-old son. It took many visits before Alice trusted the nurse, but in time they were able to discuss her feelings frankly and work toward improving this family’s health. Keith got her to attend a support group for single parents and she began counseling. Emphasizing strengths had provided a bridge for Alice and assisted in bringing her into a helping relationship.

emotional, and spiritual needs; shows respect for members’ various points of view; or fosters self-discipline in its children. An illustration of this principle is found in the family nursing care of the Stevensons (Display 19.6).

## FAMILY HEALTH ASSESSMENT

The focus of each family visit is different. On a first visit, initial assessment data must be obtained in addition to helping the family set goals they want to accomplish. On subsequent visits, action and activities are taken to reach the goals. To assess a family’s health in a systematic way, three tools are needed: (1) a conceptual framework on which to base the assessment, (2) a clearly defined set of assessment categories for data collection, and (3) a method for measuring a family’s functional level.

## Conceptual Frameworks

A **conceptual framework** is a set of concepts integrated into a meaningful explanation that helps one interpret human behavior or situations. Several conceptual frameworks have been used historically to study families (Hill & Hansen, 1960; Kantor & Lehr, 1975; Reiss, 1981). Beavers and Hampton (1990) and Anderson and Sabatelli (2003) have also published models describing family functioning. Three frameworks that are particularly useful in community health nursing are presented here: the interactional, structural–functional, and developmental frameworks.

The **interactional framework** describes the family as a unit of interacting personalities and emphasizes communication, roles, conflict, coping patterns, and decision-making processes. This framework focuses on internal relationships but neglects the family’s interactions with the external environment.

The **structural–functional framework** describes the family as a social system relating to other social systems in the external environment, such as church, school, work, and the health care system. This framework examines the interacting functions of society and the family, considers family structure, and analyzes how a family’s structure affects its function.

The **developmental framework** studies the family from a life-cycle perspective by examining members’ changing roles and the tasks in each progression of life-cycle stage. This framework incorporates elements from interactional and structural–functional approaches, so that family structure, function, and interaction are viewed in the context of the environment at each stage of family development.

Others have combined these concepts in various ways to design family assessment and intervention models that focus on human–environmental interactions, interactional and structural–functional frameworks, self-care, responses to stressors, and a developmental framework.

The six characteristics of healthy families already discussed serve as an initial framework for assessing family health by a combination of interactional, structural–functional, and developmental concepts.

## Data Collection Categories

When using a conceptual framework for family health assessment, the community health nurse selects specific categories for data collection. The amount of data that one can collect about any given family may be voluminous, perhaps more than necessary for the purposes of the assessment. The assessment process is lengthy, time-consuming, and ongoing. The nurse must gather the most essential on the first visit. By selecting one or two priority concerns of the family and the nurse, it is possible to focus assessment on these identified areas. The nurse then uses this information as a guide to obtaining additional information needed on subsequent visits.

Certain basic information is needed, however, to determine a family’s health status and to design appropriate nursing interventions. From many sources in the family health literature, particularly Turk and Kerns (1985), Edelman and Mandle (2002), and Friedman and co-workers (2003), a list of 12 data collection categories has been generated. Table 19.1 lists the 12 categories, each grouped into one of three data sets: family strengths and self-care capabilities, family stresses and problems, and family resources.

1. *Family demographics* refer to such descriptive variables as a family’s composition, its socioeconomic status, and the ages, education, occupation, ethnicity, and religious affiliations of members.
2. *Physical environment* data describe the geography, climate, housing, space, social and political structures, food availability and dietary patterns, and any other elements in the internal or external

**TABLE 19.1 Categories of Data Collection for Family Health Assessment**

8. Family decision-making patterns			
9. Family problem-solving patterns			
10. Family coping patterns			
11. Family health behavior			
12. Family social and cultural patterns			

physical environment that influence a family's health status.

3. *Psychological and spiritual environment* refers to affective relationships, mutual respect, support, promotion of members' self-esteem and spiritual development, and life satisfaction and goals.
4. *Family structure and roles* include family organization, socialization processes, division of labor, and allocation and use of authority and power.
5. *Family functions* refer to a family's ability to carry out appropriate developmental tasks and provide for members' needs.
6. *Family values and beliefs* influence all aspects of family life. Values and beliefs might deal with raising children, making and spending money, education, religion, work, health, and community involvement.
7. *Family communication patterns* include the frequency and quality of communication within a family and between the family and its environment.
8. *Family decision-making patterns* refer to how decisions are made in a family, by whom they are made, and how they are implemented.
9. *Family problem-solving patterns* describe how a family handles problems, who deals with them, the flexibility of a family's approach to problem-solving, and the nature of solutions.
10. *Family coping patterns* encompass how a family handles conflict and life changes, the nature and quality of family support systems, and family perceptions and responses to stressors.
11. *Family health behavior* refers to familial health history, current physical health status of family members, family use of health resources, and family health beliefs.
12. *Family social and cultural patterns* comprise family discipline and limit-setting practices; promotion of initiative, creativity, and leadership; family goal setting; family culture; cultural adaptations to present circumstances; and development of meaningful relationships within and outside the family.

## Assessment Methods

Many different methods are used to assess families. These methods serve to generate information about selected aspects of family structure and function; the methods must match the purpose for assessment and are done in conjunction with the family. Assessing family health may be done informally through observation and occasional questioning, or it can take a more formal approach. Specific questions may be asked of each family member, and information such as health data and family history may be included. Physical data such as height, weight, pulses, temperature, and blood pressure are recorded on an assessment tool. The developmental level of the family will guide specific assessment questionnaires, tools, or tests that the community health nurse can use for gathering information on individuals within the family, for example, the use of developmental screening tests for young children or a high-risk infant flow sheet (Fig. 19.1) for a newborn with an identified or potential

health problem (e.g., high-risk newborn, drug-exposed newborn, failure-to-thrive, birth-defect).

Two assessment tools are the eco-map and the genogram. The **eco-map** is a diagram of the connections between a family and the other systems in its ecologic environment. It was originally devised to depict the complexity of the client's story. Developed by Ann Hartman in 1975 to help child welfare workers study family needs, the tool visually depicts dynamic family-environment interactions. The nurse involves family members in the map's development. A central circle is drawn to represent the family, and smaller satellite circles on the periphery represent people and systems, such as school or work, whose relationships with the family are significant. The lines to and from the central circle to the satellite circle depicts the strength of the relationship (Fig. 19.2). The map is used to discuss and analyze these relationships (Hanson, Gedaly-Duff, & Kaakinen, 2005; Hartman, 1978; Wright & Leahey, 2005).

The **genogram** displays family information graphically in a way that provides a quick view of complex family patterns. It is a rich source of hypotheses about a family over a significant period of time, usually three or more generations (McGoldrick & Gerson, 1985). Family relationships are delineated by genealogic methods, and significant life events are included (e.g., birth, death, marriage, divorce, illness). Identifying characteristics (e.g., race, religion, social class), occupations, and places of family residence are also noted (Meyer, 1993). Again, this tool is used jointly with the family. It encourages family expression and sheds light on family behavior and problems (Fig. 19.3). Recognizing the value of this type of assessment, the *U.S. Surgeon General's Family History Initiative* was launched in 2005. This ongoing initiative seeks to bring awareness of the familial links between health outcomes and the need to develop prevention strategies based on potential health risks (U.S. Department of Health and Human Services [USDHHS], 2005). Using the downloadable materials provided on the website, families can create their own family health portrait; this is also a valuable tool for the nurse to use with the family.

Community health nurses use several different family assessment instruments to gather data on family structure, function, and development. Public health nursing agencies usually develop their own tools, often in the form of questionnaires, checklists, flow sheets, or interview guides. The format varies to fit organizational needs. For example, most agencies have changed to computerized information management systems and have adjusted data collection to be technologically compatible. Two sample assessment tools are shown in Figures 19.4 and 19.5. Figure 19.4 shows a checklist format with scores and dates of assessment gathering. It is useful over a span of time for observing family growth or decline, especially for the novice community health nurse, who can document assessment data as rapport with the family is established or as the comfort level with home visits increases.

Figure 19.5 offers an open-ended assessment tool. Such a tool may be useful in a teen perinatal program or a senior support program, in which a primary nurse makes the home visits and an additional nurse visits occasionally. The open-ended format is brief and lends itself to subjectivity. The goal is to create a document that is informative for all who use it while limiting subjective observations—a difficult

task with open-ended tools. However, there may be an agency or program for which this tool fits best.

Other methods may use assessment tools or technology (e.g., videotaping family interactions, structured observation, analysis of life-changing events). The Self-Care Assessment Guide (Cleveland & Allender, 1999) measures a family member’s ability to provide self-care (Fig. 19.6). In a public health nursing agency or other community-based agency, documentation is completed for individuals after family assessment information data are gathered. Useful information can be gathered about stressors and self-care practices, including prescription medicines, over-the-counter (OTC) medicines, herbal remedies, nutritional supplements, and other complementary therapies. Such tools are useful adjuncts, especially for families coming from cultural groups different from that of the health care provider. They are often used in combination with other tools to enhance the breadth of data collection and understanding of the family.

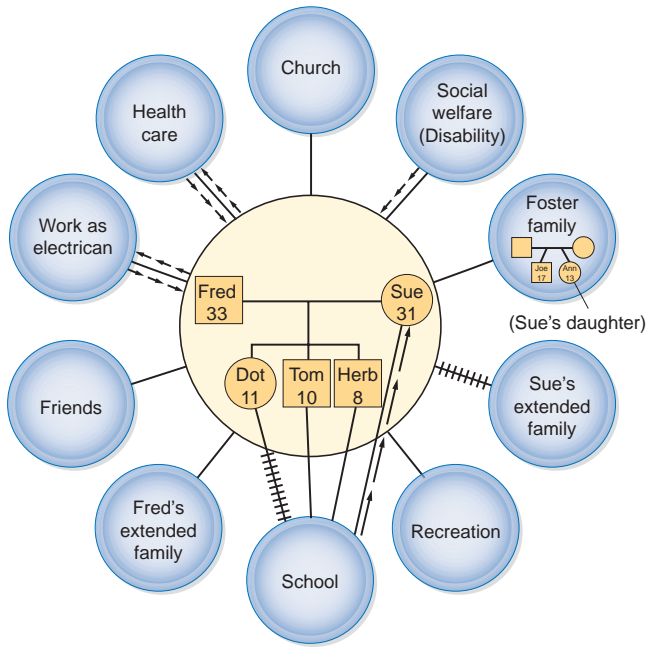

**GUIDELINES FOR FAMILY HEALTH ASSESSMENT**

An assessment of family health will be most accurate if it incorporates the following five guidelines:

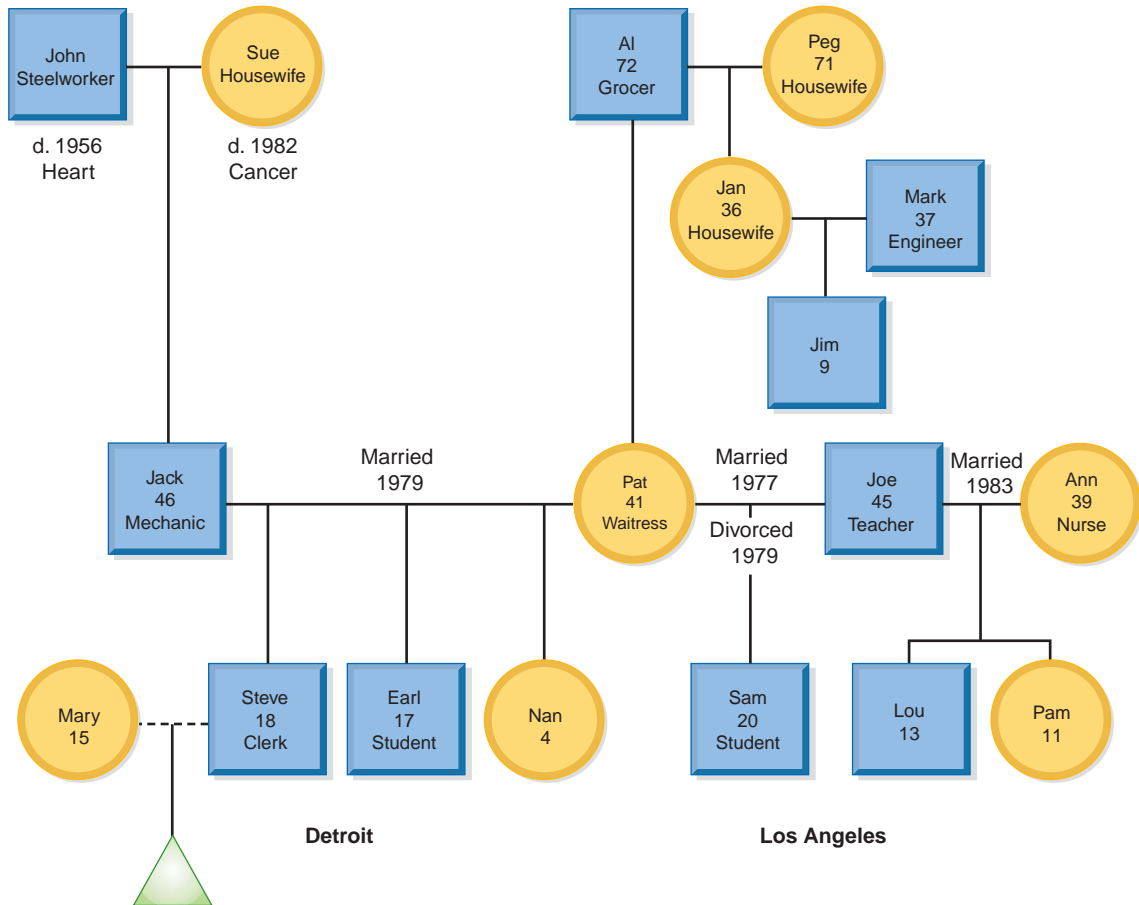

1. Focus on the family as a total unit.
2. Ask goal-directed questions.
3. Collect data over time.
4. Combine quantitative and qualitative data.
5. Exercise professional judgment.

**Focus on the Family, Not the Member**

Family health is more than the sum of its individual members’ health. If the health of each person in a family were rated and the scores combined, the total would not show how healthy that family is. To assess a family’s health, the nurse must consider the family as a single entity and appraise its

**FIGURE 19.2** Eco-map of family's relationship to its environment. Lines indicate types of connections: *solid lines*, strong; *dotted lines*, tenuous; *lines with crossbars*, stressful. *Arrows* signify energy or resource flow, and absence of lines indicates no connection.

aggregate behavior (Centers for Disease Control and Prevention, 2008; Wright & Leahey, 2005). As each criterion in the assessment process is considered, the community health nurse asks, “Is this typical of the family as a whole?” Assume that the nurse is assessing the communication patterns of a family. The nurse observes supportive interaction between two members in the family. What about the others? Further observation shows good communication among all but one member. It may be decided that, despite that one person, the family as a whole has good communication. If individual

behavior deviates from that of the aggregate, the nurse notes the differences. They can influence total family functioning and need to be considered in nursing care planning.

### Ask Goal-directed Questions

The activities of any investigator, if fruitful, are guided by goal-directed questions. When solving a crime, a detective has many specific questions in mind. So, too, does the physician attempting a diagnosis, the teacher trying to discern a student’s

knowledge level, or the mechanic repairing a car. Similarly, the nurse determining a family’s level of health has specific questions in mind. It is not enough to make family visits and merely ask members how they are. If relevant data are to be gathered, relevant questions must be asked. The family assessment tool shown in Figure 19.4 provides a sample set of questions that community health nurses use to assess a family’s health. Built on the framework of the characteristics of a healthy family, these questions guide thinking and observations. They direct attention to specific aspects of family behavior to facilitate the goal of discovering a family’s level of health.

Consider the characteristic, “Active Coping Effort.” When visiting a family, the community health nurse watches for signs of the family’s response to change and its problem-solving ability. The nurse asks, “Does this family recognize when it needs to make a change?” or “How does it respond

when a change is imposed?” Perhaps a health problem has arisen; for instance, the baby has diarrhea. Does the family assume responsibility for dealing with the problem? Do family members consider a variety of ways to solve it? How do they respond to the nurse’s suggestions? Do they seek out resources on their own, such as reading about causes of infant diarrhea, using home remedies, or consulting with the community health nurse, the doctor, or a nurse practitioner? How well do they use resources, once identified? Do they try creative methods for solving the problem and see it through to resolution? As the nurse focuses on these behaviors, he is asking goal-directed questions aimed at finding out the family’s coping skills. This investigation is one part of the nurse’s assessment of the family’s total health picture.

The set of questions presented in Figure 19.4 is one useful way to appraise family health. Another, more

**FIGURE 19.5** Open-ended family assessment.

open-ended format is used by some community health nursing agencies. This approach, displayed in Figure 19.5, proposes assessment categories as stimuli for nursing questions. When exploring family support systems, for example, the nurse asks, “What internal resources or strengths does this family have?” “Who outside the family can they and do they turn to for help?” “What agencies such as churches, clubs, or community services do they use?” The open-ended style of this assessment tool allows questions aimed at determining family health to be raised.

### Allow Adequate Time for Data Collection

Accurate family assessment takes time. The assessment initiated on the first or second visit will most likely give only a partial picture of how a family is functioning. Time is needed to accumulate observations, make notes, and see all the family members interacting together in order to make a thorough assessment. To appraise family communication patterns, for instance, the nurse needs to observe the family as a group, perhaps at mealtime or during some family activity. The family needs to feel comfortable in the nurse’s presence, so that they will respond freely; time and patience are needed for such rapport to develop.

Consider one nurse’s experience. Jolene Burns had talked with the Olson family twice, first in the clinic, and then at home. Because Mr. Olson had not been present either time, Jolene asked to see the family together and arranged an early evening visit. The Olsons were receiving nursing

services for health promotion. They were particularly interested in discussing discipline of their young children. They contracted with Jolene for six weekly visits to be held in the late afternoon, when Mr. Olson was home from work. Jolene’s assessment began with her first contact with the Olsons. She made notes on their chart and, guided by questions similar to those in Figure 19.5, kept a brief log. After the fourth visit, she filled out an assessment form to keep as a part of the family record. It was not until then that Jolene felt she had collected enough data to make valid judgments about this family’s level of health.

### Combine Quantitative with Qualitative Data

Any appraisal of family health must be qualitative. That is, the nurse must determine the presence or absence of essential characteristics in order to have a database for planning nursing actions. To guide planning more specifically, the nurse can also determine the degree to which various signs of health are present. This is a quantitative measure. The nurse asks whether a family does or does not engage in some behaviors and how often. Is this behavior fairly typical of the family, or does it occur infrequently? Figures 19.4 and 19.5 demonstrate ways to measure family health quantitatively.

For example, if the nurse were to use the tool in Figure 19.4 to assess the Beck family’s ability to enhance individuality, he could score behavior on a scale from 0 (never) to 4 (most of the time). After several observations, the nurse

**FIGURE 19.6** Self-care assessment guide. Adapted from Cleveland, L., & Allender, J. A. (1999). *Environment: Self-care issues*. In L. Cleveland, D. S. Aschenbrenner, S. J. Veneable, & J. A. P. Yensen, *Nursing management in drug therapy*. Philadelphia: Lippincott Williams & Wilkins, with permission.

would probably conclude that responses to the members' developmental needs were appropriate most of the time (*a* under "Enhancement of Individual Development"). Opposite *a* on the assessment form, the nurse would write the numeral 4 and the date of assessment.

The value of developing a quantitative measure is to have some basis for comparison. The nurse can assess a family's progression or regression by comparing its present score with its previous scores. For instance, had the nurse conducted a family health assessment of the Kovacs 6 months ago and compared it with their present level of health, he would probably have discovered a drop in their scores in several areas. Many of their communication patterns, role relationships, and coping skills, in particular, would show signs of deterioration. A scored assessment gives a vivid picture of exactly which areas need intervention. For this reason, it is useful to conduct periodic assessments when a case is reopened, or every 3 to 6 months if it is kept open for an extended period. The nurse can monitor the progress of high-risk families through early introduction of preventive measures when a trend or regressive behavior is observed. Periodic quantitative assessments also provide a means of evaluating the effectiveness of nursing action and can point to documented signs of growth.

Quantitative data serve another useful purpose. The nurse can compare one family's health status with that of another family as a basis for priority setting and nursing care planning. The difference in the level of health between the Becks and the Kovacs, for example, shows that the Kovacs need considerably more attention right now.

### Exercise Professional Judgment

Although nurses seek to validate data, their assessment of families is still based primarily on their own professional judgment. Assessment tools can guide observations and even quantify those judgments, but, ultimately, any assessment is subjective. Even though it may be observed that a family makes good use of a community agency, the decision that use of this external resource contributes to the health of the family is a subjective one. This determination is not bad. Indeed, effective health care practice depends on sound professional judgment. However, nurses must be cautious about overemphasizing the value or infallibility of an assessment tool. It is only a tool, and should be used as a guide for planning, not as an absolute and irrevocable statement about a family's health status. Caution is particularly important when dealing with quantitative scores, which may seem to be objective.

Ordinarily, assessment of a family is best conducted unobtrusively. An assessment tool used by the nurse is not a questionnaire to be filled out in the family's presence but rather a way to guide the nurse's observations and judgments. Before going into a family's home, the community health nurse may wish to review the questions. He may find it helpful to keep the assessment tool in a folder for easy reference during the visit. Depending on the nurse's relationship with the family, notes may be made during or immediately after the encounter. Like Jolene, the nurse may choose to keep a short log—an accumulation of notes—until enough data have been collected to complete the assessment form. Occasionally, a family with high self-care capability may be involved in the assessment. The nurse should introduce the idea carefully and use profes-

sional judgment to determine when the family is ready to engage in this kind of self-examination.

## EDUCATION AND HEALTH PROMOTION

Teaching health promotion activities should begin only after family members express an interest and recognize a need. If the family is not at a level of functioning that enables members to use anticipatory guidance and teaching, the nurse can provide more basic services, such as gathering resources and acting as a counselor (Tapia, 1997). If family members are ready to learn ways to improve their health status, the nurse needs to assess the best teaching approach to use (see Chapter 11). Consideration of language barriers, previous knowledge and experience, family and community resources, and time available will influence the choice of approach.

## EVALUATING IMPLEMENTED FAMILY HEALTH PLANS

The final step in the nursing process is evaluation. The evaluation process leads to a reassessment of your work with the family and a determination of what is needed in preparation for the next visit. This reassessment helps you in further individualizing services to the family. Evaluation of the structure-process of the visit and your self-evaluation can be done informally in a reflective manner. Outcomes are documented in the client record, and the evaluation becomes formalized. A thorough evaluation also assists you in making the most appropriate referrals and contacting key resources to meet family needs.

### Types of Evaluations

Each family visit should be evaluated in three ways: structure-process, outcome, and self-evaluation. Each provides a different piece of information about the success of the visit. If the visit was not successful, what part made it less than successful? Most importantly, were the outcomes achieved? If not, is there something about the structure-process or your own preparedness or behavior that needs to be changed? When conducting an evaluation of the home visit, you are looking for answers to these questions.

#### Structure-Process

The structure-process of a visit should be analyzed first. Were there aspects of the organization, timing, environment, or sequencing of the components that needed to be changed or modified to make it a more effective visit? What could you have done about these factors? Were you organized? Would better preparation help with your organization? Were there distractions in the home that influenced organization? Ask yourself questions such as these, and then make plans to avoid or reduce disorganizing distractions. For example, if you made the visit based on limited information from a referral, you now have additional family data and can be better prepared for the next visit. If transportation schedules made the family late to the clinic, perhaps other transportation could be arranged. If the distraction on a home visit occurred because children were arriving home from school, visits could be made earlier in the day. If the television was

playing loudly, you could make it a point to ask the family whether they would mind turning down the volume, or visit at a time when they do not watch television. Make the modifications that you can to assist with the visit process.

### Outcome Evaluation

Second and most important is evaluation of the outcomes of the visit. Were the anticipated outcomes achieved? If not, why? If so, what made it possible? The **outcome evaluation**, or the assessment of change in the family's (client's) health status based on mutually agreed activities, is a formal process demonstrated in the documentation of the home visit. The agency may use the Nursing Outcomes Classification (NOC) System along with the Nursing Intervention Classification (NIC) System, or it may use the Omaha System discussed in Chapters 12 and 14. Alternatively, there may be agency-driven criteria for success and expectations for each client category or visit type. On a visit-by-visit basis, the changes observed in the family may be small; progress toward an expected outcome is noted. At the conclusion of agency services to the family, the cumulative changes in the client's health and the success or failure to achieve various outcomes are evaluated. Depending on the conclusions that can be drawn, the decision to terminate services may need to be reevaluated. It is possible that continuance of service is required, and the terms must be renegotiated. Whatever the decision, the family must be included in the decision-making process.

### Self-evaluation

The third component of evaluation is self-evaluation. What aspect of your performance as a community health nurse during the home visit facilitated the achievement of a desired outcome? Were you prepared? Did you gather all the data needed to assist the family on the next visit? What would you do differently if you could do the visit over? What went right? What went wrong? What are you going to do on the next visit to make it better? This closer look at yourself is important for your own growth and effectiveness as a community health nurse.

Sometimes, we cannot see our own strengths or flaws, and evaluations by others are helpful. In some agencies, regular peer evaluations are conducted. An agency staff nurse makes a family visit with the community health nurse and provides feedback based on her observations. This is a useful technique to use even at times other than planned evaluations of all staff members in the agency. You might ask a colleague to accompany you on a home visit to a family that has not made progress toward outcome achievement or to a family you have not been able to "reach" or find difficult to work with (Drummond, Weir, & Kysela, 2002). For a variety of reasons, consultation with peers regarding certain visits and how best to conduct them can assist you in being better prepared or more focused. It can improve your interaction with families from different cultures or in difficult situations (Spector, 2000; Walsh, 1999).

### Planning for the Next Visit

Part of the evaluation of one family visit is planning for the next. Use what occurred on the previous visit to guide you toward activities on subsequent visits. Goals may need to be

modified, or family situations may change and specific outcomes become irrelevant. For example, you may plan to visit a prenatal family one last time before the baby is born to reinforce prior teaching about when to leave for the hospital with a second pregnancy. You intend to remind the parents to arrange babysitting for the older child and to assess the pregnant woman's rising blood pressure and complaints of backache. When you arrive for the visit, the husband is home alone with the younger child and is about to leave to bring his wife and new baby home from the hospital. He asks you about the diaper rash that just appeared on the 2-year-old. He also asks how to secure the new car seat into the car, because the instructions do not seem to make sense for his make of car. Outcomes for a problem-free pregnancy and healthy birth are no longer relevant; there are new outcomes to be formulated and worked on with this young family.

More frequently, planning for subsequent visits is relatively predictable and is done to ensure that steps toward outcome accomplishment are achieved on the visit. Being totally prepared each time is the best predictor of a successful family visit. Once you have met and gotten to know a family during a visit, the planning can be individualized and tailored to meet the family's unique needs. This information is not available from a paper referral, which makes planning for a first home visit important. The tone set during the first visit can affect your continued success with the family.

### Referrals

A referral in written or verbal form (by agency-created form, telephone, fax, or e-mail) initiates contact with a family. In addition to responding to a referral, which begins the relationship with a family, the nurse makes referrals on behalf of the family. Families often need access to services beyond the agency's scope, and the nurse's knowledge of other resources can mean the difference between their having and not having access to additional services. Therefore, nurses must have information available to them about the eligibility requirements and availability of services provided by a bevy of official, voluntary, religious, and neighborhood organizations. If this information is not readily at hand, community health nurses need to know how to locate needed services. This is a daunting challenge, because the services are many, and organizations frequently change telephone numbers, services, and the populations they serve. Networking with colleagues on a regular basis helps keep nurses up to date with community services from which they can generate referrals for clients.

### Contacting Resources

At times, community health nurses implement their roles as client advocates by facilitating easier access to services for the family. Community health nurses know how to access key personnel in agencies and can eliminate some of the red tape involved in obtaining services. Nurses can provide pointers that may help families procure needed services; for example, clients may have an advantage if they go to an agency early in the morning in the middle of the week. The fact that they should have all forms completely filled out and should bring their last 3 month's rent and utility receipts, or that they should ask to speak with a certain worker, may also be helpful information.

When nurses seek informal services for families, a relationship with the director of the agency can help them gain services for the clients. For example, a client family has a personal crisis and needs a donation of food and a volunteer to stay with a handicapped child for 3 days while a spouse undergoes surgery. The nurse telephones the religious leader of a neighborhood church and shares the family's requests, clarifies the situation, and gets a donation of food from the church's food pantry. The name of a member of the church who can stay with the child is also provided. The family may not have been aware that such services were available to them, and the links provided by the nurse are as important as other community health nursing functions.

## Summary

The family unit remains the focus of service in community health nursing. Family health and individual health strongly influence each other, and family health also affects community health. Assessing, planning, implementing, and evaluating nursing care are steps used to deliver care to clients in acute care settings, in the extensive clinic system, and in the home.

It is important for the nurse to understand healthy family characteristics and to use a variety of tools so that family assessments are thorough.

Healthy families demonstrate six important characteristics:

1. A facilitative process of interaction exists among family members.
2. Individual member development is enhanced.
3. Role relationships are structured effectively.
4. Active attempts are made to cope with problems.
5. There is a healthy home environment and lifestyle.
6. Regular links with the broader community are established.

To assess a family's health systematically, the nurse needs a conceptual framework on which to base the assessment, a clearly defined set of categories for data collection, and a method for measuring the family's level of functioning. The six characteristics of a healthy family provide one assessment framework that community health nurses can use. Assessment tools to aid the nurse in appraising the health of families include the eco-map and the genogram.

There are 12 main categories of family dynamics for which the nurse must collect data: family demographics, physical environment, psychological/spiritual environment, family structure and roles, family functions, family values and beliefs, family communication patterns, family decision-making patterns, family problem-solving patterns, family coping patterns, family health behaviors, and family social and cultural patterns.

Community health nurses enhance their practices with families by observing five principles: work with the family collectively, start where the family is now, fit nursing interventions to the family's stage of development, recognize the validity of family structural variation, and emphasize family strengths.

During assessment, the nurse should focus on the family as a total unit, use goal-directed assessment questions, allow adequate time for data collection, combine quantitative with qualitative data, and exercise professional judgment.

Making family health visits is a unique role for nurses and is one of the activities common to most community health nurses. In some agencies, family health visits are conducted for only the most high-risk families. In other agencies, a visit is the method of choice for most care.

When nurses visit families, they must use acute observational skills, good verbal and nonverbal communication, assessment skills, and a "sixth sense" to guide them safely in the community and with the families they visit. Some visits are conducted with families in settings other than their homes. Neighborhood clinics, schools, work places, or recreational settings may be the preferred or the only locations in which you can gather most of the family members for the visit. Other families may be in transition and living in homeless shelters or with relatives or neighbors. These settings are familiar to the family and provide a unique environment for the nurse in which to visit the family.

Pre-visit preparation, conduct of the visit, and post-visit documentation are the main components of a family health visit. Each step is important and has value for the success of the next step. Being well prepared for a visit is the first concern (e.g., know the location, have family health status information and needed materials). The visit should be conducted in an orderly and organized fashion. Time should be allowed for getting acquainted, for the body of the visit, including teaching and anticipatory guidance, and for any other nursing care that may be a part of the visit. Concluding with a summary of the important parts of the visit and planning for the next visit ensures an appropriate ending.

Being safe in a neighborhood is important for all people. Community health nurses spend a great part of the day in the community, and safe travel is of constant importance. Use of a personal or agency car, public transportation, or walking to visit families each has its own set of precautions for personal safety. Even in a family's home, personal safety must be a consideration. If family members are arguing or under the influence of drugs or alcohol, the situation may deteriorate rapidly and become unsafe; at this point, it is best to terminate the visit.

During the implementation phase of the family health visit, the nurse establishes a verbal or written contract with the family. This permits understanding by both the family and the nurse of the personal roles and responsibilities in the relationship. Empowerment of family members is significant for clients. People who are empowered can help themselves for a lifetime and can make independent decisions about their own health.

Evaluation and preparation for the next visit completes the family health visit cycle. Three types of evaluation can be conducted at the end of a visit. Recall of the structure-process assists the nurse in reflecting on the physical aspects of the visit that were positive or negative. Discovering these factors can help enhance the positive and eliminate the negative. Evaluating whether the outcomes of the visit were achieved is done in a more formal way with agency documentation. Because the purpose of conducting family health visits is to bring about positive changes in family behaviors, it is necessary to evaluate the achievement of mutual goals made by the nurse and the family. The hardest part of evaluation is looking at yourself and how you conduct home visits. Often, peer evaluation is a helpful way to obtain feedback, because people tend to minimize their own strengths and overlook their weaknesses.

Conducting family health visits involves making referrals to other agencies and services on behalf of the family. One agency cannot provide all the services that a family needs. Written or verbal forms of communicating a need involve contacting resources available in the community. Community health nurses have unique skills in knowing and locating both official and voluntary services within their community. Such skills come with experience. ■

### ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Construct an eco-map of your family. Ask a peer to do the same thing. Assess the balance between your family and the resources in its environment. How does your eco-map compare with that of your peer? What changes are needed in each family system? Are you able to influence the changes that are needed?
2. Draw a genogram of your family and ask a peer to discuss it with you. Make your drawing of the genogram as complete as possible. Then analyze your thoughts and feelings. How did you feel while tracing your family history? Did you learn anything new about your family? Did any family trends or traits appear? Did any uncomfortable or suppressed information come to the surface? Do you have any new insights about your family?
3. Assess a family (other than your own) that you know well by completing a family assessment guide. You may use one of the forms in this chapter or an available form from another source. Based on your assessment, determine as many nursing interventions as you can think of that could be used to promote this family's health as practically as possible.
4. Invite a peer to go on a family health visit with you, and be open to feedback regarding your strengths and weaknesses. How does it make you feel to have someone else on a family health visit with you, knowing they are observing your skills? Offer to do the same for a peer and provide him with feedback. Discuss your experience.
5. Go on several family-health visits with an experienced community health nurse and observe the nurse's visiting techniques. Observe how he contacts the family, knocks on the door, greets the family, conducts, summarizes, and concludes the visit, and makes plans for the next visit. Discuss the various techniques used, and ask questions about your observations to get a better idea of why things are done as they are. Use some of this information on your next home visit.
6. Initiate a small group discussion among your peers about safety on your school campus and in your community. Encourage each person to share the safety habits used. How are these techniques different from safety techniques used when making home visits in the community? If they are different, why? Should they be different?

# Violence Affecting Families

## LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Explain the difference between developmental crises and situational crises and give examples of each within families.
- ◆ Discuss strategies to prevent the impact of a situational crisis and a developmental crisis at a primary, secondary, and tertiary level of prevention.
- ◆ Discuss the global incidence and prevalence of family violence.
- ◆ Describe how the United States has responded to family violence.
- ◆ Identify characteristics of abuse against infants, children, and adolescents.
- ◆ Describe the “cycle of violence” seen in intimate partner/spousal abuse.
- ◆ Explain common types of elder abuse.
- ◆ Describe the community health nurse role with families in crises at each level of prevention.
- ◆ Use nursing process to outline nursing actions in developmental and situational crises.

*“The right things to do are those that keep our violence in abeyance; the wrong things are those that bring it to the fore.”*

—Robert J. Sawyer (1960–), *Calculating God*

## KEY TERMS

Adolescent dating violence (ADV)  
 Battered child syndrome  
 Child abuse  
 Coping  
 Corporal punishment  
 Crisis theory  
 Cycle of violence  
 Developmental crises  
 Domestic violence  
 Elder abuse  
 Emotional abuse  
 Family crisis  
 Family violence  
 Femicide  
 Gender-based violence  
 Home invasion  
 Homicide  
 Incest  
 Interpersonal violence  
 Intimate partner violence (IPV)  
 Intrafamilial sexual abuse  
 Mandated reporters  
 Munchausen syndrome by proxy  
 Neglect  
 Pedophile  
 Physical abuse  
 Rape  
 Sexual abuse  
 Sexual exploitation  
 Shaken baby syndrome  
 Situational crisis  
 Spousal abuse  
 Suicide  
 Violence against women

**family crisis** is a stressful and disruptive event (or series of events) that comes with or without warning and disturbs the equilibrium of the family. A family crisis can also result when usual problem-solving methods fail. All families experience periods of crisis: a toddler is diagnosed with a serious illness; a teenager discovers she is pregnant; a father and sole breadwinner in a family loses his job; a mother's social drinking becomes habitual after her children go off to college; or a family's home is destroyed in a hurricane, earthquake, flood, or fire. If you think back on your family's history, you probably can identify one or more periods of crisis that you and your family members experienced. If so, how directly were you affected? How did the crisis resolve? As a result of the crisis, did any permanent changes occur in your family's dynamics or individual behaviors?

People respond to crises differently. Some people approach crises as a challenge, an event to be reckoned with, while others may feel overwhelmed and defeated or give up. Some individuals seek help if needed and come through the experience unscathed or as survivors, perhaps even stronger than before. Other individuals who are unable to cope with the crisis, or who do not cope well, may suffer severe psychological damage or may inflict their feelings of rage, frustration, or powerlessness onto their children, partners, or elders. This chapter focuses on families that have responded to stressors with violence, neglect, or abuse and those that have experienced stress and loss as a result of violence initiated by others.

Regardless of their responses, families in crisis need help, and community health nurses have a unique opportunity and responsibility to provide that help in a broad variety of situations. For example, in one family, an 8-year-old boy begins doing poorly in school; he wets his pants during class twice in one week and starts a small fire in the schoolyard. The school nurse is astute enough to begin an investigation into the family dynamics that may be contributing to these symptoms. In another family, a pregnant woman reschedules her appointment at a community clinic twice, then arrives at the appointment with multiple faded bruises on her face and arms. The clinic nurse uses sensitivity and caring while screening her for domestic violence.

Primary and secondary prevention measures used by community health nurses that help prevent crises include teaching families parenting skills, coping strategies, and informing them about community resources. In addition to assessment and education, community health nurses provide tertiary responses with direct assistance during times of crisis. This chapter discusses the knowledge and skills that community health nurses use in their practice of crisis prevention and intervention aimed at promoting improved health for families in the community.

## DYNAMICS AND CHARACTERISTICS OF A CRISIS

Researchers have studied the nature of crises and have developed a body of knowledge called **crisis theory**. Initially limited to the field of mental health, crisis theory now influences every field of health care. The theory helps to explain why people respond in certain ways during a crisis and predicts phases people go through during and after a

crisis. These responses and phases are important ideas for the community health nurse to understand before working in prevention or management of crises.

How does a crisis occur? Each of us is a dynamic system living within a given environment under circumstances unique to us alone. Our behavior—both consciously and subconsciously—is gauged to maintain a balance within ourselves and in our relations with others. When some internal or external force disrupts our system's balance and alters its functioning, a loss of equilibrium occurs. The individual then attempts to restore equilibrium by using whatever resources are available to him, in an effort to cope with the situation. **Coping** refers to those actions and ways of thinking that assist people in dealing with and surviving difficult situations. If individuals cannot readily cope with a stressful event—for example, if one's home is destroyed by fire, or one fails a final examination—the person experiences a crisis.

Crises are precipitated by a specific identifiable event that becomes too much for the usual problem-solving skills of those involved. Often, a single distressing event follows a host of previous difficulties and becomes the “straw that breaks the camel's back.” For example, a wife who suffers years of spousal abuse finally becomes unable to cope and shoots her husband during a violent attack. Occasionally, tragic events occur suddenly without previous stressors, as when a father is killed in a plane crash or a child drowns in the family swimming pool.

Crises are normal in that all people feel overwhelmed occasionally. A person intervening in a crisis today may well be tomorrow's crisis victim. No individual is immune from sudden overwhelming difficulties. For example, Barbara, a hospice nurse, assists families through crises as part of her job, and suddenly her own spouse is diagnosed with cancer. Her coping skills are strained as she feels overwhelmed with personal and increased demands that require her support and attention.

Often a crisis is not an event per se, but rather a person's perception of the event. Each person reacts in his own way. A situation that throws one person off course may merely create an interesting detour for another (Display 20.1). It is usually the individual's interpretation of the event, rather than the event itself, that is crucial. At other times, a community crisis occurs on a large scale or is so unexpected that the crisis directly involves people who are known by others hundreds of miles away, causing distant friends and relatives shock and sorrow. Examples of such crises are Hurricane Katrina, or a night-club fire that kills dozens of people, or the terrorist attacks on September 11, 2001. Even strangers, knowing no one involved directly, are affected and experience signs and symptoms of stress (Levy & Sidel, 2002).

Crises are resolved, either positively or negatively, within a brief period, usually 4 to 8 weeks (Aguilera, 1998; Hoff, 2001). People's strong need to regain homeostasis and the intense nature of crises contribute toward making the crisis a temporary condition that will not continue indefinitely. In the family in which the wife shot her abusive husband, as shocking as the event might seem, life returns to a recognizable pattern within a few weeks. Even though family members will feel the change for years, the crisis soon subsides. The husband is hospitalized and recovers from his wound; the wife's case goes to trial, and she is sentenced to 2 years in prison; the children stay with relatives and attend school.

## DISPLAY 20.1

## TWO FAMILIES' RESPONSE TO CRISIS

The Redondos and the Fosters will be moving to a town in another state, 900 miles away, because of a job change. The Redondos are in crisis over the move. They have never lived in any other town. They will have to leave relatives and lifelong friends who live nearby and a community in which they have been very involved. Mrs. Redondo is the secretary at her family's house of worship. Their teenage daughter, a cheerleader, just started high school. Their son is in kindergarten; Grandma happily watches him in the mornings before school. Everyone is upset because of how the move will affect them. The family is stressed and argues each evening. They don't want to put their house up for sale or even to visit the new community to which they will be moving. Mr. Redondo is second guessing his decision to move, but his choices were limited as his company is relocating. The Redondos, in crisis, are not exploring alternatives that may allow them to stay in their present community. One possible alternative might be for Mrs. Redondo to work while Mr. Redondo looks for another job. When people perceive that they are in crisis, decision making and problem solving become more difficult.

The Fosters, however, are excitedly looking forward to their move. They have two young children who are not yet in school. The move will bring them only 50 miles from old college friends. They hope to realize a significant profit on their house, which they recently remodeled. They can't wait to go "house hunting" in the new town. Everyone is enjoying planning the anticipated move; their two children, aged 3 and 4, have been playing "moving day" with their favorite toys.

Both families are experiencing the same event. The difference is each person's situation and perception of the event. The Redondos' equilibrium is being disrupted. They have not developed previous coping skills and do not see the move as a positive experience. They are at a different time in their family life cycle than are the Fosters. Although the move upsets their equilibrium, too, the Fosters experience it as an exciting event that conjures positive feelings; they are passing these feelings on to their children. They see this move as an opportunity.

Crisis resolution can be an adaptive process in which growth and improved health occur, or it can be maladaptive, resulting in illness or even death. The battered wife reevaluates her life, gets divorced, learns employment skills in jail, becomes more assertive, with stronger self-esteem; after she is paroled, she returns to her children, now able to support them financially and emotionally. She finds personal growth and health while successfully resolving the crisis. The children settle into their aunt's home with minimal difficulty, start a new school, and visit their mother and father regularly. After release, the mother finds an apartment near her sister's home, so that the children can continue in the same school district. The husband recovers from his wounds, gets counseling, relocates to another town, and sees his children frequently. The

crisis situation is resolved at a higher level of wellness for all members than existed before the crisis. In this example, the members are determined to improve their situation by working with skilled health care professionals. By using the resources within the community, this family is healthier after the crisis.

## Developmental Crises

**Developmental crises** are periods of disruption that occur at transition points during normal growth and development (Display 20.2). When developmental crises occur, people feel threatened by the demands placed on them and have difficulty making the changes necessary to fit the new stage of development.

During the process of normal bio-psycho-social growth, people go through a succession of life cycle stages, from birth through old age. Each stage differs from the previous one, and transitions from one stage to the next require changes in roles and behavior. Popular and classic authors such as Levinson (1978), Bridges (1980, 2001), Sheehy (1976, 1992, 1999), and Sheehy and Delbourgo (1996) have called these periods "passages" and "transitions." These transitions are times when developmental or maturational crises occur.

Most family developmental crises have a gradual onset. The change is evolutionary rather than revolutionary. People usually anticipate and even prepare to start school, enter adolescence, leave home, marry, have a baby, retire, or die. Individuals move into and through each transitional period knowing in advance that some kind of change will be required. In many instances, people have already seen others experience these transitions. As a result, developmental crises have a degree of predictability. These developmental crises offer a time for anticipation and adjustment.

Developmental crises arise from both physical and social changes. Each new life stage confronts people with changed relationships, responsibilities, and roles. The transition to parenthood, for example, demands a change in role from caring for oneself and one's mate to include nurturing, caring for, and protecting a completely helpless infant. Relationships with adults, children, and even one's parents also change. Parenthood is an entrance into a previously inexperienced part of the adult world.

## DISPLAY 20.2

## MAJOR DIFFERENCES BETWEEN TYPES OF CRISES

### Developmental Crisis

- Part of normal growth and development that can upset normalcy
- Precipitated by a life transition point
- Gradual onset
- Response to developmental demands and society's expectations

### Situational Crisis

- Unexpected period of upset in normalcy
- Precipitated by a hazardous event
- Sudden onset
- Externally imposed "accident"

## DISPLAY 20.3

## A DEVELOPMENTAL CRISIS

Marcia Sand is 39 years old. Married for 22 years, she has been a capable homemaker and mother of four children. Her husband, Lou, a construction worker for the past 20 years, thinks Marcia does a “super job at home.” In the past, Marcia’s time was filled with cooking, laundry, cleaning, shopping, and meeting the endless demands of the family. Their limited income prompted her to adopt many money-saving strategies. She made most of her own and the children’s clothes, did all her own baking, and raised vegetables in her backyard garden. Now the youngest of the children, Tommy, has just left home to join the Navy. Her husband spends much of his spare time at the local bar with his friends, leaving Marcia alone. With a nearly empty house and little need for cooking, baking, and sewing, Marcia has lost her sense of usefulness. She thinks of taking a job, but knows her choices are limited because she has only a high school education. Marcia has not slept well in weeks; she wakes up tired and drags through the day barely able to manage the simplest task. She cries frequently but does not know why. Her hair, always neat and attractive in the past, looks bedraggled, and her shoulders slump. “I just can’t seem to get on top of things any more,” she complains.

Marcia has entered a developmental crisis that is sometimes called the “empty nest syndrome.” She faces a turning point in her life, a time when parenting has seemingly ended. Leaving her satisfying homemaker role, she faces a new life stage filled with unknowns, changes, and a seeming lack of purpose. The transition came about gradually, almost imperceptibly, but now she must deal with it. Yet she feels unable to cope and wishes to turn to someone who would understand and lend her strength. She can be helped, but her crisis could also have been prevented at the pre-crisis phase. Anticipatory planning could have prevented the dilemma Marcia finds herself in now.

New parents may fear the unknown. Will this infant develop normally? Can I give adequate care? Parents often feel anxiety about the responsibility of shaping this new person’s life, satisfying society’s expectations for their child’s proper education and training, or bringing children into a world that is in crisis and already overpopulated. Parents may worry about the increased financial burden while struggling with mixed feelings about giving up a large measure of freedom. These transitions put people under considerable stress, which contributes to tension, feelings of helplessness, and resultant crisis. Some people adapt quickly; others cannot cope, probably because earlier developmental crises went unresolved. If people lack a repertoire of adaptive skills, even positive and planned changes can develop into crises (Display 20.3).

### Situational Crises

A **situational crisis** is a stressful, disruptive event arising from external circumstances that occur suddenly, often without warning, to a person, group, aggregate, or community.

Typically, the external event requires behavioral changes and coping mechanisms beyond the abilities of the people involved.

Such events are not predicted, expected, or planned. The crisis occurs to people because of where they are in time and space. For instance, a baby grabs her mother’s hot cup of tea and burns her chest; a college student is raped in the library parking lot; an older adult falls and fractures a hip; a mother with a van full of Little League baseball players has a crash at a busy intersection; or a hurricane devastates a state. These events, which involve loss or the threat of loss, represent life hazards to those affected. Some crisis-precipitating events can be positive, such as a significant job promotion or sudden acquisition of great wealth; however, the change still makes increased demands on individuals who must make major life adjustments. Even positive events involve a modified grieving process, because the individuals involved may be losing or giving up old, familiar, and comfortable situations and facing stressful changes.

Community health nurses see an almost infinite variety of situational crises, including debilitating disease, economic misfortune, unemployment, physical abuse, divorce, unwanted pregnancy, drug and alcohol abuse, sudden death of a loved one, tragic accidents such as a drowning or plane crash, and many others. In each situation, people feel overwhelmed and need help to cope. Skilled intervention can make the difference between a healthy or an unhealthy outcome.

### Multiple Crises

Different kinds of crises can overlap in actual experience, compounding the stress felt by the persons involved. For example, a couple may experience a developmental crisis (birth) and a situational crisis (birth defect) simultaneously, thus compounding the resulting stress. The developmental crisis of midlife may be complicated by situational crises such as a divorce or job change. With older adults, the developmental crisis of retirement may be compounded by the situational crisis of a fire that destroys the family home. The transition a child faces entering school may occur at the same time the family moves to a new neighborhood and a new infant joins the family. The child must share the parent’s attention and affection with a new sibling at a time when all the child’s resources are needed to cope with starting school and adjusting to the new neighborhood. Classic research shows that accumulated stresses can lead to ill health (Holmes & Rahe, 1967). Those who normally work through one crisis in a healthy way may find that compounding events overwhelm them, causing more stress than they can handle.

### HISTORY OF FAMILY VIOLENCE

Family crisis is not limited to the developmental crises people experience or the situational crises that come upon us suddenly, usually from forces—such as nature—that are external to the family. Many women and children in the world also experience the crisis of domestic violence. The terms **domestic violence**, **family violence**, and **interpersonal violence** refer to morbidity and mortality attributable to violence within the home setting, involving action by a family member or intimate partner. Domestic violence involves “a systematic pattern of assaultive and coercive behaviors, including physical, sexual, and psychological

attacks and economic coercion, that adults or adolescents use against their intimate partner” (Kramer, 2002, p. 190). This type of violence occurs worldwide and is becoming more of a global public health burden.

## Global History

Family violence is not new. For centuries, children were thought of as the property of their parents, and any treatment doled out by the parents was their prerogative. In fact, most countries had animal welfare laws long before child welfare laws were adopted. In addition, the ideology of childhood that emerged in the Western world in the late 1800s assumed that only “abnormal” children needed protection. These children were casualties of an urban-industrial society, and were abandoned, dependent, or delinquent—the products of social dislocation such as orphans or refugee children.

In the early 1900s, sensitive leaders concerned with child welfare issues emerged. Several international agencies were created designed to positively affect the health of children. The British Children’s Act was passed in 1908, and the first White House Conference on children was held in 1909. These were early attempts to define a role for the state in the welfare of children. The U.S. conference was the forerunner of the United States Children’s Bureau (USCB) and a national voluntary organization, later known as the Child Welfare League of America, was established to complement federal agency efforts (Bolen, 2001). The USCB became a model for other countries, with well-developed programs targeting infant mortality. In one innovative program of the early 1900s, a heated, mobile, child welfare center was used in rural communities and was staffed by a female physician and a public health nurse to improve health care to children.

Other international organizations emerged in the early 1900s including the International Association for the Promotion of Child Welfare (IAPCW), the League of Red Cross Societies (LRCS), the Save the Children Fund (SCF), and the Save the Children International Union (SCIU). The latter two agencies were immensely successful in raising funds for children in Germany, Austria, France, Hungary, and Serbia. As these organizations began serving the needs of children internationally, they moved from a sentimental depiction of victims to a medico-social-scientific view of children at risk, expanding and uncovering the concepts of child victimization, exploitation, and abuse (Bolen, 2001).

By the mid-1920s, the work of these agencies began to focus on children from non-European countries. The first conference on children from non-European countries focused on African children in 1931 and included such issues as infant mortality, child labor, education, and child slavery. In 1924, the League of Nations adopted the Declaration of the Rights of the Child, which would influence the League of Nations’ successor, the United Nations, in the years to come in the form of the Declaration of the Rights of the Child (1959) and the Convention on the Rights of the Child (1989). The United Nations continues to hold annual hearings on the Rights of the Child, and has addressed global concerns, such as children without parental care, indigenous children, violence against children, HIV/AIDS, children with disabilities, and the economic exploitation of children (Office of the United Nations High

Commissioner for Human Rights, Committee on the Rights of the Child, 2007).

Children are not the only victims of family morbidity and mortality from violence. Historically, women were also treated as property and often suffered physical and psychological damage. **Gender-based violence, or violence against women (VAW)**, has global public health and human rights ramifications (World Health Organization [WHO], 2007a). Between 16% and 52% of women in some parts of the world experience domestic violence and other forms of violence ranging from emotional abuse to rape and genital mutilation. One in five women worldwide experience rape or attempted rape in their lifetime, and an estimated 100 to 140 million girls and women alive today have undergone genital mutilation (WHO, 1998, 2007a). As with children, the rights of women are socially, culturally, and religiously influenced, with change coming slowly.

## United States History

The history of treatment of children, women, and elders in the United States began with emigration in the 1500s and has been influenced by the cultural and religious practices of early settlers. In addition, necessity, attitudes of the time, and the stress and hardship of life in the colonies and on the frontier influenced how people were treated.

Children were born into families to help with the chores of an agricultural society. Families had many children, infant mortality rates were high, and it was not uncommon for half of the children in a family to die before their second birthday. Older people did not retire; they contributed to family survival until they died. There were no special considerations for children, women, or elders. The best a woman could hope for was that the man she married would not abuse her emotionally, physically, sexually, or fiducially (taking advantage of a person’s financial resources). Women had limited or no education, resources, or rights, and children had none. If a woman married “poorly,” she would have to live with the consequences. Separation and divorce were either unheard of or were a “death sentence” for the woman and her children, because there was nowhere they could go and no way for the woman to support her family.

## Public Laws and Protection

It took many years for the United States to establish laws that benefited women and children. Nonetheless, the United States began earlier than many other countries to protect children, women, and elders. The Children’s Bureau began to focus on child abuse in the 1960s, supporting development of a child abuse mandatory reporting law in 1962 to be used as a model by the states. The law required health professionals and child care workers to report suspected child abuse to appropriate officials.

In 1974, the Child Abuse Prevention and Treatment Act was passed, becoming Public Law 93-247 (PL 93-247). This law served to reinforce the earlier mandatory reporting law model and was aimed at solving the growing problem of child abuse in the country. Public Law 93-247 has been amended several times since 1974. The Child Abuse Prevention and Treatment and Adoption Reform Act of 1978 was followed by the Family Violence Prevention and Services Act

of 1984. Later, all three acts were consolidated into the Child Abuse Prevention, Adoption, and Family Services Act of 1988 (Public Law 100-294), and most recently, the Act was amended and reauthorized as the Keeping Children and Families Safe Act of [Public Law 108-36] (Child Welfare Information Gateway, 2004).

Public Law 108-36 supports funding to states in their efforts to prevent violence in families and to identify and treat victims. The funding comes in the form of the Child Abuse Prevention and Treatment Act (CAPTA) and state grants that meet eligibility requirements (Administration for Children & Families, 2006b). One aspect of the funding supports the National Child Abuse and Neglect Data System (NCANDS) that tracks reports of child abuse and neglect, and all fatalities from child abuse or neglect in the United States. In 2006, NCANDS reported an estimate of 1,530 child deaths “caused by an injury resulting from abuse or neglect, or where abuse or neglect was a contributing factor” (Child Welfare Information Gateway, 2008a, para. 2). Information on adoption, out-of-home care for children, preventing and responding to child abuse and neglect, supporting and preserving families, and resources are available via the Child Welfare Information Gateway, a program under the United States Department of Health and Human Services (USDHHS), Administration of Children and Families. The Administration on Aging, also under the USDHHS, supports similar programs including the National Center on Elder Abuse that works to educate and assist families, seniors, and health care and legal providers regarding elder abuse (2006).

### Healthy People 2010 Goals

The goal for *Healthy People 2010* regarding violence and abuse is to reduce injuries, disabilities, and death due to violence among all people of the United States. On an average day in America, 70 people die from homicide, 87 people commit suicide, as many as 30,000 people attempt suicide, and a minimum of 18,000 people survive interpersonal assaults. The problem of violence is pervasive, affecting the victim directly and family members indirectly. Selected violence and abuse objectives for *Healthy People 2010* include the following:

- ◆ Reduce maltreatment and maltreatment fatalities of children from 13.9 victims per 1,000 by the year 2010
- ◆ Reduce physical assault by current or former intimate partners from 4.5 per 1,000 people to 3.6 per 1,000 by 2010
- ◆ Reduce the annual rate of rape or attempted rape of persons aged 12 years and older to less than 0.7 per 1,000 persons by 2010, down from 0.8 per 1,000 in 1998
- ◆ Reduce sexual assault other than rape to less than 0.2 per 1,000 people in 2010, down from 0.6 in 1998
- ◆ Reduce weapon carrying by adolescents on school property (grades 9 through 12) from 8.5% in 1997 to 6% by 2010 (USDHHS, 2000)

Injury and violence prevention, one of the 28 identified focus areas in *Healthy People 2010*, is also in the top 10 high-

priority leading health indicators (LHI) chosen to track national progress toward meeting the *Healthy People 2010* national health goals (Office of Disease Prevention and Health Promotion, n.d.). Types of injury and violence prevention tracked for *Healthy People 2010* include motor vehicle accidents, firearm injuries, poisonings, suffocation, falls, fires, and drownings. In the *Healthy People 2010 Midcourse Review* of violence and abuse prevention, four objectives—sexual assault other than rape in those 12 and older, physical assault of those older than 12 years, physical fighting in 9th to 12th grade students, and carrying weapons on school property by students in grades 9–12—demonstrated a 40% or higher improvement (Office of Disease Prevention and Health Promotion, *Healthy People 2010: Midcourse Review*, 2005, p. 15-6).

Some injury and violence prevention objectives did not demonstrate improvement in the *Healthy People 2010 Midcourse Review* including firearm-related deaths (–2%), non-fatal poisonings (–89%), deaths from poisonings (–38%), deaths from suffocation (–22%), deaths from unintentional injuries (–9%), deaths from homicides (–3%), and maltreatment fatalities for those under 18 (–100%) (pp. 15-11–15-14). Gender, education, race/ethnicity, and location are identifiers used in tracking and measuring *Healthy People 2010* injury and violence objectives. Of particular concern in these identifiers are findings that: (1) males are three times more likely than females to be a victim of homicide; (2) a person with a high school education or less is four times more likely to be a homicide victim than an individual who had at least some college; and (3) American Indian, Alaska Native, Hispanic, and Black non-Hispanic populations were three to seven times higher than White non-Hispanic populations to be victims of homicide (p. 15-20). Firearm related deaths reflected the lowest rate in Asian or Pacific Islander populations (p. 15-19), whereas nonfatal firearm injuries notably decreased in the Hispanic population between 1997 and 2001 “from 39.4 injuries per 100,000 population to 21.8 injuries per 100,000 population” (p. 15-19). Ongoing data collection and review of the *Healthy People 2010* goals promote identification of issues for specific populations and an opportunity to revise and update objectives reflecting current science, data gathering, and presentation of information (Office of Disease Prevention and Health Promotion, *Healthy People 2010, Midcourse Review, Executive Summary*, 2005). This review process allows new programs and approaches to be planned and implemented, such as the Positive Parenting Program (Triple P), a parent education program that addresses the risks of child mistreatment (p. 15-17), or advocacy for legislation that supports increased domestic violence services, a finding that has been linked to decreased intimate partner homicides, and possibly to a reduction in intimate partner physical assaults (p. 15-24). More importantly, this review and attention to new measures support the overarching goals of *Healthy People 2010*: to increase quality and years of healthy life, and to eliminate health disparities.

### Myths and Truths About Family Violence

Many myths about family violence need to be dispelled. Strongly held myths by members of society, including community health nurses and other health care providers, may interfere with their ability to help families in crisis get the

**TABLE 20.1 Common Myths and Truths About Abuse in Families**

Myth	Truth
Violence in families is rare	Family violence is common and increasing
Violence occurs most frequently among low-income families	Family violence occurs across all incomes
Violence occurs more frequently in some racial and cultural groups	Family violence occurs across all racial and cultural groups
Violence in families does not coexist with love	Love may exist but is unable to be displayed appropriately due to conflicting emotions
Men who batter women are mentally ill	The percentage of batterers who are mentally ill is the same as in the general population
Women who accept battering are mentally ill	The percentage of battered women who are mentally ill is the same as in the general population; however, they have low-esteem and a damaged spirit
Violence occurs only in heterosexual relationships	Domestic violence has no gender or sexual boundaries; it can occur among all people
Abused women instigate the battering	Quite the contrary, they go out of their way not to agitate or confront the abuser
Abuse occurs when the abuser is under the influence of drugs or alcohol	It can, but many abusers do not drink or use drugs
Children should not be taken from their parents	In some violent families, the safest place for the child is with another family member or a foster home (temporarily or permanently)
Even abusive parents are better for a child than a child living elsewhere	Children must be protected, and living away from abusive parents may save their lives
Abused children become abusive adults	Some may, but most can learn how to channel their emotions positively if the cycle of violence is broken

help they need. Table 20.1 displays some common myths and truths about family violence.

## FAMILY VIOLENCE AGAINST CHILDREN

Communicable diseases, as a cause of morbidity among children, “are coming under control through a combination of health promotion, prevention, and simplified standard treatment regimens. At the same time, the healthy growth and development of many children is threatened by very rapid, often disruptive social, cultural, and economic changes” (WHO, 1998, p. 71). This emerging new morbidity is psychosocial in nature and is associated with behavioral problems that are more difficult to prevent than the diseases known for centuries. In 2001, the World Health Organization (WHO)’s Committee on the Rights of the Child stated, “Globally, around 40 million children are subjected to child abuse each year . . . violence [that] results from individual, family, community, and structural factors” (para. 5-6), yet this violence directed at children is preventable.

**Child abuse** defined by the federal Child Abuse Prevention and Treatment Act (CAPTA; 42.U.S.C.A., 5106g) from the *Keeping Children and Families Safe Act* of 2003, is “at minimum: any recent act or failure to act on the part of a parent or caretaker which results in death, serious physical or emotional harm, sexual abuse or exploitation; or an act or failure to act which presents an imminent risk of serious harm” (Child Welfare Information Gateway, 2008b, para. 1). More commonly, child abuse is defined in identifying cate-

gories of maltreatment toward a child that may include physical, emotional, general neglect, medical or educational neglect, physical punishment or battering, emotional or sexual maltreatment and exploitation, or a combination of these mistreatments.

Child abuse and the associated psychosocial developmental problems are taking a toll globally in human costs and economically in health care services. Countries vary in risk toward children; for example the homicide rate for children in Japan is 0.6 per 100,000, yet 7 per 100,000 in the United States, to a high of 25 per 100,000 in Estonia (WHO, Committee on the Rights of the Child, 2001, para. 8). Worldwide, fatal abuse of infants and very young children is nearly double that of children who are between 5 and 14 years old and varies with lower rates of child homicide in countries with higher levels of income (WHO, 2007b, chap. 3, p. 60). Identifying and gathering worldwide data about child abuse is difficult because many cases are not investigated and death reports may not be classified as the result of abuse or homicide.

Another concern for children is their role in families that may require very young children to aid the family financially. A child’s “chores” may include spending the whole day scrounging around city dumps gathering bits of food, clothing, or other useful or saleable items. Some children are sold for sexual favors to whomever asks, while others spend all day working in fields, home businesses, or “sweat shops” for the equivalent of pennies a day. In some societies, female children are not valued and are killed at birth, given away, or sold into slavery for a pittance.

Child abuse in the United States has seen a slight increase over the past few years from “1.96 per 100,000 in 2001, increasing to 1.98 in 2002, 2.00 in 2003, 2.03 in 2004, decreasing back to 1.96 in 2005, and increasing to 2.04 in 2006” (Child Welfare Information Gateway, 2008a, p. 2). Many researchers think child abuse cases are underreported due in part to variation in reporting requirements, state investigation requirements, and the amount of time an investigation may require, along with difficulty in coding and sharing information between agencies and jurisdictions. The National Child Abuse and Neglect Data System (NCANDS) estimated 1,530 child fatalities in the United States in 2006 (Child Welfare Information Gateway, 2008a, para. 2). Most of these fatalities were in children under 3 years old, with 45% of the fatalities in children under 1 year (para. 9). The dependence of small children makes them vulnerable to abuse and neglect, as reflected in the 2004 child fatalities rate, when 35.5% died as the result of neglect, 28.3% died of physical abuse, and 30.2% of multiple types of abuse (para. 11).

Representation of children of color is higher in child abuse data. “While there were 10.6 cases of substantiated maltreatment for every 1,000 white children, the rates for Black, Hispanic, and Indian/Alaskan Native children were 25.2, 12.6, and 20.1 cases per 1,000 children, respectively” (Lane, Rubin, Monteith, & Christian, 2002, p. 1603). These rates may give a false picture of the actual rates among racial groups. It may be that minority children are abused more frequently, or that abuse of minority children is more likely to be reported, or that reports among minority groups are more likely to be substantiated. Mandated reporters may have biases that contribute to the differences, while characteristics of the community in which the child resides have also been cited as a factor in the over-representation of children of color in abuse reporting (United States Children’s Bureau, 2003).

Of the four types of reportable child abuse—physical, emotional, sexual, and neglect—the majority of reports in the United States are for neglect. The National Child Abuse and Neglect Data System (NCANDS) reported in 2006, “approximately 905,000 children were found to be victims of child abuse or neglect,” and of that number 64.2% suffered from neglect, 16% were physically abused, 8.8% were sexually abused, 6.6% were emotionally or psychologically maltreated, 2.2% were medically neglected, while 15% were victims of “other” types of maltreatment such as abandonment, threat of harm to the children, and congenital drug addiction (Administration for Children & Families [ACF], 2006a, pp. iii, 27). Similar to the worldwide data, younger children were at greater risk, as 38.6 per 1,000 children under 3 years were victims, with 13.5 per 1,000 in the 4 to 7 year old range, decreasing to 10.8 per 1,000 in 8-11 year olds, 10.2 in 12-15 year olds, and 6.3 in those 16-17 years (ACF, 2006a).

Nationally, measures have been taken to improve data gathering and information about violence toward children, as well as outcomes for these children. The *National Survey of Child and Adolescent Well-Being* (NSCAW) is a longitudinal study on the well-being of children who have encountered the child welfare system (ACF, 2007). Another important source of tracking child maltreatment occurs in conjunction with the *Healthy People 2010* goals that set a target for a 20% improvement in reducing child (under 18 years old) maltreatment and maltreatment fatalities from the 1998 baseline of 12.9 child victims per 1,000 children (USDHHS, 2000, *Healthy People 2010: 15 Injury and Violence Prevention*, 15-33).

## Child Neglect

**Neglect** occurs when the physical, emotional, medical, or educational resources necessary for healthy growth and development are withheld or unavailable. Neglect is obvious to an observer if a very young child is playing unattended outside, is not dressed appropriately for the weather, or has an unkempt appearance. However, neglect is not always so obvious. Parents may refuse to buy eyeglasses for a child who needs them or to access dental care for severely decayed teeth (medical neglect). An 8-year-old may get to school only 3 days a week, possibly without breakfast and no lunch money or packed lunch (educational neglect). A family with three children may live in a sparsely furnished apartment with very little food available and only intermittent heat and multiple people coming and going in the residence, while the children may appear at school unwashed and without coats in winter weather (general neglect). Emotional neglect may be seen when demands placed on a child are excessive or inappropriate for her development, or the caretaker berates or verbally humiliates a child frequently and without reason.

Thousands of children in the United States experience neglect each day. They are frequently “invisible” victims. At times, sensational stories of severe child neglect are reported in the media and cause public outrage. Examples include 12 children found among piles of garbage in an abandoned apartment building during a drug raid; parents vacationing in Florida while their two daughters, aged 6 and 4, were left unattended at home; or three young children found barely alive, kept in a basement closet. However, most children suffering from neglect do not make newspaper headlines or television reports. They go to school like others. If they are fortunate, their plight is uncovered by a community health nurse, a teacher, neighbor, or counselor. Because of the invisibility of neglect, its prevalence is hard to estimate. Often cases of neglect are brought to the attention of the proper authority only during the investigation of other forms of abuse or family issues (Display 20.4).

### DISPLAY 20.4

### SIGNS AND SYMPTOMS OF NEGLECT

Neglect may be suspected if one or more of the following conditions exist:

- The child lacks adequate medical or dental care.
- The child is often sleepy or hungry.
- The child is often dirty, demonstrates poor personal hygiene, or is inadequately dressed for weather conditions.
- There is evidence of poor or inadequate supervision for the child’s age.
- The conditions in the home are unsafe or unsanitary.
- The child appears to be malnourished.
- The child is depressed, withdrawn, or apathetic; exhibits antisocial or destructive behavior; shows fearfulness; or suffers from substance abuse or speech, eating, or habit disorders (e.g., biting, rocking, whining).

## Physical Abuse

**Physical abuse** is intentional harm to a child by another person that results in pain, physical injury, or death. The abuse may include striking, biting, poking, burning, shaking, or throwing the child. **Corporal punishment**, which involves violence against a child as a form of discipline, was an acceptable form of discipline earlier in our country's history and is still condoned in some subgroups. Many parents today were raised in families in which physical punishment was used as a form of discipline. Even today, it is not unusual to see a parent slap the hand of a toddler to get his attention after he has been told not to do something several times or to prevent him from touching something that would hurt him more than a slap on the hand. Most families know where to draw the line. Others—especially if they were raised with “the belt” or “the switch”—see no harm in using the same physical disciplinary practices with their children.

Some parents cannot control the degree of physical punishment they give their child. In one case in 2002, a mother repeatedly physically assaulted her young daughter while getting her into the car. The mother's behavior was recorded by the store's parking lot surveillance camera. Intervention and follow-up occurred, including incarceration and counseling for the mother and foster home placement for the child. If physical punishment is administered in anger, while the parent is under the influence of mind-altering substances or out of a sense of frustration, the punishment may cross over to become battering of the child.

C. Henry Kempe identified the **battered child syndrome** in the 1960s, now defined as “the collection of injuries sustained by a child as a result of repeated mistreatment or beating” (United States Department of Justice

[USDOJ], 2002, p. 1). Battered child investigations require thorough follow-up and interviews with caretakers, medical personnel, family members, and school personnel. Investigators should be aware that “A major trait of abusive caretakers is either the complete lack of an explanation for critical injuries or explanations that do not account for the severity of injuries” (p. 4). Display 20.5 lists behavioral indicators of physical abuse (USDOJ, 2002).

## Sexual Abuse

**Sexual abuse** of children includes acts of sexual assault or sexual exploitation of a minor and may consist of a single incident or many acts over a long period. Sexual assault includes rape, gang rape, incest, sodomy, lewd or lascivious acts with a child younger than 14 years of age (in most states), oral copulation, fondling of the child's genitals, penetration of the genital or anal opening by a foreign object, and child molestation. **Sexual exploitation** of children includes conduct or activities related to pornography that depict minors in sexually explicit situations and promotion of prostitution by minors (USDOJ, 2007). **Incest** is sexual abuse among family members who are related by blood (e.g., parents, grandparents, older siblings, aunts and uncles); it constitutes the most hidden form of child abuse. **Intrafamilial sexual abuse** refers to sexual activity involving family members who are not related by blood (e.g., step-parents, boyfriends).

More than 88,000 children were confirmed victims of sexual abuse in 2002, while studies cite victimization as 12% to 25% of girls and 8% to 10% of boys under the age of 18 (Kellogg, 2005). In most reported cases, the father or male caretaker is the initiator, and the victim is a female

### DISPLAY 20.5

## SIGNS AND SYMPTOMS OF PHYSICAL ABUSE

### Types of Injuries

Types of physical abuse injuries include bruises, burns, bite marks, abrasions, lacerations, head injuries, internal injuries, and fractures.

### Behavioral Indicators of Physical Abuse

The following behaviors are often exhibited by physically abused children:

- The child is frightened of parents/caretakers or, at the other extreme, is overprotective of parent or caretakers.
- The child is excessively passive, overly compliant, apathetic, withdrawn or fearful or, at the other extreme, excessively aggressive, destructive, or physically violent.
- The child and/or parent or caretaker attempts to hide injuries; child wears excessive layers of clothing, especially in hot weather; child is frequently absent from school or misses physical education classes if changing into gym clothes is required; child has difficulty sitting or walking.
- The child is frightened of going home.
- The child is clingy and forms indiscriminate attachments.
- The child is apprehensive when other children cry.
- The child is wary of physical contact with adults.

- The child exhibits drastic behavioral changes in and out of parental/caretaker presence.
- The child is hypervigilant.
- The child suffers from seizures or vomiting.
- The adolescent exhibits depression, self-mutilation, suicide attempts, substance abuse, or sleeping and eating disorders.

Other indicators of physical abuse may include the following:

- A statement by the child that the injury was caused by abuse (chronically abused children may deny abuse).
- Knowledge that the child's injury is unusual for the child's specific age group (e.g., any fracture in an infant).
- Knowledge of the child's history of previous or recurrent injuries.
- Unexplained injuries (e.g., parent is unable to explain reason for injury; there are discrepancies in explanations; blame is placed on a third party; explanations are inconsistent with medical diagnosis).
- A parent or caretaker who delays seeking or fails to seek medical care for the child's injury.

child; however, boys are victims more often than previously believed, and adolescents were reported as “perpetrators in at least 20% of reported cases” (Kellogg, 2005). The initial sexual abuse may occur at any age, from infancy through adolescence. However, the largest number of cases involves girls younger than 11 years of age. Regardless of how gentle, trivial, or coincidental the first approach may have seemed, sexual coercion tends to be repeated and to escalate over a period of years. The child may blame himself or herself for tempting or provoking the abuser.

The mother, who is expected to protect the child, may purposely isolate herself from a problem of sexual abuse. Sometimes the mother is distant, uncommunicative, or so disapproving of sexual matters that the child is afraid to speak up. Sometimes she is extremely insecure, and feels confrontation may cause anger or the loss of her husband or boyfriend, or the mother’s economic security may depend on her partner/spouse. The mother may feel threatened or feel that she cannot allow herself to believe or even to suspect that her child is at risk. She may have been a victim herself of child abuse and may not trust her judgment or her right to challenge the man’s authority in the home. Some mothers consciously acknowledge that their children are being sexually abused but, for whatever reason, choose to “look the other way.” Until the victim is old enough to realize that incest or intrafamilial sexual abuse is not a common occurrence or is strong enough to obtain help outside the family, there is little chance of escape unless the abuse is reported (Crime and Violence Prevention Center, 2003b).

Indicators of sexual abuse are seen in various ways, and attention should be given to a history of sexual abuse; sexual behavior indicators; behavioral indicators in younger children, and behavioral indicators of sexual abuse in older children and adolescents, and physical symptoms of sexual abuse (see Display 20.6). As mandated reporters, community health nurses should be aware that sexual abuse of a child may surface through a broad range of physical, behavioral, and social symptoms. Some of these indicators, taken separately, may not be symptomatic of sexual abuse and should be examined in the context of other behaviors or situational factors.

Community health nurses can be part of the (SART). This group’s responsibilities include obtaining the evidence and providing support to the victim and family after an episode of sexual abuse has been reported. Sexual abuse response team members include nurses, physicians, social workers, police, laboratory personnel, lawyers, and district attorney staff. Care for children who have been sexually abused varies, as the duration of the molestation, the age, and symptoms of the child will influence their care measures. “Poor prognostic signs include more intrusive forms of abuse, more violent assaults, longer periods of sexual molestation, and closer relationship of the perpetrator to the victim” (American Academy of Pediatrics, Committee on Child Abuse and Neglect, 1999, para. 24). Parents may also need counseling and support following the investigation and proceedings involving their child’s victimization.

The sexual assault nurse examiner (SANE) role is more explicit in assisting the victim and appropriate family members immediately after the victim presents to the police or to an emergency department setting. The nurse has very specific actions to take to promote trust, obtain needed speci-

men evidence, and treat the sexual abuse victim. The victim has already been significantly traumatized, and the nurse can be effective in this role only if trust can be established during this critical time after the sexual assault. The SANE is trained to work with victims of all ages, both genders, and under all sexual abuse situations.

Although there are several classifications of child molesters, pedophiles present the greatest danger. A **pedophile** is an adult whose main sexual interest is a child. A pedophile tends to be well-liked by children. Pedophiles, who most often are men, frequently choose to work in professions or volunteer organizations that allow them easy access to children, where they can develop the trust and respect of children and their parents. The pedophile believes that sex with children is appropriate and often lures children into sexual relationships with love, rewards, promises, and gifts. He may be among a child’s family members (e.g., grandfather, father, uncle, cousin) or a trusted community leader the child knows (e.g., next-door neighbor, teacher, coach, or religious leader). Recent reports of pedophiles among clergy in the Roman Catholic Church have clearly rocked the church’s status and stability. As of July 2006, the National Sex Offender Public Registry (NSOPR), sponsored through the Department of Justice, is used in all 50 states, thereby improving efforts to safeguard all children (Rape, Abuse, & Incest National Network [RAINN], 2006). This resource provides information regarding the more than 500,000 registered sex offenders throughout the United States.

## Emotional Abuse

**Emotional abuse** of children involves psychological mistreatment or neglect, such as when parents do not provide the normal experiences that produce feelings of being loved, wanted, secure, and worthy (Crime and Violence Prevention Center, 2003c). This type of abuse is commonly associated with other types of abuse, and may involve verbal abuse, such as name calling, belittling, or threatening. A mother may shout at the child, “You’re just like your father, a good-for-nothing, lazy bum.” A father may say, “You’re ugly. You look just like your mother.” If the child spills some juice, a parent may scream, “Everything you do, you do wrong. Can’t you do anything right?”

Emotional abuse may also take the form of emotional abandonment. Some parents “shun” their children as a form of punishment. They will not speak to them and do not look at them; they behave as if their child does not exist. This behavior may continue for a day or longer, whenever a child displeases the parent. In some cases, the shunning lasts for days.

Verbal threats, although a common discipline practice, are also a form of emotional abuse. Examples of verbal threats include, “Take your feet off the furniture or I’ll chop your feet off” and “Do that again, and you’ll really know what my belt feels like.” In the first instance, the child might realize that the parent wouldn’t really chop her feet off, but hearing the parent say such a violent thing can be emotionally scarring. In the second instance, the parent may have beaten the child with a belt in the past, so merely threatening to use the belt again causes emotional trauma.

Emotional abuse alone is rarely reported because it is another “hidden” form of abuse. However, **mandated reporters**, people who have a responsibility for the welfare

## DISPLAY 20.6

## INDICATORS OF SEXUAL ABUSE

**I. History of Sexual Abuse**

- A child confides to a friend, classmate, teacher, a friend's mother, or other trusted adult that she/he has experienced sexual abuse.
- A child may disclose information indirectly by such statements as:  
 "I know someone . . ."  
 "What would you do if . . .?"  
 "I heard something about somebody..."
- The child has torn, stained, or bloody underclothing (among her/his clothing or is wearing it).
- Knowledge that a child's injury/disease (vaginal trauma, sexually transmitted disease) is unusual for the specific age group.
- Unexplained injuries/diseases (parent/caretaker unable to explain reason for injury/disease); there are discrepancies in explanation; blame is placed on a third party; explanations are inconsistent with medical diagnosis.
- A very young girl is pregnant or has a sexually transmitted disease. Pregnancy alone does not constitute sexual abuse, but if there are indications of coercion or significant age disparity between the minor and her partner, this may lead to reasonable suspicion of sexual abuse that must be reported.

**II. Sexual Behavioral Indicators of Sexually Abused Children**

- Detailed and age-inappropriate understanding of sexual behavior (especially among very young children).
- Sexually explicit language.
- Inappropriate, unusual, or aggressive sexual behavior with peers or toys.
- Compulsive indiscreet masturbation.
- Excessive curiosity about sexual matters or genitalia (self or others).
- Unusually seductive or flirtatious behavior with classmates, teachers, and other adults.
- Excessive concern about homosexuality, especially by boys.

**III. Behavioral Indicators of Sexual Abuse in Younger Children**

- Enuresis (wetting pants or bedwetting).
- Fecal soiling.
- Eating disturbances such as overeating or undereating.
- Fears or phobias.
- Overly compulsive behavior.
- School problems or significant change in school performance (attitude and grades).
- Age-inappropriate behavior that includes pseudomaturity or regressive behavior such as bedwetting or thumb sucking.
- Inability to concentrate.
- Sleeping disturbances (nightmares, fear of falling asleep, fretful sleep pattern, sleeping long hours).

- Drastic behavior changes.
- Speech disorders.
- Frightened of parents/caretaker or of going home or being at home.

**IV. Behavioral Indicators of Sexual Abuse in Older Children and Adolescents**

- Withdrawal.
- Chronic fatigue.
- Clinical depression, apathy.
- Overly compliant behavior.
- Over or under reaction (hysteria or cavalier attitude) to a genital exam.
- Poor hygiene or excessive bathing.
- Poor peer relations and social skills; inability to make friends.
- Acting out, running away, aggressive, antisocial or delinquent behavior.
- Alcohol or drug abuse.
- Prostitution or excessive promiscuity.
- School problems, frequent absences, sudden drop in school performance.
- Refusal to change clothes for physical education class.
- Nonparticipation in sports and social activities.
- Fearful of showers or restrooms.
- Fearful of home life as demonstrated by arriving at school early and leaving late.
- Suddenly fearful of other things (going outside or participating in familiar activities).
- Extraordinary fear of males (in cases of male perpetrator and female victim).
- Self-consciousness of body beyond that expected for age.
- Sudden acquisition of money, new clothes, or gifts with no reasonable explanation.
- Suicide attempt or other self-destructive behavior.
- Crying without provocation.
- Setting fires.

**V. Physical Symptoms of Sexual Abuse**

- Sexually transmitted diseases, especially in pre-pubescent girls.
- Genital discharge or infection.
- Physical trauma or irritation to the anal/genital area (pain, itching, swelling, bruising, bleeding, lacerations, abrasions), especially if injuries are unexplained or there is an inconsistent explanation.
- Pain during urination or defecation.
- Difficulty in walking or sitting due to genital or anal pain.
- Psychosomatic symptoms (stomach aches, headaches, chronic pain).

Adapted from the Crime and Violence Prevention Center. (1996). *Child abuse: Educator's responsibilities*. Sacramento, CA: California Attorney General's Office.

## DISPLAY 20.7

## SIGNS AND SYMPTOMS OF EMOTIONAL ABUSE OR DEPRIVATION

Emotional abuse should be suspected if the child displays the following behavioral indicators:

- Is withdrawn, depressed or apathetic.
- Is clingy and forms indiscriminate attachments.
- “Acts out” and is considered a behavior problem.
- Exhibits exaggerated fearfulness.
- Is overly rigid in conforming to instructions of teachers, doctors, and other adults.
- Suffers from sleep, speech, or eating disorders.
- Displays signs of emotional turmoil that include repetitive, rhythmic movements (rocking, whining, picking at scabs).
- Pays inordinate attention to details or exhibits little or no verbal or physical communication with others.
- Suffers from enuresis and fecal soiling.
- Unwittingly makes comments such as “Mommy always tells me I’m bad.”
- Experiences substance abuse problems.

Emotional deprivation should be suspected if the child

- Refuses to eat adequate amounts of food and therefore is very frail.
- Is unable to perform normal learned functions for a given age (e.g., walking, talking).
- Displays antisocial behavior (aggression, disruption) or obvious delinquent behavior (drug abuse, vandalism); conversely, the child may be abnormally unresponsive, sad, or withdrawn.
- Constantly “seeks out” and “pesters” other adults such as teachers or neighbors for attention and affection.
- Displays exaggerated fears.

of children, including public and private school employees; administrators and employees of youth centers and recreation programs; child welfare employees; foster parents; group home and residential facility personnel; social workers; probation workers; health care workers including nurses, doctors, and chiropractors; animal control workers; and personnel working in film development laboratories, are required by law to report *suspected* cases of severe emotional neglect or abuse or deprivation in addition to *suspected* neglect and physical or sexual abuse (Crime and Violence Prevention Center, 2003a, 2003c) (see Display 20.7).

### Specific Abusive Situations

The previous information addressed the major types of child abuse in families, yet other patterns of abuse against children need to be discussed. Shaken baby syndrome and Munchausen syndrome by proxy are fairly rare, but by the time the condition is discovered it is often too late, with the diagnosis made during subsequent visits to the emergency department or at autopsy.

In addition, Internet crimes against children, child abduction, and crimes against children by babysitters are an

increasingly common fear of parents. These types of abuse are occurring more often as children and adolescents have increased time and access to computers, and because both parents (or a single parent) must work, children are spending more time alone or with babysitters. Community concern regarding child abductions by family members or strangers has resulted in the institution of Amber Alert systems in many states. School violence is also an area of increasing concern for families and will be addressed.

### Shaken Baby Syndrome

**Shaken baby syndrome** is the intentional abusive action of violently shaking an infant or toddler, usually child of 2 years or younger (National Institute of Neurological Disorders and Stroke, 2007). The type of damage that occurs to these infants very seldom occurs through play, as in minor falls at play, or as a result of tossing a baby in the air. The classic medical symptoms associated with infant shaking are bilateral retinal hemorrhage, subdural or subarachnoid hematomas, absence of other external signs of abuse, and symptoms that may include breathing difficulties, seizures, dilated pupils, lethargy, and unconsciousness (USDOJ, 2002). These injuries occur from a violent, sustained action in which the infant’s head, which lacks muscular control, is violently whipped forward and backward, hitting the chest and shoulders. According to experts, an observer would describe the shaking as being “as hard as the shaker was humanly capable of shaking the baby” or “hard enough that it appeared the baby’s head would come off” (USDOJ, 2002). Within minutes to hours after the injury, the baby begins to show symptoms such as irritability, lethargy, vomiting, breathing problems, seizures, or unconsciousness. A typical explanation given by the parents or caretakers is that the baby was “fine” and then suddenly went into respiratory arrest or began having seizures—both common symptoms of shaken baby syndrome. Children who survive shaken baby syndrome may require lifelong care (National Institute of Neurological Disorders and Stroke, 2007).

### Munchausen Syndrome by Proxy

Munchausen syndrome is a psychological disorder in which a client fabricates the symptoms of a disease in order to undergo medical tests, hospitalization, or even medical or surgical treatment. Clients with this disorder may intentionally injure themselves or induce illness in themselves. In cases of **Munchausen syndrome by proxy**, a parent or caretaker attempts to bring medical attention to herself by injuring or inducing illness in her child. The following scenarios are typical of these cases:

- ◆ The child’s parent or caretaker brings the child to the emergency department or calls paramedics repeatedly for alleged problems that have no medical basis.
- ◆ The child experiences “seizures” or “respiratory arrest” only when the parent or caretaker is present—never in the presence of a neutral third party or when hospitalized, unless the parent or caretaker reports that the incident occurred in her presence.

- ◆ While the child is hospitalized, the parent or caretaker shuts off intravenous tubes or life-support equipment, causing the child distress, and then turns everything back on and summons help.
- ◆ The parent or caretaker induces illness by introducing a mild irritant or poison into the child's body; chronic ingestion of such substances may cause the child's death.

Health providers, mental health professionals, and attorneys may be involved in working with such cases, requiring careful attention to the history of the illness/injury, the treatment, documentation, and communication with the parent/caretaker. Attention to the child's safety is paramount, although the parent may remove the child from care or take the child to another facility if the caregiver's suspicions are aroused (Stirling, 2007).

### Internet Crimes Against Children

Internet crimes are insidious because they come right into the home. A recent national survey found that annually, one in five youth had been sexually solicited over the Internet (Finkelhor, Mitchell, & Wolak, 2000). Children either unintentionally or intentionally may access an Internet chat room or website developed or used by pedophiles. The perpetrator establishes contact, usually passing himself off as a teen or young man who has similar interests, and states affection for and understanding of the youth's "problems." Eventually, the pedophile either sets up a meeting time and place or engages in sexually explicit dialogue with the minor (USDOJ, 2001b). Many minors find the attention from this stranger inviting or exciting and make plans to meet the person. When this happens, the minor falls victim to this individual who preys on children, putting the child/adolescent at great risk. This computer-based child abuse risk has led the United States Attorney General to authorize a federal awareness and justice program focusing solely on technology-facilitated sexual exploitation and abuse against children, named *Project Safe Childhood* (USDOJ, 2006).

Community health nurses can assist families to prevent such Internet crimes in various ways by:

- ◆ Encouraging placement of "blocks" on computers via the Internet server
- ◆ Urging parents to discuss with their children the dangers of online "friendships" that seek face-to-face meetings
- ◆ Establishing parent-child contracts for Internet use
- ◆ Monitoring the time and Internet sites a child uses
- ◆ Keeping the computer in a high-traffic area in the home, affording easy observation
- ◆ Setting the Internet browser security feature to "high"
- ◆ Installing a firewall, antivirus, and anti-adware/spyware programs that increase privacy
- ◆ Discouraging downloading of games and other media that might contain Trojan or worm programs that enable remote access by unauthorized users (Dombrowski & Gisclhar, 2004)

Furthermore, parents can contact the Cyber Tip Line at (800) 843-5678 or [www.cybertipline.com](http://www.cybertipline.com) if they suspect

that an online predator has contacted their child (Dombrowski & Gisclhar, 2004, para. 5).

### Child Abduction

Child abduction is a crime that every parent fears, and although stranger abduction happens infrequently, it remains the greatest fear for parents. However, intense media coverage gives the impression that such crimes occur frequently, and this causes great stress among parents and community members. Nationally, the Amber Alert program and the Child Abduction Response Teams (CART) were established to provide a prompt and professional response to child abduction (USDOJ, 2005).

Child abduction by family members or intimate partners, such as a divorced mother, father, step-parent, boyfriend, or grandparents, is more common. Nonetheless, the parent from whom the child was taken may be unaware that the abduction was by a relative or known person and may experience the same type of stress and loss as parents who lose a child by stranger abduction. In some cases, knowing the relative or person who abducted the child causes just as much fear, because the abductor may have a history of violence or sexual abuse crimes.

Prevention of child abduction is difficult, and at times parents who think they have taught their children well may have a false sense of security. Some studies assessed the effects on children of taking a "stranger awareness" class. The class included lessons on avoiding strangers, not talking to strangers, identifying who is a stranger, saying "no" to strangers, and running away and screaming if addressed by a stranger. Yet, researchers found that when the children left the classroom, if an unknown person (a stranger sent in by the researcher) asked the child to help him find a lost puppy or go help them get candy, many of the children responded readily without using any of the actions learned in the stranger awareness class. Parents who watched their children on tapes of these studies could not believe what they saw. Children are trusting and curious, and they may not consider people who look like their parents as *strangers*.

Community health nurses can help parents improve their child's safety by promoting close supervision of young children and practicing behaviors that promote anonymity. Ideas that help improve the child's safety include:

- ◆ Holding the child's hand while in malls or stores
- ◆ Keeping the child in the seat of a shopping cart
- ◆ Keeping a young child in sight at all times when playing outside
- ◆ Sharing parental supervision with another mother when children play, so that an adult is always supervising the children
- ◆ Not putting the child's name or initials on clothing or backpacks
- ◆ Teaching the child a "password" that only the parents and child know to use when a different person is picking them up from a neighborhood activity

Older children and teens who go outside the home unattended by parents should be encouraged to use the following behaviors that promote safety: staying with groups of other children or teens, having a cell phone, leaving an itinerary with the parents, and not changing their plans without

contacting parents. Other measures that can benefit older children and adolescents are attending a self-defense class and carrying a whistle and/or pepper spray.

### Crimes Against Children by Babysitters

Crimes against infants and young children by babysitters have been given attention by the media in recent years (USDOJ, 2001a). Some parents who have suspected mistreatment of their children by caretakers have used hidden cameras to reveal the problem. Abuse by caretakers is a fear of parents who must work and leave their children with others.

The community health nurse can help parents assess day care settings by providing them descriptors for finding good day care providers. Parents who use neighbors as babysitters should get references and should drop by the home or day care setting at various times during the day. They should assess their infants and follow-up on any bruises, rashes, burns, conditions, or behaviors they observe that are not normal for their child. With older children, parents need to listen to them and ask about their day and activities. Parents must not ignore signs, such as a child's fear of going to the babysitter or reports of spankings, being shouted at, or other inappropriate treatment. Day care centers and many home day care programs are licensed by the state. Programs for which parent complaints have been filed with licensing agencies are monitored more closely, and the state is mandated to make changes or close the facility if necessary. Parents need to know that their child is safe and cared for when they leave them to pursue their employment or educational activities.

### School Violence

An area of growing concern regarding violence against children has been in school settings. Random shootings and hostage situations in schools over the past decade have fueled fears about the safety of students and promoted research into how to prevent this type of community violence affecting children. The United States Department of Education, Department of Health and Human Services, and Department of Justice have collaborated to provide funding, programs, and trainings that improve school safety through the *Safe Schools Healthy Students* initiative. Six areas identified for attention in building safe school climates are:

- ◆ Creating a safe school environment
- ◆ Providing alcohol, drug, and violence prevention and early-intervention programs
- ◆ Supporting school and community mental health prevention and treatment intervention services
- ◆ Providing early childhood psychosocial and emotional development programs
- ◆ Addressing education reform
- ◆ Designing safe school policies (Safe Schools Healthy Students Initiative, 2006).

### PARTNER/SPOUSAL ABUSE

Adult violence is rooted in childhood violence. A father hits a mother. The mother hits her son. The son hits his sister. The sister hits her little brother. The little brother sets fire to the cat, pulls wings off butterflies, and grows up to be a spouse

## PERSPECTIVES VOICES FROM THE COMMUNITY

### Family Violence

My family was always shouting at each other—it was just the way it was. The hitting—well, that happened, but it wasn't nearly as bad as all that yelling. Now here I am in the same boat all over again—the yelling, the hitting, and I've got this new baby to take care of. I'm just so tired. When the nurse showed up today to check on the baby and me, I swore to myself I wouldn't tell her about the fight we had last night (anyway it wasn't nearly as bad as the other times). Then she looked at me and asked if I felt safe and that was it . . . I said NO before I realized my mouth was even open. I told her that he punched me in the side while I was changing the baby's diaper. She was so kind—she didn't tell me how stupid I was for staying with him, but she did help me look at my options. Since I was holding the baby when he hit me, she said she was required to make a report of child abuse. That was awful news, and I started to cry; but like she said, I could have dropped her or he could have missed me and hit her. I knew he'd be furious when he found out—then I was really in a panic. Well, she told me about a place in town I can stay for a time with the baby, and she helped me make arrangements. I'm so tired and scared, but I know now that I need to keep my baby safe. I still don't know what made me tell the nurse—I guess it was because she asked. I know I'm doing the right thing for me and the baby.

batterer. Although abused girls may grow up to be abusing mothers, more often they grow up to be abused wives. Researchers operationalize domestic violence as punching, grabbing, shoving, slapping, choking, kicking, biting, hitting with a fist or some other object, being beaten, or being threatened with a knife or gun by a spouse or cohabiting partner. See Perspectives: Voices from the Community.

Partner violence often begins during adolescent dating or dating at any age, with a push or shove that at first is overlooked by the girlfriend (Hanson, 2002). As these minor episodes of violence continue, the victim typically feels that she is doing something wrong and attempts to modify her behavior. She also assumes wrongly that once she and her boyfriend are married, these physical assaults will stop automatically or that in time she will be able to “change” him, yet the cycle of violence has already begun.

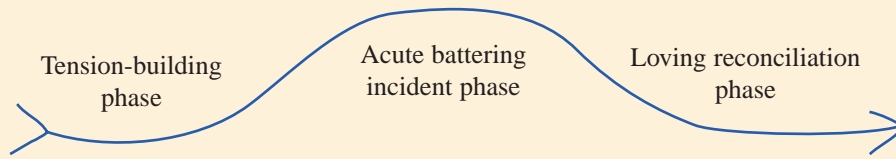

### Cycle of Violence

The **cycle of violence** is a repetitive, cyclic pattern of abuse seen in domestic violence situations. This theory of family violence was first described as a three-phase cycle by Walker in 1979, after she studied more than 1,000 battered women and a smaller group of battering men. The cycle includes the tension-building phase, the acute battering incident, and the

## DISPLAY 20.8

## THE CYCLE OF VIOLENCE

### Tension-Building Phase

The woman senses her partner's increasing tension. She may or may not know what is wrong. The partner is "edgy" and lashes out in anger. He challenges her, calls her names, and tells her she is stupid, incompetent, and unconcerned about him. She "tries hard" not to make any "mistakes" that may upset him. She takes the responsibility for making him feel better, and begins to set herself up to feel guilt when he eventually explodes in spite of her best efforts to calm and please him. During the increasing tension, the woman is rarely angry even at the most outrageous demands or blame. Rather, she internalizes her appropriate anger at the partner's unfairness and, instead, experiences depression, anxiety, and a sense of helplessness. As the tension in the relationship increases, minor episodes of violence increase, such as pinching, tripping, or slapping. The batterer knows his behavior is inappropriate, and he fears the woman will leave him. This fear of rejection and loss increases his rage at the woman and his need to control her.

### Acute Battering Incident

The tension-building phase ends in an explosion of violence. The incident that sets off the man's violence is often trivial or unknown, leaving the woman confused and feeling helpless. The woman may or may not fight back. She may try to escape the violence or call for help. If she cannot escape the beating, she may have a sense of unreality—as if it is a dream. Following the battering, the woman is in a state of physical and psychological shock. She may be passive and withdrawn or hysterical and incoherent. She may not be aware of the seriousness of her injuries and may resist help. The man discounts the episode and also underestimates the woman's injuries. He may not

summon medical help even when her injuries are life-threatening.

### Loving Reconciliation

The loving reconciliation phase may begin a few hours to several days following the acute battering incident. Both partners have a profound sense of relief that "it's over." Although the woman is initially angry at the man, he begins an intense campaign to "win her back." Just as his tension and violence were overdone, his apologies, gifts, and gestures of love may also be excessive. Showering her with love and praise helps her repair her shattered self-esteem. It is nearly impossible for her to leave him during this phase as he is meeting her desperate need to see herself as a competent and lovable woman. The woman's feelings of power and romantic ideals are nurtured. She believes this gentle, loving person is her "real" lover. She believes that if only she can find the key, she can stop him from further violent episodes. She believes that, no matter how often it has happened before, somehow this episode seems different this time and it will never happen again.

### The Increasing Spiral of Violence

One aspect of the cycle of violence of particular concern is its progressive and spiraling nature. Once violence has begun, every study indicates that it not only continues but over time increases in both frequency and severity. As the violence continues, the three-phase cycle begins to change. The tension-building phase becomes shorter and more intense, the acute battering incidents become more frequent and severe, and the loving reconciliation phase becomes shorter and less intense. After many years of battering, the man may not apologize at all.

loving reconciliation (Jenkins & Davidson, 2001). The psychological dynamics of these three phases help explain why women feel so guilty and ashamed of their partner's violence toward them, and why they find it so difficult to leave, even when their lives are in danger (see Display 20.8). Often, as the cycle of violence continues, the frequency of the cycle increases, with the tension-building phase and the acute battering incident occurring more often, and elimination of the loving reconciliation phase. Without intervention, this shorter, more violent cycle becomes increasingly risk-filled for outcomes that may lead to injury or maiming of a partner, incarceration, or death of a partner.

The Domestic Abuse Intervention Project in Duluth, Minnesota, developed a wheel of violence, identifying power and control at the center, and citing eight categories of perpetrator behaviors. This model is a useful tool for visu-

alizing the multidimensional nature of abuse in which threats, coercion, isolation, blaming, intimidation, and use of children, male privilege, and economics convene to control the victim (Fig. 20.1).

## Dating Violence

Dating violence in adolescent relationships is a serious and prevalent problem. Because of its prevalence, community health nurses should include screening for dating violence in all encounters with teens. **Adolescent dating violence (ADV)** includes physical, sexual, emotional, and verbal abuse between teenagers who are or have been in a casual or serious dating relationship (Hanson, 2002). Adolescent dating violence begins on average at age 15 years. About 50% of rape victims are between 10 and 19 years old, which indicates

**FIGURE 20.1** Wheel of Violence.

that teenage girls are vulnerable to the violence of sexual abuse (Jackson, Cram, & Seymour, 2000).

## Partner/Spousal Abuse

**Spousal abuse** is violence against an intimate partner and is pervasive globally. The WHO reported in a multistudy review that 10% to 52% of women reported being physically abused by an intimate partner at some point in their lives, and 10% to 30% of women had experienced sexual violence by an intimate partner (WHO, 2005, p. 1). Because of the nature of **intimate partner violence (IPV)**, the problems are difficult to study and believed to be under-reported. Much remains unknown about factors that increase or decrease the likelihood that men will behave violently toward women, factors that endanger or protect women from violence, and the physical and emotional consequences of partner violence on women and their children.

The United States Department of Justice defines domestic violence as “a pattern of abusive behavior in any relationship that is used by one partner to gain or maintain power and control over another intimate partner” (USDOJ, Office of Violence Against Women, n.d., para. 1). Although domestic violence is categorized as physical abuse, sexual abuse, emotional abuse, economic abuse, or psychological

abuse, the victim commonly experiences a combination of these abuses or threats of abuse in these areas. Intimidation and threats create an atmosphere of fear for the victim and may include humiliation, isolation, terrorizing, coercing, blaming, manipulating, stalking, and/or destruction of property or pets valued by the partner.

Domestic violence is a leading cause of morbidity and mortality in women nationwide, as battering exceeds rapes, muggings, and motor vehicle crashes combined as the leading cause of injury to women age 15 to 44 years (Sheehy, 2000a). Intimate partner violence resulted in nearly 2 million injuries and 1,300 deaths in 2003; while Fox and Zawitz (2004), cited by the CDC, found females accounted for 76% of IPV homicides and males were 24% of IPV homicides (Centers for Disease Control [CDC], 2006a). It is important to note that of those who died from IPV homicide, 44% had been to an emergency department within the last 2 years, and, of those, 93% had at least one injury at that time (Crandall, Nathens, Kernic, Holt, & Rivara, 2004; CDC, 2006a). Health care providers have a responsibility and opportunity to assess and initiate a safety plan when these patients are seen in the emergency room. A compendium of assessment tools for IPV can be found on the CDC website.

*Healthy People 2010* identified the reduction of physical assault by current or former intimate partners as one of the

nation’s health objectives (USDHHS, 2000). In a 1998 survey by the Commonwealth Fund, almost one-third of American women (31%) reported having been physically or sexually abused by a husband or male partner at some point in their lives, whereas for women with disabilities, the abuse ranges from 33% to 83% (Kramer, 2002). Additionally, more than 25% of female homicide victims in the general population are killed by a husband, ex-husband, boyfriend, or ex-boyfriend.

### Violence During Pregnancy

Pregnancy increases a woman’s vulnerability, as 4% to 8% of all pregnant women are abused at least once during the pregnancy (CDC, 2006a; Gazmararian et al., 2000). Abuse is more likely to be reported by pregnant adolescents than pregnant adults and by women with unplanned pregnancies compared with other pregnant women.

Abuse during pregnancy has been linked with maternal health problems such as smoking, decreased weight gain, and substance use (Cokkinides & Coker, 1998). The fetus is also endangered, with spontaneous abortion, preterm delivery, fetal distress, and lower birth weight often seen. Curry, Doyle, & Gilhooley (1998) found that pregnant teens who were abused were more likely to be high school dropouts, smoked more, and experienced more second-trimester bleeding. Once born, the infant of an abused teen or adult is at risk for child abuse.

The most serious aspect of domestic violence as a threat to a woman’s safety is the link between abuse during pregnancy and homicide, called femicide. **Femicide**, the killing of women, is now the leading cause of maternal mortality, rather than medical complications of pregnancy in several cities in the United States. Men who abuse their partners during pregnancy are more likely to own guns or knives

or both, which puts the women at greater risk, and batterings that occur during pregnancy tend to have increased severity (Campbell, 1998, 1999).

Studies indicate that the prenatal care visit is one of the few times when women are seen by the helping professions. This visit is an important opportunity to identify women who are abused and therefore at risk for homicide. It is imperative that nurses conduct an assessment for danger and lethality, so that the women can be aware of their own level of risk and take safety precautions as needed. A series of questions requiring a “yes” or “no” response and inquiries about occurrences of abuse, escalation of abuse, frequency, severity, weapons, drugs or alcohol use by the perpetrator, and safety of other children should be incorporated into prenatal home visit assessments. This is especially important with women who have not followed through with prenatal care, thereby allowing health care professionals to monitor the progress of their pregnancies (Display 20.9).

### Batterer Characteristics

Although men who batter come from all walks of life educationally, culturally, and socioeconomically, perpetrators have some common characteristics. The following attributes represent personal characteristics often seen in batterers:

- ◆ Low self-esteem
- ◆ Low income
- ◆ Low academic achievement
- ◆ Involvement in aggressive or delinquent behavior as youth
- ◆ Heavy alcohol and drug use
- ◆ Depression

DISPLAY 20.9
**DOMESTIC VIOLENCE RISK ASSESSMENT TOOL**

**Frame the Questions**  
 “Because abuse and violence are common in the lives of women, I have begun to ask about it with all women (or all pregnant women). I don’t know if this is a problem for you, but I would like to ask you some questions, talk about ways to reduce your risk of being hurt, and give you some information and phone numbers that might be helpful to you.”

**Universal Questions**

	Yes	No
1. Do you feel safe in your current relationships? Comments: _____	_____	_____
2. Have you ever been physically abused (pushed, shoved, hit, punched, bitten, burned, etc.)? Comments: _____	_____	_____
3. Have you ever been emotionally abused (neglected, called names, controlled, threatened, had your activities or decisions hindered,	_____	_____

been denied resources to meet your physical or financial needs)?  
Comments: \_\_\_\_\_

4. Have you ever been sexually abused \_\_\_\_\_ (forced to have an unwanted sexual act)?  
Comments: \_\_\_\_\_

5. Do you want to talk to someone about \_\_\_\_\_ receiving help?  
Comments: \_\_\_\_\_

Domestic violence: How to ask and how to listen. *Nursing Clinics of North America*, 37(1), 189–210; and Davis, R.E., & Harsh, K.E. (2001). Confronting barriers to universal screening for domestic violence. *Journal of Professional Nursing*, 17(6), 313–320.

- ◆ Anger and hostility
- ◆ Personality disorders
- ◆ Prior history of being physically abusive
- ◆ Having few friends and being isolated from other people
- ◆ Unemployment
- ◆ Emotional dependence and insecurity
- ◆ Belief in strict gender roles (e.g., male dominance and aggression in relationships)
- ◆ Desire for power and control in relationships
- ◆ Being a victim of physical or psychological abuse (consistently one of the strongest predictors of perpetration) (CDC, 2006a, para. 24).

Relationship, community, and societal factors have also been identified that affect a perpetrator's risk for battering. Identified relationship factors include: marital fights and tension, divorce and separations, money problems, and problematic and difficult family relationships, as well as the male's need for dominance and control in the relationship. Societal factors associated with increased risk are strict role stereotyping about the roles the husband and wife should follow in a relationship. Aspects identified within a community that lead to increased risks for IPV may be a lack of resources in the community, a failure or unwillingness of others to intervene or contact authorities when they are aware of the abuse, and factors associated with poverty, such as overcrowding and unemployment (CDC, 2006a).

### Victim Characteristics

Studies have also revealed risk factors associated with victims. Increasing the victim's abilities to manage and improve their behaviors and understanding of relationship patterns and abuse allows victims to change their risk of being a victim. Individual risk factors for IPV victims include:

- ◆ A prior history of IPV
- ◆ Being female
- ◆ Young age
- ◆ Heavy alcohol and drug use
- ◆ High-risk sexual behaviors
- ◆ Witnessing or experiencing violence as a child
- ◆ Being less educated
- ◆ Unemployment
- ◆ For men, having a different ethnicity from their partner
- ◆ For women, having a greater education level than their partner
- ◆ For women, being American Indian/Alaska Native or African American
- ◆ For women, having a verbally abusive, jealous, or possessive partner (CDC, 2006, para. 19).

Marked differences between partner's incomes, levels of education, or job status places a victim more at risk for IPV. Community characteristics are similar to those of the perpetrator, revealing that those communities with fewer available resources, in areas of poverty, and having a lack of sanctions against violent behaviors increases one's risk. Traditional gender roles, such as a belief that men work and women are submissive and should stay home, are societal risk factors associated with higher IPV risk (CDC, 2006a, para. 19).

### Effects of Violence on Children

Children who are exposed to family violence are more at risk for abuse and for violence later in their life as either a perpetrator or victim. Although domestic violence may not be directed at a child, that child may become a victim as a bystander or when trying to protect a parent. Effects of family violence are often seen in emotional, cognitive, physical, and/or behavioral manifestations of the child. Symptoms to be aware of in children are anxiety, hostility, depression, guilt, impaired concentration, confusion, fear of losing control or of a recurrence of the violence, sleep disturbances, nightmares, an exaggerated startle response, psychosomatic symptoms, social withdrawal, distrust, avoidance, or substance abuse (Volpe, 1996).

Most often, wife abuse and child abuse occur together. Literature reviews consistently suggest that a positive correlation exists between children's witnessing IPV and some aspects of impaired child development (Lemmey et al., 2001). Young children are particularly vulnerable to the effects of violence, as they lack the ability to understand the trauma and are likely to exhibit somatic complaints (headaches, eating or sleep problems) and/or behavior regression (clinging, whining, or becoming nonverbal) (Volpe, 1996). Meanwhile, school-age children and adolescents are more likely to either act out with delinquent behaviors or withdraw. It is more common for girls to become withdrawn and an important reason for health care providers to include an assessment for family violence concerns. Children in families with domestic violence are at risk for depression, negative mental health effects, and consequences that last far into their adult lives. These maladjustments may be behavioral (aggression and conduct problems), emotional (withdrawal, anxiousness, fearfulness), social, cognitive (learning disabilities), and/or physical. Providers who work with children need to listen in a sincere, nonjudgmental manner, and provide ongoing support when assisting the child and family with resources, such as counseling, education, or community violence prevention programs (Fig. 20.2).

### MISTREATMENT OF ELDERERS

It is estimated that as many as 10% of older adults are victims of abuse (Gray-Vickrey, 2001). **Elder abuse**, the mistreatment or exploitation of older adults, may involve neglect; physical, sexual, emotional, or fiduciary abuse; or any combination of these mistreatments. Among substantiated cases of elder abuse, 25% involve physical abuse, 49% intentional or unintentional neglect, 35% emotional abuse, and 30% financial or material exploitation. Elders are abused by family members in similar ways that younger family members are abused: by abandonment or neglect (physical or emotional); by physical, sexual, or emotional abuse; or by exploitation. Two-thirds of elder abuse is perpetrated by family members (Kramer, 2002). Adult children, divided between males and females equally, are the most frequent abusers of the elderly. However, spouses who were batterers do not stop at age 65; they commit about 14% of the reported cases of elder abuse in the United States. Victims of elder abuse have a median age of 76.5 years, and 65% of them are White.

## My Daddy is a Monster

He hurts my mommy  
 He hurts me too  
 Sometimes he hits  
 Sometimes he says things  
 That scare me and  
 make my mommy cry  
 after he leaves  
 Sometimes I wish he  
 won't come back ... ever  
 I love my daddy.

National Coalition Against Domestic Violence • P.O. Box 34103 • Washington, DC 20043-4103 • 1-800-799-SAFE

**FIGURE 20.2** Poster of “My Daddy Is a Monster.”

Abuse against elders is not new, but research on elder abuse is new. Until recently, the reasons for elder abuse were extrapolated from the literature on abuse in younger populations. But, by the mid-1980s, more research was being conducted about elder abuse, and the findings indicated that elder abuse results from multiple, interrelated variables associated with the perpetrator or the victim (Menzey, 2001).

Forms of physical abuse were found to include rough handling during caregiving, pinching, hitting, and slapping. Emotional abuse, which can take many forms, included being shouted at or threatened, and having needed care withheld. More rarely, elders are sexually abused, which may include rape. Some elders are neglected by those they depend on to meet their caregiving needs. Elders with dementia and those requiring assistance for all activities of daily living (ADLs) are more at risk because of caregiver stress or burnout, which increases an elder’s risk for abuse and neglect. With neglect, the elder may appear unwashed and unkempt or may suffer from malnutrition and dehydration, or even pressure sores. Elders who are dependent on others for their care often do not report abuse for fear of

being abandoned. They feel powerless and at a loss about how to change a bad situation. They often fear reprisal from the perpetrator if they tell others about the abuse.

Older adults are frequently exploited in a variety of ways. Family members may take their Social Security retirement money, savings, or investments and use these funds on themselves. Criminals often approach elders with get-rich-quick schemes, sham investment opportunities, overpriced home repairs, or as collectors for illegitimate charities, thereby preying on the trusting nature of older adults.

### Perpetrator and Victim Characteristics

The dominant underlying factors that contribute to abuse of an elder by a family member are social isolation and pathology on the part of the perpetrator. Research has identified emotional or financial dependence on the victim, alcohol use, and isolation or few external contacts as major contributing factors. Men are more likely to exploit or physically abuse elders, whereas women are more likely to neglect elders physically or abuse them psychologically. Because women are more frequently the caretakers of elders, they are in a position to provide either appropriate or neglectful care to frail older adults (Menzey, 2001).

Some characteristics of older people appear to increase their risk of abuse. These risks include dementia and poor health (Menzey, 2001). Newly diagnosed cognitive impairment correlates with occurrences of abuse. If violence or threats of violence by the elder toward the caregiver accompany dementia, this contributes to elder’s risk for abuse. The failing health of an elder may also contribute to self-neglect or diminished ability for self-defense or escape from maltreatment. Finally, if the abuser and victim live together, the close proximity can bring up unresolved family conflicts or create new conflicts and tension (Menzey, 2001).

### Risk Factors

Regardless of the type of abuse an elder suffers or the motivation of the abuser, two factors are common to all elder abuse situations. The first factor is the *invisibility* of elders in general and of abused elders specifically. It is estimated that fewer than 10% of elder abuse cases are reported. In 1988, Pillemer and Finkelhor found that only one of every 14 cases of elder abuse came to public attention in Massachusetts, a state with model reporting laws. Reasons for invisibility among the elderly are multifaceted. Older people usually have less contact with the community. They are no longer in the workforce or in public on a regular basis, which keeps their problems hidden longer. In addition, older adults are reticent to admit to being abused or neglected. Because the abuser is most often a family member, the elder desires to protect the abuser; without this abusing family member, the elder may be entirely alone. On the other hand, the elder may fear reprisal from the abuser for coming forward with a self-report of abuse or telling someone about the home situation. Cultural and societal values also contribute to keeping “family matters” private, while shame and embarrassment make it difficult for many elders to tell others of the abuse (American Psychological Association, 2007).

The second risk factor is the *vulnerability* of older adults. Many elders who are frail are dependent on others for

some aspect of their day-to-day survival. At first, they may need to rely on others for transportation, shopping, and housekeeping. Later, they may need help with financial affairs, cooking, and laundry. In time, the elder may need help managing medications, bathing, and eating. The degree to which an elder needs assistance is often kept hidden from others because the elder person fears being removed from his present living situation and being placed in a more restrictive environment. Additionally, vulnerability in elders is increased when any of the following characteristics are present: (a) impairment and isolation, (b) poverty and pathologic caregivers, (c) learned helplessness and living in a violent subculture, and (d) living in deteriorating housing and crime-ridden neighborhoods.

## Prevention of Elder Abuse

Awareness of elder abuse and education about the types of abuse via media campaigns has improved community awareness of the problem. The unique care needs for elders, resources for the elderly, along with recognition of the need for respite for caregivers has also received increased attention and services. Training for caregivers as well as health care and social service providers that focus on recognizing stress and initiating measures for intervening has developed new understanding of effective interventions (e.g., use of physical therapists, occupational therapists, and geropsychiatrists). Statutory requirements for reporting abuse and providing crisis hotlines for reporting elder abuse are also integral aspects of a community's response to the problem of elder abuse (American Psychological Association, 2007).

## OTHER FORMS OF FAMILY VIOLENCE

Three other forms of violence that directly affect families are suicide, homicide, and rape. These three forms of violence demonstrate the ultimate extreme of violence to the victim and are the most traumatic to the surviving family members.

### Suicide

**Suicide** is taking action that causes one's own death. In the United States, suicide is the 11th leading cause of death, as more than 31,000 people kill themselves each year (CDC, 2006b). Not all suicide attempts are successful and each year over 425,000 people are treated in emergency rooms from self-inflicted injuries (CDC, 2006b). These attempts to cause or actually cause self-harm are known as *parasuicidal acts*. Gender has an influence on suicide rates and fatalities—men are four times more likely than women to die, yet women are three times more likely than men to report a suicide attempt (CDC, 2006b). The *Healthy People 2010* goal is to reduce suicides to not more than 6.0 per 100,000 people, yet in 2004, there were 32,439 suicides, a rate of 89 suicides/day, or one suicide every 16 minutes (American Association of Suicidology, 2006).

Worldwide, the suicide rate has been increasing for the past 45 years. In 2000, “a global mortality rate of 16 per 100,000 people, or one death every 40 seconds” occurred, which translates to nearly 1 million people (WHO, n.d., Suicide prevention [SUPRE], para. 1). The estimate for suicide

attempts is up to 20 times more frequent than the fatality rate. Older men have traditionally had the highest suicide rate, although a noted increase in younger people is occurring in both developed and developing countries (WHO, para. 3). Ninety percent of suicides are associated with mental disorders, the most common are depression and substance abuse, which commonly occur during times of individual or family crisis (e.g., loss of a loved one, loss of employment) (WHO, para. 4).

It is important to be aware of warning signs of potential suicide when working with people in crisis. Threats or comments that indicate a plan or giving personal items away are potential indicators of a person contemplating suicide. Access to guns increases one's risk regardless of age, gender, or ethnicity because firearms are the most utilized method of suicide. Health providers and others may find *IS PATH WARM*, a mnemonic from the American Association of Suicidology (AAS), is helpful when looking at possible warning signs for suicide. These signs are:

- I— ideation
  - S— substance abuse
  - P— purposelessness
  - A— anxiety
  - T— trapped
  - H— hopelessness
  - W— withdrawal
  - A— anger
  - R— recklessness
  - M— mood change
- (American Association of Suicidality [AAS], n.d.)

Completed suicides are carried out in a variety of ways, some more violent than others. Women usually choose less violent methods, such as overdosing on medications. Men choose more violent forms of suicide, such as hanging, use of firearms, or vehicle crashes. Deaths from suicide are under-reported because of a tendency to group them as accidental deaths or deaths from undetermined causes.

Community awareness campaigns and education programs are needed to help a person recognize the risks and the importance of initiating prevention for someone who is suicidal. Crisis hotlines with 24-hour access are a vital resource for a distraught individual, friend, or loved one to contact and find help during a crisis and to learn about local resources to contact. Appropriate and consistent treatment, most often a combination of antidepressants and psychotherapy approach, is needed for those suffering from depression, because individuals with a major depressive disorder have approximately a 20 times higher risk for suicide than the general population (AAS, 2007). The surviving loved ones require attention to their grief and bereavement. Support groups often provide benefits, allowing the bereaved to share their intense feelings of guilt and learn how to deal with any sense of a stigma, embarrassment, or shame felt by the survivors.

### Homicide

**Homicide** is any non-war-related action taken to cause the death of another person. Violence has historically been associated with crime and is generally categorized by the method or age group affected. The WHO cites, “On an average day,

1,424 people are killed in acts of homicide, almost one person every minute” (2002b, para. 2). More shocking is the report that violence is the leading cause of death for those from ages 15 to 44 years, and precipitating factors are often fighting, bullying, and drunkenness (para. 5).

In the *Healthy People 2010 Midcourse Review*, the homicide rate between 1999 and 2002 increased to 6.1 deaths per 100,000 population (up from 6.0 deaths/100,000), while leading researchers and public health providers continue their efforts toward understanding these trends (Office of Disease Prevention and Health Promotion, n.d., p. 15-8). In the United States, homicide was the 15th leading cause of death in 2004, with 17,357 deaths (Minino, Heron, Murphy, & Kochanek, 2007, Table 2). Many homicide casualties are victims of domestic abuse as the cycle of violence escalates; a partner may be killed during a violent episode or by a recruited third party. Homicide in young infants and children is most often perpetrated by the parent, step-parent, or caregiver. Conflict between adolescent males may escalate if weapons or guns are available, resulting in homicide.

Evidence suggests that violence can be prevented by measures aimed at individuals, families, and communities. Although biologic and personal factors may influence one's predisposition to violence, an interaction between one's family, community, cultural, and other factors combine to create violence (WHO, 2002b). The WHO cites four key steps in developing a public health approach to violence; these steps are:

- ◆ Uncovering as much knowledge as possible about all aspects of violence
- ◆ Investigating why it occurs
- ◆ Exploring ways to prevent violence
- ◆ Taking action, which includes disseminating information, and evaluating programs' effectiveness (WHO, 2002a, p. 1)

Prevention methods include education programs for pre-school, school-age children, and adolescents to decrease bullying and improve social skills; parent education courses and parent resources such as advice lines, support groups, or a crisis nursery; and community measures that improve firearm safety and reduce firearm injuries (WHO, 2002b).

## Rape

**Rape** is an act of aggression in which the perpetrator is motivated by a desire to dominate, control, and degrade the victim. Once considered an act of sexuality, rape is now believed to be a combination of domination and sexuality, or defined as a “sexual expression of aggression.” The National Violence Against Women Survey (NVAWS) working with the CDC and National Institute of Justice, reports that 302,091 women and 92,748 men are raped each year in the United States. Furthermore, the survey estimates that one in six women and one in 33 men have been a rape victim at some time during their life, with over half of all rapes occurring before the age of 18, and one-third of the rapes occurring before age 12 (CDC, 2004). Rape, in more than eight of ten cases (83%), is perpetrated by someone the victim knows (CDC, 2004).

The violence of rape creates physical and psychological harm for the victim and those close to them. Health problems for the victim may include head, pelvic, back or facial

pain, depression, suicidal ideation, eating disorders, gastrointestinal disorders, or substance abuse (CDC, 2004). Fear, anxiety, or shame may become debilitating for the victim. Counseling and professional care are necessary for the rape victim from the time the rape is reported through any legal process that may result.

Community measures useful in preventing rape include rape prevention education (RPE) programs for adolescents and college students, date rape education, hotlines staffed to provide help for victims of rape or violence against women, and having trained professionals, such as a sexual assault response teams (SART) on hand (CDC, 2004). SART members are trained to understand the psychological and physical assessment needs of the victim, as well as the legal requirements for an investigation and court proceeding. Rape crisis centers and state sexual assault coalitions work together with law enforcement, health care providers, and community-based organizations (CBOs) to provide community education, and care and support to victims.

## LEVELS OF PREVENTION: CRISIS INTERVENTION AND FAMILY VIOLENCE

Family violence is a family crisis and needs intervention. Community health nurses are in a unique position to prevent, identify, and intervene during crisis situations. Because community health nurses encounter people in their own settings, a more accurate assessment with direct observation, discussion, and intervention can occur. The community health nurse's assessment skills, familiarity with the community, and access to resources, enhances her ability to help families in crisis. By using the three levels of prevention, the nurse can begin to assist families in a variety of ways to counter problems arising from domestic violence.

### Primary Prevention

The cycle of violence within the family can be interrupted. Even when partners, spouses, or parents have been brought up in violent homes by abusive parents, they can learn to rechannel and control their emotions and behaviors and use more appropriate coping strategies. Primary prevention is the most effective level of intervention in terms of promoting clients' health and containing costs. Primary prevention reflects a fundamental human concern for well-being and includes planned activities undertaken by the nurse to prevent an unwanted event from occurring, to protect current health and healthy functioning, and to promote improved states of health for all members of a community. For the community health nurse, any activity that fosters healthful practices will counteract unhealthy influences, thereby empowering an individual or family help prevent a crisis. Health promotion must take into account the physical, psychological, sociocultural, and spiritual needs of the individual and family.

Opportunities for families to improve relationships with their partner or spouse and children may begin with learning social problem-solving skills. Both partners benefit by participating in these learning sessions/opportunities. Assertiveness skills for women provide a foundation on which additional empowerment can build. Many people have not learned positive problem-solving skills that are socially acceptable, while women may have learned passivity

and submissiveness in response to their own childhood parenting or from an abusive upbringing.

Healthy self-esteem improves education and occupational success. If poverty is a factor related to the violence, adequate educational preparation and having a successful employee role may eliminate this stressor. Violence occurs across all socioeconomic levels; however, if a family is so impoverished that its basic needs cannot be met, stress can lead vulnerable family members to seek illegal ways to solve their financial problems. Living in neighborhoods where criminal activity is common often leads to increased violence and risk of abuse.

Parenting, one of life's most difficult roles, influences children in their coping strategies, decision making, and sense of self-confidence. Parenting classes are an important resource to assist parents, particularly parents who are at high risk, such as teens, people with no exposure to children in their upbringing, and people raised in violent and abusive families. Parenting classes offer an opportunity for parents to share information and the stresses of parenting, while learning new strategies for managing their children's behaviors and appropriate physical, emotional, and developmental expectations for their children's ages.

Community health nurses often make home visits to families based on referrals from hospital perinatal departments. During the mother's postpartum stay, a nurse may have noted some inappropriate parenting behaviors or that the parents may meet high-risk parameters set by the hospital, such as being age 17 or younger, being a single parent, or having a history of substance abuse. On the first few visits to the family, the nurse can assess parenting skills and need for further teaching. If a parenting class is recommended, the course should cover age-appropriate content, such as safety, breast-feeding, formula preparation, food progression, anticipatory guidance for growth and development, discipline techniques including behavior modification and time-out, well-baby care, and immunizations. Additional benefits for the parents are the social support they receive from participating with other parents and having the opportunity to share their needs and concerns about child-rearing.

Home visiting has been formalized into public health nursing model programs around the country, based on two decades of work by David Olds and others. This model program has shown that nurse follow-up and interventions during the pregnancy and for the first 2 years of the child's life was effective in preventing child abuse, decreasing the mother's reliance on government assistance, having mothers with longer spacing between their children and fewer subsequent pregnancies, and improving health habits, such as less smoking by mothers (Olds et al., 1988, 1997, 1999, 2004). In these programs, a nurse visits the mother and child on a regular basis over 1 to 3 years, teaching and role-modeling parenting techniques, providing needed support, and initiating necessary referrals.

The interrelatedness between families and communities cannot be overlooked or underestimated. Neighborhoods need to be enfranchised, developed, and attentive to the needs for health and safety for all community members. Empowered families can take back their neighborhoods from criminals, and their empowerment acts as a source of growth for other families.

## Secondary Prevention

Early diagnosis and prompt treatment of the effects of family crisis or violence is the focus at a secondary level of prevention. Secondary prevention seeks to reduce the intensity and duration of a crisis and to promote adaptive behavior. By creating a positive relationship with family members and seeing them in their homes, the community health nurse can often uncover and intervene in a crisis or stop abusive situations.

People in crisis need help. Often they desperately want help. The crisis or violence and its associated disequilibrium has a twofold effect on the individuals involved: it renders them temporarily helpless and unable to cope on their own, and it makes them especially receptive to outside influence. Community health nurses can implement crisis resolution models to assist clients at the secondary level. The following process has been used successfully in the mental health field by those working on crisis hot lines, in mental health centers, or in emergency departments. These steps are:

1. Establish rapport.
2. Assess the individual and the problem for lethality.
3. Identify major problems and intervene.
4. Deal with feelings.
5. Explore alternatives and coping mechanisms.
6. Develop an action plan.
7. Follow up, including anticipatory planning for coping with future crises (Aguilera, 1998).

People in crisis will seek and generally receive some kind of help, but the nature of that help may act in favor of or against a healthy outcome from which the participants can grow and evolve. A client's desire for assistance gives the helping professional a prime opportunity to intervene; this opportunity also presents a challenge to make the intervention as effective as possible. Behaviors found to be helpful in these interventions include the following:

- ◆ *Respect confidentiality.* Discussions must occur in private, without other family members present or in within the proximity for hearing. Confidentiality is essential to build trust and ensure the client's safety.
- ◆ *Believe and validate the client's experiences.* Listen to and believe him. Acknowledge the client's feelings and validate that many others have had similar experiences.
- ◆ *Acknowledge any injustice.* In the case of violence, acknowledge that no one deserves to be abused.
- ◆ *Respect clients' autonomy.* Respect their right to make life decisions, particularly regarding whether to involve the police. Validate and respect clients' choices. They are the experts in their lives.
- ◆ *Help the client plan for future safety.* What past strategies have been successful for self-protection? Does the client have a safe place to escape to if necessary? If children are involved, what plans are available to protect them? Help clients to recognize danger in their lives.
- ◆ *Promote access to community services.* Know the resources in your community. Is there a shelter for battered or homeless clients? A domestic violence

hotline? A rape crisis center? Give clients the appropriate phone numbers (Davis & Harsh, 2001; Kramer, 2002).

One goal of crisis intervention should be to help clients reestablish a sense of safety and security while allowing them to ventilate their feelings and have those feelings validated. This process helps reestablish equilibrium at as healthy a level as possible and can result in client change and growth. Minimally, the goal is to resolve the immediate crisis and restore clients to their pre-crisis level of functioning. Ultimately, however, intervention seeks to raise their functioning to a healthier, more mature level that will enable them to cope with and prevent future crises. As discussed earlier, crises tend to be self-limited; intervention time generally lasts from 4 to 8 weeks, with resolution, one way or another, within 2 or 3 months (Aguilera, 1998). The urgency of the situation represents a window of opportunity that invites prompt, focused attention by the client and nurse in working together to achieve intervention goals.

Special programs for children who live in homes where crises and violence are chronic include Head Start programs for pre-kindergarten children who meet certain socioeconomic characteristics. These programs are designed to give children social and academic stimulation, thereby increasing their skills for when they enter kindergarten. Other programs for social skills development may include a Special Friends program explicitly for children who have survived abusive situations, or primary intervention programs (PIP), in which the child works with a trained, supportive, and caring adult.

Abuse survivors and those living in homes with domestic violence experience multiple developmental and psychological problems. Children who are experiencing academic and social failure should receive ongoing services as needed through their elementary, middle, and high school grades. Early identification and intervention with conduct-disordered youth ensures that appropriate resources are obtained and, hopefully, that behavior outbursts and violence will be eliminated. School nurses are important interprofessional team members in providing assessments and programs for these youth.

Intervention at the secondary level for adults who experience abuse focuses on women and their children. Shelters for women and children are available in most communities and offer a variety of services, including counseling, classes in self-esteem building and assertiveness training, referrals to or programs for job training, and even money/budgeting and time management classes. Some shelters offer programs that last up to 2 years with progressive independence and employment skill development while the women and their children live in a protected home environment with their addresses kept confidential from abusers.

Depending on the situation that brings the woman to a shelter, the perpetrator may or may not be incarcerated or on probation. If arrested during the most recent violent episode, the abuser may be released, on parole, or incarcerated. Even while incarcerated, the abuser may be able to take part in an anger-management class, psychological counseling, substance abuse treatment, Alcoholics Anonymous (AA) meetings, or Narcotics Anonymous (NA) meetings. Visits between the abuser and the children are supervised, if that is part of a court order.

At times, the nurse may be responding to a referral regarding suspected abuse; at other times, an abusive or neg-

lectful situation may be uncovered on a home visit made for another reason. In any case, the community health nurse has an important role in reporting suspected abuse and encouraging the child, partner/spouse, or elder to go to the appropriate facility to seek care and to file required documentation about the abuse (see From the Case Files).

### Reporting Abuse

All states have reporting laws for suspected abuse, although states differ on aspects of the timeline for reporting, who to notify, and the sequence of events. The following steps represent one state's guidelines for reporting suspected child abuse (Crime and Violence Prevention Center, 2003b):

1. All mandated reporters must report known or suspected abuse.
2. Immediately, or as soon as reasonably possible, a local child protective agency (police department after normal working hours) must be contacted and given a verbal report. During this verbal report, mandated reporters must give their name—which is kept confidential and may be revealed only in court or if the reporter waives confidentiality (others can give information anonymously)—the name and age of the child, the present location of the child, the nature and characteristics of the injury, and any other facts that led the reporter to suspect abuse or that would be helpful to the investigator.
3. Within 2 working days, a written report must be completed by the mandated reporter and filed. If a mandated reporter fails to report known or suspected instances of child abuse, she may be subject to criminal liability, punishable by up to 6 months in jail or a fine of \$1,000.

Similar steps are required for nurses when reporting elder abuse. Cases of maltreatment and neglect among elders are reported to a local area agency on aging, Adult Protective Services, or to the police, and a screening/documentation form is used to gather and record pertinent information. Guidelines for filing the report and agency notification are specific within each state.

In cases of partner/spousal abuse, adults who are mentally competent cannot be removed involuntarily from the abusive situation. The community health nurse can encourage the victim to leave the perpetrator for the victim's safety until the perpetrator gets professional help, and can give information regarding community resources, such as a shelter for women and children. If the adult has a life-threatening injury or illness, medical follow-up must be encouraged; however, the victim may still be reluctant to seek help. At times, another family member or neighbor who witnesses the abusive event calls 911; when the police and paramedics arrive, the victim may have support to seek care and needed protection. A domestic violence screening/documentation form is completed by the nurse as a part of the official health records for the client.

### Tools

Assessment of suspected abuse cannot be overemphasized. The community health nurse may be the only person entering the home of a family in crisis where abuse is occurring.

## From the Case Files I

### Community Health Nursing and a Potential Family in Crisis

You are a community health nurse working for Smithville Health Department. You are following up on a referral from a community clinic's family planning clinic. The referral was made for a 19-year-old woman, Sandy, who presented in clinic and exhibited inappropriate behaviors with her 6-month-old daughter. In their referral, staff stated that they observed the mother shouting at the child, accusing her of "being spoiled rotten." They added that the mother appeared quite anxious and seemed to have difficulty waiting the 15 minutes for her examination. Although the behaviors described in this referral were insufficient to warrant a report to social services, the staff felt that this young mother would benefit from intervention on the part of the nurse.

You prepare for this home visit by reviewing the medical records of both Sandy and her child to determine whether the family has had previous involvement with social service agencies such as child protective services. You find that the maternal grandparents made a referral to Child Welfare on behalf of Sandy when she was 15. They were concerned about the relationship between Sandy and her step-father. The report cited suspected sexual involvement between the two. An investigation occurred but was inconclusive, and the charges were never pursued.

You also discuss the case with family planning and immunization clinic staff, since the family receives services at both clinics. The staff advise you that they are familiar with Sandy and her husband Nick. They state that their only interaction with Nick was during a family planning clinic 2 months ago. They report that Sandy appeared anxious and in a hurry on that day, stating, "I really need to hurry, Nick is waiting in the car and he gets impatient." Shortly after that, the staff tells you, Nick came running into the clinic shouting, "What the hell is taking you people so long?" He reportedly glared at Sandy, and the two quickly exited the clinic.

You phone the client and advise her that you are a nurse with the local health department. You inform her that nurses often visit new mothers to assist them in finding resources. You add that as a community health nurse, you will be available to talk with her about her child's growth and development.

The client expresses interest in the visit and states, "I want you to show me some things about feeding her and stuff. I need help figuring out what to do at night, she still isn't sleeping much and it's driving me crazy." You advise the client that you will be happy to discuss those issues with her, that you will bring information which you will review with her. You add that you noted in her medical record that the father of the baby is living in the home and assure her that she may involve other family members, including the father of the baby, in the home visit. You jointly decide that the visit will occur the following day at 10:30 a.m. and that the father of the baby will be present if his work schedule allows.

On the day of the visit, as you walk up the stairs toward the apartment, you notice someone looking at you through the curtains. As you near the apartment door the curtains close. Your repeated knocking on the door is met with no response. You call the client's name but there is no answer.

### Questions

1. Would this scenario provoke anxiety for you? How would you deal with your reaction?
2. How is this different from a scenario in the acute care setting in which a supervisor would be readily available?
3. Given this scenario, what actions will you take?
4. If you had been working in the family planning clinic on the day that Nick came in, what, if anything, would you have done differently?
5. As young parents, Nick and Sandy are part of an aggregate that has unique risk factors for parenting. List as many of these risk factors as you can think of and brainstorm about possible community health nursing interventions for each.
6. What methods would you suggest the clinic staff utilize to detect signs and symptoms of physical, sexual, or emotional abuse among this aggregate?

Asking the right questions, being a careful observer, and following the correct reporting process and recording procedures may mean the difference between life and death for a victim of violence.

Displays 20.10, 20.11, and 20.12 consist of three sample tools that the community health nurse and other advocates use in their role as a mandated reporter. These forms include a Suspected Child Abuse Report, a two-page Med-

ical Report of Suspected Child Abuse, and a Domestic Violence Screening/Documentation Form.

### Tertiary Prevention

Tertiary prevention focuses on the rehabilitation of the family from the violence and crisis they have sustained. The family may never again have the same connections because

partners may separate—by choice, motivated by fear or hatred; by court order, if the perpetrator is incarcerated; or by death. If the family chooses to stay together, long-term intervention for all family members is needed to establish a climate more conducive to family normalcy. Many of the services discussed as part of the secondary level of prevention are continued into the tertiary prevention phase to promote healing and to restore and promote family growth.

If incarceration is a part of tertiary prevention, the effects of having one family member living in this environment must be factored into the services and support provided by the community health nurse to the family as a whole (see Chapter 30 for information on correctional facilities). Even if the partner/spouse has separated from the perpetrator emotionally and/or legally, the perpetrator usually has legal rights to see the children. This may mean that other family members, usually from the abuser's side of the family, can bring the children to the prison to visit their parent. Just making arrangements for these visits can cause stress to the visitors. The community health nurse needs to be aware of the complicated dynamics and emotional stress such difficult situations can produce for all family members. The victim–perpetrator relationship is as complex as the forces that created the violence and abuse.

## FAMILIES FACING VIOLENCE FROM OUTSIDE THE FAMILY

The concern of violence coming into the family from outside the home, often beyond the family's control, is a relatively new phenomenon in the United States. There has always been some degree of violence that affects families in their homes, such as burglaries, or at times murder, or abduction. Increasingly, however, home invasion, a form of forced entry to terrorize family members, is a violent crime perpetrated most frequently by strangers. Other forms of violence of which families are more aware include the potential for terrorist activities through planned community violence (such as the plane crashes on September 11, 2001), biologic, chemical, or radioactive actions (see Chapter 17). Communities have developed resources such as the National Organization for Victim Assistance (NOVA) and crisis response teams (CRT), to assist individuals and groups experiencing a disaster or violent event (e.g., child murder or school shootings).

Home invasion is an increasing new form of terror. It occurs mainly in large cities, although rural areas are not immune. **Home invasion** is the purposeful and sudden entry into a home by force while the family is home and awake. The effectiveness of this form of terror relies on surprise. Motivation may be material or thrill; household belongings are frequently stolen while family members are incapacitated by being bound, blindfolded, and/or gagged. In some cases, family members are killed. Often the perpetrators are under the influence of drugs or alcohol, and at times the violence may be gang related.

The community health nurse most likely will not encounter families who have experienced such violence. However, nurses may work with extended family members of the victims or families who have reported such a happening in their neighborhood and are now fearful of a recurrence. Fear of violence can create psychological and physi-

ologic stress reactions similar to the sensations that occur when one actually experiences the violence. These fears should not be ignored. The role of the nurse includes four steps discussed in the generic approach to crisis intervention (see discussion in “Generic Approach”).

## METHODS OF CRISIS INTERVENTION

Crisis intervention in community health nursing uses either a generic or individual approach, or both. For the majority of crisis encounters, the generic approach is more appropriate. Family violence is a major situational crisis in which community health nurses intervene. However, many other situational and developmental crises affect families, and these families are benefited by the skills of the community health nurse. Newly recognized crises include community violence coming into the home and the potential of terrorism at home.

### Generic Approach

The generic approach creates interventions to fit a particular type of crisis, focusing on the nature and course of the crisis rather than on the psychodynamic of each client (Aguilera, 1998). Crisis intervention using the generic approach is tailored to a specific kind of crisis, situational or developmental, and comprises four important elements: (1) use of adaptive behavior and coping strategies, (2) support of the individual/family, (3) preparation for the practical and emotional future, and (4) anticipatory guidance.

As an example, the generic approach is used with families experiencing child abuse. The child may be in foster care while the family receives needed services and rebuilds itself. The nurse encourages the parents to discuss and analyze their feelings, teaches stress-reduction techniques and positive coping skills, and creates a supportive, caring atmosphere, especially through self-help groups such as Parents Anonymous. The nurse can help individual family members strengthen their self-esteem by encouraging positive interpersonal relationships. The community health nurse also teaches needed parenting skills, providing anticipatory guidance, so that parents are prepared to raise their children with consistent and age-appropriate discipline techniques.

The generic approach does not require advanced professional psychotherapy skills. More importantly, this approach works well with families, groups, and even communities in crisis. The community health nurse may work with a group of cancer clients, abused elders, adolescents struggling with developmental crisis, or an entire community recovering from a natural or man-made disaster. The generic approach allows the nurse to intervene with any group of people who have a crisis in common. This approach also offers a broad base of support, because the crisis group members can provide resources for one another beyond those brought by the nurse.

### Individual Approach

The individual approach is used for clients who do not respond to the generic approach or who need special therapy. Individual crisis intervention should not be confused with individual psychotherapy, which tends to focus on a client's developmental past. In contrast, crisis intervention directs

treatment toward the immediate state of disequilibrium, identifying its causes and developing coping mechanisms. Family members or significant others are included during the process of crisis resolution. An entire group may need this type of intervention. If this approach is needed, clients should be referred to a professional with specialized training.

### ROLE OF THE COMMUNITY HEALTH NURSE IN CARING FOR FAMILIES IN CRISIS

Crisis intervention in community health assumes that clients have resources. If their potential for managing stressful events can be tapped, people in crisis will need minimal direct assistance. In accordance with the self-care concept, crisis intervention seeks to identify and build on client strengths. Aguilera (1998) outlined a series of four steps for intervention during crisis: assessment, planning, intervention, and resolution. Interventions to promote crisis resolution are presented using the three levels of prevention in Table 20.2.

#### Assessment and Nursing Diagnosis

Initially, the nurse must assess the nature of the crisis and the client’s response to it. How severe is the problem, and what risks are the clients facing? Are other people also at risk? Assessment must be rapid but thorough and focused on specific areas.

First, the nurse concentrates on the immediate problem during the assessment. Why have clients asked for help right now? How do they define the problem? What precipitated the crisis? When did it occur? Was it a sudden accidental or situational event, or a slower developmental one?

Next, the nurse focuses on the clients’ perceptions of the event. What does the crisis mean to them, and how do they think it will affect their future? Are they viewing the situation realistically? When a crisis occurs to a family or group, some members see the situation differently from others. During intervention, all family members should be

encouraged to express themselves, to talk about the crisis, and to share their feelings about its meaning. Acceptance of the wide range of feelings is important.

Determine who is available to offer support to the individual or family. Consider family, friends, clergy, other professionals, community members, and agencies. Who are the clients close to, and who do they trust? One advantage of group intervention is that the members provide some of this support for one another. In subsequent sessions, the quality of support should be evaluated. Sometimes a well-meaning individual can worsen the situation or deter clients from facing and coping with reality.

Finally, the nurse assesses the clients’ coping abilities. Have they had similar kinds of experiences in the past? What techniques have they tried in this situation, and if they did not work, why not? Clients should be encouraged to think of other stress-relieving techniques, perhaps ones they have used in the past, and to try them.

The nurse gathers all of this data and mentally begins to form nursing diagnoses. As a plan of care is developed for the client, these nursing diagnoses are formalized in writing. Standardized nursing diagnoses are available for reference, or the agency where the nurse works may have a preferred format for nursing diagnoses. These nursing diagnoses are effective tools for the nurse to begin planning interventions.

#### Planning Therapeutic Interventions

Several factors influence clients’ reaction to crises. Nurses should try to determine what factors are affecting clients before making intervention plans. The major balancing factors—clients’ perceptions of the event, situational supports, human resources, and clients’ coping skills—have been assessed in the first step (Aguilera, 1998). While continuing to explore these, the nurse now also considers the clients’ general health status, age, past experiences with similar types of situations, sociocultural and religious influences, and the actual assets and liabilities of the situation. This assessment helps clarify the situation and gives the nurse an

TABLE 20.2 Levels of Prevention to Promote Crisis Resolution

Phase	Goals	Interventions
Precrisis	Health promotion Disease prevention Education	PRIMARY PREVENTION
		Anticipatory guidance Reduce factors that increase vulnerability Reduce hazards in some events (safety and multiplicity of stressors) Reinforce positive coping strategies Mobilize social support and other resources
Crisis	Reduction of stress load Cure or restoration of function	SECONDARY PREVENTION
		Assist with reaction to the event and functioning Allow behavior: dependence, grief Set goals with client Refer to resources
Postcrisis	Rehabilitation and maintenance	TERTIARY PREVENTION
		Promote adaptation to a changed level of wellness Promote interdependence Reinforce newly learned behaviors, lifestyle changes, coping strategies Explore application of learned behaviors to new situations Identification and use of additional resources

opportunity to further encourage the clients' participation in the resolution process. If clients are defensive, resistant, and rigid, they are not processing clearly and can complete only simple tasks. It will take time before these clients can begin to solve problems related to the effects of the crisis on themselves and the loss they are experiencing, but the nurse will want to encourage them to reach this level.

A therapeutic plan is based on multiple factors:

- ◆ The kind of crisis (situational or developmental, acute or chronically recurring)
- ◆ The effect the crisis is having on clients' lives (can they still work, go to school, and keep house, or are they secured within their home for an indefinite period, not knowing whether other family members have survived a major natural or manmade crisis?)
- ◆ Where they are in coming to resolution of the crisis
- ◆ The ways in which significant others are affected and respond
- ◆ Their level of preparation for such a crisis
- ◆ The clients' strengths and available resources

Using this problem-solving process, the nurse and clients develop a plan. They review the event that precipitated the crisis, obvious symptoms, and the disruption in the clients' lives. The plan may focus on several areas. For instance, clients may need to grasp intellectually the meaning of the crisis, to engage in greater expression of feelings, or work both on the intellectual and emotional aspects. Part of the plan may be directed toward finding appropriate and safe shelter, counseling, or physical care. Another part may focus on helping clients identify and use more effective coping techniques or locate supportive agencies and resources. The plan may also include development of realistic goals for the future.

## Implementation

During implementation, communication between the nurse and clients is important. Discussions about what is happening, reviewing the family's plan and rationale for this approach, and making appropriate changes are necessary parts of this communication. Assigning definite activities at the end of each session will help clients try out different solutions and evaluate various coping behaviors. Implementation is enhanced by using the following guidelines (Levy & Sidel, 2002; Vastag, 2001):

1. *Demonstrate acceptance of clients.* A crisis often shatters the ego. Clients need to feel the support of a positive, caring person who does not judge their feelings or behavior. Some negative expressions, such as anger, withdrawal, and denial, are normal aspects of the crisis phase. Accept them as normal.
2. *Help clients confront crisis.* Clients need to face and discuss the situation. Expressing their feelings reduces tension and improves reality perception. Recounting what has actually occurred may be painful, but it helps clients confront the crisis. Do not assume that once clients have told about the event, no further recounting is necessary. Each time the story is told, the client comes closer to dealing realistically with the crisis.

3. *Help clients find facts.* Distorted ideas and unknown factors of the situation create additional tension and may lead to maladaptive responses. For instance, it would help inexperienced parents to know that children younger than 2 years of age cannot deliberately misbehave. Facts about childhood development and parenting training may be important for preventing crisis.
4. *Help clients express feelings openly.* Suppressed feelings can be harmful. For instance, a widow may feel guilty that she is glad her husband is gone. Expression of such feelings helps reduce tension and gives clients an opportunity to deal with them.
5. *Do not offer false reassurance.* Clients need to face reality, not avoid it. A statement such as "Don't worry, it will all work out" is demeaning and meaningless. Instead, make positive statements about faith in the clients' ability to cope: "It is a very difficult situation, but I believe you will be able to deal with it."
6. *Discourage clients from blaming others.* Clients often blame others as a way to avoid reality and the responsibility for problem solving. Withhold judgment when clients blame others, but point out other causal factors and avenues for dealing with the situation.
7. *Help clients seek out coping mechanisms.* Explore and test old and new techniques to reduce stress and anxiety. Ask questions. What are the things that need to be done? What do clients think they can do? This assistance gives clients more adaptive energy to work toward resolution.
8. *Encourage clients to accept help.* Denial in the early phases of crisis cuts off help. Encouraging clients to acknowledge the problem, is a first step toward acceptance of help. Often clients fear the loss of their independence and the invasion of their privacy. A client may say, "We ought to be able to handle this problem." At this point, the community health nurse can reassure clients that people in a crisis of this sort almost always need help. Preparing people to accept help enables them to make the best use of what others have to offer.
9. *Promote development of new positive relationships.* Clients who have lost significant others through unintentional or intentional death, divorce, incarceration, or an act of perpetrated violence should be encouraged to find new connections, purpose, and people to fill the void and provide needed supports and satisfactions.

## Evaluation of Crisis Resolution and Anticipatory Planning

In the final step, clients and the nurse evaluate, stabilize, and plan for the future. Evaluating the outcome of the intervention might address the following:

- ◆ Are the clients using effective coping skills and exhibiting appropriate behavior?
- ◆ Are adequate resources and support persons available?

- ◆ Is the diagnosed problem solved?
- ◆ Have the desired results been accomplished?

Analysis of these outcomes will provide a greater understanding for coping with future crises.

To stabilize the change that has occurred, identify and reinforce all of the positive coping mechanisms and behaviors. Discuss why they are effective, and explore ways to use them in future stressful situations. Summarize the crisis experience, emphasizing the clients' successes with coping, reconfirm their progress, and reinforce their self-confidence. It is especially important to point to the evidence that the client has reached their pre-crisis level, or an even higher level of functioning.

Clients' plans for the future should include setting realistic goals and means to implement them. Review with clients how their handling of the present crisis can help them cope with, minimize, or preferably prevent future crises.

## Summary

Crisis is a temporary state of severe disequilibrium for persons who face a threatening situation. A crisis is a state that individuals can neither avoid nor solve with their usual coping abilities, and occurs when some force disrupts normal functioning, thereby causing a loss of balance or normalcy in life. Crises create tension; subsequently, efforts are made to solve the problem and reduce the tension. If such efforts meet with failure, people feel upset, redefine the situation, try other solutions, and, if failure continues, the person eventually reaches the breaking point.

Two main types of crisis are developmental and situational. Developmental crises are disruptions that occur during transitional periods in normal growth and development. These transitions usually have a gradual onset and are often predictable. Situational crises are precipitated by an unexpected external event and occur suddenly, sometimes without warning.

Family violence constitutes a unique crisis for the victim and the entire family and is becoming disturbingly prevalent in the world. Historically, family violence is not new. Only in the last half century of our nation's history have laws and societal concerns been raised about the treatment of spouse/partners, children, and seniors. Although advances in human rights have been made, abuses against women and children remain socially and culturally accepted in some countries, and attitudes have been slow to change.

Child abuse occurs among children of all ages, from infancy through the teen years, and may be physical, emotional, and/or sexual. Neglect and sexual exploitation are additional forms of child abuse. Neglect may be described as general neglect or specific, such as medical or educational neglect. Child abuse, such as shaken baby syndrome or Munchausen syndrome by proxy, is sometimes identified only on autopsy. Teen dating violence, violence during pregnancy, and violence against women in general constitutes partner/spousal abuse. Finally, a most unsettling form of violence—elder abuse, neglect, and exploitation—is occurring with an increased frequency than previously suspected.

New and unexpected forms of violence are becoming a reality in our unsettled world. Within communities, violence comes into the home in the form of Internet crimes against

children, child abductions, and home invasions. Globally, terrorist groups threaten attacks on civilians in the United States and abroad. For people in the United States, this form of terror is a new reality. Preparation against and survival of such attacks is a new concern for most Americans, and the community health nurse has an important role to play (see Chapter 17).

Community health nurses use three levels of prevention when working with families. Primary prevention focuses on providing people with the skills and resources to prevent violent situations. Secondary prevention involves immediate intervention at the time of the violent episode. This secondary level includes providing different services for each family member, such as medical attention, emotional support, and police involvement. Tertiary prevention offers family rebuilding services and helps the family establish equilibrium with a structure that may be different, but healthier.

People in crisis need and often seek help. Crisis intervention builds on these two phenomena to achieve its primary goal—reestablishment of equilibrium. The two major methods of crisis intervention are the generic and the individual approaches. The generic approach is used with groups of people involved in the same type of crisis, such as rape victims, mothers who have lost children because of drunken driving, or a family experiencing child abuse. The individual approach is used if clients do not respond to the generic approach or need additional therapy. Crisis intervention begins with assessment of the situation, followed by planning a therapeutic intervention. The nurse then implements and carries out the intervention, building on the strengths and self-care ability of clients. Crisis intervention concludes with resolution and anticipatory planning to avert possible future crises.

Regardless of the method of intervention the community health nurse uses, the steps of the nursing process provide a framework within which to intervene. Assessing the family's assets and liabilities, their willingness to change, and the nature of the violence helps the nurse form a nursing diagnosis. With this diagnosis, the nurse can begin to plan appropriate interventions and implement plans in concert with the family. Evaluation of the intervention techniques provides the nurse with new data to assist with ongoing assessment of the family's progress and additional anticipatory guidance needs. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. What are the major differences between a developmental and a situational crisis? Give examples of each from personal experiences.
2. Describe a developmental crisis experienced by a family. What was this family's response? Describe some actions a community health nurse might have taken (alone or within an interdisciplinary team) to help the family cope with the crisis.
3. Watch a news station on television. Listen for examples of developmental or situational crises occurring to families in the world. Analyze the situations and

anticipate what the role of a community health nurse would be during the crises selected.

4. Family violence is a significant public health problem. Assume that a battered wife becomes a community health nurse's client, and the nurse suspects there may be more women with this problem in the community. Describe how the nurse might provide assistance using the crisis intervention steps. Then discuss how a three-level preventive program might be instituted in the community.
5. Using the Internet, select a situational crisis, such as spousal abuse, adolescent sexual exploitation, or neglect of the elderly and read the most current information on this topic. Depending on your personal interests or current community health nursing experiences, develop a file of articles you have uncovered using the Internet. This file can be useful to you, to agency staff in your clinical setting, and to families you visit.

# Maternal–Child Health: Working with Perinatal, Infant, Toddler, and Preschool Clients

## LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Identify major health problems and concerns for infant, toddler, and preschool populations globally and in the United States.
- ◆ Identify the *Healthy People 2010* goals established for the maternal child population.
- ◆ Discuss major risk factors and special complications for childbearing families.
- ◆ Describe the important considerations in developing effective health promotion programs to fit the needs of diverse maternal child populations.
- ◆ Describe various roles of a community health nurse in serving the maternal child population.
- ◆ Describe a variety of programs that promote and protect health and prevent illness and injury of infant, toddler, and preschool populations.
- ◆ State the recommended immunization schedule for infants and children, and give the rationale for the timing of each immunization.
- ◆ Give examples of methods and interventions the community health nurse might use in working with infants, toddlers, and preschool populations to help promote their health.

“Be gentle with the young.”

—Juvenal (55–127 AD)

## KEY TERMS

Alcohol-related birth defects  
 Alcohol-related neurodevelopmental disorder  
 Child abuse  
 Drug dependent  
 Drug exposed  
 Environmental tobacco smoke  
 Fetal alcohol effects  
 Fetal alcohol spectrum disorders  
 Fetal alcohol syndrome  
 Gestational diabetes mellitus  
 Head Start  
 High-risk families  
 Infant  
 Low-birth-weight  
 Preconception care  
 Preschooler  
 Shaken baby syndrome  
 Smokeless tobacco products  
 Sudden infant death syndrome (SIDS)  
 Toddler  
 Very-low-birth-weight

 Many of the community health nurse's clients are pregnant teens and women, along with infants and young children. Working with maternal and infant populations is a primary facet of community health nursing. Often, more than half of nursing practice in official health agencies involves primary preventive work with mothers and infants, as well as provision of prenatal care. Maternal child expenses are a large part of the health care dollar. The average cost of maternity care in 2004 was \$7,737 for vaginal deliveries and \$10,958 for cesarean section deliveries, with facility costs and professional fees accounting for the largest proportion of expenses (Thomson Healthcare, 2007). Why should maternal/infant populations require this amount of attention from community health nursing? Despite advanced technology and availability of excellent perinatal services in the United States, certain segments of the maternal and infant populations, such as adolescent mothers and those who are economically disadvantaged, remain at high risk for disease, disability, and even death. Although some women receive excellent prenatal care and benefit from diagnostic and technological resources, many others are without access to prenatal care and adequate nutrition. The Save the Children (2008, p. 31) report on maternal–child health notes that:

The United States spends more money on health care per capita than nearly any other country in the world, yet has the highest rates of child poverty and the lowest levels of child health and safety of the rich countries. As a result, infant and child mortality rates in the United States are higher than in any other industrialized country, the only exceptions being Latvia, Lithuania, and Slovakia.

For an example of a country that has implemented successful policies to eliminate maternal child inequities, see Evidence-Based Practice: How Sweden Achieved Maternal–Child Health Equity.

Historically, the health of U.S. women and children has largely fallen under the umbrella of Title V of the Social Security Act, enacted in 1935. (For more on the Social Security Act see Chapter 6.) Funding for state Maternal and Child Health and Crippled Children programs were part of this original legislation, as was some provision for child welfare services. Title V is “the longest-standing public health legislation in American history,” and came to fruition after other legislation established a National Birth Registry; provided *Infant Care*, the first educational pamphlet; established the Children's Bureau; and enacted the first Child Labor Law of 1916 (Maternal Child Health Bureau [MCHB], 2008, para 4). For an illustration of MCHB functions and programs see Display 21.1.

In 1909, formal prenatal care was first provided in Boston by the Instructive District Nursing Association, and spread across the country to outpatient clinics (MCHB, 2008). Since the inception of Title V, other legislation has included Emergency Maternity and Infant Care Program (1943) that funded maternity and infant care for the wives of lower-income servicemen in the early days of the Baby Boom, and the 1970 Family Planning Act that provided the first federal funds for birth control to prevent unintended pregnancies. In 1976, the Improved Pregnancy Outcome Projects sought to decrease the levels of infant mortality by strengthening the efforts of states to better plan and implement maternal child health programs, and Healthy Start programs were begun in 1991—starting with 15 demonstration project sites exhibiting

## EVIDENCE-BASED PRACTICE

### How Sweden Achieved Maternal Child Health Equity

For mothers and children of any income level, Sweden is a wonderful place to live. However, this was not always the case; the poorest infants were 3.5 times more likely to die before age 1 in the 1920s. In the 1930s, due to public concern about the “child survival gap” (p. 32), the government instituted a set of comprehensive new policies that included free prenatal and other maternal–child health services, along with housing reforms and welfare support—including financial support for low-income families. Around 60% of pregnant women and 80% of infants were covered by 1950. Currently, the inequity related to infant mortality rates has virtually been eliminated, and the decreases in social inequality have led to “one of the lowest rates of child mortality in the world” (p. 32). This case study highlighting how government policies can affect population health outcomes is an example for other countries, such as the United States, that struggle with less than adequate maternal–child health indicators and significant disparities in health outcomes.

#### DISPLAY 21.1

### TYPES OF SERVICES OFFERED THROUGH FEDERAL MCH FUNDING

#### Direct Health Care Services (gap filling)

Examples: Basic Health Services, and Health Services for CSHCN

#### Enabling Services

Examples: Transportation, Translation, Outreach, Respite Care, Health Education, Family Support Services, Purchase of Health Insurance, Case Management, Coordination with Medicaid, WIC, and Education

#### Population-Based Services

Examples: Newborn Screening, Lead Screening, Immunization, Sudden Infant Death Syndrome Counseling, Oral Health, and Injury Prevention

#### Infrastructure Building Services

Examples: Needs Assessment, Evaluation, Planning, Policy Development, Coordination, Quality Assurance, Standards Development, Monitoring, Training, Applied Research, Systems of Care, and Information Systems

U.S. Department of Health and Human Services. (2008). *State MCH-Medicaid Coordination: A Review of Title V and Title XIX Interagency Agreements* (2nd ed). Retrieved August 13, 2008 from <http://mchb.hrsa.gov/IAA/appendices.htm>.

high infant mortality rates and growing to 96 within two decades—to provide preconception, postpartum, and infant care to at-risk women (MCHB, 2008). Evaluation of Healthy Start programs reveals that almost all programs provide home visitation to clients, and most continued these visits to infants and toddlers. Health education, smoking cessation counseling, services for perinatal depression, and involvement of male partners are hallmarks of most programs. Barriers to success of Healthy Start include mobility of clients and unstable housing, along with lack of transportation (MCHB, 2006).

**Preconception care** seeks to improve the health and well-being of adolescents and women before they become pregnant. Its goal is to decrease birth defects through health education, screening, and interventions that reduce risk factors for the future mother and infant (Association of State & Territorial Health Officials [ASTHO], 2006). The community health nurse has always had a prominent role in planning, implementing, and evaluating these programs.

This chapter addresses major areas of concern regarding the health of maternal–infant populations. It also explores the global needs of and related services available to the youngest and most vulnerable of society’s members. Health services that are commonly available in the United States for pregnant and postpartum women, infants, toddlers, and the preschool population are examined, and the role of the community health nurse in providing those services is explored.

## HEALTH STATUS AND NEEDS OF PREGNANT WOMEN AND INFANTS

Community health nurses constitute a key group of health care workers involved in both program planning and the actual delivery of services to mothers and babies. A solid understanding of vital statistics and other data regarding mothers and infants serves nurses as they determine the appropriateness and the effectiveness of programs and services. A review of some global and national vital statistics of the past decade provides insight into the key problems facing this population.

### Global Overview

In 2005, an estimated half million women died of maternal causes, 88% of them in sub-Saharan Africa and South Asia. In these areas, maternal mortality rate (MMR) exceeds 1,000 per 100,000 live births, but it is less than 10 per 100,000 live births in Canada, Australia, New Zealand, Japan, and most European countries—a very wide disparity. The U.S. maternal mortality rate was 13 in 2004. Ireland’s MMR is one, making it a very good place for mothers (World Health Organization [WHO], 2008a). The MMR is a measure of obstetric risk and is determined by dividing the number of maternal deaths by the number of live births per 100,000. Most maternal deaths are the result of direct causes (complications of pregnancy, labor, and delivery), interventions, omissions, or incorrect treatment, or of the chain of events resulting from any one of these. Eclampsia, hemorrhage, sepsis, and unsafe abortions account for 70% of maternal deaths (Graham & Hussein, 2006; WHO, 2008b).

### Infant Mortality

Globally, 3.5 to 4 million neonatal deaths and 3.3 to 4 million stillbirths occur each year; they are largely caused by the same factors that result in death and disability for mothers. Causes

include poor maternal health, inadequate care, poor hygiene, and inefficient management of delivery, as well as lack of essential newborn care (Ten Hoop-Bender, Liljestrand, & MacDonagh, 2006; Tinker, Paul, & Ruben, 2006; WHO, 2008b). For example, two 20-cent injections given to mothers during or before pregnancy can prevent the deaths of 250,000 infants from neonatal tetanus each year (Tinker, Paul, & Ruben, 2006). Infant mortality rate is regarded as a valid indicator of population health worldwide. Sadly, a substantial number of neonatal deaths or stillbirths are likely due to hypoxia/asphyxia because of failure to establish effective breathing at birth resulting from lack of appropriate neonatal resuscitation (Reidpath & Allotey, 2003; Spector & Daga, 2008). Infections and low-birth-weight (LBW) or premature birth account for 64% of neonatal deaths, and most newborns die at home, without the presence of a skilled health care provider. Of the total of neonatal deaths, 99% are found in low- and middle-income nations, and 66% occur in Africa and Asia (Tinker, Paul, & Ruben, 2006). A mother from sub-Saharan Africa is 83 times more likely to have her child die before age 5 than a mother from an industrialized nation, and almost four of every five mothers there will lose a child during their lifetime (Save the Children, 2008). In the United States, Black infant mortality rates (13.6) are 2.4 times higher than the rate for Whites (5.7), and the rate for American Indian/Alaska Native infants is 1.5 to 2 times higher (Save the Children, 2008). About 1.3 million infants would survive annually if mothers were able to exclusively breast-feed their infants for 6 months. The lack of breast-feeding is related to decreased survival and increased morbidity from infections, lower intelligence test scores, increased cardiac risk factors, and inadequate nutrition (Labbok, 2006).

Across the world, 6.5 million children die before age 5, and there are great disparities between nations: a child is 40 times more likely to die in the country with the highest rate than a child in the country with the lowest rate (WHO, 2008b). Worldwide, over 200 million children under age 5 cannot get the basic health care they need, and 26,000 of them die each day from such preventable and easily treatable illnesses as respiratory infections and diarrhea (Save the Children, 2008; WHO, 2008b). Although bleak, these figures actually represent substantial gains in reducing the rate of under-5 child deaths worldwide. Ten million children die each year, the lowest number in recorded history, because of the efforts of international groups promoting basic health care interventions targeted to vulnerable infants and children. Over 11% of all U.S. children have no health insurance, public or private, and 20% of Hispanic children are uninsured (Save the Children, 2008).

### Teenage Pregnancy

About 10% of all births worldwide are to adolescent mothers (Hanna, 2001). Teenage mothers have a higher rate of pregnancy-related complications, and their infants are more likely to have LBW or to be premature, injured at birth, or stillborn. Mortality rates for infants born to adolescent mothers are higher than for those born to older women. Long-term problems for both mother and child may result typically from educational and employment limitations for moms and less cognitive stimulation and emotional support for babies. In 2005, the U.S. birth rate for 15 to 17 year olds was 21 per 1,000 (for Hispanics the rate was 48)—a record low rate, having declined from a rate of 39 per 1,000 in 1991 (Forum on Child & Family Statistics, 2007).

## HIV/AIDS

Worldwide, human immunodeficiency virus (HIV) rates are rising faster among women than men; in 2005, about 17.5 million women were estimated to have HIV (Mehta, 2006). Perinatal transmission of HIV is a global health issue: 1,600 infants every day acquire HIV from their mothers and the HIV/AIDS pandemic has orphaned 12 million children (Greene, 2007). Most children with acquired immunodeficiency syndrome (AIDS) are children of HIV-positive mothers. Mother-to-child transmission (MTCT) of HIV can be reduced by a stunning 67% with a single antiretroviral drug taken for a short time, and combination therapies are even more effective in reducing MTCT (Bassett, 2001; Harris, Fowler, Sansom, Ruffo, & Lampe, 2007). However, even after 25 years of the HIV/AIDS pandemic, only 20% of all persons who need antiretroviral medications and who live in low- and middle-income nations can receive them (Merson, 2006). Worldwide, HIV/AIDS is among the leading causes of death for women. In poor areas of the world, the death of a mother often means that her children, especially those under age 5, will die also (Bellamy, 2004). To reduce MTCT, it is important to prevent HIV infection among women of childbearing age—but, in some areas, girls are six times more likely to be infected than boys. Women must seek prenatal care early enough in their pregnancies for the antiretroviral drug to be effective. Also, breast-feeding benefits and risks must be weighed (Bellamy, 2004). In Botswana, routine HIV testing began in 2004 and rates of HIV transmission from mother to baby dropped from 35% to 40% down to 5% to 10% due to intervention with maternal antiretroviral therapy and infant formula feeding (Seipone, et al., 2004). Most of the population favors routine HIV testing, and women are more likely to be tested and understand that treatment can help their unborn children (Cockcroft, Andersson, Milne, Mokoena, & Masisi, 2007).

## National Overview

In the United States, 4.1 million women gave birth in 2005; these numbers remained constant from the previous year. The birth rate was 14 per 1,000 and birth rates declined in all ethnic/racial groups except for Hispanics and American Indian/Alaska Native groups. For the 25- to 29-year-old group, the overall birth rate was highest at 115.6, with rates for Hispanic mothers at 148.8, White mothers at 109.3, Black mothers at 103, and Asian/Pacific Islander mothers at 108 per 1,000. Almost 37% of births were to unmarried women (U.S. Department of Health and Human Services [USDHHS], 2007). It is estimated that about 49% of pregnancies are unintended (Centers for Disease Control [CDC], 2006a). Many of these women do not have the financial or social resources to sustain minimal health levels for themselves and their infants.

## Teenage Mothers

In 1991, after a steady 5-year upward trend, the United States reached a 20-year high in the number of children born to teen mothers (aged 15 to 17 years). That trend then declined until 2005, when it rose ever so slightly to a rate of 21 per 1,000. Ninety percent of these births are to unmarried mothers (Forum on Child & Family Statistics, 2007). The downward trend for teen pregnancy rates has been attributed largely to better use of contraception (77%) rather than to less sexual activity (23%)

(Santelli, Lindberg, Finer, & Singh, 2007). Although most pregnant adolescents are of European-American descent, the rate of pregnant adolescents is higher among Black (35) and Hispanic (48) populations, and lower among Asians/Pacific Islanders (8) and Whites (12) (Forum on Child & Family Statistics, 2007). For older age groups (ages 25 to 44), the pregnancy rate has increased since 1991, but the rate for younger teens (10 to 14 age group) declined at about the same rate as older teens (Hamilton, Martin, Sutton, & Menacker, 2005). Additionally, there continues to be an increasing trend for unwed teenage mothers to keep their babies. These “children having children” with limited educational and economic advantages will affect the health of society well into the future. See Chapter 22 for more on adolescent pregnancy.

## Substance Use and Abuse

Another area of concern is substance use and abuse among the childbearing population. The range of adverse consequences associated with the use of tobacco, alcohol, and illicit drugs during pregnancy is wide and includes preterm birth, LBW, and fetal alcohol syndrome (described later in this chapter). Two studies showed that many women who abuse drugs while pregnant do not receive prenatal care (Armstrong et al., 2003; Chasnoff et al., 2001). This puts these women and their unborn children in double jeopardy: not only are they at risk from the consequences of alcohol or drug use, but they also do not receive the preventive prenatal care that can eliminate or reduce other obstetric complications. Mothers who smoke also are at risk of having premature or lower birth weight babies, along with other sequelae (Mercer, Merlino, Milluzzi, & Moore, 2008).

## Violence

Violence is often the cause of injuries and death for pregnant and postpartum women, as well as their unborn and infant children (Janssen et al., 2003), and homicide is the leading cause of injury death for women who are pregnant and 1-year postpartum (Chang, Berg, Saltzman, & Herndon, 2005). It is not uncommon for physicians to note injuries consistent with blunt trauma in women who are pregnant; however, they may be explained away as accidentally self-inflicted (Grossman, 2004). One large-scale retrospective study of pregnant and postpartum women in Massachusetts from 2001 to 2005 found that in 1,675 hospital visits for assault, 1,528 physical injuries were diagnosed—largely to the head and neck (42.2%) for the total sample and torso (21.5%) in pregnant women; the percentage dropped to 8.7% in the postpartum sample (Nannini et al., 2008). Victims of intimate partner violence have high levels of stress and higher rates of smoking during pregnancy, as well as inadequate utilization of prenatal care services (Chambliss, 2008).

Prenatal care is crucial to ensure good outcomes of pregnancy. The crisis surrounding professional liability insurance has been especially critical in the case of physicians specializing in obstetrics and gynecology (OB-GYN). Over the past decade, insurance costs have risen dramatically. In some instances, premiums have equaled the obstetrician’s income. For example, average liability insurance premiums in Miami, Florida, were \$147,621 in 2000, but rose to \$277,241 just 4 years later (Hale, 2006). OB-GYNs have either moved to states where lawsuits have limits set by legislation and insurance

rates are reasonable, or they reduce the number of high-risk obstetrical cases (22%) or total deliveries (9.2%) in an effort to reduce their premium costs. Some of them chose to stop practicing altogether (14%), leaving many pregnant women without convenient access to appropriate prenatal care (Hale, 2006). Because most lawsuits involve neurologic impairment of a newborn (34.4%) and these injuries are amortized over the life of the individual, awards or settlements are often quite large (see Perspectives: Student Voices).

The *Healthy People 2010 (HP 2010)* document encompasses specific goals and objectives for the maternal child population, based on the previous achievements in the same or similar areas, and have been revised during the midcourse review (USDHHS, 2006). (See Table 21.1 for selected maternal-child health objectives and progress toward goals.) After years of working toward improving maternal-child health, the United States has made limited progress. One objective, however, has been met: 70% of infants are now being put to sleep on their backs (up from 35% baseline), largely due to public health educational efforts and reminders (USDHHS, 2006). Although the infant mortality rate (IMR, or deaths for all babies up to 1 year of age) has dropped substantially, from 20.0 per 1,000 live births in 1970 to 7.1 per 1,000 in 1999, it remained high at 6.79 in 2004—higher than in many other industrialized nations. In addition, the IMR for African-American infants remains more than twice that of White infants (Hamilton, Minino, Martin, Kochanek, Strobino, & Guyer, 2007; Save the Children, 2008).

### Birth Weight and Preterm Birth

**Low-birth-weight (LBW)** babies are those weighing less than 2,500 g (or less than 5.5 lbs) at birth; **very-low-birth-weight (VLBW)** babies weigh less than 1,500 g (or less than 3 lbs 4 oz) at birth (Child Trends Databank, 2006). Premature births account for 67% of LBW babies, and others are considered small-for-gestational age or may have been exposed to tobacco or another growth-retarding substance, for instance (March of Dimes, 2005a,b). Maternal mortality, LBW, and VLBW births are three areas requiring attention. Birth weight is one of the most important predictors of infant mortality (Tinker, Paul, & Ruben, 2006). Ethnic differences exist in the rates of infant mortality, largely as a result of ethnic differences in the rate of LBW (Hessol & Fuentes-Afflick, 2005). Congenital deformities, premature birth, LBW, newborn demise from maternal complications, and unintentional injuries were responsible for over half of all 2004 infant deaths (Hamilton, Minino, Martin, Kochanek, Strobino, & Guyer, 2007). The rate of LBW infants dropped between 1970 and 1980, but has continued to rise since then (Child Trends Databank, 2006). In 2005, the rate for LBW infants rose from 8.1% in the previous year to 8.2%, and for preterm births there was also an increase from 12.5% to 12.7%; objectives for LBW, VLBW, and preterm births all moved away from their *HP 2010* targets (UDHHS, 2006). Objectives for LBW, VLBW and preterm birth are not being met; rather they are moving away from target levels (USDHHS, 2006).

### PERSPECTIVES STUDENT VOICES

I began working as a nurse's aide at our local hospital when I started nursing school. I learned first-hand the dangers of childbirth and the long-term consequences that can result. One night, a single young female reported to the Emergency Room in labor and was admitted to the Labor and Delivery Department and seen by the nurse midwife who had provided prenatal care for the mother in the clinic. The young mother-to-be was very excited. Her contractions continued, and she did not progress with the labor process, so she was to be started on Pitocin to increase the effectiveness of her labor. The nurse midwife checked on her patient frequently, but problems began after the first 8 hours of labor. As the Pitocin dosage was increased, the fetus reacted with bradycardia, and the nurse midwife did not notify the physician. The Pitocin dosage was decreased and then the heart rate stabilized; this process continued for three cycles. The nurse midwife signed off her 12-hour shift and handed care of the patient over to the nurse midwife coming on shift. Again, whenever the Pitocin dosage was increased to the point of becoming effective, the fetus would respond with bradycardia. Report was given, and the physician in charge was still not notified. The first two times, the fetus recovered. The third time, the fetus did not recover; instead the bradycardia increased. By this time, the mother had been in labor for over 24 hours and the fetus was in irreversible distress. The physician was notified of an emergency, and reported to the

bedside within 5 minutes. An emergency cesarian section was performed, and the Apgar scores at delivery were 0 at 1 minute, 0 at 5 minutes, 0 at 10 minutes, and 3 at 15 minutes. The infant was severely neurologically damaged. I found out later that the infant was diagnosed with severe cerebral palsy and will never walk, talk, or feed normally. She cannot swallow and will require suctioning, gastrostomy tube feeding, and total care throughout her lifetime. She is also cortically blind. The hospital and physician were sued. The nurses and the nurse midwives in the labor and delivery room were found negligent in not reporting to the physician when the patient's labor failed to progress. The nurse midwives from both shifts were found negligent for failure to recognize fetal distress and summon the physician. A multimillion dollar award was given, and the nurses and nurse midwives employed by the hospital were fired. It is sad to think that this tragedy could have been avoided with prudent nurse-patient advocacy, reporting, and appropriate documentation—the things our nursing instructors are always drumming into our heads. I know that as a new graduate, I am now in a position of responsibility to make decisions to notify the physician or not. I have decided that the choice should always be to notify the physician. Even though it may seem inconvenient, it really should be done. I will never forget this case and its long-reaching consequences for the child and family, as well as for the nursing staff and nurse midwives.

Linda Marie, Student Nurse

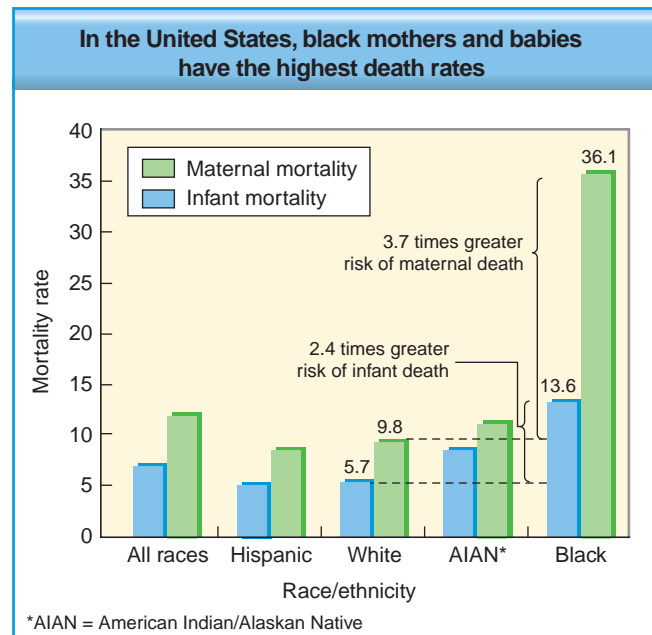

**TABLE 21.1 Healthy People 2010: Selected Maternal Child Objectives and Progress Toward Targeted Goals**

Objective	1997–1998 Baseline	2010 Target	% Change
Reduction in fetal & infant deaths	7.3 rate/1,000	4.4 rate/1,000	+ 14%
Reduction in child deaths (ages 1–4)	34.1 rate/100,000	20.0 rate/100,000	+ 21%
Reduction in maternal deaths	9.9 rate/100,000	4.3 rate/100,000	+ 18%
Reduction in cesarean births among low-risk women (first birth)	18% live births	15% live births	– 133%
Reduction in low-birth-weight infants	7.6% live births	5.0% live births	– 8%
Reduction in very-low-birth-weight infants	1.4% live births	0.9% live births	– 20%
Reduction in total preterm births	11.6% live births	7.6% live births	– 13%
Reduction in occurrence of cerebral palsy	33.3 rate/10,000	31.6 rate/10,000	– 388%
Reduction in occurrence of spina bifida and other neural tube defects	6.0 new cases/10,000 live births	3.0 new cases/10,000 live births	+ 33%
Increase in percentage of infants put to sleep on their backs	35%	70%	100% met
Increase in proportion of mothers breast-feeding at 6 months	29%	50%	+ 19%

The rate of preterm births has risen over 30% since 1981. The reasons for this steady increase are complex and “require multifaceted solutions” (Behrman & Stith-Butler, 2007, p. 4). Individual medical, psychosocial, and behavioral factors (e.g., chronic health conditions, substance abuse, infertility treatments), along with sociodemographic influences (e.g., poverty, lack of education) and neighborhood characteristics (e.g., lack of easy access to prenatal care providers, unsafe areas) overlap to influence birth outcomes. Infant complications of preterm birth include hearing and vision problems, acute respiratory, gastrointestinal and immunologic problems, and central nervous system, motor, cognitive, behavioral, and socioemotional disorders. A variety of growth concerns, as well as acute and chronic health and developmental problems, often occur, and the families of these infants are burdened with additional economic and emotional costs. In 2005, it was estimated that preterm births in the United States represented \$26.2 billion in economic burden (Behrman & Stith-Butler, 2007). As preschoolers, children born preterm were more likely than peers to have poor social, emotional, and physical functioning, indicating some continuing effects (Zwicker & Harris, 2008).

In addition to infant deaths and LBW, the effects of pregnancy and childbirth on women are other important indicators of health and reflect discrepancies in access to reproductive health care. Great strides have been made in this area over the past century, with 99% decreases in maternal deaths; however, 29 developed nations have lower MMRs (Berg et al., 2005). In the United States, the MMR is higher than in other developed countries, mostly due to the disparities found among women of color. The MMR for Blacks (36.1 per 100,000 live births) is four times greater than that for Whites (9.8), and the gap has continued to widen since 2000 (Save the Children, 2008) (Fig. 21.1). The United States is not ranked among the top 10 countries on the 2008 *Mother’s Index*. It is ranked 27th out of the 41 more developed countries listed, largely due to poor maternal and

under age 5 mortality rankings, as well as fewer children enrolled in preschool and limited maternal leave policies compared with other nations. Latvia, Lithuania, the Czech Republic, and Hungary rank higher than the United States

SOURCE: AIAN infant mortality data: *Infant Mortality Statistics from the 2004 Period Linked Birth/Infant Death Data Set*. National Vital Statistics Reports. Vol. 55, No. 14; AIAN Maternal mortality data: U.S. Department of Health and Human Services: Indian Health Service. *Indian Health Disparities*; All others: National Center for Health Statistics. *Health, United States, 2007 With Chartbook on Trends in the Health of Americans*.

**FIGURE 21.1** U.S. Mother/Infant Death Rate Disparities by Ethnicity. In the United States, infant mortality rates among Blacks are 2.4 times higher than those of Whites, and maternal mortality rates are 3.7 times higher. Note: Infant mortality is reported per 1,000 live births, maternal mortality per 100,000 live births.

(Save the Children, 2008). Pregnancy-related death risk increases with age and with lack of prenatal care for women of every race, but the risk of pregnancy-related death for Black women is three to four times greater than for White women. Sixty percent of maternal deaths occur after giving birth to a living child, and are usually related to embolism and pregnancy-induced hypertension or preeclampsia (Chang, Elam-Evans, Berg et al., 2003). Other studies indicate that cardiomyopathy (21%), hemorrhage (14%), and pregnancy-induced hypertension (10%) were the most common causes of pregnancy-related deaths—even though 90% of deaths from chronic disease and hemorrhage are largely preventable (Berg et al., 2005). However, some progress has been made toward the *HP 2010* target for MMR: it is 18% closer to meeting the target (USDHHS, 2006).

Great progress has been made toward the year 2010 goals in several areas. The neonatal mortality rate (deaths for all infants up to 28 days old) has moved 5% closer to its target level, as has perinatal deaths (28 weeks gestation to less than 7 days after birth—14% progress) and fetal deaths (over 20 weeks' gestation—15% closer to target). Progress is also being made in early prenatal care, with over 81% of Medicaid clients and over 91% of commercial care clients receiving timely prenatal care or beginning care in the first trimester (National Committee for Quality Assurance, 2006). Movement toward *HP 2010* goals is evidenced for objectives related to first trimester prenatal care and also early and adequate prenatal care (USDHHS, 2006).

Progress in other areas has been mixed. The percentage of cesarean section deliveries, while dropping between 1990 and 1996, increased considerably between 1996 and 2003 to 23.5%, representing a one third increase. Women at low risk who have had one cesarean delivery are now more likely to have repeat cesarean sections, as the rate for vaginal births after cesarean section decreased by 63% over the same time period (Menacker, 2005). These figures represent dramatic shifts away from *HP 2010* targets for both primary and repeat cesarean births to low-risk women (USDHHS, 2006).

Breast-feeding is beneficial to both mother and infant, and in 2005, almost 73% of infants were breast-fed for some period of time (USDHHS, 2007). The risk of ovarian and breast cancers is decreased among women who breast-feed, and infants who are breast-fed have a lowered risk of upper respiratory and other infections (Ip et al., 2007; USDHHS, 2007). Asian/Pacific Island mothers are more likely to breast-feed (81.4%) and Black mothers are least likely to breast-feed (55.4%). Even though the American Academy of Pediatrics (AAP) recommends that infants be exclusively breast-fed for the first 6 months of life, less than 14% of infants fell into that category in 2005. Older mothers are more likely to breast-feed their infants than younger mothers and are also more likely to breast-feed for a longer period of time (USDHHS, 2007). However, breast-feeding objectives—including the rates for early postpartum period, 6 months of age, and at age 1 year—have all moved toward their *HP 2010* targets (USDHHS, 2006).

The success in reaching the year *HP 2010* objectives for abstinence from alcohol, tobacco, and drug use during pregnancy was not assessed at the midcourse review. However, the rate of abstinence from tobacco has improved steadily since 1989 when 19.5% of pregnant women smoked. In 2000, 12.2% of women reported smoking during pregnancy,

and this was highest for non-Hispanic white women (15.6%). In 2003, approximately 11 million women were estimated to smoke during pregnancy, revealing progress toward the 1% target from the 13% baseline (CDC, 2006b).

## Risk Factors for Pregnant Women and Infants

Most pregnant women in the United States are healthy; they have normal pregnancies and produce healthy babies. Many factors contribute to the health problems of those mothers and babies who figure in the statistics on infant mortality and LBW. The factors associated with LBW and infant mortality can be grouped into three categories (MacDorman, Minino, Strobino, & Guyer, 2002):

1. Lifestyle: Smoking, inadequate nutrition, low pre-pregnancy weight, high alcohol consumption, narcotic addiction, environmental toxins, prolonged standing, strenuous work, stress, and lack of social support
2. Sociodemographic: Low maternal age, low educational level, poverty, and unmarried status
3. Medical and gestational history: Primiparity, multiple gestation, short interpregnancy intervals, premature rupture of the membranes, uterine abnormality, febrile illness during pregnancy, abortion, genetic factors, gestation-induced hypertension, and diabetes

It is in the realm of lifestyle choices that community health nurses can have the most significant impact.

## Drug Use

Substance abuse during pregnancy is a problem with staggering social and medical implications, because preterm birth is associated with a number of modifiable risk factors, including the use of illicit drugs during pregnancy (Armstrong et al., 2003; Chasnoff et al., 2001). The precise rate of substance abuse among pregnant women is difficult to determine. Nevertheless, current estimates of the number of women who are **drug exposed** (use drugs intermittently) and give birth to crack- or cocaine-exposed newborns range from 30,000 to 100,000 or greater annually. Other illicit substances may be abused in combination, contributing to higher numbers of exposed women and infants. Another 5,000 to 10,000 infants each year are born to women who are **drug dependent** (physically and psychologically require use of drugs to function). Many pregnant addicts do not receive prenatal care, and it is not until their newborns exhibit signs of withdrawal after birth that many of these women are identified (USDHHS, 2000).

In the United States, almost 90% of substance-abusing women are of reproductive age and are most commonly reported to abuse cocaine, amphetamines, opioids, alcohol, marijuana, and tobacco. Also, the use of several substances—or polysubstance abuse—is fairly common in this population (Kuczkowski, 2007). Data is not always current or complete, but 44 states reporting on pregnant women seeking substance abuse treatment during 2002 indicated that about 4% of 15- to 44-year old women admitted for treatment were pregnant. They reported cocaine/crack (22%), amphetamine/methamphetamine (21%), or marijuana (17%) as their primary drug of choice. Although 31%

of nonpregnant women reported primarily abusing alcohol, only 18% of pregnant women did. Also, pregnant women less often used their substance of abuse during the month prior to treatment admission or reported recent daily use—an indication that pregnancy may have been a consideration (Substance Abuse & Mental Health Services Administration [SAMHSA], 2004). However, this change in drug use may not happen until the pregnancy is diagnosed, exposing their unborn children to illicit drug use or substance abuse (Rayburn, 2007). Pregnant substance abusers were more likely to enter residential/rehabilitative (22%) and ambulatory services (71%) than detoxification treatment centers (7%), and were more likely to be younger and unmarried (SAMHSA, 2004).

Often associated with drug use are limited prenatal care, inadequate nutrition, low pre-pregnancy weight, hypertension and more rapid heart rate, preterm labor and birth, higher rates of depression, physical abuse, and HIV/AIDS and other STDs, as well as sometimes alcohol consumption and smoking (Alexander & Kotelchuck, 2001; National Institute of Drug Abuse, 2006). Increased risk of intrauterine fetal death is associated with maternal drug dependence, as is prematurity, LBW, increased chance of infections, birth defects, neurological problems, learning disabilities, and HIV/AIDS (McDonald, Vermeulen, & Ray, 2007; National Institute for Drug Abuse, 2006).

Specifically, maternal methamphetamine use is associated with fetal growth restriction; infants exposed in utero were 3.5 times more likely to be small-for-gestational-age than infants who were not exposed to methamphetamines (Smith, et al., 2006). Opiate-exposed infants are at increased risk of perinatal morbidity and mortality, and are more likely than healthy infants to have neurodevelopmental impairment at 18 months and 3 years of age (Hunter, Tzioumi, Collins, & Jeffery, 2008). Longer-term developmental deficiencies have also been found (Steinhausen, Blattmann, & Pfund, 2007). In addition, cocaine use during pregnancy is associated with impaired fetal growth, neonatal seizures, and congenital anomalies. Cocaine-exposed infants demonstrate dysregulation of autonomic nervous system functions (e.g., heart rate, respiratory sinus arrhythmias) within the first year of life, and this alteration of response to stressors continues into later childhood (Schuetze, Eiden, & Coles, 2007; Kable, Coles, Lynch, & Platzman, 2008). Furthermore, learning problems have been found in 8- to 10-year old children who were exposed to cocaine in utero (Mayes, Snyder, Langlois, & Hunter, 2007). Infants exposed to marijuana during pregnancy were found to have altered neurobehavioral performance when compared to those who were not exposed. This large-scale study noted altered arousal, regulation, and excitability in marijuana-exposed infants (deMoraes-Barros, Guinsberg, de Araujo-Peres, Mitsuhiro, Chalem, & Laranjeira, 2006). A longitudinal study found that marijuana exposure before birth is a predictor of that child's later use of marijuana at age 14, even after controlling for other variables, such as family history of drug use, home environment, delinquency, peer drug use, and sexual activity (Day, Goldschmidt, & Thomas, 2006).

Neonatal withdrawal is characterized by abnormal functions of the gastrointestinal tract, the central nervous system, and the respiratory system. Poor feeding, abnormal sleep patterns, long-term learning disabilities, and delayed language development may be observable results of maternal drug use. In addition, the child faces a high risk of infectious diseases,

including hepatitis B and HIV (March of Dimes, 2008). Infants prenatally exposed to opiates are also more likely to succumb to sudden infant death syndrome (SIDS) (Kahlert et al., 2007).

A lifestyle choice that includes the use of drugs during pregnancy has placed millions of children at risk. These children are seen in neonatal intensive care units, foster care, special-education programs in the public schools, and later in the juvenile court system. Maternal alcohol and substance abuse can predict child maltreatment and subsequent foster care placement (Smith, Johnson, Pears, Fisher, & DeGarmo, 2007). Family structure patterns are altered because grandparents may find themselves primary caregivers for their grandchildren. A woman who is an intravenous drug user or who engages in high-risk sexual behaviors introduces another public health problem, that of acquisition of HIV infection and possible spread of the virus to the fetus or others (De Genna, Cornelius, & Cook, 2007; Minkoff, 2003). The primary, secondary, and tertiary prevention roles of the community health nurse cannot be underestimated when drug use takes such a high toll on every aspect of society.

### Alcohol Use

Another societal problem is the use and especially addiction to alcohol, and it is often the substance of choice. Because alcohol is a legal and socially acceptable substance, it is often the drug most commonly abused by pregnant women (Weber, Floyd, Riley, & Snider, 2002). It is difficult to establish accurate statistics on the number of women who drink during pregnancy, because inquiries about drinking habits trigger denial or minimization of intake, especially in heavy drinkers (Barr & Streissguth, 2001). However, alcohol use can cause devastating effects in the fetus, even when limited to early pregnancy and in the absence of addiction, and can lead to an array of neurocognitive and behavioral disorders, sometimes with structural anomalies, now described as **fetal alcohol spectrum disorders** (FASD). For example, regular intake of alcohol during pregnancy, especially in the first trimester, can cause the most recognizable form of the disorder, **fetal alcohol syndrome** (FAS), which is characterized by structural abnormalities of the head and face (e.g., microcephaly and flattening of the maxillary area), intrauterine growth retardation, decreased birth weight and length, developmental delays related to central nervous system abnormalities that can cause intellectual impairment, hyperactivity, altered sleep patterns, feeding problems, perceptual difficulties, impaired concentration, mood problems, and language dysfunction (Manning & Eugene-Hoyme, 2007).

What was once termed **fetal alcohol effects** (FAE) syndrome, characterized as causing some but not all of the symptoms of FAS, is now separated into the more descriptive categories of **alcohol-related birth defects** (ARBD), indicating problems with hearing, bones, or heart and kidneys, and **alcohol-related neurodevelopmental disorder** (ARND), represented by mental or functional problems, including cognitive and/or behavioral abnormalities (National Center for Birth Defects [NCBDDD], 2006). Recent research has helped to better classify the fetal effects of alcohol, and may continue to lead to more specific classifications (Manning & Eugene-Hoyme, 2007). These conditions occur in children whose mothers have used varying amounts of alcohol while pregnant, and physical signs are often much more subtle than in cases of

FAS. However, those with FASD may have one or more of the following behaviors or characteristics (NCBDDD, 2006):

- ◆ Small size for gestational age, or small stature in relation to peers
- ◆ Facial abnormalities such as small eye openings
- ◆ Poor coordination
- ◆ Hyperactive behavior
- ◆ Learning disabilities
- ◆ Developmental disabilities (e.g., speech and language delays)
- ◆ Mental retardation or low IQ
- ◆ Problems with daily living
- ◆ Poor reasoning and judgment skills
- ◆ Sleep and sucking disturbances in infancy

This completely preventable leading cause of birth defects has been estimated to cost more than \$4 billion annually (Hoyme et al., 2005). FAS is estimated to occur at a rate of 0.2 to 1.5 per 1,000 live births, and the rates of FASD may be triple those of FAS (NCBDDD, 2006). Among the Native American population, the incidence of FAS is four times higher than in the general U.S. public (Struck, 2003). Common in alcohol consumption research is the underreporting of consumption by subjects (Del Boca & Darkes, 2003; Hankin, McCaul, & Heussner, 2000; Kaskutas, 2000). For example, participants may report one or two drinks a day, but when asked to show the vessel used, it is frequently a beverage container of large capacity (standard measurements of alcohol are 1 beer = 12 oz, 1 glass of wine = 4 oz, 1 drink of liquor = 1 oz). The containers from which they drink may hold 16 to 24 oz per “drink.” A large-scale survey reported that 2% of pregnant women engaged in binge drinking, and 28.5% of women of childbearing age reported drinking 5 or more drinks on “typical drinking days,” and 21.4% had at least 45 drinks in an average month. More binge-drinking women with high levels of usual alcohol consumption were found in the 18- to 24-year old age group or among women who were current smokers (Tsai, Floyd, Green, & Boyle, 2007, p. 437).

A study using volumetric MRI to examine brain volumes in 10- to 14-year-old children exposed in utero to cocaine, alcohol, cigarettes, and marijuana found that each substance was individually related to decreased head circumference and cortical gray matter, and that “these substances may act cumulatively during gestation to exert lasting effects on brain size and volume” (Rivkin et al., 2008, p. 741).

It is important to provide evidence-based primary prevention before pregnancy and to reach women before a lifestyle of drinking becomes such a part of their lives that they are unable or unwilling to abstain during pregnancy. For example, the Pregnancy Risk Assessment Monitoring System (PRAMS) is a surveillance system developed by the Centers for Disease Control and Prevention (CDC) and state health departments to collect population-based information on maternal preconception, prenatal, pregnancy, and postpartum behaviors and experiences (CDC, 2007a). Recent data collection revealed that prior to conception, 23.2% of women used tobacco, over 50% used alcohol, and 53.1% of women who were not trying to become pregnant did not use any form of birth control. Also, only 35.1% took a multivitamin tablet at least four days a week, 10.2% were anemic, and 3.6% reported physical abuse (D’Angelo et al., 2008). Working with women of childbearing age to improve their general health behaviors

and promote better preparation for pregnancy is essential. For those pregnant women and mothers already using substances, maternal drug and alcohol treatment programs that focus on supportive parent–child attachment, enhancement of parenting and childrearing capabilities, and encouragement of the use of support systems that can improve child health and cognitive development are needed. In-home family skills training and parenting education programs that are evidence-based and promote public health nurse (PHN) and client rapport are very effective methods of working with substance-abusing mothers and their at-risk children (Kumpfer & Fowler, 2007).

### **Tobacco Use**

Tobacco use has increased dramatically among women, especially since the women’s movement of the 1970s, inevitably affecting maternal and newborn health. The nicotine in tobacco is a major addictive substance, and smoking is an addiction that many people find difficult to stop. Although the risk factors of smoking are well documented, many pregnant women continue to smoke. Smoking during pregnancy is one of the most studied risk factors in obstetric history. It has been associated with ectopic pregnancy, spontaneous abortions, intrauterine growth retardation, preterm birth, stillbirths, higher perinatal mortality, small-for-gestational-age (SGA) birth, LBW birth, neonatal anomalies, and lower Apgar scores (Duncan, 2002; Weck, Paulose, & Flaws, 2008). For pregnant women, an education level below high school graduation and those with a current nicotine-dependence were at higher risk of smoking (90.5%) than college-educated women without nicotine dependence (3.9%), according to a recent Harvard study (Gillman, Breslau, Subramanian, Hitsman, & Koenen, 2008). Smoking is “one of the strongest predictors of both LBW and preterm birth” and is “often linked to stress and depression” (Hobbell, Goldstein, & Barrett, 2008, p. 345). For instance, women who may have started smoking as adolescents often continue to smoke in response to life stressors. Health problems do not end once the infant is born. Infants of women who smoked during pregnancy continue to be at higher risk for LBW, preterm birth, poor fetal growth, SIDS, respiratory infections, asthma, ear infections, and decreased lung function (Mercer, Merlino, Milluzzi, & Moore, 2008; Wang & Pinkerton, 2008; Wigle et al., 2008). As the children get older, they are at higher risk for activity and attention problems (Cornelius, Goldschmidt, DeGenna, & Day, 2007).

Passive smoking or **environmental tobacco smoke** (ETS)—exposure to tobacco smoke from other people smoking in one’s environment—also puts a person at risk for smoking-related disease. The smoke from a burning cigarette sitting on an ashtray, inhaled passively by the nonsmoker, contains a higher concentration of toxins and carcinogens than the smoke inhaled directly by the smoker; physical distance between infant and smoker correlates with the amount of cotinine (the chief metabolite of nicotine) in the baby’s urine (Blizzard, Ponsonby, Dwyer, Venn, & Cochrane, 2003). If a pregnant woman lives with a smoker, she and her fetus can be negatively affected by the other person’s addiction. Passive or environmental tobacco smoke has been associated with decreased head circumference, depressed cognitive development, and lower birth weight. When ETS is present along with poverty (e.g., deficits in housing, food, clothing), even greater cognitive deficits occur (Perera et al., 2005). The

use of **smokeless tobacco products**, such as snuff and chewing tobacco, has led to an increase in oral cancers related to tobacco exposure. Maternal smokeless tobacco use has been associated with lower birth weight and gestational age (Gupta & Sreevidya, 2004).

Community health nurses and other health care professionals must be involved in the control of tobacco products on many levels, especially in health policy development. It is also important to have skills in client assessment, planning, and intervention, to serve as positive role models, and to be active in research implementation. In the case of tobacco control, health policy development has made important strides at the grassroots level (see Chapter 13). A top priority of health care policy development is to reduce access of youth to tobacco products by restricting tobacco product advertising and promotion. Some significant steps that have been taken to discourage young people from smoking include imposing substantial cigarette excise taxes; requiring that public places such as malls, restaurants, and even bars, be smoke free; monitoring tobacco retailers for illegal sales to minors; and keeping cigarettes in locked cases. Most smokers become addicted to tobacco use in their early teens. One study of tobacco use among Wisconsin adolescents found that 31.6% were current users, although 38% of the general adolescent population currently smoked (Sims & Sims, 2005). If fewer adolescents begin smoking, there will be fewer women of childbearing age who smoke in the future.

An initial health history of a pregnant woman should always include the assessment of tobacco use, smoking status, and exposure to smoke in the personal environment. Stress should also be assessed (e.g., unintended pregnancy; nutrition; chronic stress and daily hassles; levels of social support; mental health issues, such as depression or anxiety, work stressors, racism or discrimination; and any significant life events, such as death or other significant losses) (Hobbell, Goldstein, & Barrett, 2008). The PHN must not only advise clients to quit smoking but also offer supportive and empathetic approaches to stress reduction and smoking cessation, including methods or interventions that can help. For example, the community health nurse may counsel clients individually, suggest behavioral therapy, provide self-help manuals, or recommend nicotine replacement therapy or medication. Other approaches, such as support groups, can be helpful. Any permanent reduction in the number of cigarettes smoked, amount of second-hand smoke inhaled, or amount of smokeless tobacco used is helpful in improving the health of the mother and her fetus.

Nurses can be positive role models for health and demonstrate health-promotion strategies to clients by their own behavior—if a nurse has struggled with smoking cessation, his admission of failures or explanation of successful strategies offers an opportunity to enhance his believability with clients. They recognize that he struggles with some of the same health issues as they do.

### **Sexually Transmitted Diseases**

In the United States, an estimated 880,000 pregnant women annually are infected with herpes simplex virus 2, and 100,000 have *Chlamydia*. Fewer than 1,000 annually contract syphilis and 13,200 are estimated to have gonorrhea. Hepatitis B is estimated in 16,000 pregnant women and around 6,400 women are diagnosed with HIV annually (CDC, 2008a).

Sexually transmitted diseases (STDs) can pass from mother to baby. Syphilis can cross the placenta and infect the fetus, as can HIV—which can also be passed to the infant through breast-feeding (CDC, 2008a). Other STDs (e.g., gonorrhea, hepatitis B, *Chlamydia*, genital herpes) can infect the baby as it passes through the birth canal during delivery. LBW, stillbirth, conjunctivitis, blindness, deafness, neurological damage, chronic liver disease and cirrhosis, along with neonatal sepsis and pneumonia, are possible infant complications of maternal STDs. Mothers may have premature rupture of membranes and resultant infection, or may have a premature onset of labor. Some STDs can lead to cervical and other cancers, pelvic inflammatory disease, infertility, chronic hepatitis, and many other health problems (CDC, 2008a).

Adolescent girls who are pregnant and who use marijuana or other substances may be more at risk for STDs (De Genna, Cornelius, & Cook, 2007). A pregnant woman who discovers she has an STD often feels ashamed, betrayed, embarrassed, and angry. Those who are asymptomatic may not realize they are infected or deny the existence of the disease and fail to carry out the treatment plan after diagnosis. Although educating the pregnant client about the effects of STDs is critical, providing information alone is not enough. The community health nurse has a pivotal role in enhancing the empowerment of women so they can act on the information they receive. The PHN engages with the pregnant clients and helps them understand that they have control over their bodies. Usually, STDs are first discovered in pregnancy during routine prenatal screening, which places the clinic nurse and the nurse who may make home visits in the position to take an affirmative approach to treatment and follow-up.

### **HIV and AIDS**

The HIV epidemic is the great tragedy of the final two decades of the 20th century. In 2005 in the United States, 111 infants born to HIV-infected mothers positively tested for HIV, one third the amount reported in 1994. This is related to the growing use of prophylaxis during the perinatal period in an effort to decrease virus transmission (USDHHS, 2007). HIV/AIDS infection in Black infants diminished almost 66%, and infection was reduced for Hispanic infants by over 40%. However, the largest decline was found for White infants (81.8%): 77 to 14 cases (USDHHS, 2007). Mothers who transmitted the virus to their newborn infants reported contracting it through sex with an infected partner, injection drug use, or other unspecified methods.

In a large-scale New York study, HIV prevention interventions between 1994 and 2003 were examined and researchers found that 83% of mothers of HIV-exposed infants received prenatal care and were diagnosed with HIV before delivery. Also, the use of prenatal antiretroviral agents by these mothers increased from 63% to 82%. However, 45% of mothers with infected infants had not participated in perinatal HIV prevention interventions. Prenatal, intrapartum, or neonatal antiretroviral drugs were lacking, largely due to maternal illicit drug use, and were associated with LBW babies (Peters et al., 2008).

An HIV-positive woman who is pregnant or who has delivered a baby requires special nursing management of the pregnancy and of the family after the birth of the newborn. There are many teaching opportunities for the community

health nurse during a high-risk pregnancy such as helping the client identify, change, or curtail high-risk behaviors. Success in changing behaviors often requires an interdisciplinary approach of health care, social, emotional, and financial resources.

In the United States and other developed nations, HIV-infected women are advised not to breast-feed their infants, because there is a 15% chance that the infants will become infected with HIV from breast milk (Shearer, 2008). The community health nurse focuses teaching on providing a safe, available form of infant formula. In developing countries, the lack of clean water still makes formula feeding dangerous, and breast-feeding is usually recommended. The infection rate for HIV from breast-feeding and the mortality rate from formula made with impure water are about the same, resulting in a dilemma for women and health care providers in developing countries.

### **Poor Nutrition, Weight Gain, and Oral Health**

Nutrition is very important to the unborn child, and mothers' choices, even before conception, can affect the baby's health and development. At about three weeks' gestation—often before the woman recognizes that she is pregnant—the infant's neural tube is forming, and poor nourishment during this period is associated with “incomplete interconnection between brain regions” (House, 2007). Hormones and nutrients set gene-switches that affect later life. Nutrients that are particularly important in reproductive health and that have been shown to lower the risk of obesity and childhood cancers, as well as neural tube defects, autism, and dyslexia, include B vitamins (especially B<sub>1</sub>, B<sub>6</sub>, B<sub>12</sub>, and folate), antioxidants (especially E and C vitamins), minerals (especially iron, zinc, selenium, iodine, magnesium, and copper), and essential fatty acids (Katzen-Luchenta, 2007). Important nutrients specifically associated with fetal and infant brain development include vitamin A, choline, folate, selenium, iodine, copper, zinc, and iron. Protein and certain fats are also important, and functioning of specific brain regions is associated with particular nutrients (Georgieff, 2007). Diets rich in protein, nuts, seeds, legumes, and whole grains, along with colorful fruits and vegetables, promote health for both the mother and the fetus. One Harvard University study found that women who ate more fish during pregnancy had infants who demonstrated better cognition, but researchers cautioned that fish high in mercury contamination was detrimental and should be avoided (Oken et al., 2005).

Research has demonstrated a positive correlation between weight gain during pregnancy and normal birth weight in the babies. During 2004, one-third of U.S. women reported weight gains that were outside the recommendations: 13% of women gained less than 16 lbs (19% of Black women) and 20% gained more than 40 lbs (most often White women, at 22.2%). Inadequate weight gain is related to LBW, premature births, and perinatal mortality (USDHHS, 2007). Gaining large amounts of weight can also cause problems at birth, including increased numbers of cesarean deliveries, large-for-gestational-age babies, and the mother's retention of excessive weight. Weight gain between 15 and 35 lbs during pregnancy is recommended for women with body mass indexes (BMIs) ranging from 19.8 to 25; the recommendation is 28 to 40 lbs for underweight women with a BMI under 19.8 and no standard recommendations exist for overweight

women with a BMI over 29.1 (USDHHS, 2007). Obese women have a higher incidence of gestational diabetes, urinary tract infections, wound infection, thromboembolism, pregnancy-induced hypertension, fetal monitoring difficulties, prolonged labor, and birth trauma (Sherwen, Scoloveno, & Weingarten, 2001). Some studies show that, compared with women of normal weight, women who were obese or overweight before pregnancy faced double the risk of having babies with heart defects and multiple birth defects (Watkins et al., 2003). Community health nurses who work with morbidly obese pregnant women can help them most by emphasizing good nutrition and by encouraging them to maintain their pre-pregnant weight without drastically reducing caloric intake. This can be accomplished primarily by a marked decrease in consumption of “empty calories” from junk food and replacing with increased intake of fruits and vegetables. Pregnancy is never a time for dieting. Following nutritional guidelines ensures the proper number of servings and portion sizes. Nutritional counseling can have an additional benefit in that it may ultimately decrease the risk of obesity or eating disorders in the client's children.

Underweight women have twice as many LBW babies as women whose weight is within normal range. Low maternal weight gain is associated with LBW infants who have higher incidences of growth problems, developmental delays, central nervous system disorders, and mental retardation (USDHHS, 2007).

Nutritional teaching is part of the community health nurse's role when working with a pregnant woman who has difficulty gaining the recommended weight during pregnancy. Finding ways to add calories to foods and increasing the woman's desire to eat are effective methods to improve maternal weight gain. Insufficient caloric intake in pregnant adolescents (who themselves are still growing) is an additional concern. For women who are prone to gaining too much weight, nutrition-rich, low-calorie foods are recommended. Exercise during pregnancy is also beneficial, and can reduce maternal weight gain and improve cardiovascular fitness (Gavard & Artal, 2008). After assessment, the community health nurse can determine whether the unwanted weight gain is related to the consumption of additional calories, to limited activity, or to fluid retention. Each cause must be managed differently.

Oral health during pregnancy is also very important to assess. Periodontal infection may affect around 40% of women of childbearing age, and is especially common among disadvantaged and ethnic or racial minorities who may not have adequate access to dental health care (Boggess et al., 2008). Maternal periodontal disease has also been linked to preterm birth, LBW, preeclampsia, and early fetal loss (Ferguson, Hansen, Novak, & Novak, 2007). High maternal levels of the bacteria that cause cavities has been associated with a greater chance of subsequent dental caries in the infant (Silk, Douglass, Douglass, & Silk, 2008).

Public health nurses should teach women of childbearing age the importance of regular dental health checkups and proper dental hygiene, along with making referrals for dental treatment when needed. Dental health procedures have generally been found to be effective and safe for pregnant women, especially during the second trimester (Dasanayake, Gennaro, Hendricks-Munoz, & Chghun, 2008; Silk et al., 2008). Sugar-free gums that contain xylitol and chlorhexidine may be helpful in reducing the maternal child transmission of caries-causing bacteria (Silk et al., 2008). Dental health is not

only important during pregnancy, but poor dental hygiene and disease have been linked to health conditions, such as cardiovascular disease and diabetes. Dental health should be a part of general primary preventive education for all public health clients (Ferguson et al., 2007).

### **Socioeconomic Status and Social Inequality**

As noted earlier, poverty plays a role in pregnancy and birth outcomes. Social and economic disparities are factors in preterm birth in both developed and developing nations. This relationship may be more indirect, as poorer women often lack health insurance, have less access to quality prenatal care services, and are exposed to more situational and psychological stressors. Even Canada, noted for universal health care coverage, has been noted to have inadequate levels of prenatal care related to socioeconomic status (SES) disparities (Weck, Paulose, & Flaws, 2008). Employment-related stress has been associated with risk of preterm delivery, and prolonged sitting or standing, heavy lifting, and long work hours are often associated with the type of low-paying jobs available to women living in poverty (Pompeii et al., 2005). Other factors, outlined in more detail in Chapter 25, may also affect the health of both mothers and babies.

### **Teenage Pregnancy**

The United States leads most developed nations in the rates of teenage pregnancy, abortion, and childbearing. Among 46 developed countries, the United States has the second highest teen pregnancy and birth rates, largely because U.S. adolescents are less likely to consistently use contraception (Darroch, Singh, Frost, & the Study Team, 2001; Singh & Darroch, 2000). There is a strong association between young maternal age and high IMR, and infants born to teenagers are at increased risk for preterm delivery, and for neonatal and postneonatal mortality (Briggs, Hopman, & Jamieson, 2007; March of Dimes, 2007; Usta, Zoorob, Abu-Musa, Naassan, & Nassar, 2008). These adverse birth outcomes are independent of education level, use of cigarettes and alcohol during pregnancy, or prenatal care. Simply being an adolescent puts pregnant teens and their offspring at risk (Chen, Wen, Fleming, Demissie, Rhoads, & Walker, 2007). Infants born to Black adolescents are more likely to be LBW babies than are infants of White teens. Infants born to very young adolescents (aged 10 to 14 years) are at very high risk for neonatal mortality. Teen mothers have increased psychological risks, such as isolation, powerlessness, depressive disorders, and increased somatic complaints. Developmental and maturational processes are disrupted or compromised, and young mothers face diminished prospects for completing their education. It is important for PHNs to assess each pregnant adolescent's situation (e.g., family support and living situation, relationship with the father of the baby and other supportive friends), as well as her hopes, goals, strengths, weaknesses, in order to effectively plan interventions (Rentschler, 2003).

The markers for successful pregnancy outcomes and future life events are more complex. The mother's educational attainment, marital experiences, subsequent fertility behavior, labor force experience, occupational attainment, and experiences with poverty and public assistance are all directly related to the adolescent pregnancy and are often negatively affected (Boden, Fergusson, & Horwood, 2008).

The issues of adolescent parenting are complex. They encompass many areas, including emotional, physical, and social issues, and the life experiences of adolescent mothers often are characterized as unequal to those of their peers who delayed childbirth (Smithbattle, 2007).

Pregnant adolescents are less likely to receive early and continuous prenatal care and they are more likely to use alcohol and to smoke during their pregnancies. Moreover, their diets are often lacking in essential vitamins and minerals (Moran, 2007; USDHHS, 2000). As an aggregate, their infants are at risk for lower 5-minute Apgar scores, LBW, neonatal mortality, and preterm birth (Chen et al., 2007).

The community health nurse has a unique challenge when teaching teens about pregnancy-related changes, accompanying needs, and preparation for the important role of parent. In a Virginia study, adolescent mothers felt that they were not “plainly informed” about the advantages of breast-feeding, and postpartum education classes were recommended to support breast-feeding teen mothers who only got instruction while in the hospital (Spear, 2004, p. 106). A British study of adolescent breast-feeding mothers noted that the teens felt “watched and judged, reported that they lacked confidence, complained of fatigue and discomfort, and recognized the need for both emotional and instrumental/informative support (Dykes, Moran, Burt, & Edwards, 2003, p. 391). Development of a trusting relationship helped teens to continue breast-feeding. Emotional support is provided by relationships that engender love and appreciation, and instrumental support is more concrete (e.g., a ride to the clinic, help with homework, or money to buy food). Informational support is the provision of information or advice (Orr, 2004).

Another issue with pregnant adolescents is the problem of repeated pregnancies. One Texas study found that 42% of teen mothers had another pregnancy within 2 years' time, 73% of these teens went on to deliver an infant (Child Trends, 2006a; Raneri & Wiemann, 2007). Predictors identified in the study included “not being in a relationship with father of the first child three months later,” being more than 3 years younger than the father of the first baby, “experiencing intimate partner violence” within 3 months of the first birth, not being in school 3 months after the first child's birth, and “having many friends who were adolescent parents” (p. 39). Second pregnancies during adolescence have been associated with “worse outcomes” when compared to first-time teen mothers (Reime, Schucking, & Wenzlaff, 2008, p. 4). Public health nurses can provide needed interventions to postpone subsequent pregnancies and encourage the effective and consistent use of contraception (Kershaw, Niccolai, Ickovics, Lewis, Meade, & Ethier, 2003).

### **Emotional Needs**

Teenagers who become pregnant deal with this change in their life in a variety of ways. Some have such a strong denial system that they deny the pregnancy, even to themselves. They may be 3 or 4 months into the pregnancy before they can admit it and seek a physician's diagnosis. Often, their parents are the last to know. What is difficult about this scenario is that prenatal care is delayed into the second trimester of pregnancy. If the teen chooses to continue with the pregnancy, the delayed prenatal care could compromise the well-being of both the young mother and the fetus. Holub and colleagues (2007) studied the effects of prenatal and parenting stress on a large group of 14-

to 19-year-olds and found that those who had high levels of both stressors exhibited lower maternal adjustment (i.e., positive attitude toward being a mother, care of the infant, competent parenting) and higher emotional distress after giving birth. They concluded that early interventions for both prenatal and parenting support are needed. In a small study of pregnant Hispanic teens, Lloyd (2004, p. 239) noted “poor communication and unstable relationships with parents” prior to pregnancy, and a hesitancy to communicate with parents about becoming pregnant. However, most adolescents reported improved communication and relationship with parents after talking with them. Parents and grandparents often provide emotional support. They not only serve as parents to the adolescent, but also compensate for the inadequate parenting skills of the teen with their infant (Dallas, 2004). It takes time for adolescent mothers to begin to understand the role of parent and to get to “know their baby” (Smithbattle, 2007, p. 261).

Caring and supportive parents and community health or school nurses can be instrumental in guiding an adolescent through this difficult time. Teen parents have difficult choices to make, including decisions about continuing with the pregnancy, keeping the baby, or finding adoptive parents. Some may choose abortion. These choices are difficult and are fraught with emotion. Adolescents and supportive parents, in consultation with professionals, can explore all options. This may be the time that the community health nurse first begins to work with the teen, perhaps at school or in a school-based clinic. First contact may also occur in a clinic or physician’s office, or on a home visit resulting from a referral from a health care provider. Home visiting programs for adolescent mothers have been effective in improving prenatal care parenting scores and school continuation rates. They have also contributed to reducing preterm births (Barnet, Liu, DeVoe, Alperovitz-Bichell, & Duggan, 2007; Flynn, Budd, & Modelski, 2008; Nguyen, Carson, Parris, & Place, 2003). The nurse can offer educational services, emotional support, and referrals for services as needed. Because postpartum depression is not uncommon, and adolescents are at increased risk, it may be important for PHN visitation to continue periodically for 1 to 2 years postpartum (Mayberry, Horowitz, & Declercq, 2007; Reid & Meadows-Oliver, 2007).

The goal of any pregnancy is positive maternal–infant outcomes, including a positive relationship. For some teen mothers, positive relationships are more difficult to achieve than for older mothers. Positive relationships and self-esteem have an impact on the quality of mothering and positive responses to infant distress. Typically, older adolescents have higher self-esteem than younger mothers: this was observed in classic studies conducted by Olds and colleagues (1999, 2000) and by Koniack-Griffin and colleagues (2000, 2002, 2003). These significant studies demonstrated the benefits of intensive intervention programs. Community health nurses who have special training can provide each participant with services that promote the overall health of the mother and maternal–infant bonding. Results of these studies can further guide nurses in their work with pregnant adolescents.

### Physical Needs

Pregnant teens have a gamut of physical needs that can be addressed by routine prenatal care and education, but there is need for continuity if such endeavors are to be successful.

Routine prenatal care is one of the most important needs, and teens may require assistance in recognizing the value of monitoring the pregnancy. Some may feel embarrassed and uncomfortable with male health care providers and refuse to keep appointments or may want to be accompanied by the baby’s father or a girlfriend. Whatever it takes to get the teen to prenatal appointments should be encouraged, including making arrangements for transportation (e.g., procuring bus tokens, calling a taxi, or arranging for a friend or social worker to drive the teen to her appointments) (Michels, 2000). Where feasible, specially focused clinics for pregnant and parenting teens may be most effective; a multi-center Australian study found that teens attending a specialized teen prenatal clinic had significantly lower rates of preterm births (Quinlivan & Evans, 2004). School-based clinics have shown promise in providing easily accessible prenatal care, lowering the risk of giving birth to LBW infants and reducing school dropout rates (Barnet, Arroyo, Devoe, & Duggan, 2004; Barnet, Duggan, & Devoe, 2003; Strunk, 2008).

The pregnant teen needs education regarding changes in her emotional state and her body, the growth and development of the fetus, dietary requirements, and rest and relaxation needs. She also needs anticipatory guidance for care giving and parenting. Teaching can take place as part of each prenatal appointment, in specific classes at school for pregnant teens, in the health department clinic, or during home visits. In each setting, the community health nurse can modify the teaching methods to the setting and the individual needs of the teen. Studies show that PHN home visits and preparation-for-motherhood classes are effective in promoting better outcomes for adolescents and their infants, including better use of resources (e.g., prenatal visits), fewer hospital days, lower school dropout rates, fewer repeat pregnancies 2 years postpartum, and decreased infant mortality (Flynn, Budd, & Modelski, 2008; Koniack-Griffin et al., 2000; Koniack-Griffin et al., 2003).

Changing teen behavior during pregnancy can be challenging, and PHNs must keep in mind the developmental differences between early, middle, and late adolescents with regard to intentions and health habits (Phipps, Rosengard, Weitzen, Meers, & Billinkoff, 2008). The community health nurse may focus on one important and seemingly less complex issue of nutrition during pregnancy. However, it is a more difficult task to change the eating habits of teens than it is to change those of adults. In their stage of development, teens usually are more concerned with body image than with fetal growth and development. Fad diets, peer pressure, and personal control are all issues with which the pregnant teen is struggling. If a teen has been raised in poverty, a multiplicity of other issues can affect her motivation to make dietary changes during pregnancy. Teens are more often concerned with present needs and respond better to relaxed, informal group approaches to education that involve topics of their choosing and do not resemble the school setting. Pregnancy diaries, creative activities (crafts, drawing, making snacks), small group activities and games, videos with discussions, and visits to local community resources (hospital delivery rooms, social services, lactation counselors) are more appealing than classroom lectures (Robertson, 2003). Programs that offer empowerment and group prenatal care are helpful (Klima, 2003). Also, teaching and support groups may be helpful in promoting healthy prenatal behaviors and preparing for motherhood (National Clearinghouse on Families & Youth, 2007; Quinlivan, 2004).

## Social Needs

Pregnant teens are dealing with two stages of their own growth and development at the same time, which makes their social needs complex. They are struggling with the normal adolescent challenges along with the responsibilities of pregnancy and parenting (young adulthood stage of development).

There may be changes in acceptance by social groups or in types of activities (e.g., surfing, mountain climbing). The group may participate in activities that the pregnant teen should not participate in, such as smoking, drinking, or taking illicit drugs. This causes conflict for a pregnant teen who has a strong need to be accepted by her peer group and who also knows that she has a responsibility to her unborn child. The community health nurse can help the teen solve her dilemma by providing a social support system among the attendees at prenatal classes. The nurse can also convince the teen's parents or other adults in her life to offer her more support. Often, a developmental crisis such as a teen pregnancy can help cement the mother-daughter relationship. It takes time and work on the part of the parents and the teen. The teen will need the support of her parents after the baby is born, and strengthening the relationship during pregnancy is an important start.

Another social outlet and an important resource is school. The teen should be encouraged to continue her studies, with the goal of graduation. The health and welfare of children are related to the educational levels of their parents. Higher educational levels increase the likelihood that children will receive adequate medical care and live in a safe and supportive environment with adults who are responsive to their needs (Koniack-Griffin et al., 2000). Internet support groups organized and monitored by nurses are beginning to provide another means of social support for pregnant and parenting adolescents (Hudson, Campbell-Grossman, Keating-Lefler, & Cline, 2008). Computer and Internet-based interventions have demonstrated success in providing knowledge and promoting delayed sexual activity in Appalachian high schools (Roberto, Zimmerman, Carlyle, & Abner, 2007). Greater self-efficacy in negotiating condom use was also noted in participants, and the majority of high school students (88.5%) participated in at least one activity aimed at preventing teen pregnancy and transmission of STDs and HIV. Teen pregnancy and education are discussed more thoroughly in Chapter 22.

## Maternal Developmental Disability

For couples who are developmentally disabled, having a child puts increased stress on a system that is already burdened. Past studies have shown that child abuse, neglect, and child behavior problems, along with poor academic achievement and inadequate home environments, accompany the parenting style of developmentally disabled parents (Feldman & Walton-Allen, 1997; Morch, Skar, & Andersgard, 1997). However, more recent research has found that children with an IQ at or above 85 were not at greater risk of exhibiting behavior problems, regardless of the mother's IQ level (Chen, Schwarz, Radcliffe, & Rogan, 2006). Children are still at risk, however, for understimulation and environmental insecurity, but parent training/child-care skills programs and careful home monitoring can reduce the risk of child abuse and neglect and promote more effective parenting (Bager, 2003; Feldman, Ducharme, & Case, 1999; Nitzkin & Smith, 2004).

Much of the pediatric literature discusses the needs of developmentally disabled infants and children and the roles of nurses and health care professionals in assisting the families of these children. Developmentally disabled adults, however, are rarely represented in studies of disability, so there is limited information about their success as parents. Over the past 20 years, studies identified that a primary problem affecting the children of developmentally disabled mothers is the poor quality of maternal–infant/child interaction. The parenting style of mothers with developmental disabilities is often nonstimulating, punitive, and restrictive (Feldman, Case, Towns, & Betel, 1985). In addition, unusual and sometimes bizarre behaviors can occur because the parent does not understand basic concepts regarding normal child development. Better cognitive outcomes for infants have been documented when developmentally delayed or mentally retarded parents were more responsive and involved (Feldman et al., 1985). Periodic developmental screening, infant stimulation and home visitation programs, and special health care instruction have demonstrated evidence-based results (Nitzkin & Smith, 2004). How does the community health nurse work with developmentally disabled parents effectively? Most importantly, nursing support must enhance the natural resilience of the family. Extended family support systems, along with community agencies that provide services to mentally disabled adults and children, can improve the outcomes for these families. The success of family support depends on immediate and continuing health promotion visits. The goal is to establish safe parenting routines that will serve as a foundation for parenting skills needed when the infant begins to walk and explore—a time when the infant's safety is more in jeopardy.

The establishment of a trusting relationship between the nurse and the family is of foremost importance. Teaching by demonstration with many visual aids and prompts, along with games and creative approaches to engage and sustain attention, can challenge the nurse's creativity. Modeling of appropriate parenting behavior needs to occur on each visit. Supervision and monitoring of family functioning must continue until the child reaches adulthood. Many agencies employing PHNs cannot provide the intensive follow-up that such a family requires. It is then necessary to make referrals to organizations that can provide support, such as the American Association of Retarded Citizens (AARC) or Exceptional Parents Unlimited. The nurse may stay involved as a consultant to the paraprofessionals or make periodic home visits at times of developmental or situational crisis.

## Complications of Childbearing

Some maternal deaths are not preventable (e.g., amniotic fluid embolism), but one large study in North Carolina found that 40% of pregnancy-related deaths were preventable, either through better preconception care, improved system factors, better quality of care, or patient actions (Berg et al., 2005). Morbidity is also a factor, and although some major risk factors among pregnant women and infants have been discussed, several common complications of childbearing bear mentioning. The effects of hypertensive disease in pregnancy, gestational diabetes, postpartum depression, and grief in families who have lost a child are important areas in which the community health nurse can intervene successfully.

## Hypertensive Disease in Pregnancy

Blood pressure measurements in all people show daily variation, regardless of physical and mental activities. Hypertension in pregnancy may be chronic or related specifically to pregnancy. In 2004, chronic hypertension during pregnancy was found in 9.6 per 1,000 births, and was more often found in Black women than in White and Hispanic women. The rate for pregnancy-related hypertension was markedly higher at 37.9, with lower rates for Hispanic mothers. Severe hypertension, due to either cause, is associated with premature birth, fetal growth restriction, abruption of the placenta, and stillbirth (USDHHS, 2007).

Preeclampsia is an “idiopathic multisystem disorder” related to disease of the placenta (Norwitz, Hsu, & Repke, 2002, p. 308); or, a “vascular endothelial disease” resulting in placental dysfunction (Van Pampus & Aarnoudse, 2005, p. 489). It results in new-onset high blood pressure and protein in the urine, along with nondependent edema, and can result in eclampsia (characterized by convulsions and/or coma), pulmonary edema, liver rupture, renal failure, disseminated intravascular coagulopathy (DIC), and cortical blindness (Van Pampus & Aarnoudse, 2005). Preeclampsia/eclampsia is the second leading cause of maternal death (15%), and often occurs in adolescent pregnancies or with mothers older than 35 (Norwitz et al., 2002). HELLP syndrome (named for hemolysis, elevated liver enzymes, and low platelet count) is a severe form of preeclampsia and can lead to bleeding tendencies and other complications (Matchaba & Moodley, 2001). The effects from pregnancy-induced hypertension on infants are often serious because placental health is associated with fetal growth (Salafia, Charles, & Maas, 2006), but long-term maternal consequences can also be significant. A woman who has experienced preeclampsia is at increased risk of cardiovascular disease and chronic hypertension later in life (Van Pampus & Aarnoudse, 2005).

Various methods are employed to attempt to prevent and control hypertension during pregnancy, namely, a diet rich in fresh fruits and vegetables, adequate fluid intake, weight gain limitations, rest, and regular exercise. These remain the most common preventive suggestions that community health nurses, in collaboration with the clients’ primary health care providers, can give to their pregnant clients. A calm environment, along with periods of rest with the pregnant woman either elevating her feet or reclining in a left side-lying position, are also recommended. Additional assessment data may guide the nurse to focus teaching on stress reduction techniques and modification or elimination of smoking. Public health nurses can provide frequent monitoring of blood pressure and encourage the client to be vigilant in keeping prenatal appointments. However, medication or even hospitalization may be necessary. The nurse can offer support and understanding while continuing to be a resource for the client as the pregnancy progresses and the infant is born. Calcium supplements have shown some promise in reducing the risk for preeclampsia in those women at increased risk (e.g., previous preeclampsia, mother and/or female relatives with history of preeclampsia), and in reducing the risk of death or serious problems in women with preeclampsia (Hofmeyr, Atallah, & Duley, 2005). Low-dose aspirin therapy also can prevent preeclampsia and subsequent infant complications (Meads et al., 2008).

## Gestational Diabetes

**Gestational diabetes mellitus (GDM)** is defined as “glucose intolerance of variable degree with onset or first recognition during pregnancy.” GDM occurs in about 7% of pregnancies (American Diabetes Association [ADA], 2003, p. s103). For the mother with GDM, there is a higher risk of hypertension, preeclampsia, urinary tract infections, cesarean section, and future risk of type 2 diabetes (ADA, 2003). The infant is at increased risk for fetal death because GDM has been associated with large-for-gestational-age (LGA) babies, which puts them at risk especially during delivery (Mondestin, Ananth, Smulian, & Vintzileos, 2002). An Iranian study using a 75-g glucose tolerance testing (GTT) protocol found a 6.1% incidence of GDM and a correlation between 1-hour blood glucose levels and neonatal birth weights (Shirazian et al., 2008). In 2004, the rate of GDM was 35.8 per 1,000 live births (USDHHS, 2007). Pathophysiologically, GDM is similar to type 2 diabetes, and more than one-third of women with GDM eventually develop type 2 diabetes during their lifetimes.

Because growth and maturation of the fetus are closely associated with the delivery of maternal nutrients, particularly glucose, maintenance of appropriate glucose levels is essential to the health of the fetus. Daily self-monitoring of blood glucose levels is recommended (ADA, 2003). Glucose control is most crucial in the third trimester because of fetal growth at that stage, and is directly related to the duration and degree of maternal glucose elevation.

The community health nurse can help in the control of GDM by encouraging early prenatal care, adequate nutrition, rest and exercise, and adherence to the particular regimen suggested by the woman’s health care provider. A structured walking program was shown to regulate glucose levels in women with GDM effectively, while reducing daily insulin levels (Davenport, Mottola, McManus, & Gratton, 2008). Although earlier recommendations were restricted to human insulin, a comprehensive review of current research on GDM management and outcomes found both maternal and infant benefits and a low likelihood of fetal harm with either the use of insulin or oral diabetes medications (ADA, 2003; Nicholson et al., 2008). Waist circumference measurements and a family history of diabetes along with GDM are associated with development of later type 2 diabetes (Nicholson et al., 2008; Lee, Jang, Park, Metzger, & Cho, 2008). Women should be encouraged to monitor blood glucose levels regularly 6 weeks postpartum and periodically throughout their life (ADA, 2003). Those PHNs working with pregnant women should provide education on early warning signs for GDM and the importance of regular prenatal care and follow up.

The infants of women with GDM often weigh significantly more than other full-term infants, and a large-scale Harvard study found that higher birth weight babies, as well as those born to mothers with GDM, were at higher risk of being overweight in adolescence (Gillman, Rifas-Shiman, Berkey, Field, & Colditz, 2003). Some women who have such large babies may expect more of the infant because, at birth, the baby weighs the same as a 2- to 3-month-old child. Teaching and anticipatory guidance become particularly important for these women.

Thyroid disease, the second most common endocrine disorder in pregnancy next to diabetes, is also an important

consideration in women of childbearing age as thyroid hormones factor strongly into fetal brain development (Neale, Cootauco, & Burrow, 2007).

### **Postpartum Depression**

Although most people recognize the common fleeting mood swings immediately after childbirth known as “baby blues,” high-profile cases like Andrea Yates, who suffered from postpartum psychosis and drowned her five small children, are rare (1 or 2 per 1,000 births) but nonetheless tragic (Williams, 2002). The actress Brooke Shields discussed her postpartum depression and treatment with antidepressant medications, making this condition more visible and less stigmatizing (National Institutes of Health [NIH], 2005).

Depressive disorders during a woman’s lifetime are fairly common phenomena; 20.6% of women and 11% of men were diagnosed in 2006 (Heo, Murphy, Fontaine, Bruce, & Alexopoulos, 2008). In the postpartum period, approximately 10% to 15% of women are affected by postpartum depression for a period of 1 month up to 1 year (NIH, 2005). About 20% of women are estimated to suffer from depression during pregnancy, but about half the time health care providers do not recognize it (Bennett, Einarson, Taddio, Koren, & Einarson, 2004). Depression can affect anyone, even women without a history of prior depression. Perinatal depressive symptoms may not indicate major clinical depression. Nevertheless, symptoms may cause considerable psychological distress, such as irritability and restlessness; feeling hopeless, sad, and overwhelmed; having little energy or motivation and crying unexpectedly; sleeping and eating too little or too much; problems with cognition (memory, decision-making, focus); loss of pleasure or interest in usually pleasant activities; and withdrawal from family and friends (National Women’s Health Information Center [NWHIC], 2005).

Through numerous studies over the years, researchers have identified specific risk factors associated with perinatal depression and have developed a profile of women with postpartum depression (NWHIC, 2005). Risk factors for depression during pregnancy include a personal or family history of depression, substance abuse or mental illness, lack of social support, anxiety about the fetus, marital or financial problems, recent death of family member, and problems with previous pregnancies or births, along with young maternal age. Rapid hormonal shifts within the first 24 hours after giving birth may lead to postpartum depression. Sometimes, thyroid levels drop after childbirth, and low levels can cause depressed mood, fatigue, difficulties with concentration, weight gain, and sleep problems (NWHIC, 2005).

Most depressed postpartum women experience low self-esteem, which can be reinforced by the infant’s temperament. Moreover, the demands of an irritable infant on a new mother who is fatigued and has limited support from a spouse or significant other can increase the depressive symptoms. Other mothers, who have babies who are not irritable, may feel guilty because of the apathy they feel toward their babies, or they may experience anxiety about hurting their infants or themselves (NIH, 2005). In addition, stressful life events combined with a lack of social support and everyday stressors, the greatest of which is interpersonal conflict, are etiologic factors in postpartum depressive symptoms. Postpartum depression affects maternal–infant bonding (NIH, 2005; NWHIC, 2005).

The value of confidants to new mothers is evident, and mothers should be encouraged to ask for help from family and friends or to talk with other new mothers or join support groups. Group and individual therapy are helpful, as is medication. Public health nurses can encourage new mothers with depressive symptoms to get adequate rest (nap while baby is sleeping), be realistic and not try to be the perfect homemaker, ask for help from her partner with feedings during the night and with household chores, get out of the house periodically, and spend quality time with her partner (NWHIC, 2005).

There are several nonpharmacologic interventions the community health nurse can initiate in addition to the ones mentioned above. First, caffeine can lead to sleep disturbance, and alcohol is a depressant that has been implicated in depression. The elimination of both is a simple yet helpful suggestion. Getting adequate sleep is important because sleep deprivation exacerbates psychiatric symptoms. Napping when the baby naps, resting when possible throughout the day, and going to bed early (albeit with the knowledge that sleep may be interrupted two or more times to feed the infant) will provide more hours of rest and sleep. Anxiety symptoms often coexist with depression. Relaxation techniques that reduce anxiety can be helpful, including listening to relaxing music, doing yoga, or performing a simple exercise routine. Participation in a support group allows women to identify with others who may be experiencing similar difficulties. Through discussion, women provide each other with both emotional and practical support.

A final area of assistance is client education. A woman with postpartum depression is more likely to manage her depression successfully if she is aware of the symptoms of depression; the need for a support system; the importance of adequate rest, sleep, and nutrition; and the possibility of supportive psychological or pharmacologic therapy. The critical nature of postpartum depressive symptoms and the potential negative ramifications for mothers and their children are evident. Depression during pregnancy can result in lower birth weight or premature infants, and postpartum depression can affect parenting and infant stimulation that can lead to delays in infant language development, emotional bonding, lower activity levels, and behavior and sleep problems (NWHIC, 2005). Untreated depression can lead to substance abuse, inadequate prenatal care and nutrition, poor pregnancy outcomes, family disruption, and inadequate mother–infant bonding. However, the safety of antidepressants in pregnant and breast-feeding women is not clear (Boucher, Bairam, & Beaulac-Baillargeon, 2008; Maschi, Clavenna, Campi, Schiavetti, Bernat, & Bonati, 2008; Mian, 2005; Oberlander, Warburton, Misri, Riggs, Aghajanian, & Hertzman, 2008; Pearson et al., 2007).

Even though psychotropic medications have been shown to cross the placental barrier and have been found both in amniotic fluid and breast milk, the American College of Obstetricians & Gynecologists (ACOG) cautions against leaving mental illnesses untreated and recommends that the use of antidepressants be individualized and that further research be conducted (ACOG Committee on Practice Bulletins, 2008).

Community health nurses can intervene by initiating primary preventive measures that promote health throughout pregnancy and the postpartum period. Assessment of the pregnant woman for factors that contribute to depression with standardized questionnaires or one developed by the nursing agency is a beginning (Beck & Gable, 2001). If women with compromised mental health resources can be

identified, then positive mental health outcomes may be fostered by supporting their self-esteem, optimizing the quality of their primary intimate relationships, and reducing day-to-day stressors. At times, the nurse's efforts alone are not sufficient and a referral to community mental health services is essential for the women and their children.

### **Fetal or Infant Death**

An infrequent role for community health nurses in maternal-child health is that of grief counselor. A couple may experience a miscarriage or ectopic pregnancy, stillbirth, or the death of an infant from SIDS. **Sudden infant death syndrome (SIDS)** is “the sudden death of an infant less than one year of age that cannot be explained after a thorough investigation is conducted, including a complete autopsy, examination of the death scene, and review of the clinical history” (CDC, 2008b). More than 2,250 infants die annually from SIDS, making it the leading cause of death for 1- to 12-month-old infants. Since 1990, the rate of SIDS has dropped over 50% (CDC, 2008b).

In each situation of loss, the nurse has an important supportive role. People respond to grief in a variety of ways: some express deep sadness, shock, or disbelief; some weep and are unable to talk; and others talk incessantly about regrets or guilt. Even if a miscarriage occurs early in a pregnancy, the bonding between the mother and fetus has begun and expressions of grief may be as intense as with the loss of an infant or child. Women have described feeling a sense of abandonment and bereavement, and thinking that “they are the cause of the miscarriage through something they have done, eaten, or thought” (Adolfsson, Larsson, Wijma, & Betero, 2004, p. 543). Although grief reactions vary, the grief experienced by women after a miscarriage has been described as “similar in intensity to grief after other types of major losses.” The sense of grief usually begins to diminish by around 6 months (Brier, 2008). Increased anxiety levels are also found, sometimes more frequently than depression, and can last for about the same amount of time, leaving some women more at risk for post-traumatic stress disorder (PTSD) and obsessive-compulsive disorder (OCD) (Brier, 2004; Cumming et al., 2007). Psychological counseling has been associated with greater decreases over time in levels of worry, grief, and self-blame (Nikcevi, Kuczmierczyk, & Nicolaidis, 2007). When parents are unable to identify the exact cause of their fetal loss, they have a more difficult time letting go of grief and anxiety (Nikcevi et al., 2007).

For couples who have delivered a stillborn baby, the shock is compounded by the experience of carrying the pregnancy to full term, along with the anticipation of an imminent delivery and the expectation of an addition to the family. This is especially true if all signs before the birthing event itself were positive. They may say such things as, “we felt him move just yesterday and now he's dead—what did I do wrong?” or “I did everything right during this pregnancy. Why did this happen?” These are questions for which there may be no answers, even from the family's health care provider. Frequently, a stillbirth is related to birth defects (15% to 20%), fetal entanglement in the umbilical cord (15%), placental problems (10% to 20%), reduced fetal growth (20%), or to an infection (10% to 20%). Trauma and *Rh* disease can also lead to stillbirths (March of Dimes, 2005b).

Mothers who experience stillbirths recognize the need for spiritual and psychosocial support from professional caregivers, and relate that they struggle to find meaning through their grief, which is often “emotionally complex” and long lasting (Cacciatore & Bushfield, 2007). Families must acknowledge the death of the child and integrate the loss into their family lives through “significant and meaningful family practices” (Gudmundsdottir & Chesla, 2006, p. 143). Sharing their stories of loss, facilitating sociocultural rituals regarding the loss, having a “sensitive presence,” and validating the loss are helpful nursing interventions (Callister, 2006, p. 227).

Often, the family needs reassurance that they did nothing wrong or that there is nothing they could have done differently to prevent the stillbirth. Tenderly encouraging the family to talk about the baby and the sadness they feel is important. Home visitation and simply being there for the family and listening well are invaluable nursing interventions. Referral to mental health counseling or support groups specific to parents of stillborn children where they can share their feelings may be very helpful (March of Dimes, 2005b).

When a family experiences loss of an infant after the baby has been brought home from the hospital, grief and guilt are compounded by the loss of an anticipated future and the disrupted continuity in family life. An infant may die of SIDS, a congenital anomaly, an infection, or an accident. There are constant reminders of the infant's presence in the home from memories, photos, videos, and accumulated possessions. This death disrupts family homeostasis and the psychological and physiologic equilibrium of the family. In many cases, the police are involved and an autopsy is required, contributing to the anguish of the grieving family. This promotes both guilt and loss of self-esteem and can even threaten the marriage. The lack of a clear causative factor, especially in the case of SIDS, can be very frightening to parents (Yiallourou, Walker, & Horne, 2008).

The nurse's presence at this time is important. Often, families are inundated with visits from supporters immediately after a death and during the burial ceremony. Thereafter, the parents are visited less frequently or not at all, although this is usually a very lonely and critical time for them. Providing continuity and support to the family for months after the death of an infant gives the PHN an opportunity to assess the family for signs of unresolved grief. After the loss of a child, ruminative coping (rather than distracting coping) style puts the mother at greater risk of major depression, and the incidence of depression in cases of child loss have been reported to be as high as 69% (Ito et al., 2003). Grieving families may find comfort, support, and helpful information from support groups and resources such as Compassionate Friends or First Candle.

Maternal grief can encompass the emotions of envy, jealousy, shame, and guilt. This can occur after miscarriage, stillbirth, or sudden death of an infant (Barr & Cacciatore, 2007). Thinking about and planning for subsequent pregnancies may induce feelings of “ambivalence, doubts, and insecurities,” and influence parenting of subsequent children (Lamb, 2002). Couples may experience significant distress; fathers also experience grief after the perinatal deaths (Vance, Boyle, Najman, & Thearle, 2002). The nurse should encourage the parents to express their feelings by using supportive statements and open-ended questions. The parents

may have doubts about actions or behaviors that they believe may have caused the miscarriage, stillbirth, or sudden death of their child. Reassurance and clarification of any misconceptions may alleviate the parents' feelings of guilt and help them cope with their grief in a healthy manner.

## INFANTS, TODDLERS, AND PRESCHOOLERS

Healthy children are a vital resource to ensure the future well-being of nations. They are the parents, workers, leaders, and decision makers of tomorrow, and their health and safety depend on today's decisions and actions. Their futures lie in the hands of those people responsible for their well-being, including the community health nurse.

The well-being of children has been a subject of great concern globally and in the United States. Its importance has been emphasized through development of numerous laws and services, yet the needs of many children continue to go unmet. Many young children often go to bed hungry; some infants and toddlers do not receive even the most basic immunizations before they reach school age. Accidents and injuries are a leading cause of death; preventable communicable diseases increase mortality among the very young. For a country that leads in many areas, the failure to protect and promote the health of its youngest citizens represents a significant breakdown. However, in many other nations—mostly less developed countries—infant health and well-being are in even greater jeopardy.

### Global History of Children's Health Care

Only recently in the history of the world have children been considered valuable assets, even in countries where there are now well-developed programs of infant health promotion and protection, infant and child day care services, and strict educational expectations for all children. In some countries today, however, female infants and children or those born with congenital anomalies are not valued. Countries such as India and China provide inequitable care for male and female children. Gender-selective abortions or infanticide also occur. Some birth, growth, and developmental rituals are harsh and would be considered illegal if judged by Western standards. Cultural practices that are fostered by political forces prevent many countries from improving the health of infants and young children (Save the Children, 2008).

The health of children in one country can affect that of children in other countries, including the United States. Major natural disasters place whole populations at risk, especially the very young and the very old. Examples include the severe acute respiratory syndrome (SARS) epidemic in 2003; the 2004 earthquake and tsunami that affected families from Sri Lanka, India, Indonesia, and Somalia to Thailand; and the Chinese earthquake of 2008 (International Save the Children Alliance, 2008).

### NATIONAL PERSPECTIVE ON INFANTS, TODDLERS, AND PRESCHOOLERS

The **infant** (birth to 1 year), **toddler** (ages 1 and 2 years), and **preschooler** populations (ages 3 and 4 years) are generally healthy, and most of them have a usual source of health care (96%). For children age 4 and younger, 87% were reported by

their parents to be in excellent or very good health (National Center for Health Statistics [NCHS], 2005). The major causes of death among the 1- to 4-year-old population are unintentional injuries (motor vehicle crashes, falls, drowning, fires, and burns), followed by birth defects and cancer (NCHS, 2005). Assault (homicide) and diseases of the heart are also among the five leading causes of death for this age group (Hamilton, Minino, Martin, Kochanek, Strobino, & Guyer, 2007).

### Accidents and Injuries

Toddlers and preschoolers are vulnerable to many types of accidents and unintentional injuries, such as those caused by unsafe toys, falls, burns or scalding, drowning, motor vehicle crashes, and poisonings. These injuries may result in death or significant disability. The loss of children's lives resulting from all injuries combined represents a staggering number of years of productive life lost to society. Childhood injuries lead to about 16,000 deaths each year, and 70% of these are the result of unintentional injuries. Over 20 million nonfatal injuries occur yearly to children, resulting in 300,000 hospital admissions and costing over \$347 billion (Schnitzer, 2006).

Suffocation is the leading cause of death in infants (66%). Most causes of suffocation death are related to either prone sleeping position, wedging between the wall and mattress, soft bedding or sleeping surface obstructing the nose and mouth, head entrapment, hanging, and "overlaying by another person" (Schnitzer, 2006, p. 1867). Infants should go to sleep on their backs, in a crib or child-friendly bed without soft bedding or pillows, and parents should be cautioned about risk factors for SIDS and the potential dangers of sleeping with their babies (Kemp, Unger, Wilkins, et al., 2000; Lahr, Rosenberg, & Lapidus, 2005). Information about the SIDS prevention campaign *Back to Sleep* should be provided to all parents of infants and education should begin with hospital nurses and continue with PHNs in the community (Association of Maternal & Child Health Programs, n.d.).

Infants and toddlers are at risk of falling when they are not adequately supervised. Falls are a leading cause of nonfatal injuries and hospitalizations for infants, toddlers, and preschoolers (Schnitzer, 2006). Falls from stairs, a bed, or other furniture can cause permanent injury or death. Public health nurses should teach families that infants should never be left unattended when not in a crib or play yard. As the infant grows and learns to walk, frequent falls are common and continuous supervision and childproofing the home are essential activities. Pointing out to parents the potential dangers related to falls and teaching them about effective preventive measures they can take (e.g., window guards, dangers of infant walkers) are viable means of preventing serious injuries (Committee on Injury & Poison Prevention, 2001a; 2001b). Young children are curious, and their explorations can lead to injuries from other sources (e.g., burns, drowning, poisoning).

Burn injuries can affect children of all ages. Over 116,000 children are treated yearly for burn- and fire-related injuries. Spilled hot liquids or foods cause most scald burns for 6 month olds to 2 year olds (Safe Kids Worldwide, 2007). Bath water that is too hot can also cause serious scalding injuries. Scalding is the most common cause of burns requiring hospitalization in toddlers; reducing water heater temperature settings to below 130°F is an effective preventive measure that PHNs can promote (Schnitzer, 2006). Infants are often burned

by touching a parent's cigarette or by reaching for a cup of hot coffee or the handle of a pot on the stove. A crawling or toddling child can pull an iron cord, causing the iron to topple on him, resulting in a burn or injury. Electrocution can result from inserting a finger or toy into an electrical outlet. Young children playing with lighters and matches often cause house fires; proper installation and maintenance of smoke alarms help to prevent deaths and injuries (Istre, McCoy, Carlin, & McClain, 2002). Cigarette lighters and matches are fascinating to young children. Toddlers or preschoolers may be able to start a flame, injuring or killing themselves or others. The sound of a smoke alarm may frighten young children, and it is important for community health nurses to instruct parents not only to teach their young children about fire prevention, but also to be aware of the sound of the alarm and know what actions to take when they hear it (Schnitzer, 2006).

Preventing the sources of injury or death from burns may be accomplished by eliminating opportunity and source. Through child supervision, safe storage of matches and lighters, and keeping children away from stoves and electrical outlets, burns can be prevented. Adults can protect children from burns by keeping pot handles turned toward the center of the stove, by not using stove burners or ovens to heat their homes, by reducing the temperature setting on water heaters, by always testing bath water with an elbow before placing a child in the bath, and by keeping electrical outlets covered with inexpensive plastic inserts. Many local fire departments and public health programs offer safety education in this area. Such programs emphasize the use of heat- and smoke-detecting systems; fire drills; home evacuation plans; use of less flammable structural materials, furnishings, and clothing; and not permitting smoking inside the house. Child-resistant cigarette lighters, which have been mandated by the U.S. Consumer Product Safety Commission, have resulted in a 58% decline in the number of fires caused by children playing with lighters and a 31% reduction in deaths (Safe Kids Worldwide, 2007; Smith, Greene, & Singh,

2002). Flame-resistant sleepwear for children and anti-scald plumbing for new construction have also been developed.

The rates of drowning are highest for children between the ages of 1 and 3. One-fourth of all injury-related deaths of toddlers are due to drowning (Schnitzer, 2006). Brief lapses in supervision can have disastrous consequences. Young children are at risk for drowning wherever water occurs in depths exceeding a few inches—such as in toilet bowls, bathtubs, mop buckets or cans filled with rainwater, puddles, ponds, spas, and swimming pools. Lakes, rivers, streams, and irrigation ditches or canals are other water hazards. Infants, toddlers, and preschool-aged children are especially vulnerable because they are not aware of water dangers and they explore without fear. Parents need to provide a drown-free environment. Guidelines include the following:

- ◆ Bathe young children in shallow water
- ◆ Never leave young children unattended during a bath
- ◆ Keep toilet lids down and bathroom doors closed—preferably secured with childproof safety handles
- ◆ Never leave full mop buckets unattended
- ◆ Eliminate water-collection sites around the home by turning over or removing empty buckets, containers, flower pots, and other items that can collect rainwater
- ◆ Fence swimming pool areas and install childproof locks or alarm devices that sound when the water is disturbed
- ◆ Promote water safety measures, including teaching young children to swim
- ◆ Vigilantly observe young children at play to protect them from wandering off toward neighborhood water sources

The AAP recommends that while supervising children in or around bathtubs, spas, or pools, adults remain within an arm's length and not be distracted by other activities (Brenner, 2003). The real dangers of accidental drowning are related in From the Case Files I.

## From the Case Files I

### Mop Bucket Drowning

I am a Head Start nurse, and one of my assigned centers is located within a farm labor camp. There are many large, hardworking families in the camp. Older siblings often watch over young children and help with household chores. Most families keep their cinderblock homes tidy and clean, and floors are constantly being mopped (no one has carpeting—it is a bare-minimum type of accommodation). One day, several children were absent from school, and when I made home visits to determine the cause of the absences, I discovered that one of the Garcia family's children, a toddler named Miguel, had unexpectedly died. Because many of the absent children were cousins, parents had kept them home while attending to the family. I knew the Garcia family well, and when I stopped by to check on them they told me that Miguel had fallen into a large mop bucket the older sister had been using to clean the kitchen floor. She had gone outside for just a minute to separate the 5-year-old twins who were fighting, and when she returned she found Miguel head first in the bucket. She tried to revive him, but could not. The parents were working, trying to earn extra money for an elderly grandmother who needed surgery, and only learned of the tragedy when they returned home at the end of a long day. It was a very sad situation, and it reminded me of how even an everyday item can become deadly. Safety and prevention of unintentional injuries, especially with curious toddlers and preschoolers, is extremely important to teach all families.

*Myra, Head Start Nurse*

Injuries and deaths from motor vehicle crashes continue to be a major safety problem in the United States. Approximately one third of injury-related deaths of toddlers and 58% of those for school-age children are a result of motor vehicle crashes (Schnitzer, 2006). Some families do not use infant safety seats or child booster seats consistently, even though these devices have been required by law for decades. Other families have them and use them regularly, but do not install them properly, placing the child at as much risk as if there were no restraint. A study found that of almost 3,500 child-restraint systems inspected, 72% were not placed or used correctly and could increase the risk of child injury if a crash occurred (National Highway Traffic Safety Administration, 2006). Children under age 12 are generally safer in the back seat (CDC, 2007b). There is much opportunity in this area for the community health nurse to educate the public and ensure that parents have the information and skills to secure their children properly when traveling by car. Safety seat clinics, where installations are checked and corrected, can help to promote the correct use of age-appropriate child restraints. See Evidence-Based Practice: Getting Families to Use Child Booster Seats for an example of effective interventions.

## EVIDENCE-BASED PRACTICE

### Getting Families to Use Child Booster Seats (Carrot or Stick?)

Many health departments, law enforcement, and social service agencies educate parents about the laws and benefits related to the use of child safety seats. Still, not every family consistently uses them. What is the best method to use to ensure compliance with laws? Should we offer incentives (carrots), or should we rely on tickets and fines (sticks)?

Researchers conducted a systematic review of research involving the “acquisition and use of booster seats,” those child safety seats that should be used for children up to 80 pounds and 58 inches. They found five quality studies with a total of 3,070 participants, and concluded that interventions which included incentives—like gift certificates or discount coupons for booster seats—or gifts of booster seats, along with education about their proper use, were the most effective. They only found one study that looked at enforcement of laws related to use of booster seats, and it was without significant findings. Therefore, researchers concluded that public health professionals could be more effective in their use of carrots rather than sticks when promoting the use of booster seats or, possibly, other child safety seats or restraints.

Interventions for promoting booster seat use in four to eight year olds traveling in motor vehicles. *Cochrane Database of Systematic Reviews*, Issue 1, Art. No.: CD004334. Retrieved August 13, 2008 from <http://www.cochrane.org/reviews/en/ab004334.html>.

Poisoning is a constant safety concern for young children, and toddlers are most often at risk. Poisoning is one of the leading causes of injury-related hospitalization in this age group (Schnitzer, 2006). Sources of poisoning include household plants, prescription medications, over-the-counter drugs, unintentional medication overdoses, household cleaning products, other chemicals stored within a child’s reach, and lead. “Mr. Yuk,” a sticker displaying a scowling green face with a protruding tongue, has not proved effective in preventing toddler poisonings, and the Poison Prevention Packaging Act of 1970 has also failed to reduce poisoning cases significantly (Schnitzer, 2007). However, PHNs can provide parents with the number for the Poison Help Hotline (1-800-222-1222) and encourage them to post it next to each telephone and call immediately in the event of a suspected poisoning or overdose (American Association of Poison Control Centers [AAPCC], 2008a).

Childproofing the home to eliminate major sources of poisoning is the best way to keep children safe. This includes keeping plants out of a child’s reach or eliminating them from the home until the child is older, locking up household chemicals (e.g., toilet bowl cleaner, bleach, mouthwash, oven and drain cleaners, pesticides, gasoline, paint thinner, hair products) and storing them out of a child’s sight and reach, using childproof medication containers, and storing all medicines in a locked box with a key that is kept out of reach (AAPCC, 2008b). Alcoholic beverages should also be kept out of reach, as should tobacco products. Outside hazards, such as wild mushrooms and poisonous plants, flowers, and berries, must also be considered (AAPCC, 2008b). It is also important to eliminate sources of lead in and around the home.

Lead is a major cause of childhood poisoning. There is no safe level of lead, and the elimination of elevated blood lead levels in children is a *Healthy People 2010* objective. During the three decades between 1970 and 1999, new state and federal regulations to control lead exposure were enacted and enforced, and resulted in the reduction of blood lead levels. The primary sources of lead exposure in preschool-aged children continue to be lead-based paint and lead-contaminated soil and house dust. The critical age of exposure (or peak level) is thought to be between 18 and 36 months. Levels generally begin to decline after age 3. High blood levels of lead in children between 6 and 24 months of age are correlated with lower IQ levels at older ages (CDC, 2005a). Children who live in poverty and play in substandard housing areas remain at risk for direct exposure to significant sources of lead. For example, in Louisville, Kentucky, 35% of all children with high blood lead levels were found to reside in just 79 housing units—representing less than 1% of units in that community (CDC, 2005a). Lead safety and housing code enforcement, along with periodic monitoring to detect new lead hazards, can help prevent future lead exposures. Community health nurses, working together with environmental health sanitarians, should promote opportunities for blood lead screening, especially if it is suspected that children in certain homes, apartments, or neighborhoods are at risk for lead poisoning. Children have also been exposed to lead in some toys, candies, cosmetics, traditional medicines, and eating or drinking utensils imported from other countries. Many of these have been tested and revealed to have high levels of lead. Thirty five percent of children with elevated blood lead levels were found to have this type of exposure (CDC, 2005a).

Education and public awareness campaigns can help prevent this type of lead poisoning.

Among infants aged 1 year or younger, American Indian/Alaska Natives and Blacks have had higher total injury death rates over the past few years than other racial and ethnic populations—two times the rate of injury death compared with White infants. Black infants were affected by the highest rate of homicide (Bernard, Paulozzi, & Wallace, 2007). The percentage of children under 1 year of age who have died violent deaths is 1.6%, almost twice the percentage for children below the age of 15 (Karch, Lubell, Friday, Patel, & Williams, 2008). Almost 20% of child maltreatment deaths occur to infants under age 1 (CDC, 2008c).

## Child Maltreatment

Child abuse and neglect are major concerns for the United States. Abuse and neglect comprise the third leading cause of death for young children under the age of 3 and the fifth leading cause of death for those between the ages of 1 and 9. Almost 20% of child maltreatment deaths occur to infants under age 1 (CDC, 2008c). **Child abuse** is the maltreatment of children, which may include any or all of the following: physical abuse, emotional abuse, neglect (physical, medical, or educational), and sexual abuse (including sexual exploitation and child pornography) (Goldman, Salus, Wolcott & Kennedy, 2003). In 2006, an estimated 91,000 infants were abused or neglected before age 1, almost 40% of them within the first month of life. About 30,000 were maltreated during their first week of life. Of these, 13% were physically abused and 68.5% were neglected (CDC, 2008c). Exposure of infants to drugs in utero is a form of neglect (ScoutNews, 2008). In recent years, there has been an increase in reported cases of physical and sexual abuse in day care centers, nursery schools, children's organizations, and churches. However, only about 10% of abuse cases involve nonparental perpetrators, such as foster care staff or day care personnel—80% of child abuse perpetrators are parents (USDHHS, 2008).

A large, national prospective cohort study following at-risk children from birth to age 8 recently determined that children who are victims of neglect in the first 2 years of life are more likely to have symptoms of childhood aggression than those who were physically abused or neglected later in life (Kotch et al., 2008). It is believed that many more children also suffer from forms of abuse and neglect, but thousands of cases are not reported and not reflected in the statistics. The problem is often difficult to detect and is underreported (ScoutNews, 2008). One example of an often-overlooked form of abuse is shaken baby syndrome. **Shaken baby syndrome**, suspected in infants or toddlers who exhibit traumatic brain injuries caused by violent shaking or impact, is characterized by a triad of symptoms: retinal hemorrhage, subdural hemorrhage, and/or subdural hemorrhage with few signs of external trauma (Gutierrez, Clements, & Averill, 2004; Altimer, 2008). The soft brain tissues are injured as they move violently against the rough cranial bones as the infant is shaken or thrown against a hard object. Failure to thrive (FTT), or "inadequate physical growth diagnosed by observation of growth over time using a standard growth chart," is a condition that derives from a variety of causes, such as poor sucking and appetite, poor feeding techniques, organic diseases, and mother-infant attachment problems. However, it

can also be related to neglect (Krugman & Dubowitz, 2003, p. 879). Risk factors that point to child neglect as the basis for FTT include those most often cited for abuse and neglect, along with specific concerns about parents intentionally withholding food, being resistant to recommended interventions, and having rigid beliefs about nutrition and health regimens that may jeopardize the infant (Block et al., 2005). Growth problems in the first 2 months of life may result in IQ deficits in later childhood, and early intervention programs that involve home visitation have been effective in attenuating the long-term effects of FTT (Black, Dubowitz, Krishnakumar, & Starr, 2007; Emond, Blair, Emmett, & Drewett, 2007).

Child abuse is seldom the result of any single factor, but rather a combination of chaotic environments, stressful situations, and parents who have difficulty coping with problems and stress. Risk factors for child maltreatment are found in four areas:

- ◆ Parent or caregiver behaviors
- ◆ Family characteristics
- ◆ Child factors
- ◆ Environment

Parental factors may include personality characteristics that include an external locus of control and poor self-esteem, along with problems with impulse control and anti-social behavior. Depression and anxiety may also play a role, and about one third of parents who had a childhood history of abuse or neglect will go on to maltreat their children (Goldman, Salus, Wolcott, & Kennedy, 2003). Substance abuse is a factor in roughly one-third to two-thirds of child abuse and neglect cases. Alcohol and drug abuse often lead to neglect, as parents use money meant for household expenses on substances. Little knowledge of normal child development can result in unrealistic expectations. Holding negative attitudes toward their children, viewing them as property, exhibiting harsh parenting styles and verbal aggression, not knowing how to handle children's behaviors, and being easily frustrated are parental characteristics that have also been associated with risk of child maltreatment. Young parental age is also a factor, although this may be because it is also associated with poverty, lower levels of social support, and higher levels of stress (Goldman et al., 2003).

Family characteristics that include domestic violence and marital conflict, financial stress and unemployment, and social isolation may lead to increased risk of child maltreatment. Children living with single parents (most often mothers) are at higher risk of physical and sexual abuse, as well as neglect; they are also more likely to live in poverty. Single parents have the sole caretaker burden and experience more stress than parents who have joint responsibilities. Children from single parent homes are 77% more likely than those living with both parents to experience physical abuse, and are 80% more at risk of a resultant injury. Families in which child neglect occurs often are characterized by greater numbers of children or report a larger number of people living in the household. The household is frequently more chaotic, with constantly changing players—e.g., mothers and children living on and off with grandmothers, aunts, boyfriends, or others (Goldman et al., 2003). Families at high risk for child abuse may be those that are either chronically troubled or temporarily stressed.

Slightly more girls than boys were reported to be victims of maltreatment in 2006 (51.5% versus 48.2%), and

rates were highest for the youngest children (24.4 per 1,000 for birth to age 1; 14.2 for ages 1 to 3; 13.5 for ages 4 to 7). Almost 75% of children from birth to age 3 were neglected, and American Indian/Alaska Native and Black children had the highest rates of maltreatment (15.9/15.4 and 19.8, respectively) when compared to White and Hispanic children (10.7 and 10.8 per 1,000) (USDHHS, 2008). Children who are premature or LBW may be at greater risk of maltreatment because of the greater maternal stress engendered by more demands on the caregiver. Significant relationships between child maltreatment and LBW, unintended pregnancy, and developmental problems or poor health in infancy have been found (Sidebotham & Heron, 2003). Children with difficult temperaments or behavior problems, or whose parents perceive them to have problems, could be at greater risk of abuse or neglect, but some research has noted that these child characteristics are probably less significant than negative parental attitudes (Sidebotham & Heron, 2003). Disabled children have higher rates of maltreatment than those without disabilities, and may be at risk for repeated abuse or neglect. If bonding or attachment has been disrupted by infant hospitalizations or parental incarcerations, for instance, the child may be at risk of maltreatment (Goldman et al., 2003).

The environment can play a part, along with parental, family, and child factors, in determining risk for child abuse and neglect. Parents who maltreat their children have reported more loneliness, greater isolation, and lower levels

of social support. Social isolation may indicate a lack of positive role models to help them better understand parenting and the consequences of child maltreatment. Unemployment, poverty, and neighborhood factors such as crime, violence, and substance use play a part in the stress placed on families. Strong, significant relationships have been found between unemployment, poverty, and child maltreatment, especially child neglect. Certainly, this is not true in all cases—not every poor and/or unemployed parent abuses or neglects his children—however, these stressors can interact with others (e.g., substance abuse, depression) to amplify the likelihood of abuse. Theories of how poverty may contribute to higher levels of child abuse and neglect include higher levels or perceptions of stress, inability to provide basic needs, and disproportionate reporting of child abuse because of more frequent contact with those who are mandated reporters (Goldman et al., 2003). Although poverty and lack of education are often linked with child abuse and neglect, no socioeconomic level is immune. Parent training programs can help teach parents to cope with fussy infants and difficult toddlers, and child sexual abuse prevention programs may also be helpful. However, PHN home visitation programs, like the Nurse Family Partnership, have been researched and found to be “the most effective and longest enduring intervention for high-risk families” (Krugman, Lane, & Walsh, 2007, p. 711). See Display 21.2. See also Chapters 20 and 22 for more on child abuse and neglect.

## DISPLAY 21.2 REPORTS OF AN EMERGENCY FOSTER HOME

The following are examples of the various situations from which abused and neglected children come, as reported by a couple who had an emergency foster home for the county department of social services. The examples represent children placed with them over a 2-year period in which they cared for 256 children.

- Two-week-old Jose was taken to their home because the parents (under the influence of drugs) were found swinging Jose upside down in circles in an infant carrier as they walked along a downtown street at 3 a.m. After being returned to his parents, he returned to foster care 1 month later after being found abandoned in an infant carrier at the county fair.
- Andre, Otis, and Selma, ages 8, 5, and 4, went to the foster home when the social services agency discovered they had been living with their father in an abandoned car for 2 years. They stayed for 3 weeks while the social worker found suitable housing for this family and counseling for the father.
- Victoria, 5 years old, a loving and passive child, arrived wearing a diaper and appeared developmentally delayed. She had a history of being physically and sexually abused. Her family was very dysfunctional, and it took the social worker several weeks to sort out relatives and their intentions before placing Victoria in a long-term foster home.
- Ronald and Randall, 6-year-old twin boys who were forced to “sexually please their mother” for several years, came to the emergency foster home before

being placed with relatives while their mother underwent psychiatric treatment. The boys began counseling during their stay in the emergency foster home.

- Antoinette, age 7, had severe asthma and was very withdrawn. She came to the emergency foster home because her mother (and the mother’s boyfriend) refused to care for her. The child came with every photograph of herself and personal mementos because the mother wanted no reminders of the child. The social worker located a grandmother who would be the child’s guardian.
- Thirteen-year-old Robert came home from school one day and found his mother and all their furniture gone. After a few weeks of Robert living in the basement of the apartment building, someone alerted the social services agency and he was placed in the emergency foster home for 2 months. His mother finally called social services after 6 weeks, saying Robert was too difficult for her to handle, but she may want to see him again someday. Robert was eventually placed in a group home for boys.
- Quyn, a 17-year-old Laotian girl, came into foster care after being referred by the school nurse because of wounds observed on her wrists and ankles. Quyn reported being strapped to a chair for 12 or more hours at a time by her father because she was not following the old ways and was shaming the family by being seen in public, unchaperoned, with a boy. Several meetings were held between the parents, a Southeast Asian community leader, and the social worker to resolve this situation so that Quyn could go home safely.

## Communicable Diseases

Infants, toddlers, and preschool-aged children experience a high frequency of acute illnesses, more than any other age group. Common types of acute conditions seen from birth to age 5 include fever, respiratory infections (including ear infections, colds, influenza), conjunctivitis (pink eye), and gastrointestinal problems (Kwok, Vazquez, & Isaacman, 2006). Communicable diseases are prevalent in these age groups, as very young children are building an immune system and are just beginning to come in contact with a greater number of people outside their families. In 2008, Yorita, Holman, Sejvar, Steiner, and Schonberger found that almost 43% of infant hospitalizations were due to infectious diseases; about 1 in every 14 infants were hospitalized. Males and non-White infants were most at risk, and the annual cost of hospitalization of U.S. infants was almost \$700 million. The most common diagnoses were infections of the lower respiratory tract (59%) and upper respiratory tract (6.5%), septicemia (6.5%), and urinary tract, kidney, and bladder infections (76%). The incidence of pneumonia in North America is about 35 to 40 cases per 1,000 children under age 5, but most are handled with outpatient care and medication (Durbin & Stille, 2008).

Acute respiratory illnesses (ARIs) are common in children under age 5. In a community-based prospective cohort study tracking children from birth through age 5, researchers found that before age 2, an average of four ARIs occurred each year. Between ages 2 and 5, the number of ARIs dropped to two or three episodes yearly. Most of the infections were upper respiratory, but about half of the children had at least one lower respiratory infection during their first year of life. They also noted that symptoms generally lasted for 4 weeks and resolved with or without the use of cough and cold medications and antibiotics (Kusel, de Klerk, Holt, Landau, & Sly, 2007). This information is especially helpful for community health nurses who need to emphasize that over-the-counter cough and cold medications should not be used for children under age 2. The U.S. Food and Drug Administration (FDA) deemed them unsafe and ineffective and most manufacturers took them off the market in fall of 2007 in response to emergency room visits and deaths linked to their toxic effects. However, parents may be uninformed about this, and may use old bottles or try to give smaller doses of adult medications to their infants and toddlers. Public health nurses should inform parents of the dangers and suggest safer interventions that may help alleviate symptoms, such as use of a bulb syringe and saline nose drops, a cool-mist humidifier, or petroleum jelly under the nose (Dowshen, 2008).

Bronchiolitis is the most common type of lower respiratory infection among infants. It is the leading cause of hospitalization in this age group. The majority of hospitalizations for bronchiolitis are for infants 6 months and younger. Respiratory syncytial virus (RSV) is the cause in 70% of cases, and can rise to 100% during winter epidemics. Although wheezing, tachypnea, and chest retractions can be frightening to parents, most healthy infants survive (95%). However, PHNs working with at-risk infants need to work with parents and pediatricians to ensure that palivizumab (monoclonal antibody) or RSV immunoglobulin are given to preterm infants, or those born closer to term but exposed to environmental pollution or to other children (Worrall, 2008). An effective RSV vaccine has not yet been found.

As with older children and adults, air pollution may make infants and children under age 5 more susceptible to bronchitis and other respiratory illnesses. Preschool-age children are thought to be especially “vulnerable to air pollution-induced illnesses” (Hertz-Picciotto, Baker, Yap, et al., 2007, p. 1510). Public health nurses can inform families who live in areas where air pollution is significant to take the necessary precautions.

Vaccines are one of the greatest achievements of public health. Since 1980, there has been a 99% or greater decrease in deaths due to the vaccine-preventable diseases of mumps, pertussis, tetanus, and diphtheria, and 80% or greater decline in deaths associated with vaccines instituted since 1980: hepatitis A and B, *Haemophilus influenzae* type B (HiB), and varicella (Roush, Murphy, & the Vaccine-Preventable Disease Table Working Group, 2007). Smallpox has been eradicated worldwide, and the viruses for polio, rubella, and measles are no longer endemic in the United States. The decline in the number of cases of measles, mumps, rubella, pertussis, and tetanus has been dramatic (99.9%, 95.9%, 99.9%, 92.2%, and 92.9%, respectively), and cases of varicella have declined 88%. Intensive campaigns have promoted immunizations that stimulate “protective immune responses against acute and chronic infectious diseases, as well as some infectious diseases that result in cancer” (Roush et al., 2007, p. 2155). Their immature immune systems and lack of exposure to antigens, along with somewhat porous physical barriers to microbes, put infants at high risk of infection. By 4 to 6 months, however, a brisker antibody response to vaccines becomes possible (Nadel, 2008). Successful infant and childhood immunization programs have been responsible for high vaccine coverage and the subsequent decline in morbidity and mortality from these preventable diseases (Roush et al., 2007).

The CDC’s Advisory Committee on Immunization Practices develop policies and guidelines, based on review of current scientific research, recommending “specific licensed vaccines for infants, children, adolescents, and adults” (Roush et al., 2007, p. 2156). The committee provides suggestions for available immunizations for the 17 vaccine-preventable diseases through the Vaccines for Children Program, a federal program providing uninsured and low-income families vaccines at no charge through their primary care providers and local health department clinics. The National Immunization Survey provides surveillance for this program, and the *Healthy People 2010* goal regarding immunization administration was met and exceeded in 2004 when more than 80% of children received all recommended vaccines (CDC, 2008e). State level immunization registries help track vaccine coverage at all age levels. Because day care centers and schools require proof of immunization, vaccination rates have improved over the last two decades (Roush et al., 2007).

The financing of immunizations for infants and children has significantly improved as a result of two major initiatives. The Vaccines for Children Program and the Child Health Insurance Program (CHIP) cover children on Medicaid, uninsured children, and American Indian/Alaska Native children. In addition, underinsured children who receive immunizations at federally qualified health centers and rural health clinics are covered. Additional state programs and funds help provide free or low-cost vaccines for children who are not covered by the other programs. There are several ways for community health nurses to help all families obtain free or low-cost immunizations.

Even if financial barriers are removed, there are other barriers. Transportation is a significant problem for some parents, especially in rural areas and for families in urban areas who have several children and need to take public transportation. All 50 states provide for medical exceptions to mandatory vaccination, and 49 allow religious exemptions; 20 permit philosophical or personal exemptions (Steele, 2005). Despite public health announcements in the media, some mothers remain unaware of the disabling consequences of diseases such as polio and do not realize the importance of fully vaccinating their children. In a survey of parents, 25% of them believed that receiving too many vaccines would weaken their child's immune system (Offit & Jew, 2003). Also, as more vaccines become available and the deadly diseases they prevent become a distant memory in the public's mind, more concerns about the safety of vaccines emerge. Numerous websites have emerged that advise against childhood immunizations and provide graphic horror stories about the handful of severe reactions to vaccination. Media coverage about vaccine adverse events also contributes to decreased compliance on the part of parents in getting their children immunized (Steele, 2005). Specifically, antivaccine individuals and groups have been very vocal and have appeared on television programs such as *Oprah* and *Larry King Live* to “make strong emotional appeals” against vaccinating children (Parikh, 2008, p. 622). They have linked childhood immunizations to their children's autism, even though extensive scientific research has failed to find any significant association. Parikh (2008) notes that, logical or not, people “do not forget this kind of emotional prowess,” and notes that scientific and medical experts only counter these emotion-laden arguments with dry evidence and statistics that “do not resonate with many parents” (p. 622). Public health nurses and other health professionals are encouraged to provide parents of very young children with meaningful stories of preventable deaths due to these diseases, and to “defend our beliefs . . . more strongly” rather than relying solely on dispassionate facts and figures (Parikh, 2008, p. 622).

## Chronic Diseases

Infants and young children can be afflicted with chronic diseases that affect their quality of life. For instance, the most common chronic disease in early childhood is *dental caries*, which is five times more common than asthma (Douglass, Douglass, & Silk, 2004). Some children begin to show signs and symptoms of cavities by the age of 10 months, and decay can begin to develop as soon as teeth erupt. Enamel defects, and subsequent caries, are more prevalent in children living in poverty and in preterm or LBW infants (Douglass et al., 2004).

*Asthma* symptoms may begin in infants and toddlers. Asthma is considered by some to be the most common chronic disease of childhood, with 13% of children younger than age 18 years diagnosed with asthma in 2003 (Forum on Child and Family Statistics [FCFS], 2005). Inner city, low-income, and minority children are disproportionately affected, and asthma hospitalizations are common (Jacobson et al., 2008). Public health nurses can assist families in finding appropriate health care providers and encourage proper administration of asthma medications and treatments. They can also teach families to reduce the presence of asthma triggers in their homes (see Chapter 22 for more information on asthma and other chronic diseases of childhood and adolescence).

*Autism* is a developmental spectrum disorder that is often first noticed in toddlers. Parents become aware that the child's communication and interaction with others is different, and that the child may also display obsessive and narrow interests. The CDC estimates the prevalence of autism at 1 in 150 children, and boys are four times more likely than girls to develop autism (2007). What causes autism is unclear, but some theories suggest faulty early neural patterning and overgrowth as a possible explanation (Courchesne et al., 2007). Families may need to be referred to early educational intervention programs and social services agencies for assistance.

*Sickle cell anemia*, an inherited blood disorder, affects thousands of children in the United States, most often those of African or Hispanic Caribbean ancestry. The characteristic chronic and severe anemia is common in young children with this condition, and it can affect memory, learning, and behavior (Schatz & Roberts, 2007). When both parents have the genetic mutation, the newborn will be afflicted with the disease. Those with the sickle cell trait have no symptoms of the disease, but can pass it on to their offspring. In many states, routine newborn screening for sickle cell anemia is offered. Because sickle cell anemia can lead to splenic sequestration (or pooling of blood in the spleen), many children have either nonfunctioning spleens or have had them surgically removed. Risk of infection is always a concern when this occurs before age 5 (University of Maryland Medical Center, 2007). Public health nurses working with populations at risk for this disease can educate and refer families for diagnosis and treatment.

The incidence of *food allergies* is increasing in the population. Infants with close family members who have atopic diseases are at risk for development of allergies. Prolonged breast-feeding for 1 year is recommended for these infants, or the use of hypoallergenic infant formula, and delayed introduction of solid foods is also important: i.e., dairy foods after age 1, eggs after age 2, nuts and fish after age 3 (Kleinman, 2000). Fortunately, once allergies are diagnosed, they can be managed through dietary changes and by avoidance of allergy-producing foods. Parents need to be educated, so that they can consistently read food labels and alert family members to the young child's allergy so that inappropriate foods are avoided.

Other chronic illnesses can have a profound effect on child and family. *Muscular dystrophy* (MD) and *cystic fibrosis* (CF) are two diseases that not only affect quality of life, but also severely shorten the child's life. Muscular dystrophy is a constellation of 30 genetic diseases characterized by progressive atrophy and weakening of skeletal muscles. The onset of some forms of MD begins in infancy or early childhood, and MD is more common in boys than in girls. *Duchenne MD* usually begins between ages 3 and 5, and progresses rapidly until most boys are wheelchair bound and require a ventilator (Emory University, 2007). Genetic testing can determine who is a carrier of the gene, and can aid in confirming the clinical diagnosis.

Cystic fibrosis usually begins in infancy and is characterized by a persistent cough or wheeze, shortness of breath, poor weight gain despite a good appetite, and a salty taste to the skin. Greasy and bulky stools are also common, as are respiratory infections that become increasingly more frequent with age (American Lung Association, 2006). It is the major cause of severe chronic lung disease in children. Cystic fibrosis occurs in 1 in 3,200 White and 1 in 11,500 Hispanic live births. About 80% of new cases are diagnosed before age 3,

often by the “sweat test.” Routine newborn screening is recommended (Grosse, Boyle, Botkin, et al., 2004).

Chest physiotherapy to help mobilize secretions is performed daily, usually by the parents. Aerosolized antibiotic treatments and mucus-thinning medications help to improve lung function and reduce respiratory infections. Community health nurses reinforce these techniques and teach the family to avoid exposure to respiratory infections and to initiate prescribed antibiotic prophylaxis promptly. As much as feasible, the young child should be involved in his own care, offered valid choices, and encouraged to participate in decision making. The family needs emotional support as members work through feelings of anticipatory grief.

Antecedents for a number of chronic diseases that develop in adolescence and adulthood may be found in infancy and early childhood. Some evidence of the influence of fetal or infant birth weight, weight gain, and nutrition in later development of specific chronic diseases has been studied (Kleinman, 2000). For instance, a protein in cow’s milk formula has been linked to greater risk of later type 1 diabetes, and a longitudinal Canadian study is underway to determine if delaying the introduction of cow’s milk formulas may prevent or delay the development of diabetes in at-risk children (American Chemical Society, 2008; Canadian Diabetes Association, 2003; Kleinman, 2000). A systematic review of the literature found that infants who experience rapid growth or who have higher BMIs are at greater risk for later obesity (Baird, Fisher, Lucas, et al., 2005). Some evidence also demonstrates a relationship between adult hypertension and LBW with rapid weight gain between the ages of 1 and 5, with “part of the risk of adult hypertension . . . set in fetal life” (Law et al., 2002, p. 1088). More epidemiologists are beginning to recognize the importance of a life course approach to chronic disease and the societal costs of disadvantaged fetal and child health and development (Ben-Shlomo & Kuh, 2002; Guyer et al., 2008). Among other variables, diet and nutrition play an important role in later health.

### Poor Nutrition and Dental Hygiene

Other health problems found in the birth to preschool age group include nutritional problems (underfeeding or overfeeding, overeating, and inappropriate food choices) and poor dental health. Nutritional and dental health needs are great during this period of rapid growth. Many factors contribute to early nutritional and dental problems.

A healthy start is foundational to well-being later in life. Nutrition is basic in strengthening this foundation. Bonding between mother and infant and overall maternal health are predictors of infant weight gain. Both nutrition and bonding can be accomplished by breast-feeding. Some of the benefits of breast-feeding include (Goldman, Hopkinson, & Rassin, 2007; Office of Women’s Health, 2005; Wiggins, 2001):

*Convenience:* Milk is always at the perfect temperature, and no preparation is needed; the infant can instantly begin feeding when hungry.

*Cost:* No formula or bottles to buy; costs are limited to healthy diet for the mother, breast pads, nursing bras, and (possibly) a breast pump.

*Nutrition:* Breast milk is species specific; the proteins are easily digested, and fats are well absorbed; it is the most complete form of nutrition for human infants.

*Anti-infective and anti-allergic properties:* Breast milk contains immunoglobulins, enzymes, and leukocytes that protect against pathogens, and it decreases the incidence of allergy by eliminating exposure to potential antigens; babies exclusively breast-fed for 6 or more months have fewer respiratory illnesses, ear infections, and cases of diarrhea.

*Infant growth:* Breast-fed babies usually gain weight at a more moderate rate and are leaner than bottle fed babies; rapid weight gain in infancy has been associated with later chronic diseases.

*Long-term health effects:* Breast-feeding exclusively for at least 6 months is associated with reduced risk of overweight in later life, and breast-fed infants have slightly higher IQ scores.

*Benefits for mothers:* Breast-feeding burns extra calories, helps to reduce postpartum bleeding, and delays ovulation and menstruation; it also lowers the risk of later ovarian and breast cancers.

The benefits of breast-feeding for the infant are well-established and include protection against respiratory infections and diarrhea, long-term increased cognitive development through adolescence, and some improvement in blood pressure and total cholesterol (Klein et al., 2008; Martin, Gunnell, & Davey-Smith, 2005; Office of Women’s Health, 2005; Turck, 2007). Higher levels of docosahexaenoic acid, important to brain development, are found in breast milk, and its benefits are correlated with the duration of breast-feeding (Turck, 2007). Several systematic reviews have found that the longer a mother breast-feeds her infant, the greater the protection against later obesity. This is thought to be due to the “growth acceleration hypothesis” that associates faster growth in infancy with later obesity levels and the fact that breast milk permits slower growth when compared to infant formulas (Singhal, 2007, p. 15).

Public health nurses can encourage pregnant women to consider the benefits of breast-feeding their infants carefully, and provide education and interventions to assist them with the most common barriers: concern about insufficient supply of breast milk, problems with the baby latching onto the breast, painful nipples, and scheduling problems (Lewallen, et al., 2006; McCann, Baydar, & Williams, 2007). Women often choose to breast-feed their babies when they fully understand the health effects for their infants and themselves and when they receive positive influence from family and friends (Brodrigg, Fallon, Hegney, & O’Brien, 2007). The community health nurse can join with labor and delivery nurses and lactation consultants in promoting breast-feeding among mothers in the community. Nurses can lobby local hospitals to educate new mothers about the benefits of breast-feeding and stop the routine distribution of free samples of infant formula (Kaplan & Graff, 2008). It is important to establish breast-feeding early, as 70% of women in a nationwide study made the same feeding choice (bottle or breast) for subsequent infants (Taylor, Geller, Risica, Kirtania, & Cabral, 2008).

Overfeeding of an infant can lead to childhood obesity and becomes a risk factor for heart disease, hypertension, and diabetes. Eleven percent of school-age children are overweight, with the foundation begun in the preschool years (Hodges, 2003). The propensity for obesity begins as early as infancy and by childhood for most people. Obesity is a contributing factor

to the worldwide increase in type 2 diabetes and has been reported to result in lower health-related quality of life (Kimm & Obarzanek, 2002; Schwimmer, Burwinkle, & Varni, 2003).

Although overfeeding can lead to problems, poor infant growth is also problematic. Small body size at age 1 and poor rates of growth through infancy are predictive of later coronary heart disease. The risk was threefold for those weighing less than 8 kg at age 1 (Forsen, Eriksson, Osmond, & Barker, 2004). The pattern of growth may also be important, as growth problems in infancy along with overweight in later childhood has been associated with adult development of hypertension and elevated serum lipid and glucose levels (Stein, Thompson, & Waters, 2005).

The most common sources of energy and nutrients for infants and toddlers are breast milk, formula, and milk. For toddlers, juices and fruit-flavored juice drinks are the next two sources of nutrition. Fortified foods (e.g., grain-based foods with added vitamin A, folate, and iron) become increasingly more significant in diets of toddlers, as do supplements (multivitamins). Dieticians recommend feeding older infants and toddlers a “wide variety of fruits, vegetables, and whole grains, as well as food naturally rich in iron” (Fox, Reidy, Novak, & Ziegler, 2006, p. s28). Generally, inadequate intake of vitamins and minerals for infants and toddlers is rare (fewer than 1% to 2%), and the recommendation of dietetic professionals is to allow infants and toddlers to use food, rather than supplements, as the primary source of these nutrients (Briefel, Hanson, Fox, Novak, & Ziegler, 2006). The Continuing Survey of Food Intakes by Individuals and Feeding Infants and Toddlers Study shows that over time, infants and toddlers demonstrate a gradual increase in portion size of most foods which are generally comparable to recommended portions for formula, juice, meats, and cheese and a bit higher than recommended portions for milk, breads, cereal, fruits, and vegetables. Researchers advised against “clean-your-plate” admonitions. They suggested that offering a wide variety of foods—especially whole grains, vegetables, and fruits—and allowing infants and toddlers to eat until they are satiated was the best approach (Fox, Reidy, Karwe, & Ziegler, 2006). A large-scale study comparing Hispanic and non-Hispanic infants and toddlers found that between age 12 and 24 months 80% to 90% of toddlers ate an afternoon snack, and that Hispanic toddlers’ snacks were higher in fiber and lower in saturated fats. Researchers discouraged the use of fruit drinks, crackers, and cookies, and encouraged more culturally appropriate whole grains, fruits and vegetables. They also noted that new foods might need to be introduced to toddlers 8 to 10 times before they are accepted and healthy eating habits are established (Ziegler, Hanson, Ponza, Novak & Hendricks, 2006). Public health nurses can encourage parents to continue to introduce new healthy foods to their toddlers and not give up or give in too soon. Home visiting programs that promote fruit and vegetable consumption in preschoolers have been shown to be effective in increasing the number of servings for both children and parents (Haire-Joshu et al., 2008).

Young children’s diets, often unreasonably high in sugar, increase the incidence of dental caries in this population group. The combination of sugar, bacteria that cause dental disease, and the composition of the teeth determines the severity of dental caries (Douglass, Douglass, & Silk, 2004). Also, passive exposure to tobacco smoke increases the risk of dental caries, and bacteria responsible for caries can be transmitted from mother to infant (Aligne, Moss, Auinger, & Weitzman, 2003;

Douglass, Douglass, & Silk, 2004). The practice of allowing infants to feed from the bottle beyond 15 to 16 months, or to fall asleep with a bottle, can lead to *baby bottle tooth decay* or *nursing caries*. This causes the decay of the front teeth and, eventually, the molars, requiring extraction of the affected teeth (American Academy of Pediatrics [AAP], 2003). Mothers may persist in giving toddlers and preschoolers bottles filled with milk, juice, or sugared drinks in an effort to buy time by assuaging crying children, who often cease crying when they see the bottle (Freeman & Stevens, 2008). Frequent snacking and sippy cups filled with juice or sugary drinks can also lead to cavities. It is recommended that sugary foods be eaten at mealtimes and not as snacks, and that regular snack times be established. Also, between ages 6 and 12 months, sippy cups are often used to wean infants from the breast or bottle, but between-meal drinks should consist of water or milk. Juice should be given only with meals (American Academy of Pediatrics Committee on Nutrition, 2001; Douglass, Douglass, & Silk, 2004).

Parents of infants older than 6 months who have several erupted teeth should be instructed to rub the infant’s gums with a damp, clean cloth and to begin tooth brushing, using a soft pediatric toothbrush with a very small amount of fluoride toothpaste—about the size of a grain of rice. It is best done while the parent stands behind the child, supporting his head, and the area where the teeth and gums meet should be the main focus (Douglass, Douglass, & Silk, 2004). It is also important to address parents’ misconceptions about dental health and question them about their cultural beliefs and practices related to dental health and hygiene (Horton & Barker, 2008; Schroth, Brothwell, & Moffatt, 2007).

Fluoride supplementation may be needed by 6 months of age if local water supplies are not fluoridated. Generally, breast-feeding infants do not require supplemental fluoride, and liquid or chewable fluoride supplements should not be given with formula or milk because absorption will be decreased (Douglass, Douglass, & Silk, 2004). As children reach the toddler years, they are able to brush their own teeth with enthusiasm. Toothpaste should be used sparingly, and adults should continue to supervise tooth brushing. Children of this age can get overzealous with the amount of toothpaste they use and it should not be ingested. Some physicians and dentists suggest that parents need to assist children with tooth brushing until age 8 (Douglass, Douglass, & Silk, 2004). The American Academy of Pediatric Dentistry recommends an initial dental visit at 12 months of age. However, the AAP recommends that only children at risk for caries be referred to a dentist at this age (Hale et al., 2003). Children at lower risk are typically referred to a dentist at around age 3 years (Douglass, Douglass, & Silk, 2004).

Dental caries is a preventable condition that can be addressed with proper nutrition and hygiene. Reducing consumption of sugar-sweetened beverages in childhood not only helps to decrease cavities but also reduces the risk of chronic disease later in life. One recent study found an association between higher intake of sugary beverages in childhood and an increased risk of developing metabolic syndrome in adolescence (Snider, 2007). Untreated early dental caries can lead to self-esteem issues and body-image disorders when children live with teeth that are discolored, misshapen, or missing. Beyond that, poor dental health can interfere with the young child’s growth and nutrition, as well as cognitive development (Sheiham, 2006). The younger the age when dental caries first

appear, the more the child is at risk for future tooth decay that sets up inflammatory responses leading to chronic health conditions, such as heart disease and stroke, in adulthood (Smoots, 2008; Yost & Li, 2008). Significant untreated dental disease is especially harmful in children who are medically fragile (Foster & Fitzgerald, 2005).

Many health departments are using fluoride varnishes as a means of preventing dental caries in young children. Dental hygienists and PHNs may be trained to apply the varnishes while making home visits, or children and families may visit clinics for treatment. Systematic reviews have found that fluoride varnishes can substantially reduce decay in both deciduous and permanent teeth (Marinho, Higgins, Logan, & Sheiham, 2002).

## HEALTH SERVICES FOR INFANTS, TODDLERS, AND PRESCHOOLERS

A variety of programs that directly or indirectly serve the health needs of very young children may be found in most communities. Community health nurses play a major and vital role in delivering these services. In community health, programs fall into three categories, which approximate the three priorities of public health nursing practice: prevention, protection, and promotion.

### Preventive Health Programs

Neighborhood community centers found in urban and rural settings provide families with parenting education, health and safety education, immunizations, various screening programs, and family planning services. In some areas, nurse-run clinics are established at local schools or community centers to assist in outreach services to the community. Community health nurses, in collaboration with an interdisciplinary team, are often the primary care providers in these programs. The major goals are to keep communities healthy by focusing on primary and secondary prevention services. Three examples of preventive health programs for infants and young children are immunization programs, parent training programs, and quality day care services.

### Immunization Programs

Health departments, community clinics, and private health care providers continue to offer immunizations against the major childhood infectious diseases—measles, mumps, rubella, varicella, polio, diphtheria, tetanus, pertussis, Hepatitis A and B, and HiB—some of which can cause permanent disability and even death. Pneumococcal, meningococcal, and influenza vaccines are also recommended, as is the vaccine for rotavirus (CDC, 2008d; Committee on Infectious Diseases, 2008). Many of these diseases no longer plague infants and children, and newer vaccines offer even greater promise of health. Pneumococcal conjugate vaccine has been associated with reductions in the incidence of otitis media and insertion of pressure-equalizing tubes in children under age 5, resulting in reduced expense for antibiotic prescriptions and ambulatory medical visits (Grijalva et al., 2006; Poehling et al., 2007; Zhou, Shefer, Kong, & Nuorti, 2008). See Figures 21.1 and 21.2.

Although the threat of these diseases has been substantially reduced, vigilance is still essential. Low immunization

levels in many areas, particularly among the poor and medically underserved, and increased disease rates signal the need for constant surveillance, outreach programs, and innovative educational efforts (Rosenthal et al., 2004; Roush et al., 2007; Stringer, Ratcliffe, & Gross, 2006). A study comparing vaccination coverage among 19- to 35-month-old children found that those children with special health care needs had roughly the same rate of coverage as children in the general population. However, White, affluent children were more likely to be underimmunized, and poor, Hispanic children on Medicaid were more likely to be immunized (O'Connor & Bramlett, 2008). This was one case of disadvantaged populations having an advantage over those with access to private health care and insurance. One large study, examining the rates of underimmunization of 3 month olds in underserved areas of Manhattan, Detroit, San Diego, and rural Colorado, found that vaccination coverage varied between 70.5% and 82.4%. The most commonly cited reasons involved missed opportunities for immunization; other factors involved either no insurance or public insurance, two or more children in the household, and living with an unmarried parent (Bardenheier et al., 2004). Whenever infants and young children come in contact with public health and other community clinics, it is always important to check immunizations and provide the necessary vaccines. Community health nurses are deeply involved in preventive activities that promote immunizations. Health departments and day care centers often work collaboratively to provide vaccinations. However, a study of inner-city, subsidized child care centers found that only 73.3% of 3 month olds were up to date on vaccines, and 12 month olds had even worse compliance at 44.2% (McCaskill et al., 2008). A compulsory immunization law, varying in its application from state to state, has enabled public health personnel to carry out these preventive services.

### Parent Training Programs

Parent education and training programs have been useful in providing parents with the tools needed to deal with the stresses and challenges of parenting effectively. A meta-analysis of 77 program evaluations revealed that effective programs consist of teaching parents to use time-out rather than corporal punishment as a means of discipline; promoting consistency in discipline; encouraging emotional communication skills and positive parent-child interaction; and requiring that parents practice these skills during classroom sessions (Kaminski, Valle, Filene, & Boyle, 2008). An effective training program for parents of preschool children is the Incredible Years Parent Training Program. Parent participants report decreased levels of stress and positive changes in their children after participating in this program (Levac, McCay, Merka, & Reddon-D'Arcy, 2008). Some health and social service agencies offer this program for high-risk families of young children, and some evaluation studies have found this program to improve behavior and reduce symptoms of attention-deficit hyperactivity disorder (ADHD) in preschool age children (Jones, Daley, Hutchings, Bywater, & Eames, 2007; 2008).

### Quality Day Care and Preschool Programs

Quality child care provides a significant avenue for preventing illness and injury among young children. In 2005, 66% of children younger than age 6 spent time in the care of someone

# Catch-up Immunization Schedule

UNITED STATES • 2008

## for Persons Aged 4 Months–18 Years Who Start Late or Who Are More Than 1 Month Behind

The table below provides catch-up schedules and minimum intervals between doses for children whose vaccinations have been delayed. A vaccine series does not need to be restarted, regardless of the time that has elapsed between doses. Use the section appropriate for the child's age.

CATCH-UP SCHEDULE FOR PERSONS AGED 4 MONTHS–6 YEARS					
Vaccine	Minimum Age for Dose 1	Minimum Interval Between Doses			
		Dose 1 to Dose 2	Dose 2 to Dose 3	Dose 3 to Dose 4	Dose 4 to Dose 5
Hepatitis B <sup>1</sup>	Birth	4 weeks	8 weeks (and 16 weeks after first dose)		
Rotavirus <sup>2</sup>	6 wks	4 weeks	4 weeks		
Diphtheria, Tetanus, Pertussis <sup>3</sup>	6 wks	4 weeks	4 weeks	6 months	6 months <sup>3</sup>
<i>Haemophilus influenzae</i> type b <sup>4</sup>	6 wks	4 weeks if first dose administered at younger than 12 months of age 8 weeks (as final dose) if first dose administered at age 12–14 months No further doses needed if first dose administered at 15 months of age or older	4 weeks <sup>4</sup> if current age is younger than 12 months 8 weeks (as final dose) <sup>4</sup> if current age is 12 months or older and second dose administered at younger than 15 months of age No further doses needed if previous dose administered at age 15 months or older	8 weeks (as final dose) This dose only necessary for children aged 12 months–5 years who received 3 doses before age 12 months	
Pneumococcal <sup>5</sup>	6 wks	4 weeks if first dose administered at younger than 12 months of age 8 weeks (as final dose) if first dose administered at age 12 months or older or current age 24–59 months No further doses needed for healthy children if first dose administered at age 24 months or older	4 weeks if current age is younger than 12 months 8 weeks (as final dose) if current age is 12 months or older No further doses needed for healthy children if previous dose administered at age 24 months or older	8 weeks (as final dose) This dose only necessary for children aged 12 months–5 years who received 3 doses before age 12 months	
Inactivated Poliovirus <sup>6</sup>	6 wks	4 weeks	4 weeks	4 weeks <sup>6</sup>	
Measles, Mumps, Rubella <sup>7</sup>	12 mos	4 weeks			
Varicella <sup>8</sup>	12 mos	3 months			
Hepatitis A <sup>9</sup>	12 mos	6 months			
CATCH-UP SCHEDULE FOR PERSONS AGED 7–18 YEARS					
Tetanus, Diphtheria/ Tetanus, Diphtheria, Pertussis <sup>10</sup>	7 yrs <sup>10</sup>	4 weeks	4 weeks if first dose administered at younger than 12 months of age 6 months if first dose administered at age 12 months or older	6 months if first dose administered at younger than 12 months of age	
Human Papillomavirus <sup>11</sup>	9 yrs	4 weeks	12 weeks (and 24 weeks after the first dose)		
Hepatitis A <sup>9</sup>	12 mos	6 months			
Hepatitis B <sup>1</sup>	Birth	4 weeks	8 weeks (and 16 weeks after first dose)		
Inactivated Poliovirus <sup>6</sup>	6 wks	4 weeks	4 weeks	4 weeks <sup>6</sup>	
Measles, Mumps, Rubella <sup>7</sup>	12 mos	4 weeks			
Varicella <sup>8</sup>	12 mos	4 weeks if first dose administered at age 7–11 months, administer 2 doses separated by 4 weeks plus a booster at age 12–15 months. 3 months if first dose administered at younger than 13 years of age			

### 1. Hepatitis B vaccine (HepB).

- Administer the 3-dose series to those who were not previously vaccinated.
- A 2-dose series of Recombivax HB® is licensed for children aged 11–15 years.

### 2. Rotavirus vaccine (Rota).

- Do not start the series later than age 12 weeks.
- Administer the final dose in the series by age 32 weeks.
- Do not administer a dose later than age 32 weeks.
- Data on safety and efficacy outside of these age ranges are insufficient.

### 3. Diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP).

- The fifth dose is not necessary if the fourth dose was administered at age 4 years or older.
- DTaP is not indicated for persons aged 7 years or older.

### 4. *Haemophilus influenzae* type b conjugate vaccine (Hib).

- Vaccine is not generally recommended for children aged 5 years or older.
- If current age is younger than 12 months and the first 2 doses were PRP-OMP (PedvaxHIB® or ComVax® [Merck]), the third (and final) dose should be administered at age 12–15 months and at least 8 weeks after the second dose.
- If first dose was administered at age 7–11 months, administer 2 doses separated by 4 weeks plus a booster at age 12–15 months.

### 5. Pneumococcal conjugate vaccine (PCV).

- Administer one dose of PCV to all healthy children aged 24–59 months having any incomplete schedule.
- For children with underlying medical conditions, administer 2 doses of PCV at least 8 weeks apart if previously received less than 3 doses, or 1 dose of PCV if previously received 3 doses.

### 6. Inactivated poliovirus vaccine (IPV).

- For children who received an all-IPV or all-oral poliovirus (OPV) series, a fourth dose is not necessary if third dose was administered at age 4 years or older.

- If both OPV and IPV were administered as part of a series, a total of 4 doses should be administered, regardless of the child's current age.
- IPV is not routinely recommended for persons aged 18 years and older.

### 7. Measles, mumps, and rubella vaccine (MMR).

- The second dose of MMR is recommended routinely at age 4–6 years but may be administered earlier if desired.
- If not previously vaccinated, administer 2 doses of MMR during any visit with 4 or more weeks between the doses.

### 8. Varicella vaccine.

- The second dose of varicella vaccine is recommended routinely at age 4–6 years but may be administered earlier if desired.
- Do not repeat the second dose in persons younger than 13 years of age if administered 28 or more days after the first dose.

### 9. Hepatitis A vaccine (HepA).

- HepA is recommended for certain groups of children, including in areas where vaccination programs target older children. See *MMWR* 2006;55(No. RR-7):1–23.

### 10. Tetanus and diphtheria toxoids vaccine (Td) and tetanus and diphtheria toxoids and acellular pertussis vaccine (Tdap).

- Tdap should be substituted for a single dose of Td in the primary catch-up series or as a booster if age appropriate; use Td for other doses.
- A 5-year interval from the last Td dose is encouraged when Tdap is used as a booster dose. A booster (fourth) dose is needed if any of the previous doses were administered at younger than 12 months of age. Refer to ACIP recommendations for further information. See *MMWR* 2006;55(No. RR-3).

### 11. Human papillomavirus vaccine (HPV).

- Administer the HPV vaccine series to females at age 13–18 years if not previously vaccinated.

Information about reporting reactions after immunization is available online at <http://www.vaers.hhs.gov> or by telephone via the 24-hour national toll-free information line 800-822-7967. Suspected cases of vaccine-preventable diseases should be reported to the state or local health department. Additional information, including precautions and contraindications for immunization, is available from the National Center for Immunization and Respiratory Diseases at <http://www.cdc.gov/vaccines> or telephone, 800-CDC-INFO (800-232-4636).

CS 113897

other than their parents; relatives cared for 22%, nonrelatives cared for 14%, and child care center-based programs cared for 36% (Child Trends, 2006b). Only half of child care centers meet standards set by the American Public Health Association and the AAP—and most quality ratings are moderate to poor (Patten & Ricks, 2003). Working mothers need quality child care services: 85% of children under age 6 whose mothers worked at least 35 hours a week were in some form of non-parental care in 2005 (Child Trends, 2006b).

Although safe, affordable child care is important, the long-term benefits of early childhood education are numerous. They include higher rates of high school completion, college attendance, and full-time employment; lower rates of felony arrests, convictions, and incarcerations; and fewer reports of depressive symptoms (Reynolds et al., 2007). Higher incomes, more positive outcomes for mental health, higher levels of health efficacy, and more positive health behaviors have been noted in adults who participated in early childhood education programs (Palfrey et al., 2005). More than half of 3- to 5-year-old children in the United States were enrolled in half- or full-day preschool programs in 2003 (Child Trends, 2004). Quality preschool program attendance can provide children with language and pre-academic skills that may lead to better learning outcomes in kindergarten (National Institute of Child Health & Development [NICHD] Early Child Care Research Network, 2002). **Head Start**, a federally funded program that offers early childhood education to low-income children between ages 3 and 5, has consistently demonstrated significant improvements in preschoolers' social-emotional and cognitive development, and those attending Head Start do better on several developmental measures than children who did not attend Head Start (Love, Tarullo, Raikes, & Chazan-Cohen, 2006). Those attending Head Start were found to be significantly more likely to finish high school and go on to attend college than their siblings who did not attend Head Start (Garces, Thomas, & Currie, 2002). Head Start children are also more likely to receive dental and health screenings, to have up-to-date immunization coverage, to have better school attendance, and to be less likely to be held back in school. The benefits of Head Start extend to families because more Head Start parents read more frequently to their children than do parents of children not enrolled in the program. Because parents of preschoolers in Head Start must demonstrate parent involvement in the program, they are more likely to demonstrate upward mobility and positive growth. These parents also report less depression, anxiety, and illness and more life satisfaction and increased coping skills (National Head Start Association, 2006).

Many states provide preschool programs, but Head Start programs generally offer higher quality, more comprehensive services than those found in state preschool programs (Barnett, 2002). The availability of affordable, quality, licensed day care facilities is recognized as one long-term solution for the prevention of child abuse. When their young children are safely cared for, two parents or a single parent can work and provide more resources for the family, thereby decreasing the stress that may precipitate abuse. The quality of day care and preschool programs varies considerably; licensing laws can regulate only minimum safety and health standards. In addition, numerous child care operations are too small to require licensing, leaving quality and compliance unevaluated. Community health nurses can influence the quality of day care and preschool programs through active educational efforts, monitoring of health and

safety standards, and working to improve the state's role in passing stronger licensing laws.

## Health Protection Programs

Health protection programs for infants and young children are designed to protect them from illness and injury. Ultimately, these programs may even protect their lives.

### Safety and Injury Protection

Accident and injury control programs serve a critical role in protecting the lives of children. Efforts to prevent motor vehicle crashes, a major cause of death, may include driver education programs, better highway construction, improved motor vehicle design and safety features, and continuing research into the causes of various types of crashes. Injury prevention and reduction have been addressed through strategies such as state laws requiring the use of safety restraints (e.g., seatbelts, child safety seats), availability of front and side driver and passenger airbags, substitution of other modes of travel (air, rail, or bus), lower speed limits, stricter enforcement of drunk driving laws, safer automobile design, and helmets for motorcyclists, bicycle riders, and skaters.

For infants, toddlers, and preschool-aged children to be safe when traveling in vehicles, they must be restrained in an approved infant carrier, child restraint seat, or booster seat. These must be positioned and secured as described by the manufacturer; used at all times, even for the shortest distances; placed in the back seat, never in the front seat; and installed in the appropriate position (facing rear or front) based on the weight or age of the infant or young child. It is recommended that booster seats be used until the child is 58 inches tall and weighs around 80 lbs (Ehiri et al., 2006). Programs that provide training, education, and child safety seats have been shown to improve child safety seat use (Letourneau, Crump, Bowling, Kuklinski, & Allen, 2008). A systematic review of booster seat intervention studies found that incentives (e.g., coupons, gift certificates), free booster seats, and educational interventions were most effective. Legislation and enforcement of laws may also be beneficial (Ehiri et al., 2006).

### Protection from Child Abuse and Neglect

Services to protect children from abuse are not as well developed or effective as safety and injury prevention programs, an observation accounted for by a variety of factors. Most child abuse occurs in the home, so only the most blatant situations become evident to outsiders. Community health nurses and physicians who see injured children may find parents' explanations plausible and may not suspect or want to believe that abuse might be responsible. Avoidance of legal involvement keeps others from reporting suspected cases. Fortunately, this attitude is changing among professionals who work with children and other community members.

For many years, states have had mandatory reporting laws. The Child Abuse Prevention and Treatment Act, enacted in 1974, provides funding to states to aid in preventing and investigating child abuse and neglect (Child Welfare Information Gateway, 2004). Over the years, numerous amendments have expanded the definition of child abuse and the persons who are required to report. People mandated to report suspected child abuse include all those who work with children:

day care providers, teachers, social workers, nurses, doctors, clergy, coaches, and so forth. In addition, animal humane workers and commercial photograph developers are mandated reporters. Procedures for reporting categories of child abuse have also been clarified, and 1990 updates included services for homeless children and families. Today, professionals and the public are more aware of the problem, and there has been an increase in reporting. In 1974, the National Center for Child Abuse and Neglect was established as a result of the Child Abuse Prevention and Treatment Act. The center collects and analyzes information on child abuse and neglect, serves as an information clearinghouse, publishes educational materials on the subject, offers technical assistance, and conducts research into the problem. The Adoption and Safe Families Act, enacted in 1997, gives further direction in working with families and promotes the safety of children, while recognizing the child's need for a permanent home.

Child and family well-being are also a concern of child protection agencies (Goldman, Salus, Wolcott, & Kennedy, 2003). In addition, these acts spurred all of the states to pass mandatory reporting laws and design procedures for investigation of suspected cases of child abuse and neglect. All states have some form of child protective services or family services, whose charge is to protect children and strengthen families. They often work with law enforcement and the judicial system, but health professionals and educators are also important team members. The basic dilemma facing those who work in this area is maintaining the family unit and still providing a safe environment for the child (Goldman et al., 2003). Most professionals adopt the *levels of prevention* model to describe child abuse and neglect prevention efforts.

### Primary Prevention

Primary prevention measures include the use of public service announcements that promote positive parenting, family support groups, and public awareness campaigns about child maltreatment and how to report it, along with establishing community education to enhance the general well-being of children and their families (Thomas, Leicht, Hughes, Madigan, & Dowell, 2003). Educational services are designed to enrich the lives of families, to improve the skills of family functioning, and to prevent the stress and problems that might lead to dysfunction and abuse or neglect (Feinberg & Kan, 2008; Melnyk et al., 2007).

Prevention should focus on parent preparation during the prenatal period; practices that encourage parent–child bonding during labor, delivery, the postpartum period, and early infancy; and provision of information regarding support services for families with newborns. It is also helpful to provide parents of children of all ages with information regarding child-rearing and community resources (Goldman et al., 2003). Child sexual abuse prevention curricula, such as *Good Touch/Bad Touch*, teach children skills to avoid victimization and promote discussion. They have been found effective in utilization of protective strategies and some evidence suggests they may afford some protection against physical abuse (Thomas et al., 2003).

### Secondary Prevention

Services are designed to identify and assist high-risk families to prevent abuse or neglect. **High-risk families** are those

families that exhibit the symptoms of potentially abusive or neglectful behavior or that are under the types of stress associated with abuse or neglect. These can include families living in poverty, exhibiting substance abuse or mental health problems, and parents or children with disabilities. Early intervention with high-risk families can improve emotional and functional coping and help prevent further problems (Melnyk et al., 2004). High school parent education programs for pregnant adolescents, home visitation programs targeted to at-risk families, and respite care for families with special needs children are all examples of secondary prevention actions. Family resource centers in schools or community centers located in low-income neighborhoods can offer resource and referral services to families who may be dealing with multiple sources of stress (Thomas et al., 2003). Home visitation programs, such as the Nurse Family Partnership, Early Head Start, and Healthy Families America, provide parent support and education, and promote healthier family functioning (Olds et al., 2004a; 2004b; 2007; Thomas et al., 2003). Some home visitation programs to high-risk mothers and families have demonstrated decreased rates of child abuse and neglect (Black et al., 2007; Thomas et al., 2003).

### Tertiary Prevention

Intervention and treatment services are designed to assist a family in which abuse or neglect has already occurred, so that further abuse or neglect may be prevented and the consequences of abuse or neglect may be minimized. Often, families are referred to mental health counselors for “intensive family preservation services” to improve family communication and functioning (Thomas et al., 2003, p. 8). Some families may require crisis respite when they feel they cannot manage the stresses of child care. Role models, through the use of parent mentor programs, provide support and nonjudgmental coaching to parents who have sometimes been the victims of abuse themselves (Thomas et al., 2003).

The community health nurse has a major role in primary prevention of child maltreatment. In addition, the nurse is in a unique position to detect early signs of neglect and abuse. The PHN must establish rapport with families and assist with appropriate interventions and referrals at the secondary and tertiary levels of prevention. An interdisciplinary approach with teachers, the department of social services, foster families, and other health care providers is needed (Goldman et al., 2003; Thomas et al., 2003). The effectiveness of local programs depends, in large measure, on the willingness of community health professionals to increase their awareness and work as a team to detect, report, and develop interventions for the perpetrators and victims of abuse and neglect. Ongoing education of health care providers is recommended to increase awareness of changing child abuse patterns, new reporting laws, and resources available to families.

### Health Promotion Programs

Early childhood development and intervention programs are designed to have positive effects on the outcomes of children's cognitive and social development. Some health promotion programs have considered children's physical health, and fewer have focused on parent–child interaction and child

social development. All are considered important health promotion programs from birth through preschool years.

### **Infant Brain Development Research and Parent–Child Interactions**

New research into the normal brain development of infants and toddlers has revealed that brain maturation in the first few years of life is very rapid: the brain grows to 80% of adult size by age 3, and the myelination pattern of an 18- to 24-month-old child is similar to that of an adult (Almli, Rivkin, & McKinstry, 2006; Zero to Three, n.d.). The prefrontal cortex of 4 year olds is already functional and becomes more organized throughout later adolescence (Tsujiimoto, 2008). Maturation of the corpus callosum begins after birth, signaling a potential for vulnerability to environmental stimuli and stress (Gilmore, Lin, & Gerig, 2006). Early environment exerts a lasting influence on brain development, even in the womb (Nava-Ocampo & Koren, 2007; Rees & Inder, 2005; World Bank, 2008). Appropriate early environment and stimulation promotes healthy development.

Because brain development is thought to be “activity-dependent,” and *pruning* or selection of only the most active neural circuits occurs in early childhood, parents are encouraged to provide appropriate nutrition, avoid potentially harmful substances, and provide appropriate stimulation for their infants, toddlers, and preschoolers (Zero to Three, n.d.). During the first 2 years, when rapid myelination is taking place, 50% of total calories should come from fat, but after age 2, 1% or 2% milk should be the norm. Harmful substances, such as tobacco (cigarettes), chemicals, and radiation, should be avoided during pregnancy, as should contact with people who have infectious diseases. Meaningful parent–child interactions should be established early; they include holding, rocking, comforting, touching, talking, and singing. When parents talk to infants and read to young children, children later demonstrate more advanced language and literacy skills. Providing a caring and supportive environment, with opportunities to learn and explore, is supportive of healthy brain development and promotes secure infant attachment (Duursma, Augustyn, & Zuckerman, 2008; Jeppson & Myers-Walls, 2003; Roisman & Fraley, 2008; Zero to Three, n.d.).

Young children who do not have early exposure to this type of environment—for example, those who are in institutional care—exhibit delays in cognitive and social development, as well as attachment disorders (Johnson, Browne, & Hamilton-Giachritsis, 2006). However, when placed with foster families who provide a warm, stimulating environment, children’s cognitive development improves—especially for those who made the change at younger ages (Nelson et al., 2007).

Gazing into an infant’s eyes, paying attention to and interacting with toddlers, and listening to and answering preschoolers’ questions are important parental behaviors that promote social development (Chouinard, 2007; Grossman & Johnson, 2007; Jeppson & Myers-Walls, 2003). Providing infants and young children with secure, learning-rich environments where they can use their senses to discover new things helps them to maximize their potential. Emotional comfort and a secure environment ensure that young children will better deal with their feelings. Early social experiences affect oxytocin and vasopressin neuropeptide

systems that aid in establishing social bonds and attachment, and these systems continue to regulate emotional functions throughout adult life (Fries, Ziegler, Kurian, Jacoris, & Pol-lak, 2005). Public health nurses can provide resources and work with young families to encourage quality parent–child interactions that promote cognitive and social development.

### **Developmental Screening**

With the emphasis on infant and early childhood development, community health nurses often routinely carry out developmental screenings. Tools such as the Ages and Stages Questionnaire (ASQ), Parents’ Evaluation of Developmental Status (PEDS), and the Denver II are often used by PHNs as they make routine home visits to follow at-risk infants, children, and families (Gaines, Jenkins, & Ashe, 2005; Wagner, Jenkins, & Smith, 2006). Those working with high-risk or medically vulnerable infant programs periodically screen their clients to determine gaps in development and provide suggestions to parents that promote advancement.

Developmental screening tools are also helpful in educating parents about normal child development and can provide a means of anticipatory guidance on developmental milestones and future safety issues. *Bright Futures*, an important resource for nurses and parents, provides tools to help families determine appropriate developmental milestones and expected behaviors, along with suggestions about when to seek help from professionals (Mayer, Anastasi, & Clark, 2006). A variety of screening tools available to nurses and other health professionals, ranging from parent report instruments to those that involve direct assessment of behaviors and skills, can examine overall physical and cognitive development, or screen for such things as temperament, behavior, autism, and speech and language (AAP, Committee on Children with Disabilities, 2001). Early identification of problems can lead to interventions that help children with school readiness (Wold & Nicholas, 2007). A study of preschool children born to low-risk mothers concluded that 10% of the children screened were at high risk for developmental problems, indicating that routine developmental screening can not only promote health but also provide secondary prevention through early detection of potential problems (Tough et al., 2008).

In the last decade, more than 70% of children with disabilities were not first detected by their health care providers, but the AAP now recommends developmental screening and surveillance during preventive health care visits (AAP, 2008; Glascoe, 2000). Developmental screenings can provide parents with information on their child’s development and can assist in early detection of possible developmental delays and earlier access to interventions that may provide better outcomes (CDC, 2008e; Harris & Handleman, 2000; Rydz et al., 2006).

### **Programs for Children with Special Needs**

Many children have special needs. They may have a congenital or acquired developmental disability, birth defect, or a chronic emotional, mental, or physical disease. Approximately 16% of children have a developmental disability, and between 12% and 16% have some type of behavioral or developmental disorder (AAP Committee on Children with Disabilities, 2001; Wagner, Jenkins, & Smith, 2006). About 3% of U.S. infants are born with a birth defect. The most

## From the Case Files II

### A Case of Kernicterus

A young mother was hospitalized for the birth of her second daughter, a beautiful little girl born without incident. The infant was taken to the mother for feeding and care by the nursing staff, and the mother noticed that her daughter was not very active. The infant had difficulty latching on for breast-feeding. The mother told her obstetrical nurse that the infant seemed very different from her first child. The infant was irritable, but the nurse reassured the mother that the baby was fine and “not all babies are alike.” Still, the new mother was concerned.

By the second day, the mother noticed that the baby was not very alert and did not want to feed. She also noticed that the baby’s color was “yellowish,” and the mother notified the nurse. Again, the nurse reassured the mother that this was “normal” for infants of Asian descent. The baby still was not feeding well, and there was yellowish-orange color stool in the baby’s diaper. The mother notified the nurse, and asked the nurse to call the doctor. The nurse refused and told the mother that she was “overreacting.” The nurse again reassured the mother that the baby was “fine” and no action was taken. The mother felt that the nurse was not listening to her concerns. The baby continued to be irritable, and the nurse said that the baby just needed to breast-feed and was very insistent that the new mother was “not breast-feeding properly.” The new mother was instructed not to give the baby water or additional fluids, so that the baby would breast-feed. No additional fluids were offered. The young mother was not satisfied with the nursing care and was offended that the nurse would not listen to her. A referral was made to the breast-feeding specialist at the hospital to help the new mother feed her infant. There were no phone calls documented to the physician, or documentation of the “yellowish-orange” stool. (The young mother kept the diaper for further proof of her concerns, though.) There was no documentation of irritability, inability to breast-feed, lethargy, or jaundiced appearance of the skin. The physician discharging the infant did not receive any information regarding irritability or yellowish stool. The nursing emphasis postpartum was on breast-feeding and the nurses documented that the young mother had an “uncooperative attitude.”

The young mother and infant were discharged home on the second postpartum day. No blood work was done for the “yellowish” color of the baby’s skin, even though the yellowish tone to lower extremities and abdomen was documented in the nurse’s notes and on the discharge summary. No referrals were made to Home Health or Public Health for follow-up.

Within 48 hours of discharge, the young mother brought her lethargic baby to the hospital’s Emergency Room. On day 4 of life, the infant’s bilirubin was 46. The infant was severely neurologically damaged, and the brain damage that resulted was irreversible. She was diagnosed with severe cerebral palsy, secondary to kernicterus (excessive bilirubin). The child will never be able to walk or talk. She will be fed through a gastrostomy tube for the rest of her life. She has normal intelligence, but it is locked into a dysfunctional body. The patient and family were devastated.

The physician and hospital (nurses) were sued. The nurses on duty could not defend their actions with their charting, or lack thereof. The attorneys for the hospital, representing the physician and nurses, could not defend the actions of their clients. A multimillion dollar settlement was granted, and the nurses were fired. Unfortunately, this is not an isolated case. The irreversible brain damage that occurs as a result of untreated hyperbilirubinemia should not occur in the 21st century. This was a no-win situation that could have been avoided with proper nursing intervention. Hyperbilirubinemia should always be in the forefront of newborn assessment during the first few days of life.

The nurses involved in this case were not acting as the patient’s advocate. The young mother tried to tell the nurses, and the nurses should have listened to their patient. The physician should have been notified immediately when signs and symptoms were first noted. Incorrect assumptions were made due to the nationality of the patient, an indication of lack of cultural competence. Home Health Nursing or Public Health Nursing should have been arranged for infant follow-up after discharge, but these interventions did not happen.

*Linda O., Certified Life Care Planner, Nurse Consultant*

common birth defects involve the heart, or are classified as neural tube defects (e.g., spina bifida) or orofacial clefts (e.g., cleft palate, cleft lip), and a substantial number of birth defects, such as hypospadias or hearing loss, are generally not life threatening (CDC, 2005b). Some children suffer injuries after birth (see From the Case Files II). Autism and other

mental or behavioral disorders develop after infancy and may require special services. Educational, health, and social or recreational services should be available for all children.

Federal law mandates early identification and intervention services for those with a variety of developmental disabilities. Developmental delays are characterized by

slower development in one or more areas. The Individuals with Disabilities Education Act (IDEA) provides early intervention services, usually at home, for those from birth to age 2 who have developmental delays in physical, cognitive, communication, emotional, social, and adaptive development. Intervention services are also available to children with a mental or physical problem that is likely to result in a developmental delay. Newborns can receive infant stimulation services at home or in some schools specially designed to meet the needs of the very young. These programs are offered on a part-time basis for 1 to 2 hours, two to three times a week. Special education preschools are available for young children from ages 3 to 5. By preschool age, children may advance to half-day programs (Kupper, 2005; National Dissemination Center for Children with Disabilities [NICHCY], 2002). Additional services can be provided to assist the families in getting children to the programs. Door-to-door bus service in specially equipped small buses or vans safely transport young children who arrive at school in wheelchairs or with other assistive devices. Early stimulation programs, such as the Infant Health and Development Program targeted to preterm and LBW infants, have demonstrated improved parent-child interactions, along with greater motor skill and cognitive development (Bonnier, 2008).

Availability of health services for children with special needs varies with the size of the community. In small rural communities, children and their parents may have to travel long distances to receive specialized services, and in inner-city neighborhoods, lack of money for transportation can make even nearby services equally inaccessible. Accessibility is also influenced by lack of knowledge, attitudes, and prejudices. Community health nurses must recognize the power of these immobilizing factors and be able to deal with them effectively to make positive changes. See Chapter 25 for more on barriers to health care.

Most communities offer additional social and recreational programs for children with special needs. For example, American Lung Association affiliate offices sponsor camping programs for children with asthma or other lung diseases. Often, these are camps for school-aged children that may last up to 1 week and be located in mountain or beach areas, but they may also be day camps, with parents in attendance for preschoolers. Nationwide programs such as the Special Olympics offer recreational competition for children with special needs in a variety of sports, such as bowling, track and field, skiing, and swimming.

The community health nurse best serves families as a resource for such programs. Some parents are not aware of the rights or services available for their special needs children. Nurses can advocate for parents and help establish services in communities where needed services are lacking.

### **Nutritional Programs**

Adequate nutrition must begin before birth. One of the most productive health promotion programs is the Special Supplemental Food Program for Women, Infants, and Children (WIC). In addition to supporting women and young children with nutritious foods and achieving the initial goals of decreasing the rates of preterm and LBW babies, increasing the length of pregnancy, and reducing

the incidence of infant and child iron deficiency anemia, WIC also increases breast-feeding rates and improves pregnant women's nutritional status. Children enrolled in WIC demonstrate improved cognitive skills and vocabulary, and for each dollar spent on WIC, between \$1.77 and \$3.13 are saved in health care costs (Parraga & Doughten, 2007).

WIC provides information to parents about eating healthfully and promoting healthy rates of growth. Parents become more aware of the need to reduce consumption of saturated fat, salt, sugar, and over-processed foods. The community health nurse, through nutrition education and reinforcement of positive practices, plays a significant role in promoting the health of infants and young children (see Levels of Prevention Pyramid). For more information about WIC, see Chapter 22.

### **ROLE OF THE COMMUNITY HEALTH NURSE**

Community health nurses face the challenge of continually assessing each population's current health problems, as well as determining available and needed services. Community health nursing interventions with maternal, infant, toddler, and preschool populations are focused on health promotion and early intervention. They may include work in family planning or high-risk clinics, telephone information services and hotlines, or home visitation programs. The nurse uses educational interventions when teaching family planning, nutrition, safety precautions, or child care skills. Such interventions involve providing information and encouraging client groups (parents and young children) to participate in their own health care. Other interventions include strategies in which the nurse uses a greater degree of persuasion or positive manipulation, such as conducting voluntary immunization programs, encouraging smoking cessation during pregnancy, preventing communicable diseases, and encouraging appropriate use of child safety devices such as car seats. Finally, the nurse may use interventions that coerce people into compliance with laws that require certain immunizations or mandate reporting of suspected child abuse and environmental health standards violations, such as sanitation issues.

The community health nurse acts as an advocate and a resource for families of young children. The PHN may be called upon to provide information to young mothers about infant temperament, sleep schedules, colic, parenting, discipline, toilet training, television or video choices, and nutrition and feeding (Dopkins-Stright, Canley-Gallagher, & Kelley, 2008; Gurian, n.d.; Klassen et al., 2006; Rideout, Vandewater, & Wartella, 2003; Tempfer, 2005). The PHN should be aware of federal, state, and local laws that preserve and protect the rights of children and families. Availability of educational, medical, social, and recreational services needed by young families is a necessity. The nurse helps to secure these services in the community she or he serves. Ensuring that families have the resources to provide a safe and healthy environment for their children can take many forms. The nurse may lobby to change existing laws, initiate the effort needed to establish programs and services in the community, and teach families about infant safety or the importance of immunizations.

## LEVELS OF PREVENTION PYRAMID

**SITUATION:** Desire for a healthy, full-term infant

**GOAL:** Using the 3 levels of prevention, negative health conditions are avoided, promptly diagnosed and treated, and/or the fullest possible potential is restored.

<b>Tertiary Prevention</b>		
<b>Rehabilitation</b>	<b>Primary Prevention</b>	
<ul style="list-style-type: none"> <li>▪ The parents and significant others begin to bond with the newborn</li> <li>▪ Parents get to know the newborn and establish a successful breast- or bottle-feeding routine</li> <li>▪ The infant returns home in an age-appropriate infant car seat, which is used properly when traveling</li> <li>▪ The infant's birth is celebrated according to cultural and religious preferences</li> <li>▪ Parents resume sexual intercourse using a family planning method of their choice</li> <li>▪ The parents enjoy the new life they have created</li> </ul>	<p style="text-align: center;"><i>Health Promotion &amp; Education</i></p> <ul style="list-style-type: none"> <li>▪ Appointments are made and kept for postpartum and newborn visits to health care providers</li> </ul>	<p style="text-align: center;"><i>Health Protection</i></p> <ul style="list-style-type: none"> <li>▪ Exposure to people with infectious diseases is avoided</li> <li>▪ Infant immunization schedule begins on time and continues through childhood</li> </ul>
<b>Secondary Prevention</b>		
<b>Early Diagnosis</b>	<b>Prompt Treatment</b>	
<ul style="list-style-type: none"> <li>▪ The mother starts prenatal care early in the first trimester, and continues care at regular intervals throughout the pregnancy</li> </ul>	<ul style="list-style-type: none"> <li>▪ The mother does not use alcohol, tobacco, or other mood-altering substances during the pregnancy</li> <li>▪ The mother takes a daily prenatal vitamin with folic acid</li> <li>▪ Parents avoid exposure to people with infectious disease</li> <li>▪ The mother has adequate nutrition, rest, sleep, and exercise</li> <li>▪ The mother begins supportive services if eligible (WIC, Temporary Assistance for Needy Families)</li> <li>▪ Family and significant others continue to be supportive</li> <li>▪ The parents attend labor preparation, infant care, and parenting classes</li> <li>▪ Name(s) are selected for the infant</li> <li>▪ Delivery method and location are selected</li> <li>▪ The home is prepared for the infant: e.g., adequate infant furnishings and supplies are acquired within the parents' budget</li> <li>▪ Preparations and plans are made regarding breast or bottle feeding</li> </ul>	

(continued)

## LEVELS OF PREVENTION PYRAMID (*Continued*)

Secondary Prevention	
Early Diagnosis	Prompt Treatment
	<ul style="list-style-type: none"> <li>▪ A pediatrician or pediatric nurse practitioner is selected</li> <li>▪ An infant car seat is acquired and properly installed</li> <li>▪ Plans are made to get to the chosen health care facility when in labor</li> </ul>
Primary Prevention	
Health Promotion & Education	Health Protection
<ul style="list-style-type: none"> <li>▪ The pregnancy is planned</li> <li>▪ Pregnancies are spaced 2 years (or more) apart</li> <li>▪ Mother has a positive attitude going into the pregnancy</li> <li>▪ A health care provider is chosen</li> <li>▪ There are financial resources to meet the expanding family's needs</li> <li>▪ Family and significant others are supportive</li> <li>▪ Mother's weight is as close to ideal as possible before conception</li> </ul>	<ul style="list-style-type: none"> <li>▪ Parents do not use alcohol, tobacco, or other mood-altering substances when planning to conceive</li> <li>▪ The mother begins a vitamin regimen containing folic acid before the pregnancy</li> </ul>

### Summary

Maternal–child health clients are an important population group to community health nurses, because their physical and emotional health is vital to the future of society. The United States does not fare well in comparison to other developed nations on maternal–child health indicators. *Healthy People 2010* objectives for maternal child populations have shown mixed results at midcourse review. Some have moved away from their targets, such as those for low-birth-weight (LBW), very-low-birth-weight (VLBW), and preterm births, and others, like the maternal mortality rate (MMR), have moved closer to the target rate. The target for childhood immunization coverage has been met.

Problems of substance abuse, sexually transmitted diseases, and teen pregnancy can lead to less than optimal outcomes for newborns. Complications of pregnancy and childbirth, such as hypertension, gestational diabetes, postpartum depression, and fetal or infant death, offer opportunities for community health nurses to provide education and support.

Infant mortality rates are no longer declining. Toddler and young child mortality and morbidity are often related to unintentional injuries. Worldwide, toddlers and preschoolers are at risk for accidents (falls, drowning, burns, and poisoning); acute illnesses, particularly respiratory illnesses; and nutritional, dental, and emotional

ailments. Violence against children and deaths from homicide elicit valid concerns. These problems create major challenges for the community health nurse who seeks to prevent illness and injury among children and to promote health.

Health services for children span three categories: preventive, health protecting, and health promoting. The community health nurse plays a vital role in each. Preventive services include immunization programs, along with quality day care and preschool. Health protection services include accident and injury prevention and control, as well as services to protect children from child abuse. Health promotion services include infant development through effective parent–child interaction, developmental screening, and services to children with special needs.

The role of community health nurses include providing interventions to serve young children's health needs, such as educational interventions for the young child that include nutrition teaching to provide information and encourage parents to act responsibly on behalf of their children to assist in healthy habit formation for a lifetime. Other interventions involve encouraging age-appropriate immunizations or cessation of smoking during pregnancy, and PHNs may employ persuasive tactics to move clients toward more positive health behaviors. With reporting and intervening in child abuse, nurses practice a form of coercion to protect children from threats to their health. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. What specific objectives has your local health department developed for mothers and infants to help achieve the goals listed in the U.S. *Healthy People 2010* document? How do your county's statistics compare with those of others in your state on (1) infant mortality rates (collectively and by specific ethnic groups), (2) incidence of LBW and VLBW infants, and (3) incidence of birth defects?
2. Using the Internet, locate national websites that give you current information about progress toward meeting some of the *Healthy People 2010* goals with infants, toddlers, and preschool-aged children. Are you making progress? Will you meet or have you met the 2010 goal with these populations? What can a community health nurse do locally to promote meeting these goals? What needs to be done on the regional, state, or national level?
3. Describe three different maternal child populations in your county. What are their most pressing health needs? Do any existing services target these populations? How well, in your judgment, are clients' needs being met? Interview a city or county community health nurse and other public health professionals to help you find answers.
4. Sonia, an 18-year-old woman, is single and 14 weeks pregnant. Her first prenatal visit was made at the urging of her aunt, who uses the clinic. Sonia reluctantly admitted to the clinic nurse that the pregnancy was unplanned. She consumes alcohol two to three times a week, frequently as much as six 12-oz cans of beer and 16 oz of wine, and she smokes one pack of cigarettes a day. She has tried a variety of street drugs in the last 3 months but does not use any on a regular basis. The clinic nurse believed that Sonia might not return for regular prenatal care and made a referral to the PHN for follow-up home visits to assess Sonia's home environment and teach prenatal care and preparation for the infant. You have been assigned the case. Design a plan of care to address Sonia's needs. What specific services and programs might you recommend? What barriers might exist? How would the prenatal and postpartum teaching delivered to Sonia differ from care needed by other single teens?
5. What is the major cause of death among infants, toddlers, and preschool-aged children? What community-wide interventions could be initiated to prevent these deaths? Select one intervention for each age group, and describe how you and a group of community health professionals might develop this preventive measure.
6. Describe one health promotion program that you as a community health nurse could initiate and carry out to improve the health of children in a day care center or preschool program.

# School-age Children and Adolescents

## LEARNING OBJECTIVES

*Upon mastery of this chapter, you should be able to:*

- ◆ Identify major health problems and concerns for U.S. school-age children and adolescent populations.
- ◆ Explain how health status can influence academic achievement.
- ◆ State the recommended immunization schedule for school-age children and adolescents.
- ◆ Examine the trends in mortality and injury among school-age children and adolescents and identify the most important areas needing intervention.
- ◆ Discuss *Healthy People 2010* objectives affecting adolescents and the barriers that may be involved in attaining these objectives.
- ◆ Describe types of programs and services that promote health and prevent illness and injury of school-age children and adolescent populations.

*“Youth isn’t always all it’s touted to be.”*

—Lawana Blackwell, *The Dowry of Miss Lydia Clark*, 1999

## KEY TERMS

Anorexia nervosa  
 At risk of overweight  
 Attention deficit  
 hyperactivity disorder  
 (ADHD)  
 Binge eating  
 Bulimia  
 Learning disability  
 Overweight  
 Pediculosis

**According** to Erick Erickson's developmental framework, the school-age and adolescent years are a time of task mastery and development of competence and self-identity (Encyclopedia of Childhood & Adolescence, 1998). During these years, children grow physically, as well as emotionally and socially. They move from the total control of parents and families during infancy and toddler years to deriving more and more influence from outside the home—from school, teachers, peers, and other groups.

The challenges of childhood and adolescence include developmental issues, school concerns, behavioral and learning problems, emotional and mental health issues, and the risk behaviors characteristic of teenage years. This chapter explores the health needs of school-age children and adolescents and describes various services that address those needs, along with the community health nurse's role in assisting families with children.

## SCHOOL—CHILD'S WORK

In the United States in 2005, about 55.8 million school-age children and adolescents (5 to 18 years old) attended more than 123,000 public and private schools (Federal Interagency Forum on Child and Family Statistics, 2004; National Center for Education Statistics [NCES], 2005). In 2008, the U.S. population ages 0 to 17 was composed of 57% White, 15% Black, 4% Asian, 21% Hispanic, and 5% other groups (Federal Interagency Forum on Child and Family Statistics [FIFCFS], 2004).

Children and adolescents spend most of their waking hours in school. Their academic success can predict future education, employment, and income. The quality of their educational experiences (e.g., teacher-child interactions) can influence learning (Pianta, Belsky, Vandergrift, Houts, & Morrison, 2008). These children are the parents, workers, leaders, and decision makers of tomorrow, and their future success depends in good measure on achievement of their educational goals today (Burgess, Gardiner, & Propper, 2006). Child health has been linked to school success—healthy children are found to be more motivated and prepared to learn (Centers for Disease Control & Prevention [CDC], 2008a; O'Connell, 2005), and coordinated school health programs are linked to academic achievement (Murray, Low, Hollis, Cross, & Davis, 2007). This is well known to school nurses and public health nurses (PHNs) working in schools.

## HEALTH PROBLEMS OF SCHOOL-AGE CHILDREN

The well-being of children has been a subject of great concern in the United States since the days of Lillian Wald. For many years, international organizations, including the World Health Organization (WHO), the United Nations Children's Fund (formerly, United Nations International Children's Education Fund [UNICEF]), and U.S. governmental agencies, nonprofit groups, and charitable foundations have focused their resources on improving the health and well-being of children. Nonetheless, the needs of millions of children in the United States and worldwide remain unmet.

Even in the wealthiest nations, many children face complex and often chronic health problems that cause them to miss school days or participate only marginally in the

classroom. Because childhood is a critical period during which certain behaviors or health conditions are known to lead to more serious adult illnesses, it is vital for community health nurses and school nurses to screen children and identify problems early (Forrest & Riley, 2004). The chronic health problems of children younger than age 18 are often characterized by severity (e.g., persistence of symptoms and impact on social functioning) and duration (usually longer than 3 to 12 months) and may include:

- ◆ Diabetes
- ◆ Asthma
- ◆ Autism
- ◆ Cystic fibrosis
- ◆ Spina bifida
- ◆ Neuromuscular disorders
- ◆ Juvenile rheumatoid arthritis
- ◆ Seizure disorders
- ◆ Hemophilia
- ◆ Congenital heart disease
- ◆ Attention deficit hyperactivity disorder (ADHD).

Other conditions may also be defined as chronic, such as allergies, ear infections, and sinusitis; hearing or speech disorders; or even childhood obesity. Some chronic conditions may affect a child socially and emotionally, as well as physically. School attendance and relationships with family and peers may be affected.

## Chronic Diseases

Stomachaches, headaches, colds, and flu are frequent complaints of school-age children, but it is not uncommon for this same age group to be afflicted with some type of chronic disease: Between 6.5% and 18% of children are estimated to have a significant chronic condition (Schmidt, Petersen, & Bullinger, 2003). Common chronic problems include hay fever, sinusitis, dermatitis, tonsillitis, asthma, and hearing difficulties. Chronic health problems such as these can affect a child's ability to learn and/or his physical and social development. Other more serious conditions, such as diabetes, sickle cell anemia, or seizure disorders, have definite effects on academic achievement (Taras & Potts-Datema, 2005a).

The numbers of children with chronic conditions are increasing, and more children with significant health problems are present in schools (Perrin et al., 2007). In the school setting, some children require specialized physical health care procedures, such as catheterization or suctioning. The U.S. Supreme Court ruled that even complex nursing services (i.e., ventilator care) must be provided by schools, even though school nurses are not always present in each school building every day (American Academy of Pediatrics Committee on Children With Disabilities [AAPCCWD], 2000). (See Chapter 30 for more on school nursing.) The Individuals with Disabilities Education Act (IDEA) or Section 504 of the Rehabilitation Act of 1973 (AAPCCWD, 2000; National Dissemination Center for Children with Disabilities, n.d.) mandates that services must be provided for children identified as *disabled*. Many conditions may be characterized as disabling under these two laws, including autism, deafness or hearing impairment, blindness or vision impairment, emotional disturbances, mental retardation, specific learning disabilities, speech or language impairments, or other health impairments (e.g., ADHD,

asthma). Once they have been characterized as disabled, children may qualify for special educational services. Children with chronic health conditions that can affect learning (e.g., diabetes, seizure disorders) may receive medications or other related services while in school, to maintain their health and promote their ability to learn (Merck, 2005).

Chronic diseases of childhood and adolescence affect the entire family and can lead to developmental and social issues for children, as well as missed school days and eventual school failure (Centers for Disease Control & Prevention [CDC], 2008a; Schmidt, Petersen, & Bullinger, 2003).

### Asthma

Asthma is the most common chronic disease of childhood. In 2003, it was estimated that 13% of children younger than age 18 have at some time been diagnosed with asthma (Forum on Child & Family Statistics [FCFS], 2005). Non-Hispanic Black children exhibited the highest asthma attack rates at 13%, compared with 8% for White children and 7% for Hispanic children; overall, about 6% of children reported an episode within the past year (FCFS, 2005).

Although reasons for the increasing cases of asthma are somewhat unclear, experts speculate that better recognition and diagnosis of the disease; overcrowded conditions; and exposure to air pollution (indoor or outdoor), allergens, and irritants in the environment are probable culprits and may trigger asthma attacks. Many schools have high levels of allergens and irritants. Children and adolescents with asthma may have attacks triggered by infections, exposure to cigarette smoke, stress, strenuous exercise, or weather changes (e.g., cold, wind, rain) (Daisey, Angell, & Apte, 2003; FCFS, 2005).

Pediatric asthma led to a high rate of hospitalizations for preventable conditions in 2004—155 per 100,000, second only to pediatric gastroenteritis and substantially higher than the rate of 31.5 per 100,000 for short-term diabetes complications—and further contributed to rising health care costs (Russo, Jiang, & Barrett, 2007). Treatment for chronic asthma usually includes inhaled corticosteroids, but acute symptoms may involve inhaled beta<sub>2</sub> agonists and sometimes anticholinergics (Courtney, McCarter, & Pollart, 2005). Parent and child education, along with adequate primary medical care, can help decrease the number of emergency room visits (Boudreaux, Emond, Clark, & Carmargo, 2003; Courtney et al., 2005).

Teaching families to reduce allergens in their homes by controlling dust mites, vacuuming frequently, preventing animal dander and the entry of pollen into the home, and avoiding mold and mold spores may help minimize asthma symptoms for many children (Asthma & Allergy Foundation of America, 2007). School nurses and PHNs often work with students, families, and physicians to develop an asthma action plan to control, prevent, or minimize the untoward effects of acute asthma episodes. The goal is to control asthma symptoms and minimize school absences resulting from asthma (Courtney, et al., 2005). Asthma triggers are noted, and school staff are taught to assist the child in avoiding these triggers. Peak flow meters can be used to determine early signs of asthma problems and to facilitate early interventions. Approximately 27% of schools reported having these available for asthmatic students, and 68% allowed students to self-administer their inhalable asthma medications (CDC, 2004).

Monitoring asthma medications and teaching proper methods of inhaler use are also vital school nursing or PHN functions. Although the link between asthma and academic achievement is not definitive, some evidence exists that school nurse case management of asthmatic children can lead to fewer absences, fewer hospitalizations, and reduced emergency room visits (Taras & Potts-Datema, 2005b; Levy, Heffner, Stewart, & Beeman, 2006).

### Autism

Autism is a complex developmental disorder that is usually first noticed within the first few years of life. A child's communication skills and interaction with others is most often affected, along with obsessive behavior and narrowed interests. Behaviors associated with autism include:

- ◆ Language problems (no language, delay in language, repetitive use of language)
- ◆ Motor mannerisms (rocking, hand flapping, object twirling)
- ◆ Fixation on objects (restricted interests)
- ◆ No spontaneous play or make-believe play; no interest in peers (problems making friends)
- ◆ Little or no eye contact (may also resist hugging)

The estimated lifetime expense for an autistic child averages \$3.5 to \$5 million (Autism Society of America [ASA], 2008). Autism is not a new disorder—descriptions of autistic behavior have been identified in 18th century writings. Currently, the Autism Information Center estimates the prevalence of autism at one in 150 children, with boys four times more likely than girls to have the disorder (2007). Because autism is a “spectrum disorder” that presents differently among individuals, behaviors and severity can vary widely (ASA, 2008).

The cause of autism is not clear—some genetic links have been found, but environment may also be a factor. There is a higher risk of subsequent children having autism in a family with one autistic child (National Institute of Neurological Disorders & Stroke [NINDS], 2008). It is often associated with other disorders (e.g., congenital rubella syndrome, phenylketonuria [PKU], fragile X syndrome, tuberous sclerosis), but with early intervention some children's symptoms improve, and they can lead near-normal adult lives (Autism Information Center, 2007; NINDS, 2008).

PHNs may come in contact with families dealing with autism through work in well-child or immunization clinics. It is important to educate parents that parenting practices are now known *not* to be a cause of autism and that multiple, large-scale research studies on childhood immunizations have shown no relationship between immunization and autism (Autism Information Center, 2007; NINDS, 2008).

### Diabetes

Diabetes is another common chronic illness in children, with the National Institutes of Health's (NIH) National Diabetes Education Program (NDEP, 2006) reporting that nearly one in every 400 to 600 children has type 1 diabetes. Both type 1 and type 2 diabetes are found in school-age children. Type 2 diabetes is rising almost exponentially in this age group, leading some scientists to call this a major public health crisis. Newly

diagnosed type 2 diabetes in children has increased from less than 5% before 1994 to 30% and 50% in more recent years (NDEP, 2006). This epidemic is thought to stem from increasing rates of childhood obesity, sedentary lifestyle, and the predisposition of certain ethnic groups (e.g., American Indian, Mexican American) to the disease. A family history of type 2 diabetes may also play a role.

Younger children with type 1 diabetes, especially those who use insulin pumps, may need careful monitoring, something that is not always possible for the school nurse, who is often assigned to several school sites and may not be present when problems arise. A multidisciplinary team approach to care is needed, coordinating family, school staff, and physician collaboration.

Children and adolescents with diabetes may be reluctant to comply with medical regimens, although strict adherence has proved to reduce later microvascular complications (NDEP, 2006). Testing blood sugar levels and taking insulin at school can be frustrating and cause children to feel singled out or different from their peers. One study found that adolescents with type 1 diabetes have significantly higher rates of depression than those without diabetes (Kanner, Hamrin, & Grey, 2003). It is important for school nurses and PHNs to understand each child's unique concerns and to alert teachers and school personnel to the signs and symptoms (as well as treatment) of hypoglycemia.

In addition to the obvious emergency health-related concerns for diabetic children, a classic study showed that diabetes-related severe hypoglycemia affects memory tasks (Hershey, Bhargava, Sadler, White, & Craft, 1999). Over time, memory deficits can affect learning and progress in school, and this has been substantiated by later research (Taras & Potts-Datema, 2005a). Moreover, obesity and overweight have been found to correlate with "poorer levels of academic achievement" (Taras & Potts-Datema, 2005c, p. 291).

It is imperative to teach children and families that nutrition, oral antidiabetes medications or insulin administration, physical activity, and blood glucose testing are vital strategies to keep blood glucose levels as close to normal as possible (NDEP, 2006). The prevention of type 2 diabetes through education and improvement in exercise, nutrition, and lifestyle can be one of the most important areas of focus for health professionals who work with the school-age population—including PHNs who may come into contact with them during immunization or child health clinics. Health education and health promotion to decrease childhood obesity and sedentary lifestyles may help stem the tide of type 2 diabetes in children and adolescents (see Levels of Prevention Pyramid).

### Juvenile Rheumatoid Arthritis

Juvenile rheumatoid arthritis is a painful autoimmune disorder characterized by persistent joint swelling and stiffness with periods of remission and flare-up. It is treated with nonsteroidal anti-inflammatory drugs (NSAIDs), disease-modifying antirheumatic drugs (DMARDs) such as methotrexate, and sometimes corticosteroids or newer biologic response modifiers (National Institute of Arthritis and Musculoskeletal and Skin Diseases, 2004; Wilkinson, Jackson, & Gardner-Medwin, 2003). Exercise is often an important component of therapy, and an adapted physical education program may be developed for these children. Long-term sequelae may result,

and many adolescents with this disorder require additional support and counseling (Bowyer et al., 2003).

### Seizure Disorders

Seizure disorders are not uncommon in the school-age population. Epilepsy is a disorder of the brain in which neurons sometimes transmit abnormal signals. Epilepsy is considered to be one of the most common disabling neurological conditions, and it is most common in the very young and in elderly populations (CDC, 2007a). About 40% of children with epilepsy between the ages of 4 and 15 have "one or more additional neurological disorders" (Silver, 2004a). For almost 85% to 90% of those diagnosed, seizures can usually be controlled with medications (Freeman, Freeman, Kossoff, & Kelly, 2006). Vagus nerve stimulators are used in some cases after other treatments have failed (Buchhalter & Jarrar, 2003; NINDS, 2008). Rectal diazepam is commonly prescribed for younger children and those with developmental disabilities, yet nurses are not always available to make an appropriate nursing assessment of the child before the drug is given to stop a seizure (Fitzgerald, Okos, & Miller, 2003; Epilepsy Foundation, 2003). Often, school secretaries or health aides are trained to give the emergency medication—highlighting the conflict between education laws and nurse practice acts. Treatment of epilepsy has been greatly enhanced by the use of newer antiepilepsy drugs (AEDs) specific to the pediatric population and, in some cases, by a diet rich in proteins and fats and low in carbohydrates—a *ketogenic diet* (Freeman et al., 2006).

It is important to monitor medication compliance and teach school staff about first-aid measures for seizure victims. When teachers are anxious about having a child with epilepsy in the classroom, educational programs for them and other school staff members can be provided by community health nurses or school nurses to allay fear and promote appropriate and timely care (Price, Murphy, & Cureton, 2004).

Family dynamics are also a consideration, as behavior problems can arise from "deficient family mastery and parent confidence in managing their child's discipline" (Austin, Dunn, Johnson, & Perkins, 2004). Children and adolescents with seizure disorders may feel embarrassed or be the victims of teasing or bullying. They may exhibit signs of school avoidance, or they may have problems learning. The side effects of antiepileptic medications may lead to problems with memory and learning, as well as changes in behavior. Moreover, seizures can affect short-term memory or language functions, and almost 50% of children with learning disabilities have epilepsy (Silver, 2004a). It is important for school nurses to work with children with epilepsy and to teach all students about the disease process and the need for empathy and understanding.

### Childhood Cancers

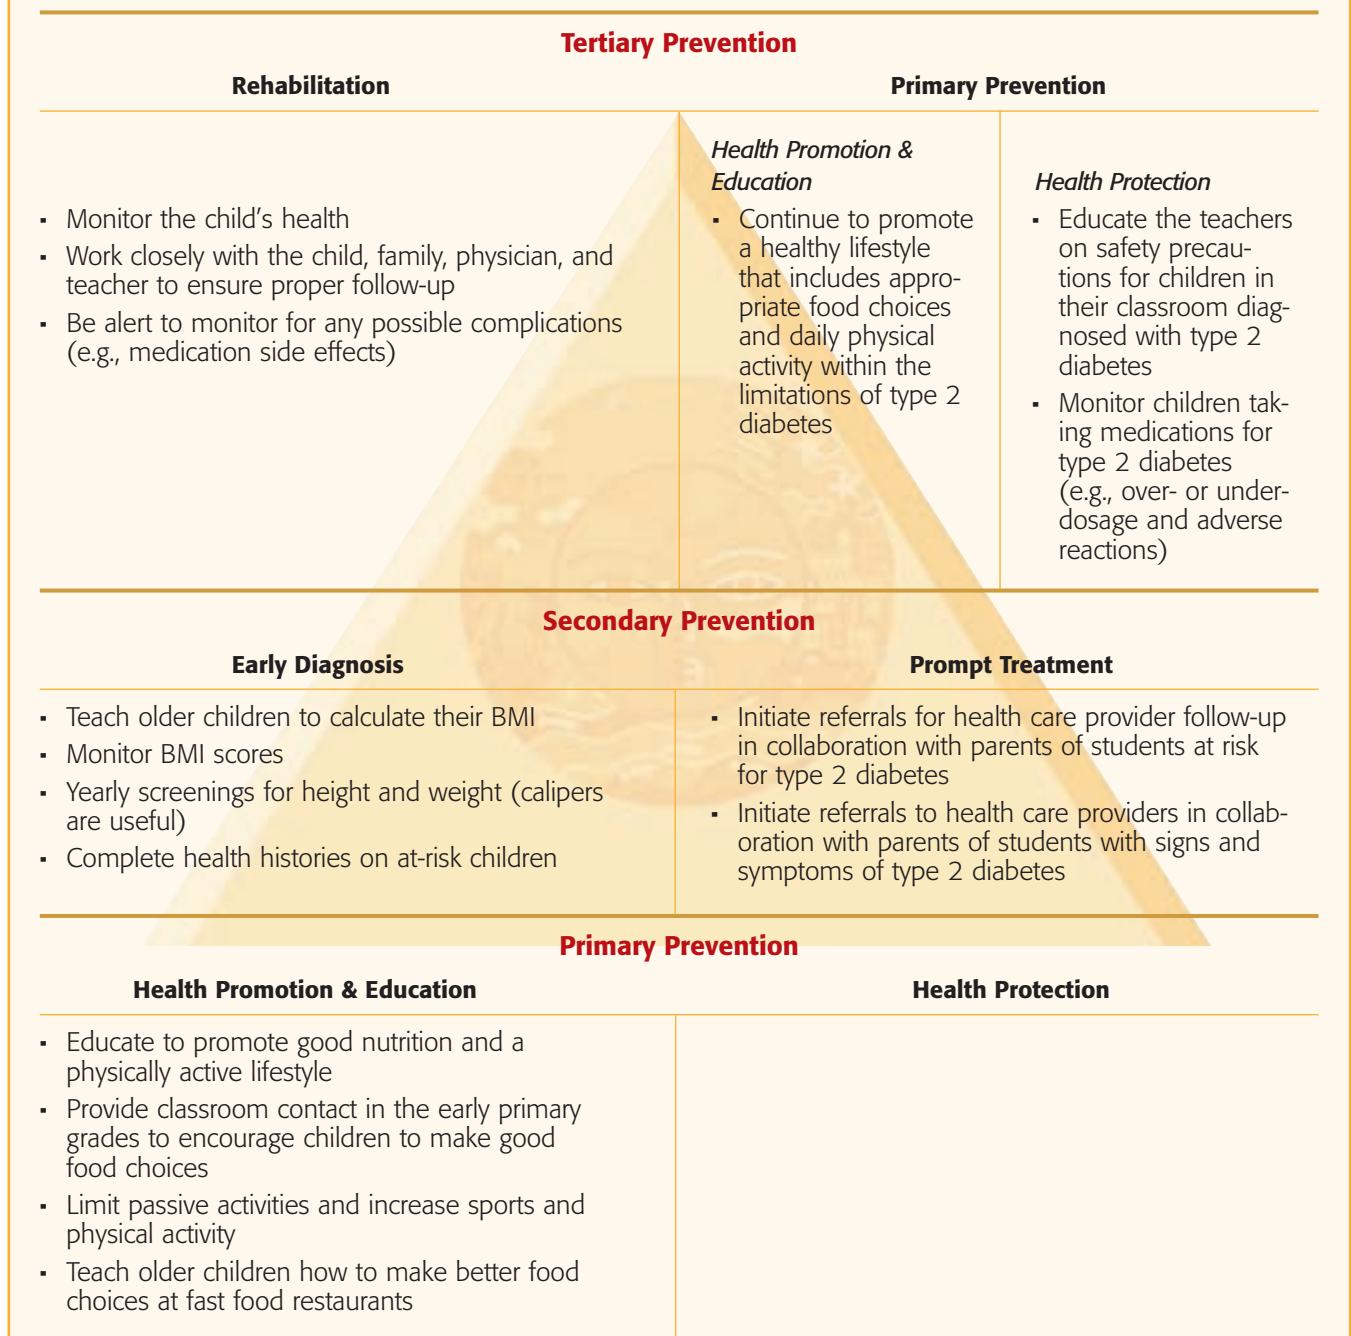

In 2007, cancer ranked as the leading cause of death from disease among U.S. children between the ages of 1 and 14. Given the generally good health of children in this age group, however, this alarming ranking is actually low, at one to two cases per 10,000 children (National Cancer Institute [NCI], 2008). Most childhood cancers are blood cell cancers (e.g., leukemias) or cancers of the central nervous system or brain.

## LEVELS OF PREVENTION PYRAMID

**SITUATION:** The public health nurse and children with type 2 diabetes

**GOAL:** By using the three levels of prevention, negative health conditions are avoided, promptly diagnosed and treated, and/or the fullest possible potential is restored.

Acute lymphoblastic leukemia is the most common childhood cancer. Childhood cancers, especially leukemias, now have better outcomes than ever before. Five-year survival rates for childhood cancers increased by almost 80% from 1996 to 2003, generally as a result of treatment advances (NCI, 2008). More than 70% of childhood cancers are now

considered curable, with survivors more concerned about later complications of treatment than about cancer recurrence (Wallace et al., 2001). However, children who have been treated with chemotherapy and/or radiation may develop a second primary cancer, and the risk of leukemia may be increased (NCI, 2008).

Acquired immune deficiency syndrome (AIDS), high levels of ionizing radiation, Down syndrome, and other genetic syndromes (e.g., Gorlin syndrome) have been linked to a higher risk for some childhood cancers. Pesticide exposure may be a factor, but research findings have not been decisive. Parental smoking may be linked to an increased cancer risk, but evidence for this is also inconclusive (NCI, 2008).

Because many children return to school after initial hospitalization and treatment for cancer, school nurses or PHNs can help make this transition easier by educating classmates about cancer (e.g., it is not contagious), helping the children make necessary adjustments, and vigilantly protecting any immunocompromised students from communicable diseases (VanDenBurgh, 2003).

## Behavioral and Learning Problems

Other childhood health problems, less easy to detect and measure but often just as debilitating, are those of emotional, behavioral, and intellectual development. Although these problems are not new, awareness and concern have increased as the rates of occurrence for other life-threatening childhood diseases have diminished. Emotional or behavior problems and learning disabilities are prevalent in childhood. In a national survey, 8% of girls and 16% of boys reported having been diagnosed with ADHD or learning disability—the most commonly reported problems. Three times more boys than girls reportedly have ADHD, and boys are more likely to have a comorbid learning disability (CDC, 2005).

### Learning Disabilities

Children and adults who have average or above-average intelligence and who demonstrate significant difficulties in one or more areas of learning (e.g., reading, writing, mathematics) may have a **learning disability**. Thinking and organization skills can also be affected. Learning disabilities may occur in one area or be overlapping—they are often lifelong conditions (NINDS, 2007). Causes of learning disabilities and emotional behavioral problems appear to have genetic, environmental, and cultural influences. Approximately 5% to 10% of students have a learning disability, formally defined as a “neurologically based processing disorder” (Silver, 2006). A U.S. Department of Education survey in 2001 revealed that 68% of those with learning disabilities were male (Cortiella, 2008). The number of children with learning disabilities in the lowest economic group is twice that in the highest economic group (CDC, 2002a). Children characterized as being in fair or poor health were more than four times as likely to have a learning disability and three times as likely to have ADHD as children with excellent, very good, or good health status (CDC, 2002a).

Children with learning disabilities can be helped through special education services. Students must first be carefully diagnosed through psycho-educational testing; then, special education or resource teachers can build on the child or adolescent’s strengths while working to compensate for weaknesses (NINDS, 2007). Some learning disabilities are apparent in early school years, whereas others do not present problems until later, in early adolescence. Battles over home-

work, poor grades, acting out in school, or frequent child complaints about school, teachers, or schoolwork, are often harbingers of learning disabilities. Common signs of learning disabilities are (Silver, 2006):

- ◆ Reading problems
- ◆ Writing problems (fine motor control and handwriting; problems with spelling, grammar, punctuation, capitalization; difficulty controlling flow of thoughts)
- ◆ Math problems (problems learning and understanding concepts, missing steps or sequencing of problems and placement of numbers in columns)
- ◆ Language problems (cannot quickly process what is heard, problems with multiple instructions, difficulty organizing thoughts and speaking in classroom situations)
- ◆ Motor problems (problems with fine-motor planning activities, such as tying, cutting, coloring, and gross-motor planning, such as jumping and running; trouble with visual–motor activities, such as hitting or catching a ball)

If learning disabilities are not dealt with in childhood and adolescence, they can lead to later, more serious problems related to employment and relationships. Approximately 19% of students diagnosed with learning disabilities reported being suspended or expelled from school, arrested, or fired by their employers (Cortiella, 2008).

### Attention Deficit Hyperactivity Disorder

**Attention deficit hyperactivity disorder (ADHD)** is a cluster of problems related to hyperactivity, impulsivity, and inattention. Its estimated prevalence has ranged from 3% to 5%, representing about 2 million children (National Institute of Mental Health [NIMH], 2006). Others have reported much higher overall rates (7%), and around 10% of 3 to 17 year-old males in 2004 were diagnosed by a health professional as having ADHD (Child Trends, 2006), and the disorder continues to be diagnosed with increasing frequency (Damico, Tetnowski, & Nettleton, 2004). One study found the rate of ADHD diagnosis had more than tripled over 10 years, with the largest increase among low-income and poor children in the 12- to 18-year-old age group (Olfsen, Garneroff, Marcus, & Jensen, 2003). Although there were fewer treatment visits, an increase was noted in stimulant prescriptions during this same period. Others have noted the trend of increasing pharmacologic treatment of ADHD (Damico et al., 2004). Another study found a positive association between stimulant treatment for ADHD and age, male gender, fewer child dependents, higher income, white communities, and living in the Midwest or South (Cox, Motheral, Henderson, & Mager, 2003). Girls, on the other hand, are at increased risk for not receiving appropriate services because they often do not exhibit the hyperactivity component and often are not appropriately diagnosed.

Although a number of parents believe that sugar, food coloring agents, or other food additives may worsen ADHD symptoms in their children, research shows no behavioral or learning differences in double-blind studies using sugar and sugar substitutes. Some research shows that prenatal exposure to nicotine and psychosocial adversity are associated

with ADHD (Biederman & Faraone, 2002; NIMH, 2006). Symptoms of ADHD may be related to such diverse causes as lead poisoning and traumatic brain injuries, but new research focuses on the inherited tendencies for problems with dopamine receptors and transporter genes, along with evidence of decreased blood flow in the prefrontal regions of the brain and smaller brain volumes in the frontal lobe, caudate nucleus, cerebellum, and temporal gray matter (NIMH, 2006). These findings support a neurobiologic basis for the condition (Kelly, Margulies, & Castellanos, 2007). Some evidence indicates that children with ADHD who are medicated properly later show white matter volumes consistent with control subjects, indicating that medication can restore brain volume to a more normal level (NIMH, 2006). Some family and twin studies reveal a higher heritability factor (0.8) for ADHD than for other psychiatric disorders, and researchers consider ADHD a “familial and highly heritable disorder” (Thapar, Langley, O’Donovan, & Owen, 2006, p. 714; Weiss & Murray, 2003). In families that have children with ADHD, about 25% of close relatives also had ADHD—much higher than the general population estimate of 5% (NIMH, 2006).

Not all behaviors related to ADHD, such as hyperactivity, may truly be ADHD (Silver, 2004b). Health and psychological professionals must take a careful history and note if sudden family changes may have recently occurred (e.g., divorce, death, family crises) that may cause children to behave erratically. Untreated chronic middle ear infections, undetected temporal lobe seizures, and anxiety or depression can also be the source of some behavior problems that mimic ADHD, as can other brain disorders (NIMH, 2006). Although some health professionals believe that many of the symptoms found in people with ADHD are part of the normal spectrum of human behavior, others note that people with ADHD have functional impairment in academic, social, or occupational areas resulting from their problem behaviors. Noted differences have even been reported in the results of electroencephalograms (Swartwood et al., 2003). Nursing researchers have documented qualitative data from children and adolescents who described their difficulties (Kendall, Hatton, Beckett, & Leo, 2003).

At each stage of development, those with ADHD are presented with distinct challenges. For example, children in elementary school are often involved in conflicts with peers and have problems in organizing tasks. They may be more prone to accidents, and may have more school-related problems, such as grade retention and suspension or expulsion. They often have problems with grooming and handwriting, and they exhibit difficulty sleeping and making friends. As adolescents, 80% still exhibit symptoms of inattentiveness, hyperactivity, and impulsiveness. Compared with non-ADHD teens, they may have more conflict with their parents, poorer social skills, and ongoing problems at school. They may face more difficulty driving and are more prone to injury while driving, biking, or walking than are their peers. They are also more likely to use tobacco and alcohol, spend less time with their families, and more often experience negative moods (Child Trends, 2006). As young adults, they are less likely to be enrolled in college, more likely to have begun sexual activity at an earlier age and to have been treated for a sexually transmitted disease (STD), and more likely to experience lower job performance ratings than their peers (Child Trends, 2006). In adulthood, they tend to have

more marital and occupational problems. They often have less formal education and lower levels of savings. Poor social skills continue to be an issue (Barkley, Fischer, Smallish, & Fletcher, 2002; Child Trends, 2006; Weiss & Murray, 2003).

ADHD is sometimes found with associated disorders, such as communication or language disorders and learning disabilities. About half of ADHD children and adolescents have learning or other mental disorders (Child Trends, 2006). Common comorbid conditions are bipolar, depressive, and anxiety disorders, as well as conduct disorders and oppositional defiant disorder (Biederman & Faraone, 2002; Child Trends, 2006). At an earlier age of onset, ADHD is associated with more parental reports of child aggressive behavior, whereas at a later age of onset, ADHD is associated with more anxious/depressive symptoms (Connor et al., 2003). For some children, ADHD might even be a precursor of a child-onset subtype of bipolar disorder (Masi et al., 2003). Differentiating between the two conditions can be difficult, as bipolar disorder in children can present as a chronic mood problem, with some symptoms related to depression, irritability, and elation (NIMH, 2006).

Collaboration among the child’s family, school, and physician is needed to diagnose ADHD and to plan appropriate interventions and educational accommodations. Although parents have a wealth of knowledge about the child, teacher confirmation of ADHD-related behaviors is very important. School nurses and PHNs can assist parents in recognizing the symptoms of ADHD and in obtaining appropriate treatment and follow-up. A multimodal treatment approach is recognized as most effective. This includes medication, usually methylphenidate (Ritalin, Metadate, or Concerta), dextroamphetamine (Dexedrine or Dextrostat), or amphetamine (Adderall); school accommodations for learning problems; and social skills training for the child with ADHD (NIMH, 2006). Family and individual counseling, parent support groups, and training in behavior management techniques, as well as family education about the condition, are also essential features of this treatment method. Not all children and adolescents respond to medication—about 10% do not—and medication dosage must be carefully monitored and adjusted.

The main goal of medical treatment for school-age children is academic improvement. If this does not occur, medication may need to be changed or discontinued. Parental depressive symptoms and severity of ADHD symptoms in children have been found to decrease the rate of response to medication and combined treatments (Owens et al., 2003). School nurses and community health nurses can work closely with school staff, parents, and physicians in determining the efficacy of treatment regimens.

Parents often voice concern about giving their children a stimulant medication to treat ADHD, and some families pursue alternative treatments. One study revealed that 54% of parents used some type of complementary and alternative medicine (e.g., acupuncture, nutritional supplements, diet), and 11% did not discuss this fact with their child’s physician (Chan, Rappaport, & Kemper, 2003). Some promising results with neurofeedback were found in a German study (Fuchs, Birbaumer, Lutzenberger, Gruzelier, & Kaiser, 2003). A new nonstimulant medication, atomoxetine (Strattera), has been used in children but has also been linked to increased suicidal thoughts or attempts.

Parental resistance to treatment may result from side effects (e.g., problems with sleep, appetite, greater anxiety) or stem from fears about later abuse of substances. As adolescents, those with ADHD may experiment with alcohol and other substances earlier than non-ADHD teens do—hyperactivity has been shown to predict low self-esteem, leading to social withdrawal and abuse of substances (Tarter, Kirisci, Feske, & Vanyukov, 2007). However, a good deal of research indicates that treatment with medication for ADHD in childhood does not lead to an increased risk for substance use or abuse in adulthood, and some studies found that adolescents who consistently took their ADHD medications were actually less likely to use or abuse substances (Barkley et al., 2003; NIMH, 2006).

### Behavioral and Emotional Problems

It is estimated that 1 in 20 children and adolescents “have one or more significant behavioral problems in school” and that a very small percentage of them receive any consistent, specialized mental health care (Hennessy & Green-Hennessy, 2000, p. 591). Between 10% and 15% of children and adolescents have symptoms of depression. About 20% of school-age children display behaviors consistent with oppositional defiant disorder (e.g., hostile, stubborn, disobedient, belligerent), and about 10% of children between the ages of 9 and 17 have been diagnosed with conduct disorder. Symptoms of this disorder, sometimes thought to be a more severe form of antisocial behavior than oppositional defiant disorder, include behaviors that “violate the rights of others and age-appropriate social standards and rules” (American Academy of Child & Adolescent Psychiatry [AACAP], 2008). These behaviors can include destruction of property, fire setting, cruelty to animals or people, and/or bullying and threatening behavior (Kazdin, 2008). Schizophrenia in childhood affects one in 40,000 children under age 12, and adult schizophrenia, which affects one in 100 people, usually begins in young adulthood (age 18 for males, age 25 for females). Bipolar disorder, most often found in adults, is also found in children and adolescents. Early identification of children and adolescents at risk for developing bipolar disorder may be accomplished through the use of behavior checklists and other psychometric tools that reveal higher scores related to aggression, delinquent behavior, and attention problems, or withdrawal and anxiety/depression (Giles, DelBello, Stanford, & Strakowski, 2007). It is important to find referral sources for these children and their families, and this may be difficult in more rural or outlying areas (Kazdin, 2008).

School-age problem behaviors stem from many causes, some of them genetic and others environmental. Corporal punishment may be a risk factor for antisocial behavior (Kazdin, 2008), and a large-scale national study found that parental corporal punishment negatively contributed to behavioral problems in preschool and first-grade children. It was thought both to trigger and maintain child behavior problems, and decreasing this parental behavior could be associated with better child mental health and lower levels of behavior problems (Mulvaney & Mebert, 2007). Children are barometers of their environment. The current rate of divorce in the United States is double what it was in the 1950s; over the last 30 years, the percentage of children

living in two-parent families decreased from 85% to 69%, and more than 26% of children today live with one parent, usually their mother (Schor, 2003).

Children of divorce are more likely to exhibit behavior problems, with children who are products of highly contentious divorces most at risk. School nurses can be alert to early symptoms and refer parents to marital counseling or suggest family therapists. Some schools also offer support groups for children of divorce.

School refusal is found in 1% to 5% of school-age children and differs from truancy. It is commonly a symptom of emotional distress—usually anxiety or depression—but may also be associated with oppositional-defiant disorder, ADHD, or other disruptive behavior disorders. School refusal is most commonly found in children ages 5, 6, 10, and 11, and rates are similar between boys and girls and for all socioeconomic levels (Fremont, 2003). Children usually present to the school nurse or PHN with headaches and/or abdominal pains. They may throw tantrums, cry, or exhibit panic and fear to their parents in an attempt to stay home from school. Sometimes, children are afraid of something in the school environment (e.g., bullies, teachers, test-taking), or they may have a type of separation anxiety. Family enmeshment or detachment, or high levels of family conflict, may contribute to school refusal problems. The best interventions include early return to school, with parental involvement in school, systematic desensitization (graded exposure to the classroom), relaxation training, and counseling being the most effective (Fremont, 2003). Occasionally, antidepressant medications are used as well. Community health nurses can serve as a liaison among the child, family, school, and health care/mental health care providers to promote a positive outcome.

### Disabled Children

Children with disabilities account for more than 10% of the total school-age population. Between 2003 and 2004, over 6,500 students were classified as disabled, or 14% of school-age students. The most commonly-cited disabilities are specific learning disability, speech or language disability, mental retardation, emotional disability, and hearing impairments (National Center for Education Statistics, n.d.). The prevalence of disability in children has increased greatly over the past 30 years, more so for Blacks than for Whites (Newacheck, Stein, Bauman, & Hung, 2003). Many children with perceived disabilities or problems are referred for assessment and possible placement in special education programs each year. However, most children receive special services in a regular classroom because *full inclusion* or *mainstreaming* legislation mandates that fewer children be segregated into special classes or separate schools.

### Problems Associated with Economic Status

After reaching a low point in 2000, in 2004, childhood poverty in the United States rose to 18% (Koball & Douglas-Hall, 2006). This increase in poverty did not vary by parents' place of birth, employment status, or educational level, leading many to speculate that this jump in the poverty rate reflects overall economic conditions. According to the Children's Defense Fund (CDF, 2008a), one in 13 children lives in extreme poverty, and one in six are poor. Every 35 seconds, a

baby is born into poverty (CDF, 2008b). It is in society's best interest to care for its children, because they will become the taxpayers of tomorrow. In the past, single-parent families (usually without an adult man present), welfare reform, and economic trends that keep less well-educated populations from entering all but the most menial jobs combined to produce a powerful synergistic effect on children and adolescents (Shields & Behrman, 2002).

Poverty has profound and lasting effects on children. More than 20% of low-income children between the ages of 6 and 17 have some type of mental health problem (Chau & Douglas-Hall, 2007). Children living in poverty have poorer health and are more likely to suffer from a chronic health condition; they are more likely to be born prematurely or at a lower birth weight. They are also more likely to experience depression and mental health problems and engage in more health-risk behaviors (e.g., smoking, early sexual activity), and they account for more adolescent delinquent behaviors and pregnancy (Cauthen, 2005; Child Trends Databank, 2008).

As adults, these children will be more likely to have lower occupational status and lower wages. Poor children and adolescents are at higher risk for negative cognitive outcomes and learning problems, resulting in fewer school days, lower math and reading scores, more grade failures, and earlier high school dropout (Child Trends Databank, 2008; National Center for Children in Poverty, 2008). A recent study found family wealth as a significant partial predictor of test scores in school-age children. The disparity in this study was stunning—white families owned more than 10 times the assets of black families and white children's test scores were significantly higher than those of black children (Yeung & Conley, 2008).

The social, emotional, and behavioral problems of some poor children may be the end result of disproportionate exposure to environmental toxins, parental substance abuse, maternal depression, trauma and abuse, divorce, violent crime, low-quality child care, inadequate nutrition, and decreased cognitive stimulation and exposure to vocabulary in early childhood and infancy (Child Trends Databank, 2008).

The relationship between lower socioeconomic status and poor health persists throughout childhood and adolescence (Chen, Martin, & Matthews, 2006), and poor adolescent and adult health are associated with childhood poverty (Cauthen, 2005). A longitudinal study in New Zealand by Poulton and colleagues (2002) found that childhood poverty can lead to health problems in adulthood (e.g., poor cardiovascular health, periodontal disease), even if socioeconomic status later increases.

Welfare reforms enacted in 1996 (i.e., The Personal Responsibility and Work Opportunity Reconciliation Act [PRWORA]) have been successful in moving many families from welfare to work. By 2000, the number of families receiving cash assistance fell to half the number served in 1996 (Shields & Behrman, 2002). However, employment rates that increased during the mid-1990s have once again fallen in the face of a declining job market in the mid-2000s (Parrott & Sherman, 2006). More than 1 million single mothers are now in the "no work, no welfare" group—with no jobs and no government support. The decline in social worker caseloads has been linked to a drop in service to qualifying families, rather than a reduction in the numbers of poor families (Parrott & Sherman, 2006).

Funding cuts to the Food Stamp Program, decreased benefits to legal immigrants, and reductions in Medicaid eligibility have impacted many poor families. Reduced allotments of food stamps to households with mixed citizens/noncitizens have led to child citizens of noncitizen parents reporting persistent and higher levels of food insecurity (Van Hook & Stamper-Balistreri, 2003). An Illinois study found that those affected by welfare reform decreased their food stamp participation while turning more to the special supplemental food program for Women, Infants, and Children (WIC) as a source of essential food items for their children. Researchers posited that cash assistance and food stamps are more closely linked and identified as "welfare programs," whereas WIC has the connotation of a "public health program" (Lee, Mackey-Bilaver, & Goerge, 2003, p. 609).

Safety-net programs—specifically, WIC and the Food Stamp program—have been shown to reduce the risk of nutrition-related problems (e.g., anemia, nutritional deficiency, failure-to-thrive). They have also been associated with a reduction in the risk of child abuse and neglect (Lee, Mackey-Bilaver, & Chin, 2006). The negative impact of welfare reform has also been noted in lower rates of first-trimester prenatal care (Gavin, Adams, Manning, Raskind-Hood, & Urato, 2007). Forty percent of families remaining uninsured 1 year after leaving welfare rolls (Secombe, Newsom, & Hoffman, 2006) and one-third of those timed-off of welfare reported housing problems, lack of access to medical care, and insufficient food (Lindhorst & Mancoske, 2006). In a comparison of Temporary Assistance for Needy Families (TANF) and Aid to Families with Dependent Children (AFDC) recipients, those leaving TANF had a decline in economic status whereas AFDC leavers reported increases (Ozawa & Yoon, 2005). Children in families in which welfare benefits were reduced or terminated due to sanctions (usually related to inability to find work or comply with program rules) had greater odds of hospitalizations and food insecurity (Cook et al., 2002). One longitudinal study found that, after 3 years, children in the child welfare or child protective system had stable insurance coverage, a finding partially attributable to the persistence of social workers finding available coverage for children in this vulnerable group or the movement of the children into the foster care system (Raghavan, Aarons, Rosch, & Leslie, 2008).

The Personal Responsibility and Work Opportunity Reconciliation Act did provide needed changes in child support enforcement—in 2005, over 50% of families in programs received child support, up from 20% in 1996 (Parrott & Sherman, 2006). And, despite problems with welfare reform, some studies show that school-age children in families that participate in these programs do better in school and exhibit fewer behavior problems than those from families that do not participate. More negative outcomes, however, were found for adolescents, even though employment and income levels increased (Morris, Huston, & Duncan et al., 2001). Some small but significant improvements in parenting practices of participating mothers were also noted (Chase-Lansdale & Pittman, 2002). There is a need for high-quality child care and after-school programs to support these families (Fuller, Kagan, Caspary, & Gauthier, 2002). Some studies indicate that about half the families who leave welfare for work actually have fewer economic resources than they had while on welfare. A good number return to the welfare rolls because of their inability to survive in the work world (Loprest, 2001).

Although almost 13 million U.S. children live in families with incomes below the federal poverty level (\$20,650 for a family of 4 in 2006), economists note that families need about twice the income of the federal poverty level to survive (Fass & Cauthen, 2007). These families are characterized as low-income, and more than 28 million children live in these circumstances. Millions more children live in moderate-income families that have inadequate child care, limited health insurance, limited access to higher education, and poor housing. In fact, a classic study by Vissing and Diament (1997) surveyed more than 3,600 high school students in New Hampshire and Maine and found that between 5% and 10% had been homeless during the past year. Almost 20% lived in distressing situations and were at risk of being homeless. About 19% of poor children have no health insurance; overall, 11.7% of children are uninsured (Fass & Cauthen, 2007). In some states, this figure is 30%, even though more than 90% of uninsured children have one or more parents who work, and more than 66% have family incomes greater than the poverty level (see Chapters 6 and 25).

Some specific physical health problems are related to poverty (e.g., lead poisoning, iron deficiency anemia, increased susceptibility to illness). Children living in poorer neighborhoods are exposed to higher levels of community violence and may be more prone to seeing the world as a hostile and dangerous place; they are often also exposed to higher levels of family violence and are more at risk of subsequent mental health issues (Linares, 2008). A longitudinal study of childhood poverty and its relationship to health status found that “the greater the number of years spent living in poverty, the more elevated was overnight cortisol and the more dysregulated was the cardiovascular response” (Evans & Kim, 2007, p. 953). This study demonstrated the physiologic effects of poverty, mediated by increased social and physical risk factors (e.g., substandard housing, environmental toxins, crowding, noise, greater family conflict, harsher parenting styles). Earlier research showed an association between crowding and noisy conditions and hypertension (Evans & Kim, 2007). The results reported by Evans and Kim (2007) align with previous research demonstrating that exposure to early childhood poverty leads to later morbidity in adulthood: “an early history of poverty appears to set children on a life-course trajectory of ill health” (p. 956).

Many school-age children suffer from the effects of poverty-related hunger. It is difficult to concentrate and learn properly if meals are often skipped or if food consistently does not provide enough nourishment (Taras, 2005). Alaimo, Olson, and Frongillo (2001) found that younger school-age children were more likely to have had difficulty getting along with other children, to have seen a psychologist, and to have repeated a grade if they reported food insufficiency. Food-insufficient adolescents were more likely to have had problems getting along with other children, to have seen a psychologist, and to have been suspended from school. Food insufficiency is defined as a child reporting that “his or her family sometimes or often did not get enough food to eat” (p. 44). Weinreb and colleagues (2002) studied the effects of hunger on preschool and school-age children. They found that, even after controlling for variables, such as housing status, mother’s distress, child life events, and low birth weight, severe hunger was a predictor for adverse outcomes of both physical health (i.e., chronic illness) and mental health (e.g.,

anxiety, depression, internalizing behavior problems). In a U.S. Department of Agriculture (USDA) survey (2006), only about half of food-insecure households reported use of any of the largest federal food assistance programs, such as food stamps, free or reduced school lunches, and WIC. Thus, children go hungry because many eligible families do not use these services. Only 60% of eligible people are enrolled in the Food Stamp program, and even lower numbers of eligible working poor participate—about 51%. In 2005, about 40% of food stamp beneficiaries lived in extreme poverty, and the average monthly income for all participants was \$648. Those children who participate in school lunch and breakfast programs suffer fewer of the side effects of hunger that affect learning; however, not all schools participate in these programs (Food Research and Action Center, 2007).

## Death from Injuries

The loss of children’s lives that results from all injuries combined suggests a staggering loss to society in the number of years of productive life lost. For children between the ages of 1 and 19, unintentional injury is the leading cause of death, and motor vehicle injury was the leading cause of injury death between 1999 and 2002 (Bernard, Paulozzi, & Wallace, 2007). Approximately 16,000 deaths yearly are the result of childhood injuries, 70% of them unintentional (Schnitzer, 2006). For the 1- to 9-year-old age group, motor vehicle/traffic injury, drowning, and fire/burn injuries were the top three causes of injury death. The injury death rate for this age group is 10.4 per 100,000, with rates for American Indians and Alaska Natives two times higher and for Blacks 1.8 times higher than for Whites (Bernard et al., 2007). Leading causes of nonfatal injuries that result in hospitalization are falls, poisoning, scald burns, and traffic crashes (Schnitzer, 2006).

For the 10- to 19-year-old age group, the overall injury death rate was 30.9 per 100,000, but for those 15 to 19 years old, the rate rises to 52 per 100,000. Motor vehicle/traffic injuries, drowning, and poisoning are the three leading causes of injury death, and Hispanics had higher rates than Whites for drowning (Bernard et al., 2007). A large-scale study examining the risk factors for passenger deaths in fatal motor vehicle crashes found that in more than 21% of cases of child passenger fatalities, alcohol was a factor. When drivers were younger than age 18, the greatest risk factors for death were most often associated with drivers younger than age 16, failure to use seat belts or other restraints, and driving on high-speed roads (Winston, Kallan, Senserrick, & Elliott, 2008). Suicides in the 10- to 19-year-old group more commonly involved firearms for Whites and Blacks, but suffocation/hanging was more prevalent for Alaska Natives/American Indians, Asian/Pacific Islanders, and Hispanics.

For all racial and ethnic groups, death rates were higher for infants and late adolescents, and dropped during the middle years. Homicide rates were highest for Black children in all age groups (Bernard et al., 2007). Injuries not resulting in death often cause permanent disabilities, or emotional and physical consequences for children and their families (Safe Kids USA, 2008).

For children and adolescents ages 6 to 19, the “choking game” is an often-misreported cause of death (CDC, 2008b). This involves self-strangulation, or strangulation by a friend through the use of hands or a noose, causing a brief

euphoric high due to cerebral hypoxia. Most of the victims are male (estimated at almost 87%), and the average age is estimated at 13.3 years. Most parents were unaware of this potentially fatal activity until a child's death occurred, but warning signs such as bloodshot eyes; disorientation after being alone; belts, scarves, and ropes tied to doorknobs or bedroom furniture; and marks on the neck should lead parents to suspect this dangerous activity (CDC, 2008b).

Childhood unintentional injury deaths in the United States have declined by more than 45% in the past 20 years (Safe Kids USA, 2008) but are still much higher than in other developed countries (Deal et al., 2000). It is estimated that the cost of childhood unintentional injuries in 2000 resulted in \$58 billion in medical bills, lost wages to caregivers, and other services (Safe Kids USA, 2008).

Community health nurses can promote injury prevention and control through education, promotion of engineering and environmental protection strategies, and legislative advocacy (Schnitzer, 2006). PHNs can advance the prevention of unintentional injuries and deaths by working with families to initiate consistent use of seat belts and child safety seats in vehicles, and the use of helmets and other protective gear for children riding bikes and skateboarding. Where water is a natural hazard, wearing life jackets while boating and swimming can help decrease accidental drowning. Promotion of smoke and carbon monoxide detectors, poison prevention, and sudden infant death syndrome (SIDS) education can help to further decrease injury death rates (Safe Kids USA, 2008). Teaching parents about presetting hot water heaters to lower than 130°F, recognizing the hazards of infant walkers, storing matches and lighters safely, and using pool fencing can help to prevent common unintentional injuries (Schnitzer, 2006). Advocacy for stricter seat belt and child safety seat enforcement, as well as programs to provide child safety seats and bicycle helmets, has been shown to affect injury rates (Bernard et al., 2007).

Community health nurses can work with their local health departments and community action groups to provide seats and helmets to families who cannot afford them, and can encourage local police offices to enforce seat belt and safety seat laws.

## Communicable Diseases

The mortality rates of school-age children 5 to 14 years old are comparatively low and have decreased substantially over the last century (Arias & Smith, 2003), a reduction that can be attributed to the effective prevention and control of the acute infectious diseases of childhood. Although mortality rates are low, morbidity due to communicable diseases among school children is high. Worldwide, communicable diseases are the leading cause of death (The World Bank, 2008). Children between ages 5 and 14 are most often affected by respiratory illnesses, followed by infectious and parasitic diseases, injuries, and digestive conditions. Among school children, the incidence rates of measles, rubella (German measles), pertussis (whooping cough), infectious parotitis (mumps), and varicella (chickenpox) have dropped considerably because of widespread immunization efforts (see Figure 22.1 for Childhood Immunization Schedule).

Over the past several decades, the incidence of vaccine-preventable diseases has generally decreased, although in

2003–2004, reported cases of mumps, hepatitis A, pertussis, and measles increased in some areas of the United States (Maternal and Child Health Bureau, 2006). Some of these illnesses carry potentially serious complications, such as birth defects from rubella and nerve deafness from mumps. Ten percent of the reported pertussis cases in 2004 occurred in infants younger than 6 months of age who had not yet received the scheduled doses of the vaccine; however, cases occurred across age groups, and increases were posted for the 3 preceding years (Maternal and Child Health Bureau, 2006).

One Wisconsin study found 261 cases of rubella and mumps in one county, and 47% of the children with confirmed cases reported using the weight room in a particular high school. An important finding was that 84% of children with reported vaccine histories had received five or more doses of pertussis vaccine, indicating that booster vaccinations may be required for adolescents and adults (Sotir et al., 2008).

Vigorous campaigns have been undertaken by health departments to get children immunized. An immunization for mumps, measles, and rubella (MMR) has been available for more than 25 years, and newer vaccines for *Haemophilus influenzae* type b (Hib), hepatitis A and B, and varicella have been developed and are now included in the childhood immunization schedule. Meningococcal, pneumococcal, and rotavirus vaccines have also been added, along with yearly influenza vaccines for all children younger than age 5 and human papillomavirus for girls age 11 and above (Advisory Committee on Immunization Practices, 2008a,b).

As increasing numbers of school-age children must show proof of required vaccinations before they are allowed to enroll in school, the percentages of children in this age group who are immunized against specific diseases may continue to rise. However, some studies reveal that immunization compliance for adolescents is a continuing problem due to lack of sufficient insurance coverage and poor systems for tracking and recall (Schaffer, Humiston, Shone, Averhoff, & Szilagyi, et al., 2001). Also, more parents of young children are choosing not to immunize their children, invoking religious or personal belief exceptions. This practice has led to outbreaks of vaccine-preventable diseases: In the first 4 months of 2008, confirmed and reported measles cases numbered 64—the greatest number for any year since 2001 (Reinberg, 2008).

Other considerations regarding communicable diseases involve their seasonality (e.g., mumps and varicella peak in April, pertussis and typhoid fever peak in August) and how climate change may affect the incidence and distribution of communicable diseases, especially vector-borne and water- and food-borne diseases (Shah, Smolensky, Burau, Cech, & Lai, 2006; Greer, Ng, & Fisman, 2008).

In the adolescent population, sexually transmitted infections (STIs) are more common, and 15- to 19-year olds are at greater risk of contracting an STI than older adults (Maternal and Child Health Bureau, 2006). Chlamydia is the most common STI, with a rate of 1,579 per 100,000; genital human papillomavirus (HPV) is also commonly found in adolescents and a relatively new vaccine is now available (see Figure 22.2, Adolescent Immunization Schedule).

With the marked rise in community-acquired methicillin-resistant *Staphylococcus aureus* (CA-MRSA), PHNs and school nurses must be alert when skin infections or other conditions do not resolve quickly in children and adolescents (Pallin, Egan, Pelletier, Espinola, Hooper, & Camargo, 2008).

# Recommended Immunization Schedule for Persons Aged 0–6 Years—UNITED STATES • 2008

*For those who fall behind or start late, see the catch-up schedule*

Vaccine ▼	Age ►	Birth	1 month	2 months	4 months	6 months	12 months	15 months	18 months	19–23 months	2–3 years	4–6 years
Hepatitis B <sup>1</sup>	HepB	HepB	HepB	see footnote 1	HepB							
Rotavirus <sup>2</sup>			Rota	Rota	Rota							
Diphtheria, Tetanus, Pertussis <sup>3</sup>			DTaP	DTaP	DTaP	see footnote 3	DTaP					DTaP
Haemophilus influenzae type b <sup>4</sup>			Hib	Hib	Hib <sup>4</sup>	Hib						
Pneumococcal <sup>5</sup>			PCV	PCV	PCV	PCV					PPV	
Inactivated Poliovirus			IPV	IPV	IPV	IPV						IPV
Influenza <sup>6</sup>							Influenza (Yearly)					
Measles, Mumps, Rubella <sup>7</sup>							MMR					MMR
Varicella <sup>8</sup>							Varicella					Varicella
Hepatitis A <sup>9</sup>							HepA (2 doses)				HepA Series	
Meningococcal <sup>10</sup>											MCV4	

Range of recommended ages

Certain high-risk groups

This schedule indicates the recommended ages for routine administration of currently licensed childhood vaccines, as of December 1, 2007, for children aged 0 through 6 years. Additional information is available at [www.cdc.gov/vaccines/recs/schedules](http://www.cdc.gov/vaccines/recs/schedules). Any dose not administered at the recommended age should be administered at any subsequent visit, when indicated and feasible. Additional vaccines may be licensed and recommended during the year. Licensed combination vaccines may be used whenever any components of the combination are indicated and other components of the vaccine are not contraindicated

and if approved by the Food and Drug Administration for that dose of the series. Providers should consult the respective Advisory Committee on Immunization Practices statement for detailed recommendations, including for **high risk conditions**: <http://www.cdc.gov/vaccines/pubs/ACIP-list.htm>. Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS). Guidance about how to obtain and complete VAERS form is available at [www.vaers.hhs.gov](http://www.vaers.hhs.gov) or by telephone, 800-822-7967.

**1. Hepatitis B vaccine (HepB).** (Minimum age: birth)  
At birth:

- Administer monovalent HepB to all newborns prior to hospital discharge.
- If mother is hepatitis B surface antigen (HBsAg)-positive, administer HepB and 0.5 mL of hepatitis B immune globulin (HBIG) within 12 hours of birth.
- If mother's HBsAg status is unknown, administer HepB within 12 hours of birth. Determine the HBsAg status as soon as possible and if HBsAg-positive, administer HBIG (no later than age 1 week).
- If mother is HBsAg-negative, the birth dose can be delayed, in rare cases, with a provider's order and a copy of the mother's negative HBsAg laboratory report in the infant's medical record.

After the birth dose:

- The HepB series should be completed with either monovalent HepB or a combination vaccine containing HepB. The second dose should be administered at age 1–2 months. The final dose should be administered no earlier than age 24 weeks. Infants born to HBsAg-positive mothers should be tested for HBsAg and antibody to HBsAg after completion of at least 3 doses of a licensed HepB series, at age 9–18 months (generally at the next well-child visit).

4-month dose:

- It is permissible to administer 4 doses of HepB when combination vaccines are administered after the birth dose. If monovalent HepB is used for doses after the birth dose, a dose at age 4 months is not needed.

**2. Rotavirus vaccine (Rota).** (Minimum age: 6 weeks)

- Administer the first dose at age 6–12 weeks.
- Do not start the series later than age 12 weeks.
- Administer the final dose in the series by age 32 weeks. Do not administer any dose later than age 32 weeks.
- Data on safety and efficacy outside of these age ranges are insufficient.

**3. Diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP).**

(Minimum age: 6 weeks)

- The fourth dose of DTaP may be administered as early as age 12 months, provided 6 months have elapsed since the third dose.
- Administer the final dose in the series at age 4–6 years.

**4. Haemophilus influenzae type b conjugate vaccine (Hib).**

(Minimum age: 6 weeks)

- If PRP-OMP (PedvaxHIB® or ComVax® [Merck]) is administered at ages 2 and 4 months, a dose at age 6 months is not required.
- TriHibit® (DTaP/Hib) combination products should not be used for primary immunization but can be used as boosters following any Hib vaccine in children age 12 months or older.

**5. Pneumococcal vaccine.** (Minimum age: 6 weeks for pneumococcal conjugate vaccine [PCV]; 2 years for pneumococcal polysaccharide vaccine [PPV])

- Administer one dose of PCV to all healthy children aged 24–59 months having any incomplete schedule.
- Administer PPV to children aged 2 years and older with underlying medical conditions.

**6. Influenza vaccine.** (Minimum age: 6 months for trivalent inactivated influenza vaccine [TIV]; 2 years for live, attenuated influenza vaccine [LAIV])

- Administer annually to children aged 6–59 months and to all close contacts of children aged 0–59 months.
- Administer annually to children 5 years of age and older with certain risk factors, to other persons (including household members) in close contact with persons in groups at higher risk, and to any child whose parents request vaccination.
- For healthy nonpregnant persons (those who do not have underlying medical conditions that predispose them to influenza complications) ages 2–49 years, either LAIV or TIV may be used.
- Children receiving TIV should receive 0.25 mL if age 6–35 mos or 0.5 mL if age 3 years or older.
- Administer 2 doses (separated by 4 weeks or longer) to children younger than 9 years who are receiving influenza vaccine for the first time or who were vaccinated for the first time last season, but only received one dose.

**7. Measles, mumps, and rubella vaccine (MMR).** (Minimum age: 12 months)

- Administer the second dose of MMR at age 4–6 years. MMR may be administered before age 4–6 years, provided 4 weeks or more have elapsed since the first dose.

**8. Varicella vaccine.** (Minimum age: 12 months)

- Administer second dose at age 4–6 years; may be administered 3 months or more after first dose.
- Don't repeat second dose if administered 28 days or more after first dose.

**9. Hepatitis A vaccine (HepA).** (Minimum age: 12 months)

- HepA is recommended for all children aged 1 yr (i.e., aged 12–23 months). The 2 doses in the series should be administered at least 6 months apart.
- Children not fully vaccinated by age 2 years can be vaccinated at subsequent visits.
- HepA is recommended for certain other groups of children, including in areas where vaccination programs target older children.

**10. Meningococcal vaccine.** (Minimum age: 2 years for meningococcal conjugate vaccine [MCV4] and for meningococcal polysaccharide vaccine [MPSV4])

- MCV4 is recommended for children aged 2–10 years with terminal complement deficiencies or anatomic or functional asplenia and certain other high-risk groups. Use of MPSV4 is also acceptable.
- Persons who received MPSV4 3 or more years prior and remain at increased risk for meningococcal disease should be vaccinated with MCV4.

The Recommended Immunization Schedules for Persons Aged 0–18 Years are approved by the Advisory Committee on Immunization Practices ([www.cdc.gov/vaccines/recs/acip](http://www.cdc.gov/vaccines/recs/acip)), the American Academy of Pediatrics (<http://www.aap.org>), and the American Academy of Family Physicians (<http://www.aafp.org>).

FIGURE 22.1 Childhood immunization schedule.

## Recommended Immunization Schedule for Persons Aged 7–18 Years—UNITED STATES • 2008

*For those who fall behind or start late, see the green bars and the catch-up schedule*

Vaccine ▼	Age ►	7-10 years	11-12 years	13-18 years
Diphtheria, Tetanus, Pertussis <sup>1</sup>		<i>see footnote 1</i>	Tdap	Tdap
Human Papillomavirus <sup>2</sup>		<i>see footnote 2</i>	HPV (3 doses)	HPV Series
Meningococcal <sup>3</sup>		MCV4	MCV4	MCV4
Pneumococcal <sup>4</sup>		PPV		
Influenza <sup>5</sup>		Influenza (Yearly)		
Hepatitis A <sup>6</sup>		HepA Series		
Hepatitis B <sup>7</sup>		HepB Series		
Inactivated Poliovirus <sup>8</sup>		IPV Series		
Measles, Mumps, Rubella <sup>9</sup>		MMR Series		
Varicella <sup>10</sup>		Varicella Series		

Range of recommended ages  
 Catch-up immunization  
 Certain high-risk groups

This schedule indicates the recommended ages for routine administration of currently licensed childhood vaccines, as of December 1, 2007, for children aged 7–18 years. Additional information is available at [www.cdc.gov/vaccines/recs/schedules](http://www.cdc.gov/vaccines/recs/schedules). Any dose not administered at the recommended age should be administered at any subsequent visit, when indicated and feasible. Additional vaccines may be licensed and recommended during the year. Licensed combination vaccines may be used whenever any components of the combination are indicated and other components of the vaccine are not

contraindicated and if approved by the Food and Drug Administration for that dose of the series. Providers should consult the respective Advisory Committee on Immunization Practices statement for detailed recommendations, including for **high risk conditions**: <http://www.cdc.gov/vaccines/pubs/ACIP-list.htm>. Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS). Guidance about how to obtain and complete VAERS form is available at [www.vaers.hhs.gov](http://www.vaers.hhs.gov) or by telephone, 800-822-7967.

### 1. Tetanus and diphtheria toxoids and acellular pertussis vaccine (Tdap). (Minimum age: 10 years for BOOSTRIX® and 11 years for ADACEL™)

- Administer at age 11–12 years for those who have completed the recommended childhood DTP/DTaP vaccination series and have not received a tetanus and diphtheria toxoids (Td) booster dose.
- 13–18 year olds who missed the 11–12 year Tdap or received Td only, are encouraged to receive one dose of Tdap 5 years after the last Td/DTaP dose.

### 2. Human papillomavirus vaccine (HPV). (Minimum age: 9 years)

- Administer the first dose of the HPV vaccine series to females at age 11–12 years.
- Administer the second dose 2 months after the first dose and the third dose 6 months after the first dose.
- Administer the HPV vaccine series to females at age 13–18 years if not previously vaccinated.

### 3. Meningococcal vaccine.

- Administer MCV4 at age 11–12 years and at age 13–18 years if not previously vaccinated. MPSV4 is an acceptable alternative.
- Administer MCV4 to previously unvaccinated college freshmen living in dormitories.
- MCV4 is recommended for children aged 2-10 years with terminal complement deficiencies or anatomic or functional asplenia and certain other high-risk groups.
- Persons who received MPSV4 3 or more years prior and remain at increased risk for meningococcal disease should be vaccinated with MCV4.

### 4. Pneumococcal polysaccharide vaccine (PPV).

- Administer PPV to certain high-risk groups.

### 5. Influenza vaccine.

- Administer annually to all close contacts of children aged 0–59 months.
- Administer annually to persons with certain risk factors, health-care workers, and other persons (including household members) in close contact with persons in groups at higher risk.

- Administer 2 doses (separated by 4 weeks or longer) to children younger than 9 years who are receiving influenza vaccine for the first time or who were vaccinated for the first time last season, but only received one dose.
- For healthy nonpregnant persons (those who do not have underlying medical conditions that predispose them to influenza complications) ages 2–49 years, either LAIV or TIV may be used.

### 6. Hepatitis A vaccine (HepA).

- The 2 doses in the series should be administered at least 6 months apart.
- HepA is recommended for certain other groups of children, including in areas where vaccination programs target older children.

### 7. Hepatitis B vaccine (HepB).

- Administer the 3-dose series to those who were not previously vaccinated.
- A 2-dose series of Recombivax HB® is licensed for children aged 11–15 years.

### 8. Inactivated poliovirus vaccine (IPV).

- For children who received an all-IPV or all-oral poliovirus (OPV) series, a fourth dose is not necessary if the third dose was administered at age 4 years or older.
- If both OPV and IPV were administered as part of a series, a total of 4 doses should be administered, regardless of the child's current age.

### 9. Measles, mumps, and rubella vaccine (MMR).

- If not previously vaccinated, administer 2 doses of MMR during any visit, with 4 or more weeks between the doses.

### 10. Varicella vaccine.

- Administer 2 doses of varicella vaccine to persons younger than 13 years of age at least 3 months apart. Do not repeat the second dose, if administered 28 or more days following the first dose.
- Administer 2 doses of varicella vaccine to persons aged 13 years or older at least 4 weeks apart.

The Recommended Immunization Schedules for Persons Aged 0–18 Years are approved by the Advisory Committee on Immunization Practices ([www.cdc.gov/vaccines/recs/acip](http://www.cdc.gov/vaccines/recs/acip)), the American Academy of Pediatrics (<http://www.aap.org>), and the American Academy of Family Physicians (<http://www.aafp.org>).

Referral to an infectious disease specialist may need to be considered.

### Head Lice

**Pediculosis** (head lice) is a frustrating and common problem for many school-age children, and the incidence has been increasing over the past three decades (Guenther, 2007). It is estimated that 6 to 12 million children between the ages of 6 and 12 years become infested with head lice each year (Frankowski & Weiner, 2002). A study conducted by a school nurse in California found the highest incidence of head lice in her school district occurred among early elementary children, and that girls were three times more likely to have head lice than boys. Hispanic and White children had the highest rates of pediculosis, and Black children had the lowest rate (Estrada & Morris, 2000). Girls are thought to be at higher risk due to social behavior (closer contact, sharing of items), and close crowded conditions can also be a risk factor (Guenther, 2007). An infestation of *Pediculus humanus* var. *capitis*, the parasite that lives and feeds on the human scalp, can be an embarrassing nuisance to families of any socioeconomic level. These very tiny, wingless insects need blood to survive and can cause itching and skin irritation. They are most often found toward the nape of the neck, where hair is usually thickest, but their pearly white eggs (nits) are distributed all over the head. They are attached to the hair shaft with a glue-like substance and can be detected by careful examination of the scalp. Because nits hatch within 10 days, and the immature louse can reach reproductive maturity within 8 to 9 days, recurring cycles of infestation are common. If no treatment is given, the cycle repeats every 3 weeks (American Academy of Pediatrics, 2006; Hansen, 2004). Complete eradication generally requires that all nits be removed along with lice.

Head lice are most often transmitted by direct contact (head-to-head) or may be passed from infected to uninfected children through shared items such as combs and brushes, hats, scarves, sheets, and towels (items called *fomites*). Contrary to some popular myths, lice do not fly or jump, and they cannot be contracted from animals—they live only on humans (Aubrey, 2006). They do not survive long off the human head, only about 3 days (Guenther, 2007). Many schools have recurring outbreaks of head lice that can be traced back to particular families who have failed to completely eradicate an infestation (Hansen, 2004). Because of perceived social stigma, some families are defensive and unresponsive to attempts at education and intervention. Some schools resort to “no nit” policies and establish routine head lice examinations, with a goal of early detection and treatment. However, the American Academy of Pediatrics discourages such policies because they have not been effective in curbing head lice infestations and they often result in significant lost school days and negative social impact (Aubrey, 2006).

Treatment of head lice commonly includes over-the-counter insecticide shampoos, such as pyrethrin-based *RID*, *R&C*, *Pronto*, or *A200*. A permethrin cream rinse (*Nix*) has been a recommended choice for treatment (Frankowski & Weiner, 2002). Other treatments include lindane (Kwell), malathion (Ovide), oral antibiotic agents, such as Septra and Ivermectin, and occlusive agents such as petroleum jelly (Fawcett, 2003; Frankowski & Weiner, 2002; Jones & English, 2003). Solvents that aid in dissolving the “cement” that

holds the nit in place have been shown to be helpful when using fine-tooth combs (e.g., *Lice Meister*)—these include white vinegar and formic acid (Guenther, 2007). The use of special combs and wet combing conditioners into affected hair has been shown in one study to be more effective than pediculicides (Dawes, 2005). In some cases, resistance to topical pediculicides has necessitated the use of other measures (Hansen, 2004).

School nurses and PHNs also need to educate families about reducing reinfestation by careful cleaning and treatment of any fomites (e.g., combs, hats, towels, sheets, clothing, upholstered furniture) and scrupulous nit removal. It is difficult, however, to prevent children—who are social creatures—from coming into close contact with one another and becoming reinfested. In some larger cities, entrepreneurs have started nit removal businesses (e.g., *Nit Pickers*, *Hair Fairies*) to assist parents with this tedious task.

### Other Health Problems

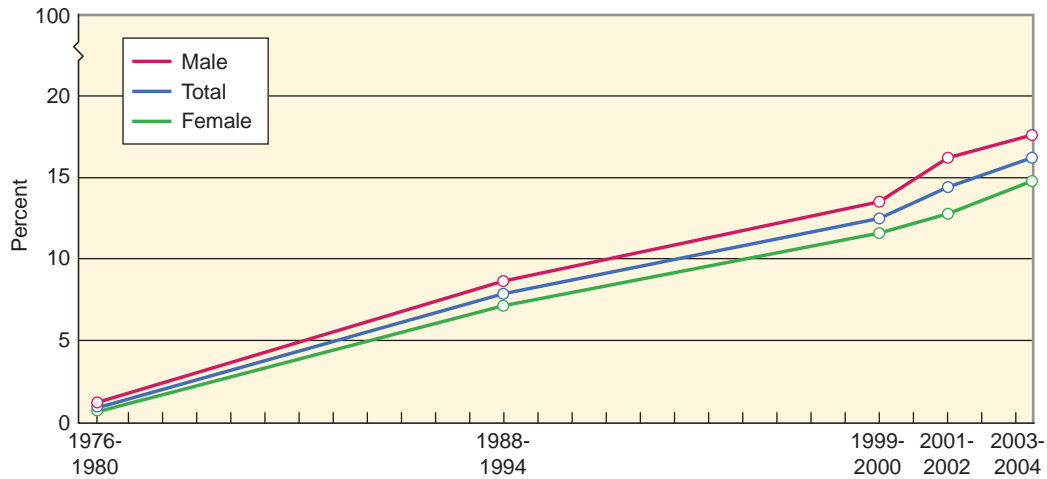

Other health problems found in this age group are nutritional problems (primarily overeating and inappropriate food choices) and poor dental health. Obesity often begins in childhood and becomes a risk factor for cardiovascular disease and diabetes later in life (Institute of Medicine, 2006). The percentage of children who are overweight has risen over 15% between 1980 and 2004 (Fig. 22.3), despite the fact that food insecurity is found in over 11% of American households and affects over 13 million children (Cook, 2002).

Food allergies can also play a role in poor nutritional status, especially with school-age children and adolescents. Although 20% of children and adolescents may report a food allergy (Noimark & Cox, 2008), one study in England noted that only 2.3% of 11- and 15-year-old children actually demonstrated sensitivity upon skin testing and double-blind food challenges (Pereira, Venter, Grundy, Clayton, Arshad, & Dean, 2005). Food allergies can be especially problematic in the school setting (see Chapter 30), and new food labeling initiated in 2006 makes identification of the eight most common food allergens a much easier process (U.S. Food and Drug Administration, 2007).

Dental caries is another common problem among school-age children. Fourteen percent of U.S. school-age children have untreated cavities; over 21% of children living in poverty need treatment for dental caries (Forum on Child & Family Statistics [FCFS], n.d.).

### Childhood Obesity

About one-third of U.S. children are classified as overweight or at risk of becoming overweight. The CDC uses the term **overweight**, rather than obese, in defining children who have a body mass index (BMI) at or above the 95th percentile. Children with a BMI between the 85th and 94th percentile are defined as **at risk of overweight** (CDC, 2007b). (See Display 22.1 for explanation and examples.) The obesity rate has tripled for preschool children and adolescents, but it has quadrupled for children 6 to 11 years of age (Institute of Medicine, 2006). Obese children are more likely to become obese adults. The Surgeon General reports that there is a 70% chance of adult overweight or obesity if an adolescent is overweight; if at least one parent is overweight, the risk jumps to

NOTE: Overweight is defined as body mass index (BMI) at or above the 95th percentile of the 2000 Centers for Disease Control and Prevention BMI-for-age growth charts. BMI is calculated as weight in kilograms divided by the square of height in meters.

**FIGURE 22.3** Percentage of children ages 6–17 who are overweight by gender, selected years 1976–2004. Retrieved July 31, 2008 from <http://www.childstats.gov/americaschildren/06/hea4.asp#health4>.

80% (2007). Results of a recent Youth Risk Behavior Survey indicated that almost 80% of high school students surveyed ate fewer than five servings of fruits and vegetables the day before, and almost 84% drank fewer than three glasses of milk per day in the previous week (CDC, 2006a).

The poor eating habits that develop during childhood are generally thought to persist into adulthood, contributing to the leading causes of death and disability—cardiovascular disease, cancer, and diabetes. Between 75% and 90% of cardiovascular disease is related to hypertension, tobacco use, diabetes, obesity, and inadequate physical activity (Gidding et al., 2005). Evidence of early atherosclerosis and fatty streaks has been found in autopsy studies of children as young as 6 years of age (Harrell, Pearce, & Hayman, 2003). Aside from its relationship with inactivity, television viewing has been associated with higher intake of fats, sweet and salty snacks, and carbonated drinks, and lower intakes of fruits and vegetables (Coon & Tucker, 2002). Watching television while eating meals has been shown to lead to increased frequency of poor food choices (Coon, Goldberg, Rogers, & Tucker, 2001; Boynton-Jarrett, Thomas, Peterson, Wiecha, Sobol, & Gortmaker, 2003). Food is the most heavily advertised product on children’s television, and highly sweetened products (e.g., sweetened beverages and sugar-rich cereals), as well as fast food, are the most frequently advertised foods (Gidding et al., 2005). In a classic study of television commercials, researchers noted that children watch 21.3 commercials per hour and that almost half of the advertisements were for food (mostly those high in sugar, salt, and/or fat). Even with the change in child advertising rules, advertising for unhealthy foods has changed little (Taras & Gage, 1995).

As children move from elementary to middle school, their food choices change dramatically. Fad diets and peer pressure become more of an issue. Media fast food promotion, targeted to middle and high school students, is common. Diets most often include fast food French fries and hamburgers, pizza, and sweetened carbonated beverages. “Excess fat, trans fat, and added sugars . . . (and) insufficient consumption of micronutrients such as calcium, iron, zinc, and potassium, as well as vitamins A, D, and C and folic

#### DISPLAY 22.1

### EXPLANATION AND EXAMPLES OF OVERWEIGHT CLASSIFICATION FOR CHILDREN AND TEENS

Body mass index (BMI) is used as a screening tool to identify weight problems in children and teens. The criteria are different from those used for adults, as body fat differs between boys and girls, and the amount of body fat changes with age. BMI-for-age growth charts for boys and girls are available at: <http://www.cdc.gov/growthcharts>.

Weight Status Category	Percentile Range
Underweight	Less than the 5th percentile
Healthy weight	5th percentile to less than the 85th percentile
At risk of overweight	85th to less than the 95th percentile
Overweight	Equal to or greater than the 95th percentile

From Centers for Disease Control & Prevention. (2007b). *About BMI for Children & Teens*. Retrieved July 31, 2008 from [http://www.cdc.gov/print.do?url=http%3A%2F%2Fwww.cdc.gov%2Fncdd/php%2Fdnpa%2Fbmi%2Fchildrens\\_BMI%2Fabout\\_childrens\\_BMI.htm](http://www.cdc.gov/print.do?url=http%3A%2F%2Fwww.cdc.gov%2Fncdd/php%2Fdnpa%2Fbmi%2Fchildrens_BMI%2Fabout_childrens_BMI.htm).

acid” are common in this age group (Gidding et al., 2005, p. 2,068). This is a time when school-based nutrition education programs can have an influence (Gidding et al., 2005; Perez-Rodrigo & Aranceta, 2001) (see *Using the Nursing Process*).

In longitudinal research, preschool children whose BMI was greater than the 85th percentile were five times more likely to continue to be overweight at age 12. Children younger than age 9 with a BMI between the 75th and 85th

percentiles have been shown to have a 40% to 50% greater chance of being overweight by age 12 (Nader et al., 2006). Parents can help their younger children develop better habits by implementing suggestions recommended by the American Heart Association (Gidding et al., 2005), for example:

- ◆ Reduce added sugars (cereals, drinks, juices, etc.).
- ◆ Use unsaturated oils in cooking (no solid fats).

## USING THE NURSING PROCESS

James Lopez is entering third grade. His teacher comes to you, the school nurse, because she is concerned about his poor performance in school. He frequently comes to school late and often puts his head on his desk and appears to be falling asleep. You notice that James has gained a significant amount of weight over the summer. His face is much fuller now than in his second grade picture.

### Assessment (Initial Visits)

You call James’ mother and make an appointment for a home visit.

You do a health history, noting family history of diabetes, current eating, and activity and sleeping patterns for James and the family, and determine whether he has a regular physician and insurance or Medicaid.

You assess his vital signs, height and weight, hearing, and vision.

You talk more with his teacher about his activity on the playground and any signs of excessive thirst, hunger, or general fatigue.

### Nursing Diagnoses

After a home visit, a meeting with James’ teacher, and two observations/interviews with James, you decide on the following nursing diagnoses:

1. Nutrition: more than body requirements related to James’ eating as a way of coping and his sedentary lifestyle.
2. Altered family process related to mother’s recent change from being a stay-at-home single mom to attending truck driving school (necessitating absences of several days at a time, with James cared for by a married teenage sister and her husband).

### Findings, Plan, and Implementation

James has been eating large quantities of snack food and fast food meals for the last 3 months, since his mother started her training. He has also quit participating in soccer and baseball, because his mother can no longer provide transportation. His bicycle was recently stolen, and he spends a lot of time playing video and computer games. James misses his mother when she is away and says that he “stays up late watching television” and has “trouble getting up for school” when he is at his sister’s house.

You plan to work with the family to refer James to his physician to rule out diabetes. A family meeting is sched-

uled so that you can provide some health education on childhood obesity and inactivity. You discuss some possible interventions that the family can put into place:

- Decrease reliance on fast food meals.
- Have a regular evening meal time and encourage less snacking.
- Provide fresh fruit and vegetable snacks and decrease purchases of high-calorie, high-fat snack foods.
- Decrease sedentary activity (e.g., video and computer games, television viewing) and increase physical activity (e.g., team sports, walking, bicycling, active outdoor games).
- Establish a reasonable bedtime and consistently enforce it.
- Offer referral for family counseling so that James can discuss his feelings in a safe environment.
- With the family’s input, seek ways for James and his mother to keep in better contact and for his sister to gain a greater understanding of good parenting practices.
- Meet with the teacher, the family, and James to discuss ways to help with his school performance.
- Continue to monitor James’ progress with monthly height and weight checks, personal interviews, home visits, and teacher conferences.

### Evaluation

The physician reported that James does not have diabetes; however, if he continues to gain weight and remains inactive he is at a higher risk for type 2 diabetes. Evaluation of nursing diagnoses 1 and 2 includes the following goals:

- The family will report less reliance on fast food and more meals cooked at home.
- The family will report more purchases of fresh fruits and vegetables and fewer purchases of high-calorie, high-fat snacks.
- James will report more physical exercise (by the use of a calendar) and less hours spent in sedentary activity (corroborated by family).
- James will exhibit less tardiness and fewer signs of sleep deprivation at school, and his school performance will improve.
- James and his family will complete sessions with a family counselor.
- James’ weight will remain stable or will decrease as his height increases over time.

- ◆ Adhere to recommended portion sizes on food labels.
- ◆ Serve fresh, frozen, or canned vegetables and fruits at every meal.
- ◆ Use lean cuts of meat and remove skin from poultry.
- ◆ Serve fish more often, and eat more beans and tofu.
- ◆ Limit high-calorie creamy sauces (e.g., cheese, Alfredo).
- ◆ Eat more whole grains (look for breads and cereals with whole grain as the first ingredient).
- ◆ Watch for high salt and/or sugar content in processed soups, prepared foods, cereals, and breads (read labels and select lower salt/sugar options).
- ◆ Use nonfat or skimmed milk/dairy products.
- ◆ Help your child to get 60 minutes of moderate to vigorous exercise daily.
- ◆ With increasing activity, allow more discretionary calories (e.g., low-nutrient dense snacks and beverages).

### **Inadequate Nutrition**

Undernutrition can also have serious consequences, including effects on the cognitive development and academic performance of children (Cook, 2002; Hall et al., 2001). Research indicates that food insecurity in kindergarten is associated with poorer mathematics performance in children and in delayed reading performance and social skills for girls (Jyoti, Frongillo, & Jones, 2005). Irritability, lack of energy, and difficulty concentrating are only some of the problems that arise from skipped meals or consistently inadequate nutrition. Infection and illness that lead to loss of school days can affect academic progress and interfere with the acquisition of basic skills, such as reading and mathematics. One study in Brazil found a link between childhood undernutrition and later risk of adult chronic degenerative diseases (Sawaya, Martins, Hoffman, & Roberts, 2003).

In children, the rate of food insecurity between 2003 and 2005 was estimated to be 18% (Cook, 2002). A national study of food insecurity found that it was associated with overweight status in children between the ages of 12 and 17, especially girls and children living in poverty (Casey et al., 2006). Another large-scale study failed to find a link between food insecurity and overweight (Rose & Bodor, 2006).

Olson, Bove, and Miller (2007) conducted a qualitative and quantitative study to examine how childhood poverty-associated food deprivation may lead to adult obesity. They found that, in some cases, early deprivation influenced later food choices and that there was an active drive to avoid food insecurity. Women in their study also developed patterns of emotional eating, and they concluded that attitudes and behaviors toward food were formed in childhood as a response to deprivation. Food insecurity in childhood has been linked to both undernutrition and overnutrition, and is most harmful during critical periods of development; it is also linked to postponed medical care and medications, lack of routine well-child medical visits, and absence of a usual source of health care for children (Cook, 2002; Ma, Gee, & Kushel, 2008). Childhood hunger was reported at 50% (severe hunger 16%) in a study of low-income homeless mothers and school-age children in Massachusetts. Hunger was related to higher chronic illness and anxiety/depression (Weinreb et al., 2002).

Undernutrition is frequently associated with poverty and hunger, but social pressure to be thin can also spark purposeful undernutrition. Because prepubertal children often exhibit a period of adiposity before a growth spurt, they are at risk for developing eating disorders (Dietz & Gortmaker, 2001). A 5-year study of the frequency of reading magazine articles about dieting and weight loss found that girls who frequently read these magazines were two times more likely to engage in unhealthy weight-control measures (e.g., skipping meals, smoking more cigarettes, fasting) than those who did not read magazine articles about dieting and weight loss. Extreme weight-control measures (e.g., laxative use, vomiting) were found three times more often in high-frequency readers versus nonreaders (van den Berg, Neumark-Sztainer, Hannan, & Haines, 2007). A longitudinal study of adolescents found that dieting and unhealthy weight-control measures predicted eating disorders and obesity 5 years later, thus emphasizing the need to encourage healthy eating and physical activity in childhood (Neumark-Sztainer, Wall, Guo, Story, Haines, & Eisenberg, 2006). School nurses and PHNs can provide families with necessary information to promote healthy eating and exercise.

### **Inactivity**

An association between poor eating habits and physical inactivity was found in studies of school-age children and adolescents (Chatrath, Shenoy, Serratto, & Thoele, 2002; Trost et al., 2001). Low levels of physical activity and more than 2 hours of watching television per day were found to be predictors of overweight status in a large longitudinal study of children (Rose & Bodor, 2006). More television watching, fewer family meals eaten together at home, and living in an unsafe neighborhood were also shown to be associated with overweight (Gable, Chang, & Krull, 2007). The Youth Risk Behavior Survey (YRBS) revealed that 67% of children surveyed who were enrolled in physical education classes did not attend class on a daily basis. In addition, fewer than 39% of respondents stated that they participated in either vigorous or moderate physical activity for at least 20 minutes on at least 3 of the past 7 days, and almost 45% watched 3 or more hours of television on school nights (CDC, 2006a). Increased physical activity was shown to decrease BMI in a large study of overweight girls and boys (Berkey, Rockett, Gillman, & Colditz, 2003). Children who watched television and were less physically active during after-school hours were more likely to become overweight by age 12 in one 12-year longitudinal study of almost 1,000 children (O'Brien et al., 2007).

School nurses and PHNs can work with families to increase their levels of physical activity and to encourage limited television viewing for school-age children. They can also advocate for increased physical education in the school setting, and for increased safe recreational opportunities in all neighborhoods.

### **Dental Health**

Dental caries affects more than half of U.S. school-age children and is the most common chronic disease for that age group. School days are lost to dental problems and dental visits, and self-esteem, along with general growth and function, can be

hindered (Sinclair & Edelstein, 2005). In a comparison of African refugee children with U.S. children, the rate of dental caries for refugee children was half that of U.S. children (Cote, Geltman, Nunn, Lituri, Henshaw, & Garcia, 2004). Poor children report twice the rate of untreated dental caries than do children from higher-income families (Division of Oral Health, 2008). One twin study found that traits for dental caries and sucrose sweetness preference exhibit an independent “genetic contribution” (Bretz et al., 2006, p. 1,156).

The cost for dental services in 2003 was estimated to be \$68 billion (CDC, 2003). The peak incidence of dental caries is found among school-age children and adolescents, although the effects of decay are observed in adulthood as caries activity recurs or various restorations fracture or wear out and must be replaced. One study found that school-age dental decay could be predicted in toddlers by determining the frequency of brushing and other variables, thus emphasizing the importance of regular brushing for young children (Clarke, Fraser-Lee, & Shimono, 2001).

Fluoridated drinking water, the availability of school-provided fluoride rinse or gel, and dental sealant programs are cost-effective, proven methods of reducing dental caries in school-age children (Lam, 2008; Levy, 2003; Marinho, Higgins, Logan, & Sheiham, 2003). The CDC found that for every \$1 spent on fluoridation, \$38 is saved in dental treatment costs (Sinclair & Edelstein, 2005). Between 11% and 72% of poor children have been found to have early childhood caries, an infectious disease thought to be caused by *Streptococcus mutans* and exacerbated by poor dietary practices. Topical antimicrobial therapies show some promise in these cases (Berkowitz, 2003; Kroll & Nedley, 2007). Some research has also demonstrated an association between passive exposure to tobacco smoke and tooth decay (Aligne, Moss, Auinger, & Weitzman, 2003).

Access to necessary outpatient dental care is much less expensive (by a factor of 10) than inpatient treatment of symptoms (Sinclair & Edelstein, 2005). Yet, access to dental care is still problematic. Barriers to dental care are more prevalent among the poor and those who are institutionalized. When children have public or private dental coverage, their incidence of at least one preventive dental visit during the previous year was 30% higher than for uninsured children (Sinclair & Edelstein, 2005). In a national survey, more than 32% of children living in poverty had a need for dental care, and more than 36% of children living within 100% to 199% of the poverty level had untreated dental caries (FCFS, n.d.). Financial barriers and lack of education lead to poor dental health values and adversely affect the appropriate use of early dental services and conscientious personal oral health care. PHNs and other community health nurses working with school-age children and families can promote good dental health through education and advocacy, as well as through collaboration to provide adequate dental services to uninsured children.

## ADOLESCENT HEALTH

Adolescence is a time of self-discovery, movement toward self-reliance, increasing opportunities, and pivotal choices that can affect the remainder of an individual’s life. Adolescence generally begins with puberty and encompasses the ages between 10 and 24; it consists of early adolescence (ages 10 to 14), middle adolescence (15 to 17), and late adolescence

(18 to mid 20s). Adult society largely segregates adolescents and often has ambiguous expectations for them (Feldman & Elliott, 1990). Adolescents are part of a subculture, one with its own language, dress, social mores, and values. The tasks of adolescence remain fairly constant: Adolescents must become autonomous, come to grips with their emerging sexuality and the skills necessary to attract a mate, and acquire skills and education that can prepare them for adult roles, all while resolving identity issues and developing values and beliefs (Feldman & Elliott, 1990; Shaffer & Kipp, 2006). The search for and expression of developing identity, along with the strong drive for social acceptance, are evident in the personal home pages and blogs of adolescents on social networking Internet sites such as MySpace and Facebook (Schmitt, Dayanim, & Matthias, 2008).

Adolescents are generally healthy, but parents and teens may differ in their perceptions of the adolescent’s health. Adolescents from lower income brackets frequently report poorer health than those from higher-income groups (Johnson & Wang, 2008). As with other population groups, socioeconomic level and health are inversely related for adolescents. Teens also exhibit inverse relationships between income level and health resilience, school achievement, and feeling that they are in good health (Starfield, Riley, Witt, & Robertson, 2002). Parental long-term unemployment is also negatively associated with adolescent self-reported health status and depressive symptoms and psychosomatic complaints. These, along with poor health behaviors related to lack of physical activity and drug use or smoking, contribute to self-perceived poor or fair health (Piko, 2007; Sleskova et al., 2006). Social stressors and strained relations with peers and parents are also related to health complaints, including psychosomatic complaints (Brolin-Laftman & Ostberg, 2006; Hjern, Alfvén, & Ostberg, 2008). Common complaints of adolescents include fatigue, sleep deprivation, chronic insomnia, acne, and concerns about weight and body image (Chung & Cheung, 2008; Koch, Ryder, Dziura, Njike, & Antaya, 2008; Roberts, Roberts, & Duong, 2008; ter Bogt et al., 2006; ter Wolbeek, van Doornen, Kavelaars, & Heijnen, 2006). As children become adolescents, their sleep patterns change—they move from early risers/sleepers to staying up later and sleeping in later, or catching up on sleep over weekends. This transition becomes more apparent through high school (Gau & Soong, 2003). Sleep deprivation, along with television viewing time, has been related to increased BMI and blood pressure, and a poor body weight perception (being overweight or underweight) has predicted problem behaviors in both male and female adolescents (ter Bogt et al., 2006; Wells et al., 2008).

In the past, routine health care visits by adolescents were not commonplace. However, newer recommended vaccines and better awareness of the health needs of adolescents have resulted in better utilization of services. In 2003, about 73% of adolescents between the ages of 12 and 17 had one or more preventive medical visits. More than 51% had one or more visits due to illness or injury—the most common reasons being bronchitis or upper-respiratory infections and trauma-related problems (National Adolescent Health Information Center [NAHIC], 2008). In 2005, over 45% of adolescents ages 15 to 24 had emergency room visits, largely for contusions.

Hospitalization was most often related to childbirth, but trauma-related injuries (e.g., wounds, fractures) were

also prominent. About 20% of 12- to 17-year olds with special health care needs do not get the health care services they need (NAHIC, 2008). About 87% of adolescents (ages 12 to 17) had insurance coverage in 2005; but the number drops to 55% for those ages 18 to 24. Hispanic adolescents have the least proportion of health insurance—public or private—and were the least likely to have had a health care visit in the past year (NAHIC, 2008).

Health literacy during adolescence is an important consideration. Teens are frequent users of mass media (Internet, television, radio, text messaging), and specific health-related educational interventions can be targeted to them by using these media (Manganello, 2007).

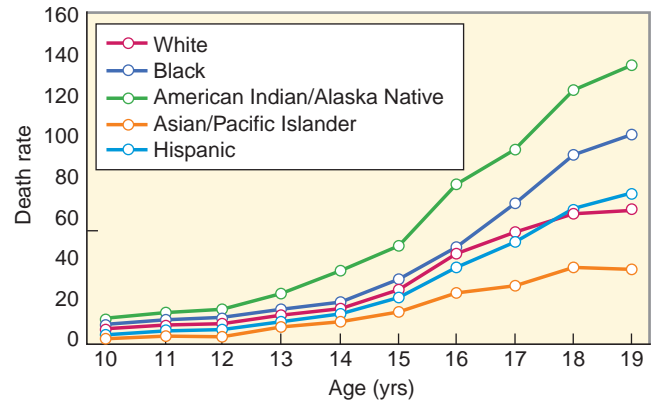

During the period that roughly encompasses the teen years, adolescents encounter many complex changes, physically, emotionally, cognitively, and socially (Steinberg, 2005). Rapid and major developmental adjustments create a variety of stresses with concomitant problems that have an impact on health. More recent advanced neuroimaging techniques have demonstrated marked changes in the adolescent brain, especially related to white and gray matter and the prefrontal cortex (Blakemore, den Ouden, Choudhury, & Frith, 2007; Casey, Jones, & Hare, 2008), along with other regions of the brain related to “attention, reward evaluation, affective discrimination, response inhibition, and goal-directed behavior,” that help explain the cognitive and affective peculiarities of this developmental period (Yurgelun-Todd, 2007, p. 251).

The uneven changes in brain development may also help explain the risk-taking behaviors and higher incidence of unintentional injuries found in this population (Paus, 2005). Unintentional injuries were the leading cause of death in the 15- to 24-year-old age group. Most deaths in this adolescent/young adult age group are due to preventable causes (NAHIC, 2006b). The overall injury death rate for adolescents (10 to 19 years of age) was 30.9 per 100,000 between 1999 and 2002. A dramatic upward trend in these figures is apparent: the rate at age 10 is 6.9, but by age 19, it jumps to 72.1. Gender differences are also apparent: girls are much less likely than boys to engage in behaviors that put them at risk for injuries, resulting in more than twice the unintentional injury death rate for males than females between the ages of 15 and 19 (NAHIC, 2000).

The overall unintentional death rate for only motor vehicle-related injuries was 14.9 (Bernard et al., 2007). The death rate from motor vehicle-related injuries for this age group peaked during the 1970s and 1980s, then declined throughout the next 2 decades, although motor vehicle-related injuries remain the number one cause of injury mortality for this age group (Bernard et al., 2007; NAHIC, 2000). Considering that 99% of motor vehicle-related injuries are nonfatal, this death rate becomes even more alarming (NAHIC, 2000). Ethnic differences are noted, with Whites having higher death rates than other ethnic and racial groups (Fig. 22.4).

## Health Objectives for Adolescents

*Healthy People 2010* objectives are focused on improving the health of all Americans. Of the 476 objectives, 107 have been identified as relevant to the adolescent population (Park, Brindis, Chang, & Irwin, 2008). However, 21 specific objectives have been ranked as critical objectives related to adoles-

**FIGURE 22.4** Rate of injury death among children aged 10–19 years, by race/ethnicity—United States, 1999–2002. Retrieved July 31, 2008 from [www.cdc.gov/mmwr/preview/mmwrhtml/ss5605a1.htm?s\\_cid=ss5605a1\\_x](http://www.cdc.gov/mmwr/preview/mmwrhtml/ss5605a1.htm?s_cid=ss5605a1_x).

cents and young adults (CDC, n.d.). Because much of the mortality and morbidity in this age group stems from risk-taking behaviors, many of these objectives address alcohol-related unintentional injuries, violent behaviors, and suicide and mental health issues, as well as more responsible reproductive health behaviors (Table 22.1). The 2007 midcourse review of these critical objectives found overall mortality trends at two times the 2010 target rate, although the 10- to 14-year-old rate is “on pace to reach the 2010 target” (p. 331). Unintentional injury results are mixed; motor vehicle-related crashes (with and without alcohol) increased slightly, but seat belt use also increased, and the number of adolescents reporting that they rode with a driver who had been drinking alcohol decreased. The objectives related to “homicide, physical fighting, and carrying a weapon have shown little or no improvement” (p. 331), and mental health objectives have shown mixed results. Suicide rates and reported attempted suicides are not significantly improved, and only modest increases are found in other objectives related to mood and treatment. Binge drinking and marijuana use demonstrate small decreases, and vigorous physical activity reports are basically unchanged. Tobacco use has gone down considerably, but obesity and overweight figures increased by more than 50%. The adolescent pregnancy rate decreased 34%—the best results of all 21 objectives—almost achieving the 2010 target rate, and related objectives are on pace to reach targets (e.g., never having sex, used a condom with last sexual contact). Chlamydia infection rates have increased, but may be an artifact of more sensitive testing and improved reporting (Park et al., 2008).

Because adolescents have less contact with the health care system than children, many conditions may go undetected. Also, a shift occurs from a childhood preponderance of physical conditions to more social behavioral problems in adolescence. Risk behaviors become much more evident, along with their attendant outcomes: unsafe sexual activity, substance use, violence, and motor vehicle-related issues (Michaud, 2008; Shaffer & Kipp, 2006).

## Emotional Problems and Suicide

The adolescent years are a time of rapid growth and change. Hormonal influences may cause a teen to be emotional and

**TABLE 22.1 *Healthy People 2010: 21 Critical Health Objectives for Adolescents and Young Adults***

The 21 Critical Health Objectives represent the most serious health and safety issues facing adolescents and young adults (aged 10 to 24 years): mortality, unintentional injury, violence, substance abuse and mental health, reproductive health, and the prevention of chronic diseases during adulthood.

Obj. #	Objective	Baseline (year)	2010 Target
<u>16-03.</u> (a,b,c)	<u>Reduce deaths of adolescents and young adults.</u> 10–to 14–year-olds 15–to 19–year-olds 20–to 24–year-olds	21.5 per 100,000 (1998) 69.5 per 100,000 (1998) 92.7 per 100,000 (1998)	(per 100,000) 16.8 39.8 49.0
<b>Unintentional Injury</b>			
<u>15-15.</u> (a)	<u>Reduce deaths caused by motor vehicle crashes.</u> 15- to 24-year-olds	25.6 per 100,000 (1999)	[1]
<u>26-01.</u> (a)	<u>Reduce deaths and injuries caused by alcohol- and drug-related motor vehicle crashes.</u> 15- to 24-year-olds	13.5 per 100,000 (1998)	[1]
15-19.	Increase use of safety belts. 9 <sup>th</sup> –12 <sup>th</sup> grade students	84.0% (1999)	92.0%
26-06.	Reduce the proportion of adolescents who report that they rode, during the previous 30 days, with a driver who had been drinking alcohol. 9 <sup>th</sup> –12 <sup>th</sup> grade students	33.0% (1999)	30.0%
<b>Violence</b>			
<u>15-32.</u>	<u>Reduce homicides.</u> 10–to 14–year-olds 15–to 19–year-olds	1.2 per 100,000 (1999) 10.4 per 100,000 (1999)	[1] [1]
15-38.	Reduce physical fighting among adolescents. 9 <sup>th</sup> –12 <sup>th</sup> grade students	36.0% (1999)	32.0%
15-39.	Reduce weapon carrying by adolescents on school property. 9 <sup>th</sup> –12 <sup>th</sup> grade students	6.9% (1999)	4.9%
<b>Substance Abuse and Mental Health</b>			
26-11. (d)	Reduce the proportion of persons engaging in binge drinking of alcoholic beverages. 12- to 17-year-olds	7.7% (1998)	2.0%
26-10. (b)	Reduce past-month use of illicit substances (marijuana). 12- to 17-year-olds	8.3% (1998)	0.7%
<u>18-01.</u>	<u>Reduce the suicide rate.</u> 10–to 14–year-olds 15–to 19–year-olds	1.2 per 100,000 (1999) 8.0 per 100,000 (1999)	[1] [1]

TABLE 22.1 *Healthy People 2010: 21 Critical Health Objectives for Adolescents and Young Adults (Continued)*

Obj. #	Objective	Baseline (year)	2010 Target
18-02.	Reduce the rate of suicide attempts by adolescents that required medical attention. 9 <sup>th</sup> –12 <sup>th</sup> grade students	2.6% (1999)	1.0%
06-02.	Reduce the proportion of children and adolescents with disabilities who are reported to be sad, unhappy, or depressed. 4- to 17-year-olds	[2]	[2]
18-07.	Increase the proportion of children with mental health problems who receive treatment.	59.0% (2001)	66.0%
<b>Reproductive Health</b>			
09-07.	Reduce pregnancies among adolescent females. 15- to 17-year-olds	68.0 per 1,000 females (1996)	43.0 per 1,000
13-05.	<u>(Developmental) Reduce the number of new cases of HIV/AIDS diagnosed among adolescents and adults.</u> 13- to 24-year-olds	16,479 (1998) [4]	[3]
25-01. (a,b,c)	<u>Reduce the proportion of adolescents and young adults with <i>Chlamydia trachomatis</i> infections.</u> 15- to 24-year-olds Females attending family planning clinics Females attending sexually transmitted disease clinics Males attending sexually transmitted disease clinics	5.0% (1997) 12.2% (1997) 15.7% (1997)	3.0% 3.0% 3.0%
25-11. (a,b,c)	Increase the proportion of adolescents (9 <sup>th</sup> –12 <sup>th</sup> grade students) who: Have never had sexual intercourse If sexually experienced, are not currently sexually active If currently sexually active, used a condom the last time they had sexual intercourse	50.0% (1999) 27.0% (1999) 58.0% (1999)	56.0% 30.0% 65.0%
<b>Chronic Diseases</b>			
27-02. (a)	Reduce tobacco use by adolescents. 9 <sup>th</sup> –12 <sup>th</sup> grade students	40.0% (1999)	21.0%
19-03. (b)	<u>Reduce the proportion of children and adolescents who are overweight or obese.</u> 12- to 19-year-olds	11.0% (1988-94)	5.0%
22-07.	Increase the proportion of adolescents who engage in vigorous physical activity that promotes cardiorespiratory fitness 3 or more days per week for 20 or more minutes per occasion. 9 <sup>th</sup> –12 <sup>th</sup> grade students	65.0% (1999)	85.0%

Note: Critical health outcomes are underlined, and behaviors that substantially contribute to important health outcomes are in normal font.

unpredictable at times (SAMHSA, 2003). The influence of peers increases, and peer pressure may influence behavior. Teens test family rules and generally search for their own identity and individuality apart from the family. Most parents and teens ride out this period with love and understanding and no long-term negative effects. For some children, however, a real or perceived lack of emotional support can lead to temporary or permanent emotional problems. Longitudinal research through late childhood into adolescence reveals that harsh parenting practices in childhood and parental rejection in adolescence lead to shame and guilt that are associated with depression and delinquency (Stuewig & McCloskey, 2005). Also, gender differences in types and trajectories of emotional and behavioral problems have been noted, with more females developing adolescent-onset depression and males demonstrating more conduct problems at an earlier age of onset (Zahn-Waxler, Shirtcliff, & Marceau, 2008). Emotional problems can affect many, often subtle, aspects of an adolescent's life: for example, positive psychosocial adjustment has been linked to fewer traffic offenses in adolescents (Bingham, Shope, & Raghunathan, 2006).

Depression, schizophrenia, and eating disorders may first appear during adolescence. About 50% of mental health conditions begin before age 14, and 75% by age 21 (Knopf, Park, & Mulye, 2008). It is estimated through parent ratings that approximately 12% of 12- to 17-year-olds have a serious behavioral or mental health problem (12% of females and 12.3% of males; low-income youth were rated at almost 18%) (Knopf et al., 2008). Common adolescent mental health problems include depression, anxiety disorders, ADHD, and substance abuse problems. Mild depression affects over 25% of adolescents, but prevalence rates vary (Fig. 22.5). Depression is two times more likely among females (ages 15 to 20), and comorbidities (e.g., anxiety disorder, and addictive and conduct disorders) are not uncommon (Knopf et al., 2008). Researchers have concluded that between 20% and 25% of adolescents display symptoms of emotional distress, and about 10% have moderate to severe symptoms (Knopf et al., 2008). Adolescent brain maturation

**FIGURE 22.5** Prevalence of past-year major depressive episode among youth aged 12–17, by age: 2005. From Substance Abuse & Mental Health Services Administration (SAMHSA). (May 3, 2007). *The National Survey on Drug Use & Health Report*. Depression and the use of alcohol and other drug use among youths aged 12–17.

may explain susceptibility to depression during this period of development (Andersen & Teicher, 2008).

Many adolescents are reluctant to seek help for emotional problems, or help may not be readily available to them. Most research shows that many adolescents with “significant emotional distress” fail to receive mental health treatment—estimates have ranged from 10% to less than 40% (Knopf et al., 2008, p. 9). Newer survey results have found that 21.3% of youth ages 12 to 17 have been given some type of mental health services, but the usual disparities apply (e.g., ethnicity, income level, rural versus urban locale). Treatment for serious mental health problems may include hospitalization or placement in a group home. However, primary care providers commonly evaluate children and adolescents for psychosocial problems in their everyday practice. Pediatricians report that almost 19% of patient visits concerned conduct or emotional problems or ADHD (Knopf et al., 2008).

Suicide is the third leading cause of death in adolescents and young adults (NAHIC, 2006a). A psychiatric diagnosis is found in 90% of suicide victims, with depression noted in over 50% of all cases (Shaffer, Gould, & Hicks, 2007). In 2003, the suicide rate in the 10- to 24-year age group was 6.8 per 100,000, down from the peak rate in the early 1990s. However, the rate increased by 8% between 2003 and 2004, reflecting the largest 1-year jump between 1990 and 2004 (Lubell, Kegler, Crosby, & Karch, 2007). It is interesting to note that, even though antidepressant medications have demonstrated effectiveness in reducing depressive symptoms in adolescents (the relationship between antidepressants and suicide has not been studied), the sudden rise in suicides in 2004 coincided with a large decline in antidepressant prescriptions. Also, selective serotonin reuptake inhibitors (SSRIs; among the more commonly prescribed antidepressant medications) are almost never found during autopsy of teen suicide victims (Shaffer et al., 2007; CDC, 2006c). In 2005, almost 17% of high school students reported that they seriously considered suicide in the previous 12 months (21.8% girls, 12% boys), and 8.4% made at least one suicide attempt—2.3% made an attempt that required medical attention (CDC 2007e; Lubell et al., 2007). Geographically, higher suicide rates occur in the West (i.e., Alaska, New Mexico, Montana), and the lowest rates are found in the northeastern United States (Shaffer et al., 2007). As teens age, they are more at risk for suicide: the rate increases from 1.2 per 100,000 for ages 10 to 14 to 12.1 for ages 20 to 24. Males are five times more likely to die from suicide than females, and male American Indian/Alaska Natives are two to four times more likely than other ethnic groups to die from suicide (NAHIC, 2006a).

Girls, especially Hispanic females, attempt suicide more frequently than boys (Lubell et al., 2007). An alarming finding is that suicide deaths by hanging or suffocation have dramatically increased for girls, whereas the use of firearms has decreased since 1997; poisoning has increased only slightly (National Youth Violence, 2007).

It is important to question a teen about her history of depression or feelings of hopelessness, as well as the quality and quantity of her social support systems and the availability of means to follow through on suicide threats (Bethell & Rhodes, 2008). School and discipline problems, family discord, and depression, as well as drug and alcohol abuse can increase the risk of suicide (NCIPC, 2007). Recent stressful events and preoccupation with suicide, as well as substance

use, are also important to note. Gay, lesbian, and bisexual youth have high rates of suicidal ideation and suicide attempts, and for all youth, having a close family member who committed suicide doubles the risk (Shaffer et al., 2007). *Suicide contagion* refers to copycat suicides, especially among high school students, after a highly publicized suicide. This can lead to suicide clusters—deaths of three to seven adolescents over a 3- to 9-month period (Shaffer et al., 2007).

Suicide hotlines are often ineffective for adolescents, as they are infrequently used (Shaffer et al., 2007). Suicide prevention programs and direct intervention by counselors or school nurses to determine an adolescent's suicide intentions are the most effective school-based approaches (Eggert, Thompson, Randell, & Pike, 2002; May, Somal, Hurt, & DeBruyn, 2005). Hendin and colleagues (2001) noted that it is important for counselors to identify markers for attempted suicide, such as a precipitating event, intense affective state, suicide ideation or actions, deterioration in social or academic functioning, or increased substance abuse. Community health nurses and community mental health counselors may serve as consultants to schools in the development of sound prevention programs. Hallmarks of good prevention programs include school policies and inservice training on suicide prevention; collaboration among teachers, counselors, and nurses; student education on suicide prevention; peer assistance programs; school–family–community partnerships; activities that increase school connectedness; and crisis intervention teams. Suicide screening, education, and peer support have been found to significantly reduce the rates of self-reported suicide attempts (Aseltine & DeMartino, 2004). Some examples of programs used in high schools include *Suicide-Awareness Voices Education*, *Lifelines*, and *SOS: Signs of Suicide* (Shaffer et al., 2007).

A behavior that can sometimes accidentally result in suicide is *self-injury* or *cutting*. Adolescents with this abnormal behavior who overdose, cut, burn, or otherwise dangerously harm themselves are attempting to find relief from profound psychological pain. The physical injury distracts them from these painful emotions, possibly giving them a feeling of control or providing a means of feeling emotions when they are cut off from them. This behavior is found in 3% to 5% of the population, and most often begins in early adolescence or late childhood. It is more common in girls and in those with a family history of suicide or self-injury. Isolation, neglect, or abuse may predispose an adolescent to this behavior. Depression, borderline personality disorder, and eating disorders are commonly associated with self-injury. PHNs and school nurses can provide education to adolescents and families about this condition, and can work with schools to promote prevention strategies, such as early detection and referral to mental health providers (Mayo Clinic, 2006).

## Violence

Arrests for violent youth crimes peaked in the decade between 1983 and 1993 (Surgeon General of the United States, 2002). The total costs of youth violence are more than \$158 billion each year (CDC, 2007d). Nonfatal violent crimes (among youth ages 12 to 24) dropped by one-half between 1994 and 2004. Simple assault was 321 times more common than homicide (Dinkes et al., 2006). Homicide is the second leading cause of death for adolescents (ages 10

to 24), and is more common in males than females. Homicide rates for 10- to 24-year-olds peaked in the early 1990s, but decreased significantly by the end of that decade. Firearms are involved in most adolescent and young adult homicides (NAHIC, 2007).

Surveys show that between 15% and 40% of teens admit to having committed a serious violent offense by age 17, and serious youth violence is part of a constellation of risk-taking behaviors that also includes precocious sex, drugs, and guns (Surgeon General of the United States, 2002). Multiple longitudinal research studies show that delinquency peaks during middle adolescence—around age 16. Preadolescent delinquency, however, has been related to a pattern of persistent criminal behavior (Landsheer & van Dijkum, 2005). Children assault and kill other children at school and on the streets. More than 20,000 children and adolescents are killed or injured by firearms each year. Adolescents (between the ages of 15 to 19 years) account for almost 85% of all firearm injuries treated in emergency rooms or hospitals. Only 1% of all firearm-related deaths for school-age children occur on school grounds (Fingerhut & Kaufer-Christoffel, 2002).

Gangs are often associated with teen violence. However, the proportion of schools reporting gang activity has dropped (Surgeon General of the United States, 2002), and the overall number of gangs and gang members has decreased since 1996 (Egley & Ritz, 2006; National Youth Violence Prevention Center [NYVPRC], 2008). However, gangs have penetrated previously untouched areas; they are now found in every state and in smaller communities with populations of 25,000 or less (Egley & Ritz, 2006). In large cities, about one-quarter of homicides are considered gang-related; in Chicago and Los Angeles, more than half are gang-related (Egley & Ritz, 2006). In schools where gang activity is reported, higher drug availability and student victimization are found (NYVPRC, 2008). Incidents of high school shootings have raised concerns among parents and teachers. School violence has been linked to bullying (Nansel, Overpeck, Haynie, Ruan, & Scheidt, 2003) and school environments. Comprehensive school safety plans are advised; grants and technical assistance are available to local school districts through the federal government.

Cultural and environmental influences on youth include the violence to which children and adolescents are exposed. Increased aggressive behavior among children and teens has been attributed to violence in the environment, the home (spousal and child abuse), and the community, as well as to what children see on television and in movies. A large-scale study across 10 U.S. cities found that adolescents (even more than children) were at higher risk for being victimized and experiencing a threat to their lives. Adolescents were more likely also to be involved with violence outside their homes and to suffer from physical injuries related to violence (Harpaz-Rotem, Murphy, Berkowitz, Marans, & Rosenheck, 2007). A study of 9- to 15-year-olds who lived in public housing demonstrated that some adolescents who witness violence (not as victims themselves) suffer the same symptoms that victims of violence experience, for example, difficulty concentrating, vigilant/avoidant behavior, and intrusive thoughts and feelings (Howard, Feigelman, Li, Cross, & Rachuba, 2002). Violence is an increasing threat for teenagers. Middle school students are reported to fight more and experience bullying more than elementary school age children or high school students (Juvonen, Le, Kaganoff, Augustine, & Constant, 2004).

Bullying can result in depression, social anxiety, internalizing and psychosomatic symptoms, loneliness, and poor school performance (Arseneault et al., 2008; Wigfield, Lutz, & Wagner, 2005). Children or adolescents with anxiety or depression are also at increased risk of being the victims of bullying (Fekkes, Pijpers, Fredriks, Vogels, & Verloove-Vanhorick, 2006). The percentage of young adolescents who do not feel safe at school is increasing dramatically: In the most recent Youth Risk Behavior Survey, 18.5% of adolescents reported carrying a weapon to school during the past month, and more than 35.9% were involved in physical fights in the last year (CDC, 2006a).

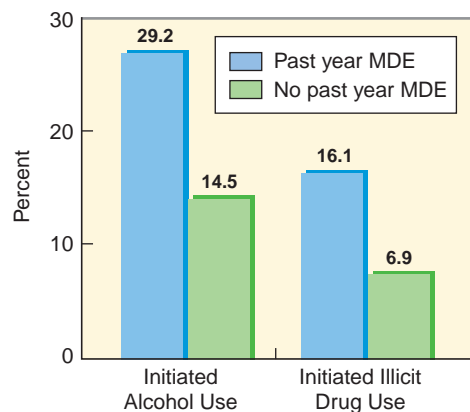

Adolescents who are better connected to school are less likely to engage in violent behaviors. School climate is important in reducing the levels of violence in this age group (Brookmeyer, Fanti, & Henrich, 2006). High levels of parental support have been found to moderate the effects of witnessing violent acts, in that children with support are less likely to commit violent acts (Brookmeyer, Henrich, & Schwab-Stone, 2005).

Following the lead of the federal government with the implementation of the Safe and Drug-Free Schools and Communities Act, most schools have developed zero-tolerance policies to counteract and prevent violence (King, Wagner, & Hedrick, 2001). Many schools now have metal detectors and security guards, and some schools conduct random searches of students' lockers in an effort to prevent violence. However, a report from the American Psychological Association Zero Tolerance Task Force (2006) that examined 10 years of research studies, found that schools are no safer after the implementation of these widespread policies and that the policies can actually lead to increased violent and disruptive behavior and higher dropout rates. The task force found that a disproportionate number of Black and Hispanic students were expelled or suspended from school, and that zero-tolerance policies do not consider children's lapses in judgment as a normal aspect of development. They recommended adaptations to zero-tolerance policies to make them more flexible and individualized to students, school sites, and situations.

## Substance Abuse

Substance abuse among young people was almost unknown before 1950, and rare before 1960. Now, adolescent drug experimentation and use pose serious physical and psychological threats. A national survey found that by the time they complete high school, 53% of teens report having tried an illicit drug, and 78% have consumed alcohol (Johnston, O'Malley, & Bachman, 2003). A more recent survey reported that 47% of high school seniors have tried an illicit drug, which reflects a slight improvement over earlier surveys (Johnston, O'Malley, Bachman, & Schulenberg, 2008). The most recent Youth Risk Behavior Survey found that 20.2% of high school students had used marijuana in the past month, and 54.8% of 12th-graders smoke marijuana regularly; 3.4% of high school students had used cocaine at some time. Over 43% reported that they currently drink alcohol (CDC, 2006a).

Why do adolescents turn to alcohol or illicit drugs? Acosta, Manubay, and Levin (2008) have described parallels between addictive behavior and obesity—especially personality, environmental risk factors, genetic predisposition, and

**FIGURE 22.6** Percentages reporting past-year substance use initiation among persons aged 12–17 who were at risk for substance use initiation, by past year major depressive episode (MDE): 2005. From Substance Abuse & Mental Health Services Administration (SAMHSA). *The National Survey on Drug Use & Health Report*. (May 3, 2007). Depression and the use of alcohol and other drug use among youths aged 12–17.

common neurobiologic brain pathways. A large-scale, 25-year prospective longitudinal study in New Zealand found that gender, novelty-seeking behaviors, childhood conduct disorder, and parental illicit drug use predicted use of illicit drugs in 16- to 25-year-olds. Marijuana use, substance-using peers, and alcohol use were also factors (Fergusson, Boden, & Horwood, 2008; Fergusson, Horwood, & Ridder, 2007). Depression has also been linked to alcohol and substance use (Fig. 22.6). Can peers lure adolescents into alcohol and drug use? Most evidence reveals both genetic and environmental influences—in other words, those who were more prone by genetics to use substances “were more vulnerable to adverse influences of their best friends” (Harden, Hill, Turkheimer, & Emery, 2008).

Alcohol is the most frequently used substance for U.S. adolescents—it is their “drug of choice” (Faden, 2006, p. 1,011). Boys begin drinking at an earlier age than girls, usually around seventh and eighth grades. According to the 2005 Youth Risk Behavior Survey (CDC, 2006a), 43.3% of high school students reported drinking alcohol within the previous month. Early drinkers more often report academic problems, use of other substances, and delinquent behavior in middle and high school. A study found that, by the time they were young adults, people with a history of early alcohol use had problems related to abuse of other substances, employment problems, and criminal and violent behavior (Ellickson, Tucker, & Klein, 2003). Analysis of national survey data found that adolescents who begin first alcohol use before the age of 13 had significantly more involvement in violent behaviors and suicide attempts than those who delayed the initiation of alcohol (Swahn, Bossarte, & Sullivan, 2008). Early use of alcohol was found to be a marker for later alcohol and drug dependence in one longitudinal study (King & Chassin, 2007), and in a large-scale twin study, early regular drinking was significantly associated with later drug abuse and dependence, as well as with alcohol use and dependence that could not be fully explained by shared family factors or genetics (Grant et al., 2006). It is

important to stress education and prevention in late childhood to delay the initiation of alcohol use.

A study on the effects of alcohol advertising on youth drinking rates (Snyder, Milici, Slater, Sun, & Strizhakova, 2006) found that youth (ages 15 to 26) who saw more advertising for alcohol drank more on average (each dollar spent per capita on alcohol advertising raised the number of drinks consumed by 3%). Alcohol promotional items (e.g., clothing, posters) have been associated with binge drinking (Fisher, Miles, Austin, Camargo, & Colditz, 2007). Binge drinking is generally defined as having five or more drinks at one time—usually within a couple of hours—and it often increases as adolescents get older (CDC, 2008c; Miller, Naimi, Brewer, & Jones, 2007). Binge drinking has been associated with poor academic achievement and other risk behaviors (e.g., sexual activity, smoking, using illicit drugs, riding with a driver who had been drinking, attempting suicide), and the more adolescents binge drink, the more they engage in risk behaviors (Miller et al., 2007).

Family drinking and perceived family norms related to drinking have been found to affect adolescents' perceptions of the benefits of drinking. This perception, in turn, predicts their drinking behavior (Epstein, Griffin, & Botvin, 2008). Parenting practices (e.g., monitoring, discipline, enforcing rules related to alcohol use) have also been found to have an influence on adolescent drinking behavior (Latendresse et al., 2008; Van der Vorst, Engels, Meeus, Dekovi, & Van Leeuwe, 2005).

Some research has suggested that adolescents who spend more meal times with their families are less likely to engage in alcohol and other substance use and are more likely to have better grades and fewer depressive symptoms (Eisenberg, Olson, Neumark-Sztainer, Story, & Bearinger, 2004). Family meal times have been shown to promote family cohesion and problem- and emotion-focused coping by encouraging parents to help their children feel part of the family and allowing them valuable time to coach them in effective methods for dealing with daily stresses and problems (Franko, Thompson, Affenito, Barton, & Striegel-Moore, 2008). To promote the health and welfare of adolescent children, it is vital to stress to families with young children the continued importance of family meals throughout adolescence.

Marijuana is the most commonly used drug among 14- to 17-year-olds—41.8% of high school seniors reported ever using marijuana (National Survey on Drug Use & Health [NSDUH], 2008). Use of marijuana by early adolescents fell, but middle to late adolescent use remained the same (Johnston et al., 2008). This is an important finding, because early marijuana use (before age 15) has been associated with a much greater likelihood of adult cocaine and heroin use and drug dependency (Office of National Drug Control Policy [ONDCP], 2008). Marijuana use has negative health effects, including anxiety, panic attacks, increased heart rate, frequent respiratory infections, impaired memory and learning, and tolerance. Regular marijuana smokers often have respiratory complications similar to those of tobacco smokers—cough, phlegm, respiratory infections, and airway obstruction (ONDCP, 2008).

Inhalant abuse is very common, and shows signs of resurgence (Johnston et al., 2008). Inhalant use begins in early adolescence—more 12- and 13-year-olds reported using inhalants than any other illicit drug. The most commonly reported inhalants used were shoe polish, glue or toluene, spray paints,

and lighter fluid or gasoline (NSDUH, 2008). Other inhalants commonly used include amyl nitrite “poppers”; locker room deodorizers or “rush”; cleaning fluid, degreasers, or correction fluid; halothane, ether, or other anesthetics; lacquer thinner or other paint solvents; butane or propane gases; nitrous oxide or “whippets”; and other aerosol sprays (NSDUH, 2008). Inhalant abuse can result in severe nervous system damage or death. Control of legal products, such as spray paint, lighter fluid, household solvents, gasoline, and glue, is difficult, making this problem almost impossible to monitor adequately.

Other drugs that are used by adolescents and young adults include “club drugs” such as MDMA (Ecstasy), a synthetic drug with amphetamine and hallucinogenic properties; Rohypnol (the date rape drug that is often mixed with alcohol to produce sedative hypnotic effects); ketamine (a rapid-acting anesthetic); lysergic acid diethylamide (LSD), an hallucinogen originally popularized in the 1960s; and gamma hydroxybutyrate (GHB, a drug that is touted as a synthetic steroid in fitness clubs and that has been associated with sexual assaults). Rates of use for ketamine, Rohypnol, and GHB have declined over the past few years, but Psilocybin, or “magic mushrooms” are still widely used. Ecstasy use has generally declined but may become popular again among younger adolescents. Over-the-counter cold and cough medications containing the cough suppressant dextromethorphan are sometimes used to produce a “high,” and between 4% and 7% of adolescents are reported to have used them (Johnston et al., 2008). Visits to the emergency department and deaths have occurred from the use of many of these drugs.

Cocaine use has remained steady in recent years, after peaking in the late 1990s. Heroin use fell below peak levels reached in 2001 but continues to remain steady. Smoking or snorting of heroin, which is popular among adolescents and young adults because they mistakenly believe it precludes the strong physical addictiveness of this drug, has been found to lead to injection drug abuse (Johnston, O'Malley, & Bachman, 2003). Methamphetamine (meth) use has demonstrated a consistent decline since 1999. It may also be smoked, along with marijuana, or injected. Meth labs are a public health hazard and can often be found in rural areas.

The illicit use of anabolic steroids is also difficult to monitor; however, 0.8% of 8th graders, 1.1% of 10th graders, and 1.4% of 12th graders report using steroids (Johnston et al., 2008). About one-third of high school students taking anabolic steroid are girls (Gober, Klein, Berger, Vindigni, & McCabe, 2006). Some coaches have, at times, turned a blind eye to steroid abuse, but educational campaigns to fight the rising level of abuse in adolescents have led to decreases in use since peak levels were reached in 2000. Sato, Schulz, Sisk, and Wood (2008, p. 647) report that animal models show “adolescent anabolic-androgenic steroid exposure increases aggression, and causes lasting changes in neurotransmitter systems.” Other symptoms include irritability, increased risk-taking behavior, extreme mood swings, and euphoria, psychiatric conditions may be intensified or induced. Some have cautioned that withdrawal from steroids may be especially difficult for adolescents who are “vulnerable to hormonal swings” (Gober et al., 2006).

Adolescents are becoming more involved with prescription drugs, often found in their parents' medicine cabinets, purchased on the Internet, or bought from friends at school (McCabe et al., 2007). Teens may have “pharming parties,” in which medication bottles are emptied onto

tables and selected like candies (Hipp, 2006). Medications are often mixed with alcohol, and half of adolescents surveyed stated that they believed prescription medicines are safer than street drugs when used to produce a high (Partnership for a Drug-Free America, 2004). Ritalin, prescribed to students with ADHD, may be given or sold to others, but the most commonly used medications are OxyContin, Vicodin, tranquilizers, and sedatives. One in 20 high school seniors has tried OxyContin, and almost 10% of high school seniors have used Vicodin (Johnston et al., 2008). This trend is very disturbing because of society's nonchalant, casual attitude toward prescription medications and their easy access. Early onset (before age 13) of nonmedical use of prescription medications is a predictor of later prescription drug abuse and drug dependence (McCabe, West, Morales, Cranford, & Boyd, 2007).

Tobacco products are also easily acquired, often from parents. Almost 70% of high school students reported in 2001 that they had smoked a cigarette, and more than 23% reported that they purchased their own cigarettes from a store or gas station (CDC, 2002b). The most recent Youth Risk Behavior Survey found that fewer students reported trying cigarettes—46% of 12th graders and 22% of 8th graders. Only 23% of high school students had smoked cigarettes on one or more days within the last 30 days (CDC, 2006a). The use of smokeless tobacco, or “chew,” has also declined. Social disapproval and heightened perception of health risks have most likely helped contribute to the downward trend of smoking and smokeless tobacco use, as have price increases and advertising bans (Johnston et al., 2008). Also, comprehensive merchant education programs have reduced illegal sales to minors (Tobacco Information & Prevention Source, 2001). In a study of adolescents who use tobacco, addictive symptoms have been shown to begin to appear within the first few weeks of initiating smoking, highlighting the need to continue to attack this problem even though rates have been in decline over the past few years (DiFranza, 2008). Smoking cessation programs for adolescents must take into account their levels of nicotine dependence and stress, as well as the effectiveness of cognitive coping methods (Siqueira, Rolnitzky, & Rickert, 2001). Adolescents with negative affect also have a more difficult time when trying to quit smoking (Stevens, Colwell, Smith, Robinson, & McMillan, 2005). An Internet-based virtual reality world, along with real-time motivational interviewing by experienced smoking-cessation counselors, is an innovative program showing promise with adolescent smokers (Woodruff, Conway, Edwards, Elliott, & Crittenden, 2007). In addition, parental influence and monitoring have been shown to have an effect on adolescent smoking behavior (Dick et al., 2007).

Primary health care providers do not always question adolescents about smoking, drinking, and use of other substances. PHNs and community health nurses can provide information to teens about smoking cessation programs and promote primary prevention by educating children and adolescents to choose not to smoke or engage in other health-risk behaviors. They can also encourage physicians and parents to question and monitor adolescents about smoking and the use of tobacco products.

## Teen Sexuality and Pregnancy

Teenage pregnancies, sexually transmitted diseases (STDs), and HIV/AIDS are public health concerns associated with

the sexual activity of adolescents. In the 2005 Youth Risk Behavior Survey, almost 47% of high school students reported ever having sexual intercourse, and almost 63% used a condom during their last sexual intercourse (CDC, 2006a). Early sexual debut has been associated with delinquency, as well as with other negative outcomes (Armour, 2007). The United States leads most developed nations in rates of teenage pregnancy, abortion, and childbearing. The United States has the second highest teen pregnancy and birth rates among 46 developed countries, largely because U.S. adolescents are less likely to use or consistently use contraception (Darroch, Singh, Frost, & the Study Team, 2001; Singh & Darroch, 2000). Hamilton, Martin, and Ventura (2007) report that, since 1991, pregnancy and birth rates for 15- to 19-year-old girls have declined by 34%; in 2006, however, rates increased for the first time (from 40.5 per 1,000 to 41.9). The rate for Hispanic adolescent girls is 83 per 1,000. For non-Hispanic whites, the rate is 26.6 per 1,000. For black teens it is 63.7 per 1,000 (CDC, 2008d). The downward trend for teen pregnancy rates has been attributed largely to better use of contraception (77%), rather than less sexual activity (23%) (Santelli, Lindberg, Finer, & Singh, 2007).

Young mothers are at high risk of bearing infants with low birth weight, and they are more likely to smoke tobacco. They are also less likely to receive adequate prenatal care or to gain the recommended weight during pregnancy. Adolescent mothers are at a greater risk than mothers over age 20 to experience a complication of pregnancy (e.g., anemia, hypertension, premature labor), and the risk increases for those under age 15 (Briggs, Hopman, & Jamieson, 2007; March of Dimes, 2007; Usta, Zoorob, Abu-Musa, Naassan, & Nassar, 2008). The babies of adolescent mothers are more likely to die before 1 year than are babies born to 20- to 30-year-old mothers, and low-birth-weight babies are more common among 15- to 19-year-old mothers than among older mothers (March of Dimes, 2007). Adolescent mothers are also at risk for a greater number of physical, psychological, and social problems, including dropping out of high school, reliance on public assistance, limited earning potential, social isolation, and mental disorders (Boden, Fergusson, & Horwood, 2008; East et al., 2007; Reid et al., 2007). A longitudinal study found that “teen mothers’ life trajectories reflected legacies of unequal life chances that began in childhood and persisted into their 30s,” but that those who were from higher socioeconomic groups “fared better over time” (Smithbattle, 2007, p. 409). Adolescent girls living with a single parent or not living with either parent have higher teen birth rates than those who live with both parents (Forum on Child & Family Statistics, 2006). Adolescents report positive outcomes, but also that teen parenting is “hard,” and they recognize that their current and future lives are profoundly affected (Herrman, 2006; Herrman, 2008, p. 42). A retrospective cohort study of women in their 70s and 80s found that those who had been teenage mothers had a higher risk of death than women who bore children after age 20, and they also had a higher prevalence of heart and lung disease, and cancer (Henretta, 2007). Also, those who choose to end their pregnancies by abortion may encounter other physical and psychosocial complications.

By 18 years of age, 7 of 10 males and 6 of 10 females have had sexual intercourse. As such, it would behoove U.S. society to provide effective sexuality education. Two thirds of U.S. school districts report that they have policies in place to provide sexuality education to students, and 86% of those

require abstinence education—35% require abstinence-only education. Ninety percent of teachers report that students should be given instruction on contraception; however, 25% are prohibited from including contraception in their lessons. No conclusive evidence suggests that abstinence-only sexuality education delays sexual activity in adolescents, but research shows that it may discourage the use of contraception among sexually active teens. More comprehensive sexuality education programs (e.g., teaching about both abstinence and contraception) have delayed sexual activity in adolescents, decreased the number of sexual partners, and—when adolescents are sexually active—increased the use of contraceptives (Alan Guttmacher Institute, 2002). Teaching about contraception did not increase the risk of adolescent sexual activity or STDs, but it did decrease the risk of pregnancy in a study of abstinence-only versus comprehensive sexual education programs in a national survey of adolescents (Kohler, Manhart, & Lafferty, 2008).

Pregnancy prevention programs can be effective in reducing teen pregnancy and birth rates, as well as in reducing the number of second births to teenage mothers. A South Carolina program, The Second Chance Club, revealed a lower repeat teen birth rate as a positive result (Key, O'Rourke, Judy, & McKinnon 2005). In Maryland, a home visiting program for adolescent mothers improved parenting scores and school continuation rates, although it did not reduce rates of depression or repeat pregnancies (Barnet, Liu, DeVoe, Alperovitz-Bichell, & Duggan, 2007). A small study of mostly African American 14- to 19-year-old abstinent girls found four themes: self-respect (I am worth it), potential negative consequences of sex (Hold on, there's a catch), impact of mothers (Mama says . . . think before you let it go), and influence of boys/other peers (Boys will be boys). Building on self-esteem and family influences, researchers cited the need to develop interventions to help adolescents maintain abstinence and delay of sexual activity (Morrison-Beedy, Carey, Cote-Arsenault, Seibold-Simpson, & Robinson, 2008).

Primary care providers often miss opportunities to provide counseling on prevention of pregnancy, HIV, and STDs (Burstein, Lowry, Klein, & Santelli, 2003; Ellen, Lane, & McCright, 2000). Nurses can provide information and counseling on emergency contraception and collaborate with schools to promote effective pregnancy prevention programs (Haynes, 2007; Key et al., 2005). It is important for community health nurses to provide education and health counseling on these subjects.

## Sexually Transmitted Diseases

More than 20 diseases can be transmitted sexually; only the most common are reportable. Each year, about half of the STD cases occur among the 15- to 24-year-old age group, even though they represent only 25% of the population of sexually active individuals. The annual cost of STD cases in the United States averages \$11 to \$17 billion (Grassia, 2007). These diseases include syphilis, gonorrhea, chlamydia, human papillomavirus (HPV), and herpes simplex virus. Approximately 30 of the 100 known types of HPV strains are sexually transmitted; some of these are related to cervical cancer and others lead to genital warts. Gardasil, a vaccine effective against some forms of HPV-related disease, can be administered in three doses to 11- to 12-year-old girls (Grassia, 2007).

Chlamydia, gonorrhea, and syphilis are other STDs found in the adolescent population. It is estimated that the prevalence rate for chlamydia in Black women is 13.95%; the overall prevalence is estimated at just over 4% (Miller et al., 2004). The highest age-specific gonorrhea rate among women occurred in the 15- to 19-year-old age group (CDC, 2006b). The rates of syphilis have increased between 2004 and 2006, and gonorrhea rates for 15- to 19-year-old men increased over 8% between 2005 and 2006 (CDC, 2006b). Compared with adults, adolescents (10 to 19 years) and young adults (20 to 24 years) are at increased risk for acquiring STDs/STIs. Reasons for this may include a greater likelihood of multiple sex partners, unprotected intercourse, and selection of higher-risk partners. Barriers to improvement include lack of health insurance and transportation, concerns about confidentiality, and lack of quality STD prevention services or clinics targeted to younger age groups (CDC, 2006b). Adolescent girls also have a physiologically amplified susceptibility to chlamydia infection because of increased cervical ectopy (CDC, 2006b). Serious complications from STDs include pelvic inflammatory disease (PID), sterility, increased risk of cancers of the reproductive system, and, with syphilis, blindness, mental illness, and death. There are also complications for the unborn children of those infected with STDs (Illinois Department of Public Health [IDPH], 2003). Medication-resistant strains of gonorrhea are spreading, especially in parts of Europe, the Middle East, and Asia, as well as in California and Hawaii (Grassia, 2007).

Even though death rates from HIV/AIDS have dramatically fallen, new HIV infections reported annually do not reflect the same steep decline. New medications are thought to be the cause of the declining death rate, whereas new cases are increasing within adolescent and young adult populations. Adolescents who were perinatally infected during the 1980s and 1990s demonstrate generational HIV. "Most pediatric HIV cases occur in 15- to 14-year-olds, and there have been no reductions in the last four years" (Grassia, 2007). New HIV infections among adolescent girls are equal to or greater than the number of cases reported in adolescent males. Teenage girls more often acquire infection through heterosexual encounters, whereas male cases are more often attributed to homosexual activity (National Institutes of Health, 2006). Sixty percent of female adolescents living with HIV are Black (Child Health USA, 2004).

A study completed at Carnegie Mellon University noted that most sexually active adolescent girls know little about STDs, becoming familiar with them only after being diagnosed with one (2006). Researchers found that, except in the case of HIV/AIDS, adolescent girls surveyed were unable to list basic facts about eight common STDs. Because schools generally focus on HIV/AIDS education, the researchers posited that other STD education was lacking. An earlier study found that girls who watched an interactive CD on sexual education were more likely than those not viewing the CD to become abstinent (2006). Effective methods of preventing STDs and HIV/AIDS include reduction of sexual activity among adolescents. This can be done by promoting abstinence or delaying sexual initiation, as well as by fostering safer-sex messages that promote the use of condoms. As noted earlier, sex education is effective at both delaying the onset of sexual activity and increasing the use of contraception in adolescents who are already sexually active. It is also effective in increasing safer-sex practices, knowledge of birth control method efficacy, and overall

sexual knowledge (Lindau, Tetteh, Kasza, & Gilliam, 2008). A comprehensive review of 73 studies of programs to reduce adolescent sexual risk taking, unintended pregnancy, and STDs revealed strong evidence that such programs can delay sex, increase condom or contraceptive use, and reduce teen pregnancies. The most effective programs included specific sex/HIV education curricula and certain intensive multimodal youth development programs (Kirby, 2002).

## Acne

Between 79% and 95% of adolescents in Western societies have acne, leading some researchers to suspect environmental influences (Cordain et al., 2002). Acne is generally recognized as a genetic disease; three of four children whose mother or father had acne as a teenager will also have it (National Institute of Arthritis and Musculoskeletal and Skin Diseases [NIAMS], 2004). Acne begins during puberty (10 to 12 years of age) with the increase in circulating male hormones that stimulate sebaceous glands in the skin. The excess sebum (oil) causes irritation in the pores and results in a buildup of cells, leading to whiteheads. Open pores are known as blackheads. A red and inflamed pustule can develop or, in serious cases of acne, cysts or nodules can form. This can lead to pitting and scarring if not treated.

It is now known that greasy foods and chocolate do not cause acne but may be aggravating factors (along with stress, environmental irritants, and certain cosmetics) in susceptible adolescents. Common treatment regimens include skin cleansers, peelers, and medications to decrease sebaceous gland activity. Girls are often prescribed oral contraceptives, which have been shown to be effective in treating acne (Rosen, Breikopf, & Nagamani, 2003). Benzoyl peroxide is used to kill bacteria on the skin and in the pores. It may be sold over-the-counter (OTC) or by prescription. Other OTC medications include salicylic acid and resorcinol. Retin A (a topical vitamin A ointment), glycolic acid, and alpha-hydroxy acids help to peel the impacted cells from the pores. Isotretinoin (Accutane) reduces the size and activity of sebaceous glands but can cause liver or kidney dysfunction. Because of an extremely high risk of birth defects, female adolescents taking Accutane are prescribed oral contraceptives (NIAMS, 2004). Oral antibiotics may be prescribed, and corticosteroids may be injected directly into the comedones. New topical therapies include dapsone gel (Aczone) and clindamycin phosphate/tretinoin combination gel (Ziana) (Del Rosso, 2007).

The best preventive measures are keeping the skin clean, eating a balanced diet that includes fresh fruits and vegetables, drinking lots of water, and getting adequate sleep. It is important for male adolescents to shave carefully and for all teens with acne to avoid touching their faces or picking at their blemishes. Adolescents with severe acne may need to be referred to dermatologists who specialize in this skin disorder.

## Poor Nutrition and Eating Disorders

Poor nutrition and obesity are not uncommon among adolescents, whose diets often consist of snacks with limited nutritional value interspersed among unhealthful meals. Increased fast food consumption has been tied to the increase in obesity in the United States (Brinkley, Eates, & Jekanowski, 2000). A national study found that adolescents

and young adults got more of their energy intake from restaurants and fast food outlets than from home, with increased consumption of pizza, cheeseburgers, and salty snacks (Nielsen, Siega-Riz, & Popkin, 2002). The eating behavior of adolescents is influenced by many things, among them psychosocial factors, family and peers, availability of fast food, and mass media marketing (Story, Neumark-Sztainer, & French, 2002). Girls are more at risk for problems with nutrition for several reasons: they tend to diet inappropriately, to have more finicky eating habits, and to be less physically active than teenage boys. Boys typically eat large quantities of food, which increases the likelihood of obtaining adequate nutrients, and they also tend to be more physically active than girls. A large study of high school students found that “consumption of fruits and vegetables and a healthful breakfast and lunch related both to family and individual factors”; as family situations deteriorated, the percentage of adolescents who ate a healthful breakfast or lunch decreased (Young & Fors, 2001, p. 487).

Issues with body image and control are at the heart of anorexia nervosa and bulimia nervosa, common problems for adolescent girls. **Anorexia nervosa** is an eating disorder with an emotional etiology that is characterized by body image disturbance (i.e., girls see themselves as fat although they may be extremely thin), an intense fear of becoming fat or gaining weight, and refusal to maintain adequate body weight (i.e., BMI of 18 or greater). **Bulimia** is an eating disorder characterized by recurrent episodes of binge eating with repeated compensatory mechanisms to prevent weight gain, such as vomiting (purging type) and fasting or exercise (nonpurging type).

**Binge eating**, also a recognized eating disorder, involves recurrent episodes of binge eating without fasting, self-induced vomiting, or other compensatory measures (Bulik, Sullivan, & Kendler, 2000). Self-esteem, depressive symptoms, and emotional eating are very sensitive predictors of binge eating. Low levels of support from peers can also be linked to binge eating, and binge eating is associated with an increased risk of becoming overweight or obese (Stice, 2002).

A woman’s lifetime risk of developing a bulimic syndrome is estimated to be 8%; the estimated risk of developing an anorexic syndrome is 3% (Patton, Selzer, Coffey, Carlin, & Wolfe, 2000). These diseases have emotional causes that pose complex challenges to treatment. Nutrition education, psychological counseling, and cognitive-behavioral techniques that teach clients how to control stimuli, substitute alternative behaviors, and use positive visualization are all part of treatment; development of a support network is also important. Self-concept is often distorted and self-esteem is low; therefore, activities are initiated to improve the adolescents’ feelings about themselves and to bolster their coping mechanisms. Medications (e.g., antidepressants) have been helpful in treating some adolescents with eating disorders (Sharma, 2001). In a sample of adolescents enrolled in a treatment program for bulimia nervosa, 62% had a comorbid diagnosis—generally a major mood disorder. Over 65% had consumed alcohol and 30% had used an illicit drug (Fisher & le Grange, 2007).

The key to prevention may be tied to girls’ perceptions of their appearance and education about the risks of dieting. One study indicated that adolescent girls who were severe dieters were 18 times more likely to develop an eating disorder than those who did not diet. Even moderate dieters

were at risk; they were five times more likely to develop an eating disorder. Psychiatric morbidity was also a factor; it increased risk sevenfold. Exercise is seen as a more viable alternative than extreme dieting for adolescents who want to control their weight (Patton et al., 2000). Girls who engage in dieting and unhealthy methods of weight control in middle school and high school are three times more likely to become overweight 5 years later than girls who did not diet. They were also found to be at higher risk for using laxatives, diuretics, diet pills, and engaging in binge eating and self-induced vomiting (American Dietetic Association, 2006).

## HEALTH SERVICES FOR SCHOOL-AGE CHILDREN AND ADOLESCENTS

A number of programs serve the health needs of school-age children and adolescents. Community health nurses play a major and vital role in delivering these services. Such programs fall into three categories that approximate the three practice priorities of community health nursing practice: illness prevention, health protection, and health promotion.

### Preventive Health Programs

Among programs to prevent physical illness and other health problems are immunizations and tuberculosis (TB) testing, as well as school- and community-based education and support programs. Private and public counseling programs and other social services are also geared to promote health and prevent illness.

### Immunizations and TB Testing

Low immunization levels for adolescents, particularly among the poor, and increased disease rates signal the need for constant surveillance, outreach programs, and better documentation and educational efforts (Vandermeulen et al., 2008). Community health nurses are deeply involved in each of these preventive activities. Health departments and schools often work collaboratively to provide immunization services. Compulsory immunization laws are helpful in carrying out these preventive services, but recent survey results reveal that the *Healthy People 2010* targets for adolescent vaccination coverage have yet to be met (Jain & Stokley, 2007).

In the recent past, adolescents were only given “catch up” vaccinations (those missed in childhood), except for a tetanus/diphtheria booster. Now, recommended immunizations include tetanus/diphtheria/acellular pertussis (Tdap), meningococcal vaccine (MCV4), pneumococcal polysaccharide vaccine (PPV), both hepatitis A and B, influenza vaccine, and HPV vaccine for girls—along with any missed vaccines (e.g., polio, varicella) (see Fig. 22.2). Often, school nurses and community health nurses work with nurse volunteers to provide immunization clinics at elementary and middle schools; these are convenient for adolescents and their parents (Mark, Conklin, & Wolfe, 2001).

Although immunization clinics may improve rates of compliance, it is recommended that 11- to 12-year-olds be scheduled for routine health care visits to their physicians, so that immunizations can be administered, checked, and updated (Jain & Stokley, 2007). Adolescents who have not had chickenpox and have not received prior vaccination should be given the varicella virus vaccine. In a recent national survey of adolescents, 69% reported a history of

chickenpox, and over 65% of those without a disease history reported receiving the vaccine (Jain & Stokley, 2007). Only 60.1% of adolescents had Tdap coverage, and MCV4 vaccination was only complete in less than 12% of adolescents surveyed (Jain & Stokley, 2007).

In addition to immunizations required for school entry, many states or local school districts now require TB skin tests for school-age children and adolescents. Children have a much higher risk of disease progression than do adults. Annual testing is often recommended for children and adolescents from high-risk populations (Pediatric Tuberculosis Collaborative Group, 2004). Targeted TB skin testing identifies adolescents and children at risk for latent TB who could benefit from treatment to prevent progression of the disease. The following questions should be asked to determine risk:

- ◆ Was the child born outside the United States? If so, where? (Asian, African, Latin American, and Eastern European births require TB skin testing.)
- ◆ Has the child traveled outside the United States? If so, where and with whom? (If child stayed with friends/family in Latin America, Asia, Africa, or Eastern Europe for 1 week or more, TB skin testing should occur.)
- ◆ Has the child been exposed to anyone with TB? Who? Did contact person have active or latent TB? When was child exposed and what was the nature of contact? (Notify the local health department if the child had contact with person having TB.)
- ◆ Does the child have close contact with a person who had a positive TB skin test? (Other questions may relate to contact with persons who have HIV, have been in jail or shelters, or are injection drug users; or if the child ingested raw milk/products? Does the child live in a household with member(s) who were born or traveled outside the United States?)

Positive skin tests for children and adolescents have three cut-off points (Pediatric Tuberculosis Collaborative Group, 2004):

- ◆ Induration greater than or equal to 5 mm (if child has close contact with known or suspected TB, if child or adolescent is suspected of having TB disease, if child or adolescent’s immune system is suppressed)
- ◆ Induration greater than or equal to 10 mm (if child or adolescent is at an increased risk of disseminated disease or if child or adolescent has been exposed to cases of TB disease)
- ◆ Induration greater than or equal to 15 mm (if child is 4 years old or older and has no known risk factors)

### Education and Social Services

The health education of school-age children and adolescents includes a wide variety of approaches and can range from the basics of hand-washing for elementary school students (Guinan, McGuckin, & Ali, 2002; White et al., 2001) to hearing conservation for students who like to listen to loud music (Folmer, Griest, & Martin, 2002).

Parental support services are commonly available through many public and private agencies, including churches. These services can have long-range effects on the health of

school-age children, because emotionally healthy parents and stable families offer a healthful environment and support system for children and can facilitate their progress in school. In most states, community health nurses provide teaching and counseling services to parents in their homes and in groups. School nurses, school mental health counselors, and school psychologists also organize parent support groups in local schools. This is particularly important during periods of transition (e.g., from elementary to middle school, from middle to high school). Discussing parenting concerns and increasing parents' understanding of normal child growth and development helps to allay fears and prevent problems. Through such efforts, family violence and abuse can be averted. Reduction in rates of divorce and the attendant consequences may also be a benefit of strengthening family resilience.

Family planning programs, often stationed strategically in inner cities, near schools, or in school-based clinics, provide birth control information and counseling to young people. In some communities, the school-based clinic dispenses condoms. In most states, adolescents have the right to consent for sexual and reproductive health care without parental permission (English, 2007). Community health nurses, in collaboration with an interdisciplinary team, are usually the primary care providers in these programs. Their major goals are to prevent teenage pregnancy, educate teens about reproduction and contraception, and encourage responsible sexual behavior. Teaching parents about adolescent sexuality is important, as parents can influence their child's sexual behavior (Morrison-Beedy et al., 2008; Rupp & Rosenthal, 2007).

Providing STD services and HIV/AIDS education can be a daunting task. Many young people with STDs are often afraid or embarrassed to seek help, and others who have been exposed to the HIV virus may not know that they are infected (Carnegie Mellon University, 2006; Ellen, Lane, & McCright, 2000; Grassia, 2007). Gay and bisexual young men are particularly at risk, as are youth who have been sexually abused (Godin et al., 2003; Saewyc et al., 2006). Furthermore, community health professionals receive very little training in these areas and may be uncomfortable and judgmental in their approaches. Quality services that are easily accessible, provide anonymity for clients, are age-appropriate or targeted to adolescents, and are staffed with health care providers who exhibit nonjudgmental attitudes are better able to attract young people who need help. Some argue that drastic changes in the provision of services to young people—achievable through working to ensure economic development, privatization of prevention activities, and employment of innovative models and strategies—are needed to effect change (Johnson, Carey, Marsh, Levin, & Scott-Sheldon, 2003; Rotheram-Borus, 2000).

Vulnerable groups, particularly minority youth, inner-city residents, incarcerated youth, and homosexuals, are reached through STD clinics, HIV testing sites in clinics and health departments, family planning clinics, private health care providers, schools, juvenile rehabilitation facilities, and employers (Godin et al., 2003). Community health nurses are available in most of these settings; they are usually the professionals who deal most directly with these clients. Improved public awareness and education, screening of high-risk groups, appropriate treatment of infected people, and identification and treatment of sexual partners can reduce the threat of STDs.

Physicians are also concerned about the health risks common to adolescents. Pediatricians, especially, have instituted

better history taking, more consistent monitoring, and anticipatory guidance for risks from unintentional and intentional injury, substance abuse, and sexual activity (Boekeloo et al., 2003; Pbert et al., 2003). Community health nurses need to collaborate with local physicians and other community care providers to ensure that adequate education and social services are available to school-age children and adolescents.

Educational efforts to prevent risk-taking behaviors that can lead to adverse health conditions have been effective. An examination of 44 studies that used interventions to reduce HIV in adolescents over a 15-year period revealed that reductions in sexual risk were greater for subjects who received HIV risk-reduction intervention than for those in comparison groups. The increased use of condoms, condom use negotiation skills, and sexual partner communication, along with delaying the onset of sexual activity and decreasing the number of sexual partners, were the outcomes of intensive behavioral interventions (Johnson et al., 2003). Peer educators are also effective in promoting personal responsibility and safer sexual behaviors, as well as in enhancing leadership roles and positive self-image (Fongkaew, Fongkaew, & Suchaxaya, 2007; Merakou & Kourea-Kremastinou, 2006).

Peer education can also be used to influence other risk behaviors. School-based educational programs have also been effective (Mahat, Scoloveno, Ruales, & Scoloveno, 2006). A drug prevention curriculum for eighth graders was found to decrease misuse of alcohol, marijuana, and tobacco in a randomized trial. At-risk ninth graders also participated in the curriculum and had five booster lessons; positive results were noted among ninth grade girls (Ellickson, McCaffrey, & St. Clair, 2007). The effectiveness of a universal drug abuse prevention program (e.g., drug refusal skills, self-management, general social skills) was studied in 29 inner-city middle schools. About one-fifth of the subjects were considered to be at high risk for substance abuse. Participating high-risk youth reported less drinking, smoking, inhalant use, and polydrug use at the 1-year posttest than did high-risk youth in the control group (Griffin et al., 2003). In addition to school-based education, peer leadership, and parental education and involvement, community-wide task forces have been developed to lobby for local legislation and to strengthen community-school ties.

Media campaigns for tobacco use prevention have been successful, as have some school-based education programs (Schar, Gutierrez, Murphy-Hoefler, & Nelson, 2006; Tingle, DeSimone, & Covington, 2003). Community health nurses often work in conjunction with law enforcement officials, school district administrators, and other community agencies to ensure compliance with local regulations and prevent or delay the use of tobacco products. Information on smoking cessation and resources to help prevent tobacco use by children and adolescents is available through the Foundation for a Smokefree America (for more information, see the Internet Resources section at the end of this chapter).

## Health Protection Programs

### Safety and Injury Prevention

Accident- and injury-control programs serve a critical role in protecting the lives of school-age children and adolescents. They are cost-effective: Seat belt laws, child safety seats, and helmet laws have saved millions of dollars in medical care (Child Safety Network, 2005). Efforts to prevent

motor vehicle accidents, a major cause of death, include driver education programs, better highway construction, improved motor vehicle design and safety features, and continuing research into what causes various types of crashes. Injury prevention and reduction have been addressed through strategies such as state laws requiring the use of safety restraints, installation of driver and front passenger airbags, substitution of other modes of travel (air, rail, or bus), lower speed limits, stricter enforcement of drunk driving laws, graduated drivers licenses for teenagers, safer automobile design, and helmets for motorcyclists, bicycle riders, and skaters.

Students Against Drunk Driving (SADD) and Friday Night Live activities can promote more responsible driving habits among teens. Communities can also work with law enforcement officials to ensure compliance with mandatory seat belt laws and to promote safe speeds and appropriate driving behaviors near schools. In 1999, the public health efforts to improve motor-vehicle safety were noted as a “20th century public health achievement” by the CDC because of the 90% decline in death rates between 1925 and 1997 despite the tenfold increase in miles traveled.

Safety programs also seek to protect school-age children and adolescents from the hazards of poisonings, ingestion of prescription or OTC drugs, product-related accidents (unsafe toys, bicycles, skateboards, skates, play ground equipment, and furniture), and recreational accidents, including drowning and sports-related injuries. Safety services assume various forms. Poison control centers in many localities offer information and emergency assistance, and have been shown to save \$290 per \$43 of call cost (Child Safety Network, 2005). Whereas the Federal Consumer Product Safety Commission monitors the safety of products, education programs in schools or through local fire or police departments teach school-age children about bicycle and water safety, fire dangers, and hazards related to poisoning. Generally, the community health nurse can educate families to recognize potentially hazardous situations and encourage efforts to eliminate them. Working with school nurses and school district officials to reduce playground hazards can contribute to the reduction of school-related injuries.

Environmental hazards and other dangers await school-age children and adolescents in the workforce. Between 1992 and 2000, 67 adolescent workers (under age 18) died, and 77,000 teen workers were treated in emergency rooms for work-related injuries in 1998. Because generally only one-third of work injuries are treated in the emergency room, it is believed that the number of teens experiencing work-related injuries is closer to 230,000. Close to 40% of teens injured on the job felt that they were “permanently injured in some way” (National Institute of Occupational Safety & Health [NIOSH], 2003, p. 2). One report states that the highest number of work-related injuries to youths younger than age 18 occurred in eating establishments and food stores (Mardis & Pratt, 2003), although the federal government lists agricultural work and retail trades as the location of most adolescent worker deaths. About 30% of teen worker fatal injuries occur in family businesses (NIOSH, 2003). Deaths caused by exposure to toxic vapors, electrocution, and work-related motor vehicle accidents are not uncommon. Community health nurses can join with occupational health nurses and school nurses to teach parents and children about the dangers and

risks inherent in the workplace, and they can work with local employers to ensure safe working conditions and reasonable hours of employment that do not interfere with school. Adolescent workers, depending upon social class and income backgrounds, may accrue either benefits or harm to their future education and employment because of high school jobs (Staff & Mortimer, 2008).

### ***Infectious Diseases***

Programs that protect school-age children and adolescents against infectious diseases encompass such efforts as closing swimming pools that have unsafe bacteria counts, conducting immunization campaigns in conjunction with influenza or measles outbreaks, and working with hospital pediatric units to reduce the incidence and threat of iatrogenic disease. Prevention of community-acquired MRSA is a new challenge for public schools, and PHNs may work with school nurses or others to provide educational programs covering a variety of infectious diseases (Alex & Letizia, 2007). Epidemiologic investigations, especially with school sports teams, may be necessary to determine the cause of outbreaks (Nguyen, Mascola, & Bancroft, 2005).

### ***Child Protective Services***

In 1974, the National Center for Child Abuse and Neglect was established as a result of the Child Abuse Prevention and Treatment Act. The center collects and analyzes information on child abuse and neglect, serves as an information clearinghouse, publishes educational materials on the subject, offers technical assistance, and conducts research into the problem (Children’s Bureau, 2006).

An estimated 1 million to 2.5 million cases of child abuse and neglect are reported annually in the U.S. (American Academy of Pediatrics [AAP], 2007; Administration for Children and Families [ACF], 2006). Most victims suffered from neglect (64.1%), but approximately 16% were physically abused, almost 9% were sexually abused, 6.6% were psychologically abused, and more than 2% were medically neglected (ACF, 2006). In 2005, almost 1,500 children died from injury or neglect—and it is estimated that 50% to 60% of child abuse/neglect deaths are unrecorded. Fathers or male caretakers are most often responsible for physical abuse fatalities; mothers are more often associated with deaths stemming from neglect (Child Welfare Information Gateway, 2008). The estimated actual cost related to child abuse in 2007 was \$103.8 billion, but the untold suffering and loss are incalculable (Wang & Holton, 2007). Consequences for affected children include lower self-esteem, depression, suicide, self-abuse, substance abuse, eating disorders, less empathy for others, antisocial behavior, delinquency, aggression, violence, low academic achievement, and sexual maladjustment (Dake, Price, & Murnan, 2003; Stuewig & McCloskey, 2005). Long-term emotional, social, cognitive, and physical consequences often follow abused children into adolescence and adulthood—posttraumatic stress disorder, poor attachment and problems with trust, difficulties with language development and abstract reasoning, high-risk health behaviors, and abusive or violent behavior (Wang & Holton, 2007).

Neglectful families are generally profiled as having high levels of adult problems, reports of stressful life events,

and a higher incidence of maternal depression, and these families often live at or below the poverty level. One study found that those mothers who were more highly educated, had fewer stressful life events, and had more positive encounters with social services generally were better able to provide physically for their children (Casady & Lee, 2002). Children and adolescents who are raised in blended homes (where one parent is not their biologic parent) are at greater risk of physical or sexual abuse (McRee, 2008). Adolescents who run away, act out at school, commit illegal acts, or engage in high-risk behaviors (e.g., drug abuse, sexual promiscuity) may be exhibiting externalizing behaviors in response to years of abuse and neglect. Young adults who have been arrested for general or violent offenses and those who use illicit drugs are more likely to have been abused or neglected in adolescence (Smith, Ireland, & Thornberry, 2005). Verbal abuse of a child by parents is a predictor of adolescent dating violence, and paternal physical abuse can predict sexual victimization as an adolescent (Rich, Gidycz, Warkentin, Lo, & Weiland, 2005).

Services to protect children from abuse are not as well developed or as effective as safety and injury-protection programs, for a variety of reasons. Most child abuse occurs in the home, so only the most blatant situations become evident to outsiders (Spivey et al., 2008). Child social workers are also often unable to assess recurrent risk of child maltreatment, even when families continue in their caseloads (Dorsey, Mustillo, Farmer, & Elbogen, 2008). A wish to avoid legal involvement keeps others from reporting suspected cases, although this attitude is changing among professionals who work with children and other community members. Teachers (16.5%), lawyers and police officers (15.8%), and social services staff (10%) were the three highest reporters of child abuse in 2006; other mandated reporters include medical staff, mental health workers, day care workers, and foster care providers (Children's Bureau, 2006).

In some areas, community health nurses are working together with social workers, mental health workers, and substance abuse counselors as part of a team that provides services to families. Improved training of mandated reporters, such as teachers and physicians, has led to better reporting of abuse; as professionals and the public become more aware of the problem, an increase in reporting has occurred. Child abuse prevention education programs can be found in many public health departments and through some school districts as a primary preventive intervention. Primary prevention of child maltreatment can also occur through home visiting programs utilizing public health nurses. These visits can also help to connect high-risk families to the community and promote better child outcomes (Russell, Britner, & Woolard, 2007).

Families often have many time constraints that can lead to difficulties in providing adequate social support and sufficient opportunities for teaching children socialization skills and appropriate methods of coping with stress. Family stressors can cause parental conflict and lead to disruptions in parent-child relationships. Outcomes for children are worse when these situations occur early in childhood and continue for longer periods of time (Schor & American Academy of Pediatrics Task Force on the Family, 2003). Programs that target at-risk families, especially adolescent mothers and young couples prone to partner violence or harsh parenting practices, may help to prevent later child

abuse (Moore & Florsheim, 2008). PHNs, school nurses, and other nurses working in the community setting must be vigilant for signs of family stress, harsh parenting practices, family violence, and other risk factors for child abuse and neglect and provide resources and respite as needed (Taylor, Baldwin, & Spencer, 2008).

Child death review teams are found at state and local levels and, through their work, improvements in interagency collaboration, procurement of more comprehensive data sets, and identification of gaps in child protective services have led to better services for families and prosecution of abusers, along with improvements in child protective and other community supportive services (Child Welfare Information Gateway, 2008).

### **Oral Hygiene and Dental Care**

School-based programs that provide fluoride rinses and dental sealants and promote tooth brushing and nutrition education for dental health can be found in most areas of the country. Fluoridation of community water supplies is considered the most effective, safe, and low-cost means of protecting the dental health of children and adolescents. Fluoridation of drinking water, school-provided fluoride rinse or gel, and dental sealant programs are cost-effective and can reduce dental caries (Lam, 2008; Levy, 2003; Marinho et al., 2003; Sinclair & Edelstein, 2005).

Fluoride makes teeth less susceptible to decay by increasing the resistance of tooth enamel to the bacterially produced acid in the mouth. Since 1945, public water supplies have been fluoridated at relatively low cost to communities. Water fluoridation has been ranked as one of the 10 greatest public health achievements of the 20th century (Division of Oral Health, 2008).

Some individuals and groups oppose fluoridation because of possible adverse effects (including fluorosis, which can cause mottling of tooth enamel). Research results have been mixed, although most studies have supported the low risk of water fluoridation and the benefits of decreased caries. A longitudinal study found that adults (ages 18 to 45) who grew up with fluoridation and a greater emphasis on preventive dentistry had significantly reduced dental caries, compared with the previous cohort studied (Brown, Wall, & Lazar, 2002). In the United States, because of children's potential for multiple exposures to fluoride through drinking water, processed foods and beverages, toothpaste, gels, and rinses, physicians may prescribe lower doses of fluoride supplements or deem that they are not needed (American Dietetic Association, 2008). In addition to regular dental care, good nutrition, and proper oral hygiene, community health nurses can promote public water fluoridation as an important program for protecting children's dental health.

### **Health Promotion Programs: Nutrition and Exercise**

Nutrition and weight-control programs form another important set of health promotion services. Children need to learn sound dietary habits early in life to establish healthy lifelong patterns. Being overweight during childhood or adolescence may persist into adulthood and may increase the risk for some chronic diseases later in life (Institute of Medicine,

2006). Some school programs teach and provide good nutrition and encourage eating patterns that prevent obesity (Baranowski et al., 2003; Food & Nutrition Service, 2008). A number of weight-control programs for overweight children and adolescents are available through schools, health departments, community health centers, health maintenance organizations, and private groups.

Children and adolescents are particularly vulnerable to media and peer pressures with regard to their food choices. Because of increased rates of childhood obesity and a greater awareness of the need for better nutrition in adolescence, legislative support to limit soft drink sales at public schools is growing (Fletcher, 2003). Parents and children are becoming more aware of the need to cut consumption of saturated fat, salt, sugar, and overprocessed foods in order to feel and look better. The community health nurse, through nutrition education and reinforcement of positive practices, plays a significant role in promoting the health of children.

## Summary

Physical health and illness, developmental issues, schooling, behaviors, and emotional and mental problems are major concerns for all Americans and especially for U.S. school-age and adolescent populations. Children and adolescents are important population groups to community health nurses, because their physical and emotional health can affect not only their academic achievement but also the future of society. This population group particularly needs the guidance and direction that can be provided by community health nurses. Among the health problems that affect learning and achievement in school-age children are chronic diseases, such as asthma, autism, and diabetes; behavioral and learning problems, such as ADHD and learning and other disabilities; poverty; injuries; communicable diseases, such as measles and mumps; and dietary problems involving inadequate nutrition, obesity, inactivity, and poor dental health.

One nationwide measure to prevent communicable diseases is the federally and state-mandated immunization program for school-age children and adolescents. Among vaccines given on schedule throughout childhood are those that prevent polio, smallpox, diphtheria, tetanus, typhoid, and many other diseases, so that these diseases will not be passed from one person to another in epidemic proportion.

Mortality rates for children and adolescents have decreased dramatically since the early 1900s, but morbidity rates remain high. Children and adolescents are vulnerable to many illnesses, injuries, and emotional problems, often as a result of a complex and stressful environment. Violence against children and deaths due to homicide occur in the United States at alarming rates. Unintentional injuries, suicide, and homicide are the leading threats to life and health for adolescents. Other health problems include alcohol and drug abuse, unplanned pregnancies, STDs and HIV/AIDS, and poor nutrition. All of these problems create major challenges for the community health nurse who seeks to prevent illness and injury among children and adolescents and to promote their health.

Among the objectives for children and adolescents proposed by *Healthy People 2010*, some key goals are reduction of alcohol-related unintentional injuries; declines in violent behaviors, suicide, and mental health issues; and more responsible reproductive health behaviors. Barriers to

achieving these goals vary. Some include economic inequities; lack of sufficient immunization, educational, and community-supported health programs; and the presence of risk behaviors typical among developing youth. Community health nurses play a large role in promoting the health of young people, their families, and communities through education programs and by developing strategies to support healthy growth and development and prevent risky behaviors that lead to injury, teen pregnancy, and sometimes death. Health services for children and adolescents span three categories: prevention, health protection, and health promotion. The community health nurse plays a vital role in each. Preventive services may include immunization programs, parental support services, family planning programs, services for those with STDs, and alcohol and drug abuse prevention programs. Health protection services often include accident and injury control, programs to reduce environmental hazards and control infectious diseases, and services to protect children and adolescents from child abuse and neglect. Health promotion services may include programs in nutrition and weight control, along with HIV/AIDS prevention, and smoking, alcohol, and drug abuse education. Community health nurses are integral to the health and well-being of children and adolescents, through their work with families, schools, and other community agencies. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. You are a community health nurse assigned to work at a school. You learn that more than 20% of the students in this school district are being treated with Ritalin, Concerta, Adderall, or some other medication for treating ADHD. What issues should you consider in determining whether these medications are being appropriately prescribed?
2. What is the major cause of death among school-age children? What community-wide interventions could be initiated to prevent these deaths? Select one intervention and describe how you and a group of community health professionals might develop this preventive measure.
3. A 14-year-old girl from a middle-class family and a 14-year-old girl from a poor family both come to the health department clinic where you work. The girls have similar symptoms that possibly indicate gonorrhea. Would your assessment and intervention be the same for the two girls? What are your values and attitudes toward people with diseases that are sexually transmitted? Does social class, race, age, or sex make any difference in how you feel about them? What is one action the community health nurse can take to prevent such diseases in this population group?
4. Discuss possible methods of doing nutritional assessments in school-age children and adolescents. What programs could be instituted to encourage healthier diets and increased exercise? What other factors might need to be considered? How could you, as a community health nurse, work with schools and

parents to increase physical activity and improve nutrition for school-age children and adolescents?

5. A new elementary school to which you have been assigned has repeated outbreaks of head lice and very limited access to health care. Using the Internet, research causes for recurrent head lice infestations and effective over-the-counter treatment products. Are head lice most often found seasonally? Discuss possible education programs you might implement or other innovative methods of treatment and control you might be able to institute.

# Adult Women and Men

## LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Identify key demographic characteristics of women and men throughout the adult lifespan.
- ◆ Provide a health profile of adult women and men living in the United States.
- ◆ Discuss the major chronic illnesses found in adult women and men in the United States.
- ◆ Compare and contrast the manifestations of chronic illnesses in adult women and men.
- ◆ Identify desirable primary, secondary, and tertiary health promotion activities designed to improve the health of women and men.
- ◆ Describe the role of the community health nurse in promoting the health of adult women and men across the lifespan.

*“Male and female represent the two sides of the great radical dualism. But in fact they are perpetually passing into one another. Fluid hardens to solid, solid rushes to fluid. There is no wholly masculine man, no purely feminine woman.”*

—Margaret Fuller (1810–1850), *Woman in the Nineteenth Century*, 1845

## KEY TERMS

Adult  
 Anorexia nervosa  
 Binge eating  
 Bisexual  
 Bulimia nervosa  
 Cancer  
 Cardiovascular disease  
 Chronic fatigue and immune dysfunction syndrome (CFIDS)  
 Chronic lower respiratory disease  
 Diabetes mellitus  
 Erectile dysfunction  
 Gay  
 Health disparities  
 Health literacy  
 Life expectancy  
 Menopause  
 Obesity  
 Prostate  
 Substance use  
 Transgender  
 Unintentional injuries

The term *adult* has many different meanings in society. To children, an adult is anyone in authority, including a 14-year-old babysitter. As people age, they tend to redefine the term upward. It is not unusual, for example, to hear an elderly person describe a couple in their mid-30s as “kids.” The United States Criminal Justice System distinguishes between adults and juveniles for purposes of delimiting types of crimes and possibilities for punishment, and labor legislation provides different protections for children than for adult workers. Even hospitals and health care systems vary somewhat as to the ages at which they distinguish pediatric and geriatric clients from middle-aged adults.

How would you characterize an adult? Does your definition rest solely on age, or is it influenced by other factors, such as marital status, employment status, financial independence, amount of responsibility for self and others, and so on? For the purposes of this chapter, an **adult** is defined as anyone 18 years of age or older. Obviously, there are tremendous differences in health profiles and health care needs as people age. As adults enter their middle years (35–65), they experience many normal physiologic changes. However, some changes are the result of disease, environment, or lifestyle and can be slowed through behavior change. A physical profile of middle-aged adults is organized by body systems and can be found in Display 23.1.

Throughout history, the health care needs of women and men have differed more often than they have been alike. Many health promotion and health protection programs are designed specifically for women or for men. Mammography screening programs and prenatal clinics are designed with a woman’s

health in mind. Teaching testicular self-examination and prostate cancer screening are health promotion programs for men. Programs in many areas, such as cardiac rehabilitation, stress management, and dating violence prevention, may have had one gender in mind at one time but are now established as programs for both genders. Nevertheless, morbidity and mortality statistics, historical development of research foci, and workforce changes required that the health care needs of women and men be examined separately. This chapter focuses on the health of women and men across the adult lifespan.

### DEMOGRAPHICS OF ADULT WOMEN AND MEN

Mortality statistics are considered the most reliable indicator of the health status of a population. In 2004, a total of 2,397,615 people died in the United States. The crude death rate was 816.5 per 100,000 for all ages. Causes of death varied by age, sex, and ethnicity, but the 10 leading causes of death for all people in rank order included the following (National Center for Health Statistics [NCHS], 2007):

1. Diseases of the heart	652,486
2. Malignant neoplasms	553,888
3. Cerebrovascular diseases	150,074
4. Chronic lower respiratory diseases	121,987
5. Unintentional injuries	112,012
6. Diabetes mellitus	73,138
7. Alzheimer’s	65,965

DISPLAY 23.1

### PHYSICAL PROFILE OF MIDDLE-AGED ADULTS BY BODY SYSTEM

Body System	Physical Characteristic
Skeletal system	Intervertebral disks flatten over time
Integumentary system	Decreased secretions by sebaceous glands leads to drier skin Sweat glands diminish in size and number Skin loses elasticity and is more prone to wrinkles Hair bulbs lose melanin usually resulting in gray hair by age 50
Muscular system	Muscle fibers decrease by approximately 10% Lean body mass is replaced by adipose tissue Decreased grip strength occurs at this age
Endocrine and reproductive system	Menses stops Synthesis of estrogen decreases Tissues of the reproductive system (e.g., cervix and uterus) gradually atrophy Uterine changes make pregnancy less likely Intercourse may be more painful due to diminishing natural lubrications
Neurologic system	Nerve impulses are conducted 5% slower Cognition is unaffected, although there is a gradual loss of neurons Eyesight is poorer due to loss of elasticity in the lens Auditory discrimination of certain tones and consonants gradually decreases
Cardiovascular system	By age 50, the heart’s efficiency may be only 80% Elasticity of heart and blood vessels decreases Cardiac output decreases
Respiratory system	Elasticity of lungs decreases Breathing capacity decreases to 75% due to diminished strength of chest wall muscles
Urinary system	Decreased glomerular filtration rate appears in women Loss of bladder tone and tissue atrophy may lead to incontinence or possibly prolapse In men, an enlarged prostate may result in nocturia or dribbling

8. Influenza and pneumonia	59,664
9. Nephritis, nephritic syndrome and nephrosis	42,480
10. Septicemia	33,373

Diseases of the heart and malignant neoplasms accounted for more than 50% of deaths in 2004, and these diseases are the top two causes of death both for women and men. However, cerebrovascular diseases were the third leading cause of death for women and unintentional injuries were the third leading cause of death in men.

Since the beginning of the 21st century, the top 10 causes of death have remained the same. This was a major shift from the turn of the 20th century, when communicable diseases, such as tuberculosis and pneumonia, were leading causes of death. The shift from communicable to chronic illness can be attributed to the significant advances in public health, prevention, technology, and biomedical research.

## LIFE EXPECTANCY

**Life expectancy** is the average number of years that an individual member of a specific cohort (usually a single birth year) is projected to live. It is another standard measurement that is used to compare the health status of various populations, typically calculated from age-specific death rates. Health statistics often report life expectancy figures for birth and 65 years of age (see Table 23.1).

In the United States, life expectancy has increased consistently over time. Between 1990 and 2004, life expectancy at birth increased 3.4 years for men and 1.6 years for women. The gap between men and women narrowed from 7.0 years in 1990 to 5.2 years in 2004. There are however, differences in the life expectancy between Whites and Blacks for both sexes. In 2004, life expectancy at birth for Whites was 5.0 years longer than for Blacks (NCHS, 2007).

Globally, the life expectancy in the United States trails that of more than 20 other countries (Table 23.2). Japan reports the highest life expectancy figures. In all countries, disparities exist between female and male life expectancy, some as much as 13 years. The smallest disparity can be found between women and men living in Canada.

## HEALTH DISPARITIES

One of the goals of *Healthy People 2010* is to eliminate **health disparities**. A health disparity is defined as a difference in health status that occurs by gender, race or ethnicity, education or income, disability, geographic location, or sexual orientation (U.S. Department of Health and Human Services [USDHHS], 2000). Disparities in health occur when one segment of the population has a higher incidence of disease or mortality rate than another, or when survival rates are less for one group than another (Institute of Medicine, 2002). Often, persons with the greatest health burden have the least access to information, communication technologies, health care, and supporting social services. Interdisciplinary, collaborative, public, and private approaches, as well as public–private partnerships are needed to develop strategies to address this goal of *Healthy People 2010*.

## HEALTH LITERACY

**Health literacy** is defined as the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions. The ability to read and understand health information is key to managing health problems. Low health literacy contributes to health disparities, and it has been documented as an increasing problem among certain racial and ethnic groups, non-English speaking populations, and persons over 65 years of age in the United States (Kutner, Greenberg,

**TABLE 23.1 Life Expectancy at Birth and 65 Years of Age According to Sex: United States, Selected Years, 1900–2004**

Year	At Birth			At 65 Years		
	Both Sexes	Male	Female	Both Sexes	Male	Female
1900	47.3	46.3	48.3	11.9	11.5	12.2
1950	68.2	65.6	71.1	13.9	12.8	15.0
1960	69.7	66.6	73.1	14.3	12.8	15.8
1970	70.8	67.1	74.7	15.2	13.1	17.0
1980	73.7	70.7	77.4	16.4	14.1	18.3
1990	75.4	71.8	78.8	17.2	15.1	18.9
1995	75.8	72.5	78.9	17.4	15.6	18.9
2000	76.9	74.1	79.5	17.5	16.0	19.0
2004	77.8	75.2	80.4	18.7	17.1	20.0

Extracted from National Center for Health Statistics (2007). *Health, United States, 2006 with Chartbook on Trends in the Health of Americans*. (DHHS Pub. No. 1232.) Hyattsville, MD: Public Health Service.

**TABLE 23.2 Life Expectancy at Birth for Selected Countries by Sex**

	Female	Male	Disparity
Japan	85.2	78.3	6.9
France	83.0	75.8	7.2
Switzerland	83.0	77.8	5.2
Spain	83.5	75.8	7.7
Canada	82.1	77.2	4.9
Australia	82.6	77.4	5.2
Greece	80.7	75.4	5.3
Germany	81.2	75.4	5.8
United States	79.9	74.5	5.4
Russian Federation	72.0	58.9	13.1

Jin, & Paulsen, 2006). See Chapter 11 for additional information on health education.

## MAJOR HEALTH PROBLEMS OF ADULTS

Morbidity and mortality among adults varies substantially by age, gender, race, and ethnicity. The six leading causes of death are presented in this section. Diseases of the heart (coronary heart disease) and cerebrovascular diseases (stroke) are the first and third causes of death in adults and are discussed together. Malignant neoplasms (cancer), chronic lower respiratory diseases, unintentional injuries, and diabetes mellitus are discussed separately. Other selected additional major causes of death are covered in detail in other chapters: suicide (Chapter 27), Alzheimer disease (Chapter 24), and homicide (Chapters 17 and 20).

### Coronary Heart Disease and Stroke

An estimated one in three adults (79,400,000) have cardiovascular disease (CVD). More than 16% of all deaths among adults aged 25 to 64 years are due to CVD, primarily coronary heart disease (CHD), and stroke. Everyday, nearly 2,400 Americans die of CVD. In 2007, CVD was projected to cost more than \$431.8 billion, which includes health services, medications, and lost productivity (Centers for Disease Control [CDC], 2007a; Rosamond et al., 2007) (Fig. 23.1).

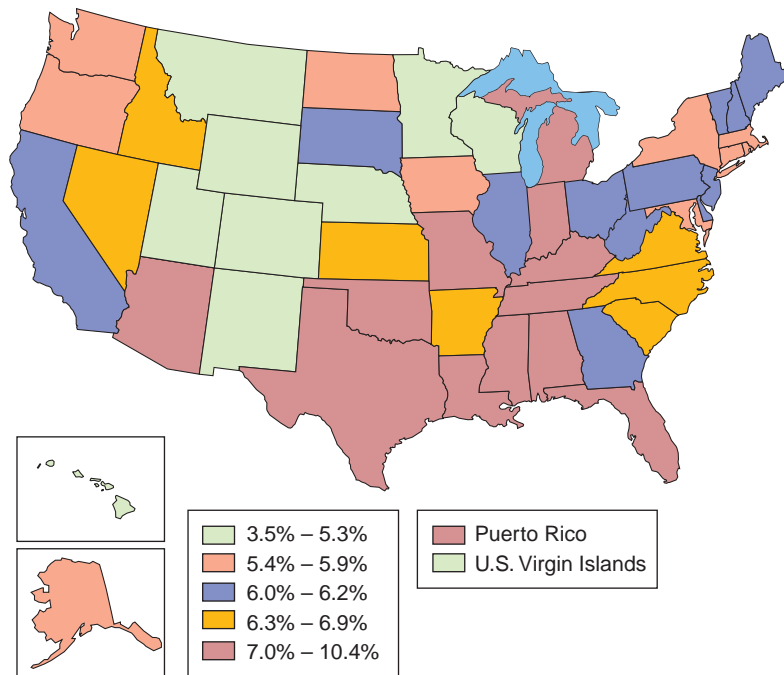

Risk factors contributing to CHD can be separated into two categories: personal and hereditary. Personal risk factors include gender, age, race/ethnicity, cholesterol level (specifically the ratio of low-density to high-density lipoproteins), diabetes, obesity, physical inactivity, high blood pressure, and cigarette smoking. The most modifiable of these factors are cholesterol, high blood pressure, cigarette smoking, obesity, and physical inactivity. Heredity obviously cannot be changed. The likelihood of heart disease or stroke multiplies with the increasing number of risk factors present.

Disparities in heart disease have remained consistent. The incidence is higher in men than in women and higher in the Black population than the White. Death rates (per 100,000) in 2004 were 335.7 for White males and 448.9 for Black males. White females had a death rate of 239.3 compared to the rate for Black females, 331.6. Over the last 10 years, death rates from CHD have declined by 25%. The age-adjusted mortality from heart disease declined 16% between 2000 and 2004 (NCHS, 2006; Rosamond et al., 2007) (Table 23.3).

For persons who have a heart attack, disparities also exist in treatment outcomes. When compared to men, women in general have poorer outcomes; 44% of women who have a

**TABLE 23.3 Primary Risk Factors for Coronary Heart Disease and Symptoms of Heart Attack in Adults**

Risks	Symptoms
• Age	• Pain: Chest, neck, jaw, arm, stomach, or back
• Gender, male	• Chest: Pressure, squeezing, or fullness
• Race, African American	• Shortness of breath
• Family history	• Cold sweat
• Sedentary lifestyle	• Nausea
• Excess body weight	• Lightheadedness
• Hypertension	
• Diabetes mellitus	
• Hyperlipidemia	
• Cigarette smoking	

\*Age adjusted to the 2000 U.S. standard population of adults.

From Centers for Disease Control and Prevention. (2007). Prevalence of Heart Disease—United States, 2005, *Morbidity and Mortality Weekly Report*, 56(6), 113–118.

**FIGURE 23.1** Prevalence of cardiovascular disease. Self-reported prevalence of history of myocardial infarction or angina/coronary heart disease among adults aged 18 years and older.

heart attack die within 1 year, compared with 27% of men. At older ages, women who have heart attacks are twice as likely as men to die within a few weeks (USDHHS, 2000).

Approximately 700,000 Americans suffer strokes each year, and strokes account for almost one in 16 deaths in the United States (Rosamond et al., 2007). Disparities also exist among people with strokes. In 2004, women accounted for 61% of all U.S. stroke deaths. Each year, approximately 46,000 more women than men have a stroke. Men are at a greater risk of having a stroke at a younger age than women; however this difference dissipates with age. Blacks are twice as likely to have their first stroke earlier than their White counterparts. In the southeastern United States (the “Stroke Belt”), stroke death rates for both Blacks and Whites are higher than in any other part of the country (Gorelick, 2004).

The hallmark Framingham Heart Study identified major risk factors associated with the development of CVD and the effects of related factors such as blood triglycerides, gender, and psychosocial issues. The study began in 1948 under the direction of National Heart Institute, now known as the National Heart, Lung, and Blood Institute (NHLBI). At that time, the death rates from CVD were rising, but little was known about the general causes of heart disease and stroke. The researchers recruited 2,336 men and 2,873 women between the ages of 30 and 62 in an effort to identify common factors or characteristics that contribute to CVD. Every 2 years, these individuals were scheduled for an extensive medical history, physical examination, and laboratory tests. In 1971, the study enrolled 5,124 of the original participants’ adult children and their spouses, and currently, a third generation (the children of the Offspring Cohort) is being recruited and examined. Findings from the Framingham Heart Study continue to make important scientific contributions regarding the development

and treatment of CVD and related health issues (NHLBI, 2002).

## Cancer

**Cancer** is a major chronic illness and the second leading cause of death in the United States. Currently the National Cancer Institute (NCI) estimates that 10.5 million Americans are living with cancer. Approximately 70% of all cancers are diagnosed in persons 55 years of age and older and, as individuals age, they are more likely to develop cancer. It is estimated in 2007 that 1,444,920 new cancer cases will be diagnosed. Blacks are more likely to develop and die of cancer. Over their lifetime, men living in the United States are more likely to develop cancer than women. The National Institutes of Health (NIH) 2006 estimates the overall costs for cancer are \$206.3 billion (American Cancer Society [ACS], 2007).

Cancer is caused by internal and external factors. External factors include tobacco smoke, chemicals, radiation, and infectious organisms. Internal factors are inherited gene mutations, hormones, immune conditions, and gene mutations that occur from metabolism. These factors can occur in isolation or together to initiate illness. About 30% of all cancer deaths and 87% of lung cancer deaths are attributed to smoking. Smoking-related diseases remain the most preventable cause of death in the United States (ACS, 2007).

Lung and bronchial cancers are the number one cause of cancer deaths among adults. In 2007, it was estimated that 70,880 or 26% of the female cancer deaths and 89,310 or 31% of the male cancer deaths were related to lung and bronchus cancers (ACS, 2007). Cigarette smoking is the predominant risk factor for lung cancer. Quantity of cigarettes smoked and the number of years smoking increase an

individual's risk of developing lung cancer. Other risk factors include occupational or environmental exposure to secondhand smoke, radon, asbestos, genetic susceptibility, and a history of tuberculosis. Current efforts to reduce mortality by early detection have been unsuccessful. The National Lung Screening Trial is currently assessing whether screening individuals at high risk with spiral computerized tomography (CT) or standard chest X-ray will reduce cancer deaths. Results are expected in 2010 (ACS, 2007).

Colon and rectal cancers are the third most common cancers in adults. Among adults, an estimated 153,760 cases of colon and rectal cancers are expected to occur in 2007, and 52,180 deaths. The risk of developing colorectal cancer increases with age and 90% of all cases are diagnosed in individuals 50 years of age or older. Other risk factors include certain inherited genetic mutations, personal or family history of polyps or colorectal cancer, and personal history of chronic inflammatory bowel disease. Screening for colon and rectal cancer should begin at age 50 for men and women who are at average risk (ACS, 2007) (see Display 23.2).

## Chronic Lower Respiratory Diseases

**Chronic Lower Respiratory Disease (CLRD)** comprises three major conditions: chronic bronchitis, emphysema, and asthma. The term chronic obstructive pulmonary disease (COPD) includes emphysema and chronic bronchitis. Chronic lower respiratory disease is the fourth leading cause of death in the United States. Every year, approximately \$43 billion is spent on direct and indirect health care costs related to chronic lower respiratory diseases (American Lung Association [ALA], 2006a).

Tobacco smoking is the major risk factor for developing COPD, accounting for about 80% of cases. The remaining 20% of COPD cases are attributable to environmental exposures and genetic factors. Over the past several years, the number of women dying of this disease surpassed the number of men. This increase is probably related to the increase in smoking by women, relative to men, since the 1940s. Chronic bronchitis sufferers are more likely to be between 18 and 44 years of age and female, whereas emphysema sufferers are mostly over age 65 and male. Both conditions are more commonly found among Whites than Blacks and among people living in the southern United States (ALA, 2006b, 2006c; NCHS, 2007).

Asthma appears to have a strong genetic basis, with 30% to 50% of all cases due to an inherited predisposition. Women are 6% more likely to be diagnosed with asthma than are men. In 2004, the prevalence of the disease in the Black population was 24% higher than in the White population. Over 4.5 million work days are lost each year due to asthma (ALA, 2006a, 2006b).

## Unintentional Injuries

**Unintentional injuries** refers to any injury that results from unintended exposure to physical agents, including heat, mechanical energy, chemicals, or electricity. The top five causes of unintentional injuries include motor vehicle crashes, fire arms, poisoning, falls, and suffocation. Together, these causes account for approximately 80% of all injury deaths. In 2004, a total of 112,012 Americans died of injuries from a variety of

causes. For persons under age 35, unintentional injuries are the leading cause of death. It is estimated that more than 20,000 adults ages 25 to 64 will die in motor vehicle crashes each year. The costs related to these deaths take into account wages and productivity losses, medical expenses, administrative expenses, motor vehicle damage, and employer's uninsured costs. In 2005, the average cost per fatal incident was \$1,150,000. The cost of a nonfatal disabling injury was \$52,900 in the same year (Finkelstein, Corso, & Miller, 2006; NCHS, 2006; National Center for Injury Prevention and Control [NCIPC], 2005; National Safety Council, 2006). In 2006, unintentional injuries in the United States included:

- ◆ Motor vehicle crashes: The leading cause of death among persons 25–44 years of age
- ◆ Suicide and homicide: The second and third leading causes of death for persons 25–34 years of age
- ◆ Falls: The leading cause of nonfatal injury related to emergency department visits by persons 25–64 years of age.

A disabling injury is one that results in restriction of normal activities of daily living (ADLs) beyond the day on which the injury occurred. Disabling injuries occur disproportionately among the young and the elderly. Seat belts, helmets, smoke detectors, and poison control centers save billions of dollars in direct and indirect medical costs. These primary and secondary prevention strategies save lives and money.

An *unsafe condition* is any environmental factor, either social or physical, that increases the likelihood of an unintentional injury. An icy walkway is an example of an unsafe condition; although it poses a hazard, it does not cause an injury, but only makes it more likely that an injury will occur. *Injury prevention* and *injury control* refer to any effort to prevent injuries or lessen their severity. These efforts often focus on assessment of the environment for unsafe conditions, such as loaded guns in the home or asbestos in school buildings and workplaces.

## Diabetes Mellitus

**Diabetes mellitus** is the sixth leading cause of death in the United States. Current prevalence is based on national estimates for 2005, with 20.8 million people having diabetes (diagnosed 14.6 million, undiagnosed 6.2 million), representing 7% of the population. Of these diabetics, 20.6 million are women and men 20 years of age and older (50% are under the age of 60). Men are affected more than are women, with a prevalence of 10.9 for men and 9.7 for women. Differences also exist related to race and ethnicity, as American Indians and Alaska Natives are 2.2 times more likely and non-Hispanic Blacks are 1.8 times more likely to have diabetes than Whites. Overall, recent incidence was 1.5 million new cases in 2005 (American Diabetes Association [ADA], n.d.b; CDC, 2005b) (see Fig. 23.2).

Diabetes is a major chronic health condition that puts individuals at risk for other serious health conditions including heart disease and stroke, hypertension, blindness, kidney disease, and nervous system disease (i.e., neuropathy, which is a loss of sensation or pain in the feet or hands). Because diabetes can affect any part of the body, damage to other body systems can be minimized by good blood glucose control (assessed by hemoglobin A1C) (ADA, n.d.a; CDC, 2005b).

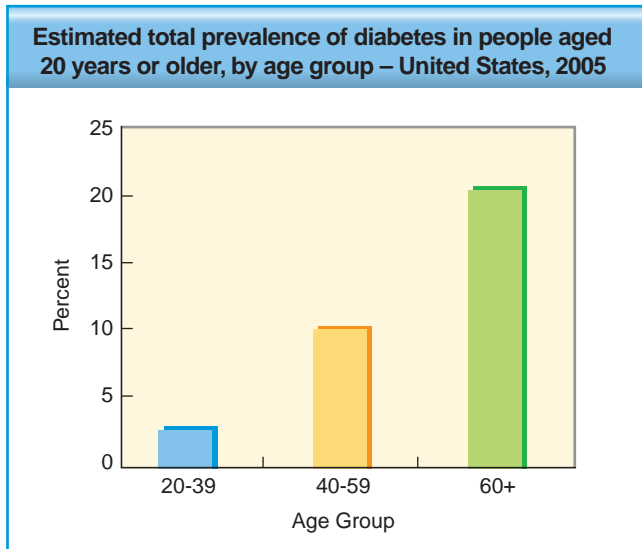

## DISPLAY 23.2

## SCREENINGS AND CHECK-UP SCHEDULE FOR ADULTS

	How Often	Ages 20–39	Ages 40–49	Age 50+
<b>Physical Exam:</b> Performed to review overall health status. Have a thorough physical examination and discuss health-related concerns and topics.	Every 3 years Every 2 years Every year	X	X	X
<b>Blood Pressure:</b> High blood pressure can have no symptoms, but can cause permanent damage to body organs and systems.	Every year	X	X	X
<b>Blood Tests and Urinalysis:</b> Screens for various illnesses and diseases, such as high cholesterol, kidney, or thyroid disorders, before problems or symptoms occur. Can be done at time of physical exam.	Every 3 years Every 2 years Every year	X	X	X
<b>EKG:</b> Electrocardiogram screens for heart abnormalities or problems.	Baseline–age 30 Every 4 years Every 3 years	X	X	X
<b>Tetanus Booster</b>	Every 10 years	X	X	X
<b>Flu Vaccine</b>	Every year	X	X	X
<b>Rectal Exam:</b> Screens for hemorrhoids, lower rectal problems, colon, and prostate cancer	Every year	X	X	X
<b>PSA Blood Test (Men):</b> Prostate specific antigen (PSA) is produced by the prostate. Levels increase when there is an infection, enlargement, or cancer. Screening for Black men and men with a family history should start at age 45.*	Every year		*	X
<b>Clinical Breast Exam (Women):</b> Breast exam by health care provider	Every year	X	X	X
<b>Mammography (Women):</b> Screening should begin at age 40 unless high-risk*	Every year		*	X
<b>Pelvic Exam and Pap Smear (Women):</b> A pelvic exam is performed to evaluate the size and position of the vagina, cervix, uterus, fallopian tubes, and ovaries. A Pap test is performed to look for changes in the cells of the cervix, such as dysplasia or cancer.	Every year Every 3 years after 3 consecutive negative pap smears	X	X	X
<b>Self Exams:</b> <i>Testicles</i> are examined to find lumps. <i>Skin</i> is checked to look for signs of changing moles, freckles, or early skin cancer. <i>Breasts</i> are examined to find abnormal lumps in their early stages.	Monthly	X	X	X
<b>Hemoccult:</b> Screens the stool for microscopic amounts of blood that can be the first indication of polyps or colon cancer	Every year		X	X
<b>Colon–Rectal Health:</b> A flexible endoscope is used to examine the rectum, sigmoid, and descending colon for cancer at its earliest stages. The exam also detects polyps that can progress to cancer if not found early.	Every 3–4 years			X
<b>Chest X-ray:</b> Should be considered in smokers over the age of 45.	Discuss with physician		X	X
<b>Bone Health:</b> Bone mineral density is measured.	Baseline As needed		X	X

SOURCE: 1999-2002 National Health and Nutrition Examination Survey estimates of total prevalence (both diagnosed and undiagnosed) were projected to year 2005.

**FIGURE 23.2** General diabetes chart.

## Substance Use

According to the Centers for Disease Control and Prevention (CDC), **substance use** refers to the selected use of potentially dangerous substances including alcohol, tobacco products, drugs, inhalants, and other substances that can be consumed, inhaled, injected, or otherwise absorbed into the body with possible damaging effects. It is a serious and continuing problem among adult women and men living in the United States. In 2005, an estimated 22.2 million persons were classified with substance dependency or abuse in the past 12 months (Substance Abuse and Mental Health Services Administration [SAMHSA], 2006).

In the United States, approximately 75,000 deaths are attributed to alcohol use each year. In 2004, 48% of adults 18 years of age and older reported being a current regular drinker (at least 12 drinks in the past year). Among males, 57% reported being a current regular drinker as compared to females at 38%. Whites are also more likely to be current drinkers than other ethnic groups. Excessive alcohol use is the third leading lifestyle-related cause of death for people living in the United States. More than 39% of automobile fatalities were alcohol related in 2004. The social and economic cost of alcohol abuse exceeds \$184 billion annually in the United States (Mokdad, Marks, Stroup, & Gerberding, 2004; Stahre, et. al, 2004; World Health Organization, 2004).

Smoking is associated with a significant increase in CVD and cancer. In 2005, approximately 21% of U.S. adults were current cigarette smokers, 2.2% cigar smokers, and 2.3% used smokeless tobacco. Among cigarette smokers, more men smoke (23.9%) than women (18.1%). American Indians and Alaska Natives (32%) smoke more cigarettes than Blacks (21.5%) and Whites (21.9%). Four of the *Healthy People 2010* objectives are related to tobacco use,

and there was no change between 2004 and 2005, which indicates a lack of progress in decreasing tobacco use. Smoking across the United States costs \$97.2 billion yearly in health care costs and lost productivity, and smoking-related diseases claim an estimated 430,700 lives annually. At least 8.6 million people in the United States have at least one serious illness caused by smoking (ALA, 2006a; CDC, 2005a, 2006d).

*Illicit drug use* refers to use and misuse of illegal and controlled drugs. The primary illicit drugs used in the United States are cocaine, ecstasy, heroin, marijuana, and methamphetamine. Rates of illicit drug use are associated with age. In 2005, the highest rate was among persons between ages 18 and 20 (22.3%). The rate was 18.7% among those between ages 21 and 25, and drug use continued to decline with age (SAMHSA, 2006).

Abuse of prescription drugs is the misuse of prescription drugs for nonmedical reasons. The illegal use of prescription drugs is one of the fastest-growing forms of drug abuse and is becoming a major public health concern. In 2004, about 48 million persons aged 12 or older (20%) had misused prescription drugs in their lifetime. Young adults aged 18 to 25 had a higher prevalence of dependence or abuse for pain relievers, tranquilizers, and stimulants compared to persons in other age groups. Men generally had higher rates than women for misuse of pain relievers, stimulants, and methamphetamine (SAMHSA, 2006). This issue is covered in greater detail in Chapter 27.

## Obesity

**Obesity** is defined as having a body mass index (BMI) of 30 or greater, and is becoming the nation's number one health problem. *Morbid obesity* is having a BMI of 40 or greater. One of the *Healthy People 2010* objectives is to reduce to 15% the prevalence of obesity among adults in the United States. In 2005, it was estimated that 23.9% of the U.S. population was obese and 3% morbidly obese. In the same year, obesity prevalence was 24.2% among men and 23.5% among women. Obesity was greatest among Blacks (33.9%). Between 1995 and 2005, a significant increase in obesity occurred, 15.3% to 23.9%, among adults 18 years of age or older. This continued increase underscores the need for additional measures to educate persons regarding healthier lifestyle choices, increasing physical activity, and decreasing caloric intake. The number of gastric bypass surgeries and other bariatric procedures performed on obese adults 18 to 44 years of age more than tripled between 1999 and 2004. These procedures were more common among women than men. Obesity-related medical expenses are estimated to range from \$87 million in Wyoming to \$7.7 billion in California (CDC, 2006c; NCHS, 2007)

## WOMEN'S HEALTH

Women have not been the focus of medical attention throughout the centuries. Health benefits achieved by women were incidental compared to men. Advances in women's health are very recent and primarily an advantage for women living in Western countries, where the women's or feminist movement has made major inroads.

## Overview of Factors Influencing Women's Health

Women's rights in the United States started in the second half of the 19th century and over time addressed issues directly or indirectly impacting the health of women: voting rights, labor laws, reproductive rights and violence against women (Imbornoni, 2006). This section of the chapter looks at women's health concerns over the adult lifespan and the major causes of acute and chronic illness and death; and the issues, trends, and policies that have affected women.

Women's health is still overlooked in much of the world. Only in the past few decades has the health of women been a formidable issue in the United States, coming not so coincidentally with the modern women's feminist movement that began in the 1960s. The landmark publication *The Feminine Mystic* (Friedan, 1997) helped launch the modern women's movement by critically examining the role of women in American society (Fox, 2006). The Boston Women's Health Book Collective publication (2005), *Our Bodies, Ourselves*, represented the first book to explore women's health issues, exclusively written by and for women (Norsigian et al., 1999).

Feminists paved the way for women to have their voices heard on many health, social, and political issues. Women sought out higher education opportunities in greater numbers and entered workplaces once solely occupied by men, especially during and after World War II. These positive changes escalated women toward greater equality and, with equality, came the freedom—and pressure—for women to compete with men in their social and work settings. Issues in women's health were discovered as a result of research that now more regularly includes women. The importance of women's research was reaffirmed in the NIH Revitalization Act of 1993, Subtitle B—Clinical Research Equity Regarding Women and Minorities to “identify projects for research

on women's health that should be conducted or supported by the national research institutes; identify multidisciplinary research relating to research on women that should be so conducted or supported . . . ” (NIH, 1993, Sec. 486).

## Women's Health Research

In response to changing priorities, researchers have designed and implemented major studies that focus exclusively on women. Four significant studies have and continue to provide important health information about women. *The Women's Health Initiative* (a major 15-year research program addressing the most common causes of death, disability, and poor quality of life in postmenopausal women—CVD, cancer, and osteoporosis); *The Women's Health Study* (evaluating the effects of vitamin E and low-dose aspirin therapy in primary prevention of CVD and cancer in apparently healthy women); *The Nurses' Health Study I* (investigating the potential long-term consequences of the use of oral contraceptives); and *The Nurses' Health Study II* (studying oral contraceptives, diet, and lifestyle risk factors in a population younger than the original Nurses' Health Study cohort).

*The Women's Health Initiative* (WHI) addressed CVD, cancer, and osteoporosis and was one of the largest U.S. prevention studies of its kind, spanning 15 years, starting in 1991. The three major components of the WHI were a randomized controlled clinical trial of promising but unproven approaches to prevention; an observational study to identify predictors of disease; and a study of community approaches to developing healthful behaviors. This study was sponsored by the NIH and the NHLBI, involving 161,808 women ages 50 to 79, and was considered to be one of the most far-reaching clinical trials for women's health ever undertaken. These studies have ended; however, the women are now participating in a follow-up phase, which will last until 2010.

*The Women's Health Study* is a randomized, double-blind, placebo-controlled clinical trial sponsored by both NHBLI and the NCI. It is the first large clinical trial to study the use of low-dose aspirin to prevent heart attack and stroke in women 45 years of age and older. This study began in 1991 and will continue through March 2009 for additional observation and follow-up of the original 28,345 participants. Current findings indicate that low-dose aspirin does not prevent first heart attacks or death from cardiovascular causes in women; however, stroke was found to be 17% lower in the aspirin group (Cook et al., 2005).

*The Nurses Health Study I*, a prospective study that began in 1976, enrolled 122,000 registered nurses ages 30 to 55 from 11 states, who responded to 170,000 mailed questionnaires. Every 2 years, participants received a follow-up questionnaire with questions about diseases and health-related topics including smoking, hormone use, and menopausal status. Later in the study, questions regarding diet and nutrition and quality of life were added. The study is still ongoing. Some findings to date indicate night-shift work can influence melatonin levels, which may increase risk for certain cancers (Schernhammer et al., 2004) and smoking can influence endometrial cancer at an early age (Viswanathan et al., 2005).

*The Nurses Health Study II* represented women who started using oral contraceptives in adolescence, hence a population with long-term exposure during early reproductive years. Participants were between 25 and 42 years of age, and

### What Do You Think?

A woman's dressing style that included a tightly laced corset was popular from the late 1700s throughout the late 1800s in Germany, England, and the United States. It was brought into question by an anatomist, S. T. von Sommerring, in 1793. He identified compression of rib cages and internal organs as contributing to digestive problems, fainting, and shortness of breath. For the next century, dress reformers advocated looser lacing and clothes that allowed for a more natural movement. However, these reformers belonged to the “radical fringe” of the feminist movement and the tiniest waists, regardless of their impact on health, continued to be in vogue as the “hourglass” figure was sought by middle class and upper class women. More recently, hiatal hernias caused by overly tight girdles and corsets have been termed “Sommerring's syndrome” in tribute to the first physician to warn of the dangers, more than 200 years ago.

Adapted from Fee, E., Brown, T. M., Lazarus, J., & Theerman, P. (2002). The effects of the corset. *American Journal of Public Health*, 92, 1085.

116,686 women were enrolled and followed forward in time. Every 2 years, participants received a follow-up questionnaire and were surveyed about diseases and health-related topics including smoking, hormone use, pregnancy history, and menopausal status. These women also received nutrition assessment and quality-of-life assessment later in the study.

### Women's Health Promotion Across the Lifespan

What health care needs do women have that are different from those of men? Is there a need to look at health promotion throughout the life cycle of adult women? How is the health of an 18-year-old different from that of a 50-year-old woman? Most of us would have no trouble agreeing that women have different health care needs that must be considered, and that these needs vary with age. Knowing what the needs are is essential to knowing how to help women promote their health.

### Healthy People 2010 Goals for Women

As a nation, we have been focusing on improving the health of all citizens through the Healthy People initiatives. *Healthy People 2000* set a standard for change and improvement in objectives that were met or exceeded in some areas and were far from being reached in others. In that initiative, the objectives in 14 areas focused specifically on women's health issues. In *Healthy People 2010*, the focus is still on improving the nation's health, but the objectives have been reevaluated. Objectives have been eliminated, broadened, expanded, or tailored to meet the changing needs of society. However, many still focus on the health of women (Display 23.3). As the community health nurse works with women at various stages in the life cycle, the objectives in *Healthy People 2010* can give structure to program planning and services offered to women in the community at the primary, secondary, and tertiary levels of prevention.

### Young Adult Women (18 to 35 Years)

Women in the earlier years of adulthood have different tasks to accomplish and issues to address than do women in later adulthood, and the transition from adolescence to adulthood can be stressful. According to Erickson (Stevens, 1983), the major developmental tasks that young women need to accomplish are forming an identity and the development of intimacy. Behaviors associated with young adulthood include attracting and choosing a significant other for the long-term and establishing a home. This task is phrased as such to include lesbian women—women who have sexual intercourse with other women. However, not all such women in this age group have “come out” or revealed to others that they are lesbian or **bisexual**—having sexual intercourse with people of both sexes. Young women during this stage also prepare and choose a life's work that is personally satisfying, plan for children by using a variety of parenting models (childbirth, adoption, foster parenting), and develop a personal philosophy that encompasses meaningful and comforting spiritual beliefs that are consistent with day-to-day living.

Women in this age group tend to be healthy. Unfortunately, during this period many women engage in health-risk behaviors such as physical inactivity, eating poorly, partici-

pating in unprotected sexual intercourse, and smoking. Some, if not all, of these behaviors may have been established in adolescence and represent modifiable behaviors. If not addressed, these behaviors can contribute significantly to the leading causes of morbidity and mortality: diseases of the heart and vascular systems, cancers, chronic respiratory diseases, and diabetes (McCracken, Jiles, & Blanck, 2007). The majority of health concerns for many of these women are related to eating disorders, reproductive health and sexually transmitted infections (STIs), physical activity, mental health and mood disorders, and substance use.

### Eating Disorders

Eating disorders are complex, chronic illnesses primarily affecting young women. The cause of these disorders is not clear, however, the incidence is on the rise in the United States and other parts of the world. The three most common are anorexia nervosa, bulimia nervosa, and binge eating. **Anorexia nervosa** is an eating disorder that is marked by weight loss, emaciation, a disturbance in body image, and a fear of weight gain. Persons affected lose weight either by excessive dieting or by purging themselves of ingested calories. This illness is typically found in industrialized nations and usually begins in the teen years. Young women are 10 to 20 times more likely than young men to suffer from the disorder. The young woman claims to feel fat even when she is emaciated, and refusal to maintain body weight can be life-threatening due to electrolyte disturbances, anemia, and secondary cardiac arrhythmias. If anorexia nervosa is suspected, the client must be referred to a health care provider for follow-up as soon as possible (Office on Women's Health [OWH], 2000, 2006a).

A related disorder, **bulimia nervosa**, is marked by recurrent episodes of binge eating, self-induced vomiting and diarrhea, excessive exercise, strict dieting or fasting, and an exaggerated concern about body shape and weight. In many ways, the two disorders are similar, except that women with anorexia nervosa rarely binge eat. The community health nurse should refer a woman suspected of practicing bulimic behaviors to an appropriate health care provider (OWH, 2000, 2007). Females in careers in which low weight is required (e.g., modeling, entertainment), individuals who have been sexually abused or who come from families with a history of eating disorders, and individuals with low self-esteem and a history of not being “in control” or with communication and emotional difficulties are at greater risk for either disorder.

**Binge eating** is an eating disorder characterized by repeated episodes of uncontrolled eating. It is the newest clinically recognized disorder. The onset of this disorder is usually in late adolescence and the early 20s, and starts following significant weight loss from dieting. Typically, individuals with this disorder eat quickly, eat until they are uncomfortably full, eat when they are not hungry, eat large amounts of food alone, have difficulty expressing their feelings, have difficulty controlling impulses and stress, and feel depressed about overeating. Of note, many persons who binge are obese. Therefore, these individuals are at risk for type 2 diabetes, high cholesterol, gallbladder disease, depression, heart disease, and some cancers (OWH, 2000, 2005).

Overall, eating disorders are not gender specific, as some men are affected—one male to every 10 females. Currently,

## DISPLAY 23.3

### HEALTHY PEOPLE 2010 OBJECTIVES FOR WOMEN (INCLUDING EIGHT DEVELOPMENTAL OBJECTIVES)

1. Reduce the breast cancer death rate, from 27.9 deaths per 100,000 women to 22.3 deaths per 100,000.
2. Reduce the death rate from cancer of the uterine cervix, from 3.0 deaths per 100,000 to 2.0 deaths per 100,000 women.
3. Increase the proportion of women who receive a Pap test; from 92% to 97% for women older than 18 years of age who have ever received a Pap test, and from 79% to 90% for women who have received a Pap test within the preceding 3 years.
4. Increase the proportion of women aged 40 years and older who have received a mammogram within the preceding 2 years, from 67% to 70%.
5. (Developmental) Decrease the proportion of pregnant women with gestational diabetes.
6. Increase the proportion of pregnancies that are intended, from 51% to 70%.
7. Reduce the proportion of births occurring within 24 months after a previous birth, from 11% to 6%.
8. Increase the proportion of women at risk for unintended pregnancy (and their partners) who use contraception, from 93% to 100%.
9. Reduce the proportion of women experiencing pregnancy despite use of a reversible contraceptive method, from 13% to 7%.
10. Reduce pregnancies among female adolescents, from 68 pregnancies per 1000 girls aged 15-17 years to 43 pregnancies per 1000.
11. Reduce maternal deaths, from 7.1 maternal deaths per 100,000 live births in 1998 to 3.3 per 100,000 in 2010.
12. Reduce maternal illness and complications due to pregnancy, from 32.2 maternal complications per 100 deliveries during labor and delivery in 1998 to 20.0 in 2010.
13. (Developmental) Reduce ectopic pregnancies and postpartum complications, including postpartum depression.
14. Increase the proportion of pregnant women who receive early and adequate prenatal care, from 83% beginning in the first trimester of pregnancy to 90%, and increase early and adequate prenatal care, from 74% in 1997 to 90% in 2010.
15. (Developmental) Increase the proportion of pregnant women who attend a series of prepared childbirth classes.
16. Reduce cesarean deliveries among low-risk women (full-term, singleton, vertex presentation), from 18% to 15% among women with no prior cesarean delivery, and from 72% to 63% among women with prior cesarean delivery.
17. (Developmental) Increase the proportion of mothers who achieve a recommended weight gain during their pregnancies.
18. Increase abstinence from alcohol, cigarettes, and illicit drugs among pregnant women: alcohol, from 86% to 94%; binge drinking, from 99% to 100%; cigarette smoking, from 87% to 99%; and illicit drug use, from 98% to 100%.
19. Increase the proportion of mothers who breast feed their babies in the early postpartum period, from 64% to 75%; at 6 months, from 29% to 50%; at 1 year, from 16% to 25%.
20. Reduce anemia among low-income pregnant women in their third trimester, from 29% to 20%.
21. (Developmental) Reduce iron deficiency among pregnant females.
22. (Developmental) Reduce human immunodeficiency virus (HIV) infections associated with heterosexual contact in adolescent and young adult women aged 13 to 24 years.
23. (Developmental) Increase the proportion of sexually active women aged 25 years and younger who are screened annually for genital chlamydia infections.
24. (Developmental) Increase the proportion of pregnant women screened for STDs (including HIV infection and bacterial vaginosis) during prenatal health care visits, according to recognized standards.
25. Increase smoking cessation during pregnancy, from 14% smoking cessation during the first trimester of pregnancy to 30%.

Adapted from U.S. Department of Health and Human Services. (2000). *Healthy people 2010: Understanding and improving health* (2nd ed.). Washington, DC: U.S. Government Printing Office.

the perception is that White females are affected more than other ethnic groups; however, trends indicate that individuals from other ethnic groups also may suffer from eating disorders. The community health nurse can play a vital role in identifying persons affected and referring them to appropriate health care providers or self-help groups. A screening tool that may be helpful in this effort is the Malnutrition Universal Screening Tool (Duffin, 2006; Malnutrition Advisory Group, 2003; Murphy, 2007; OWH, 2000).

#### Reproductive Health

By age 25, at least 50% of childbearing women have given birth, at least once. Women need to be as healthy as possible

to have positive pregnancy outcomes. Based on published research and the input of experts, the CDC has put forth recommendations for preconception care. The main goal of preconception care is to “provide health promotion, screening, and interventions for women of reproductive age to reduce risk factors that might affect future pregnancies” (Johnson et al., 2006, p. 3). Recommendations for preconception care address consumer awareness, individual responsibility, minimizing health problems, access to care, disparities, and research. Although *Healthy People 2010* does not specifically address preconception care, at least 18 of the objectives for women are directly related (see Display 23.3). Community health nurses have been at the forefront of maternal and child health for decades, and they must

## DISPLAY 23.4

## NURSING CARE PLAN MATRIX FOR HEALTH PROMOTION, YOUNG ADULTS—18 TO 35

Community health nurses can use this matrix to individualize teaching, services, and/or care to young adult clients. Use the questions to stimulate the development of an individualized approach that is client-focused and -driven with the community health nurse acting as the catalyst. In any or all of these areas, the community health nurse may (1) discuss issues and commend the client for positive attitudes and behaviors (example: when the client is making healthful decisions, such as condom use for his/her health and the health of significant others), (2) discuss the issues and guide the client to resources that will enhance more positive behaviors and decisions (example: flu shot clinic or healthy lifestyle program for adults), or (3) discuss the issues and inform the client that immediate changes must be made to protect the health of self or others and inform/utilize the appropriate resources as soon as possible (example: follow-up for symptoms related to suspected STI).

1. *Life partner.* Ascertain whether the client is looking for a life partner or is choosing to live a single life. Discuss how the single life is satisfying for the client and ways to make it richer.

Discuss settings in which client can meet others (male or female, based on sexual preference) with similar interests, philosophy, and outlook, such as work settings, school settings, faith communities, recreational communities, and the like.

Discuss what the client is looking for in a potential life partner; expectations for the relationship; what the client contributes; how the client compromises and resolves conflict, and other issues. If in a relationship, what is good; what needs improving; how to initiate change.

2. *Life's work.* How is the client preparing for his/her life's work (education, formal training, on the job training)? Will the life's work provide resources for client's life plans? Will the work choice provide long-term satisfaction? Is the work choice a "stepping stone" to another work role? How will/does he handle work and rearing children? What

needs changing or can be improved in the work/children arrangement?

3. *Planning for children.* What knowledge does he/she have about family planning? What methods fit best with his/her philosophy, religious beliefs, lifestyle? What are the long-term effects of the choices? How many children is the client planning to rear? Has he/she thought through the ramifications of this number? If choosing not to have (or unable to have) children how will he/she deal with this? Does he/she want alternative suggestions for raising a child (adoption, foster parenting) or information about interacting with children (volunteering)?
4. *Maintaining physical and mental health.* In this area, the community health nurse needs to explore all areas of health promotion and protection. This will include discussions regarding primary and secondary prevention. Primary prevention discussions could include:
  - Diet and nutrition
  - Physical and leisure activities
  - Safe sex practices
  - Periodic health examinations
  - Personal safety—seat belts, protective helmets, dating violence, etc.
  - Immunizations
  - Regular use of sun screen
  - Stress reduction activities
 Secondary prevention discussions could include:
  - Breast self-examination
  - Testicular self-examination
  - Smoking cessation
  - Pelvic exams and pap smears
  - Counseling and support at times of stress
5. *Developing a life's philosophy.* Discuss client's personal life satisfaction, which may include religiosity and spirituality, living in congruence with cultural/ethnic/family beliefs and expectations, and coming to a comfortable level of satisfaction with life choices, having few regrets.

continue to strive to incorporate components of preconception care into their practices. Nurses must advocate for their clients to influence public policy, which has the potential to improve access to care for many women and improve pregnancy outcomes (Johnson et al., 2006).

Sexual health and STIs are important health concerns for young women. Sexual activity typically commences in adolescence and continues throughout the lifespan. Sexually transmitted infections are epidemic in the United States, especially among young adults (see Chapter 8). Many of the common infections are asymptomatic, but not always. The two most common STIs affecting women are *Chlamydia* and gonorrhea. It is estimated that approximately 2.8 million cases of *Chlamydia* occur in the United States each year, and females 20 to 24 years of age have the second highest rate, preceded

by 15- to 19-year-old adolescents. Gonorrhea rates have reached a plateau in recent years, but the prevalence is still 115.6 per 100,000 persons. Both *Chlamydia* and gonorrhea are underdiagnosed, which can have deleterious consequences for women. If treatment is delayed, women can develop pelvic inflammatory disease, chronic pelvic pain, ectopic pregnancy, and infertility (CDC, 2006e).

Community health nurses working with females need to provide factual information to increase women's knowledge of STI risk. This information should be a part of frank discussions regarding condom use, sexual partners (male and female), type of sexual activity (oral, anal, vaginal), the life-threatening consequences of an undiagnosed STI, and undesirable pregnancy outcomes. Outside of abstinence, condom use is the first line of prevention against STIs.

## EVIDENCE-BASED PRACTICE

### Bridging Financial Gaps

A two-group pretest/posttest experiment was designed and implemented to examine the effect of an education program on knowledge and perceived risk of sexually transmitted infections (STIs). The Sexually Transmitted Infection Knowledge Survey and the Perceived Risk of Sexually Transmitted Infection Survey were used to measure knowledge and perceived risk among 104 women of childbearing age at two universities. The education program included a presentation on condoms, dental dams, and instructions on proper use. In addition, an informational brochure was provided. No education intervention or brochure was provided for the comparison group. Outcomes indicated that participants in the intervention group improved their STI knowledge and perceived risk from participating in a 30-minute educational intervention ( $p = 0.0001$ ).

Sexually transmitted infections are a major burden on the already overtaxed public health system. More than 12 million new cases are diagnosed annually, and more than \$8 billion is spent to diagnose and treat STIs and their complications in the United States. When interacting with clients who are sexually active, nurses need to consider incorporating brief educational interventions about STIs into client care; nurses cannot assume that persons are knowledgeable. The more informed individuals are about STI transmission and prevention, the more likely they are to protect themselves.

### Adult Women (35 to 65 Years)

Women in the adult age group of 35 to 65 years have established themselves into patterns of living that have served them well or ill. During this period, the results of years of choices may present themselves in the form of chronic illnesses. Nevertheless, many women in this age group have time to change their health habits to possibly reverse encroaching chronic illnesses. For other women, lifestyle choices and undetected diseases have shortened their lifespans, and large numbers of women in this age group are dying prematurely.

### Menopause and Hormone Replacement Therapy

Women in this age group experience **menopause**, a time that marks the permanent cessation of menstrual activity, usually occurring between the ages of 45 and 55 years. However, it can occur as early as age 30. Natural menopause is defined as cessation of menstrual periods for 12 consecutive months, with no other apparent cause. Surgical removal of the ovaries produces menopause, and 600,000 total hysterectomies are

performed each year in the United States. At least one in three women has had a hysterectomy by the age of 60. Symptoms of menopause vary among women and last from months to years. They range from hardly noticeable in some women to very severe in others. Symptoms include nervousness, hot flashes (flushes), chills, excitability, fatigue, mood disorders (apathy, mental depression, crying episodes), insomnia, palpitations, vertigo, headache, numbness, tingling, myalgia, urinary disturbances, and vaginal dryness (OWH, 2006b).

In 2002, researchers found an increased rate of breast cancer, ovarian cancer, heart disease, and stroke among healthy women in the Women's Health Initiative study who were taking combined estrogen and progestin hormone replacement therapy (HRT). The initial reaction to this information was a dramatic decline in prescribing by physicians, which included both combined HRT and estrogen alone. The debate over the risk versus benefit of long-term HRT is ongoing.

One benefit of HRT use is to support bone health. A long-term effect of low estrogen levels is osteoporosis. After menopause, lower estrogen levels affect the balance between bone removal and bone replacement. Overtime, the bone loses density, becomes fragile, and fractures easily. Bone density is, however, influenced by other factors such as heredity, race, physical activity, and nutrition. Among healthy postmenopausal women, calcium with vitamin D supplementation resulted in a small improvement in hip bone density, but did not significantly reduce hip fracture. Medications such as biphosphates (Fosamax, Boniva, and Actonel) can improve bone density (OWH, 2006b).

### Heart Disease

Diseases of the heart are the number one killer of women. In 2004, a total of 330,513 women in the United States died of heart disease. A racial disparity exists, with death rates related to CVD for Black women at 331.6 compared to 239.3 for White women in the same year. The most common heart problem, coronary heart disease, is underdiagnosed, undertreated, and under-researched in women. In addition, women have higher mortality after heart attack and poorer outcomes than do men, which may be related to delayed diagnosis and treatment. Risk factors for heart disease in women are age, family history, race and ethnicity (higher prevalence among Black women), physical inactivity, obesity, diabetes mellitus, high blood pressure, high cholesterol, and cigarette smoking (American Heart Association [AHA], n.d; NCHS, 2007).

Family history and advancing age cannot be changed, but women can make lifestyle changes to alter other risk factors. The remaining risk factors are issues that the community health nurse can discuss with female clients in this age group. Community health nurses can help raise awareness regarding heart disease when working with women at the individual, family, or aggregate levels. Some important facts that can be shared are that only 13% of women view heart disease as a health threat, even though it is number-one killer of women; 64% of women who die suddenly of coronary heart disease had no previous symptoms; one in 2.6 female deaths are from CVD, compared with one in 30 from breast cancer; women have atypical heart symptoms or less acute chest pain, which may delay them from seeking care; women are less likely to

complete secondary prevention programs; and hormone therapy does not reduce coronary events. An excellent lay resource is “Go Red for Women” a public awareness program of the American Heart Association (AHA) to help improve knowledge (AHA, 2007; NCHS, 2007; Rosenfeld, 2006).

## Cancer

Cancer is the second leading cause of death for women, killing 267,058 women in the United States in 2004. Genetic abnormality plays a role in cancer (possibly linked to environmental exposures), but only 5% of cancers are hereditary. Thus, the vast majority of cancers are random, and the majority occur in middle age. The lifetime risk of a woman getting cancer is one in three. Overall, Blacks are more likely to develop cancer and die. To help address this disparity, community health nurses can provide more opportunities for education and screening for this population (ACS, 2007; NCHS, 2007).

Breast cancer is the most common cancer among women; however, more women die of lung cancer. In 2007, it is estimated that 40,460 breast cancer–related deaths will occur. Overall, the death rates from breast cancer have declined since 1990, and the biggest decline was for women under 50 years of age. This can be attributed to early detection and improvements in treatment. The sooner breast cancer is discovered, the more successfully it is treated. By engaging in routine breast self-examinations (BSE), having regular mammograms, eating a diet low in fat and high in fruits and vegetables, breast-feeding (if possible), and avoiding prolonged use of estrogen replacement therapy, a woman is doing what she can to promote breast health. The community health nurse has many resources available to provide information and to teach BSE individually to women in their homes, small groups in clinics, or in various other community settings (see Chapter 12) (ACS, 2007). See Table 23.4.

Women should begin BSE at age 20 and continue monthly for the remainder of their lives. Clinical breast examination, conducted by a health care provider, should be

done as a part of routine gynecologic or health examinations every 3 years for women 20 to 40 years of age and then annually. Mammography is not usually recommended for women younger than 40 years of age, but is recommended annually thereafter. Women who have a first-degree relative with breast cancer (mother, sister), a breast cancer gene (BRCA 1 or BRCA 2), or have had previous breast cancer are at a higher risk for developing the disease than other women in the general population. Therefore, these individuals need to consult their physicians regarding timelines for screenings (ACS, 2007).

Papanicolaou (Pap) smears have improved early detection and prevention of cervical cancer dramatically. Both the incidence and the death rates for cervical cancer have declined dramatically in recent decades due to treatment of preinvasive cervical lesions. The major risk factors for this disease are infection with certain types of the human papillomavirus (HPV), unprotected intercourse at an early age, and multiple sex partners. In 2007, it was estimated that 11,150 new cases of cervical cancer would be diagnosed in the United States, contributing to 3,670 deaths among women from this disease. The 5-year survival rate for this cancer if prompt treatment is initiated is 92%, making it one of the most successfully treated cancers. Community health nurses can continue to improve screening and early diagnosis through education and advocating for low-cost screening, which will allow many at-risk elderly, low-income, and rural women access to regular Pap screenings. In addition, making women aware of the HPV vaccine Gardasil, approved by the U.S. Food and Drug Administration in 2006 for use in girls between the ages of 9 and 26, may reduce the incidence of cervical cancer in upcoming decades (ACS, 2007).

Ovarian cancer is the second most frequently diagnosed gynecologic cancer and contributes to more deaths than any other cancer of the reproductive system. In the past two decades, ovarian cancer has declined less than 1%, mostly because of a lack of ovarian cancer screening and early detection. For this reason, it is imperative that women have annual pelvic exams, especially those who are at risk (women have had breast cancer or a family history, BRCA 1 or BRCA 2 gene, previous ovarian cancer). The 5-year survival rate is 44% compared to cervical (77%) and breast (88.5%). Therefore, community health nurses need to continue to stress the importance of early detection for a disease that, in 2007, killed more than 15,000 women (ACS, 2007).

## Chronic Fatigue and Immune Dysfunction Syndrome

**Chronic fatigue and immune dysfunction syndrome (CFIDS)** is characterized by persistent and debilitating fatigue and additional nonspecific symptoms such as sore throat, headache, painful muscles, joint pain, difficulty thinking, and loss of short-term memory. CFIDS affects as many as 500,000 persons in the United States, and 80% of those diagnosed with the syndrome are women between 25 and 45 years old. Rest does not relieve the fatigue. Symptoms may wax and wane, and are difficult to validate objectively, but they are subjectively debilitating. Symptoms can last for months or years. Because the cause is unknown, there is no specific treatment and no prevention suggestions. Treatment is focused on supportive care for the associated pain, depression, and insomnia. The community health

**TABLE 23.4 Breast Cancer Death Rates Among All Women—2006**

(Age-Adjusted Rates per 100,000)	
Women	Rate
All Women	24.4
White	23.9
Black	32.2
Hispanic	15.6
American Indian/Alaska Native	14.8
Asian/Pacific Islander	12.7

Extracted from National Center for Health Statistics (2007). *Health, United States, 2006 with Chartbook on Trends in the Health of Americans*. (DHHS Pub. No. 1232.) Hyattsville, MD: Public Health Service.

nurse can assess activity level and degree of fatigue, emotional response to the illness, and coping ability. Emotionally supportive family members and health care providers are helpful. Referring women to mental health career counseling, or a local support group is helpful for many women and within the role of the community health nurse (CDC, 2006a; Edwards, Thompson, & Blair, 2007)

## MEN'S HEALTH

Gender is among the numerous factors that influence health. More male neonates die at birth, and men are more likely to die earlier from a chronic illness than women. This is evidenced by the difference in life expectancy between men and women: in the United States, women survive an average of 6 years longer than men (Plumb & Brawer, 2006).

### Overview of Factors Influencing Men's Health

The concept of masculinity is an influencing factor in men's health. Men are socialized to be independent and conceal their vulnerability. Therefore, even when they are aware of their personal physical or mental problems, they are less likely to access the health care system. How the male identity is maintained can include activities that are hazardous to their health, and the result is a high death rate from unintentional injuries among young men. Examples of these activities include working in dangerous jobs, engaging in behaviors that lead to increased risk of homicide or car crashes, excessive alcohol consumption, smoking, substance use, and unsafe sex practices (Galdas, Cheater, & Marshall, 2005; Gough, 2006; Lonczak, Neighbors, & Donovan, 2007).

Currently, there is no Office on Men's Health in the U.S. Department of Health and Human Services, but legislation to establish such an office has been introduced. This office would mirror the work of the existing Office on Women's Health and be responsible for coordinating the men's health awareness, prevention, and research efforts that are now being conducted by federal and state government.

Factors that contribute to the deteriorating state of men's health include a lack of quality health education programs for men, health care services that are only accessed half as much by men when compared to women, and a lack of male gender-specific research (Men's Health Network, 2003). Considering all of these factors, the community nurse must determine the health care needs of men at various stages, and how he can best meet these needs throughout the adult lifespan.

### Men's Health Promotion Across the Adult Lifespan

In the early years of young adulthood (between 18 and 35 years), men continue to grow and mature. Adult men aged 35 to 65 years have reached maturity, the peak of their physical and intellectual development, and their greatest earning power. What specific needs do men in these age groups have? Are their needs being met through services provided?

### Healthy People 2010 Goals for Men

Although *Healthy People 2010* has 25 health objectives specifically for women and just five specifically for men,

#### DISPLAY 23.5

#### HEALTHY PEOPLE 2010 OBJECTIVES FOR MEN

- 3-7. Reduce the prostate cancer death rate, from 32 prostate cancer deaths per 100,000 males to 28.8 deaths per 100,000.
- 9-6. (Developmental) Increase male involvement in pregnancy prevention and family planning efforts.
- 13-2. Reduce the number of new AIDS cases among adolescent and adult men who have sex with men, from 17,847 new cases of AIDS in 1998 to 13,385 new cases in 2010.
- 13-4. Reduce the number of new AIDS cases among adolescent and adult men who have sex with men and inject drugs, from 2,122 new cases of AIDS in 1998 to 1,592 new cases in 2010.
- 13-6. Increase the proportion of sexually active persons who use condoms, from 23% to 50%.

Adapted from U.S. Department of Health and Human Services. (2000). *Healthy people 2010: Understanding and improving health* (2nd ed.). Washington, DC: U.S. Government Printing Office.

hundreds apply to both women and men of all ages. The five men's objectives focus on prostate health, reproductive health, and disease prevention among men, especially men who have sex with men (MSM) (see Display 23.5).

### Young Adult Men (18 to 35 Years)

The young adult male has many tasks to accomplish. These tasks include the acquisition of training or education that will lead to a personally and financially rewarding career; selecting a compatible lifetime companion and establishing a life together; finding comfort with and meaning to existence through practicing and internalizing a belief and value system that works for him; actively planning for having (or not having) children; and participating in the betterment of the greater community, both actively (volunteering, committee work, leadership positions) and passively (voting, being a good citizen, obeying laws).

Depending on his attitudes and practices before a man enters this age group, he may or may not be enticed to experiment or continue with the use of tobacco, alcohol, or illicit drugs. Experimentation or usage of these substances can occur in college, the military, or working at a full-time job. Young men also engage in behaviors or take risks without thinking about the consequences. They respond to challenges such as drag racing, exceeding speed limits, and binge drinking. This is an important age group for the community health nurse to reach with health information, because the decisions made in the more formative years of this stage affect how these clients live the rest of their lives. The nurse can meet with young adult men in work settings, on college campuses, on military bases, at single-adult groups sponsored by religious communities and other organizations, and in health clubs and bars.

Another issue to address during the early years is the young man's attitudes and beliefs toward sex and sexual experimentation. Young men may question their sexuality as they mature, and during this stage some men come to the

realization that they are homosexual. **Gay** is the commonly accepted term for a homosexual—a person who has sexual interest in, or has sexual intercourse exclusively with, members of his or her own sex. Some men choose to have sex with men as well as women; these men are bisexual. Some men who have sex with either men, women, or both often do not consider themselves to be gay or bisexual. These men are categorized as men who have sex with men (MSM). When taking a sexual history, community health nurses must ask men if they have sex with women, men, or both.

**Transgender**, another term associated with sexuality, is used to describe individuals who experience and/or express their gender differently from what people might expect. These individuals express characteristics that do not correspond with the person's apparent or presumed gender. An example is when a presumed male chooses to put on make-up and clothes that a female would traditionally wear. Some transgender individuals define themselves as *female-to-male* or *male-to-female* and may take hormones and/or undergo medical procedures to enhance or make permanent their gender selection, including sex reassignment surgery. Others prefer to simply be called *male* or *female*—the gender they present to others, whether or not they have undergone medical reassignment.

Sexual experimentation, whether heterosexual or homosexual, can place young men at risk for diseases that affect their long-term health or are life-threatening. Men who are sexually active can reduce the possibility of being infected with a STI by limiting the number of sexual partners and using condoms consistently and correctly. Condoms also serve as a form of birth control for men. *Monogamy*, having sex with only one partner, and abstinence can further reduce or eliminate the chance of contracting an STI. Community health nurses can serve as a resource for young men and can help them obtain free or low-cost condoms and treatment for STIs.

## Human Immunodeficiency Virus and Men

Despite advances in the prevention and treatment of human immunodeficiency virus (HIV), the disease continues to disproportionately impact men in the United States. In 2005, an estimated 342,148 adult and adolescent males were living with HIV in the 33 states with confidential name-based reporting. This represents 73% of the total HIV/AIDS cases. Among those cases, 61% reported being exposed through male-to-male sexual contact, 18% through injection drug use, and 7% through male-to-male sexual contact and injection drug use; however, only 5% to 7% of male adults and adolescents in the United States self-identify as MSM. When examining trends in the disease based on race and/or ethnicity, the burden of the disease has shifted from White men to Black and Hispanic men. Approximately 64% of the men living with HIV are Black or Hispanic (CDC, 2006b, 2007b).

Alcohol and illicit drug use are known to decrease social inhibitions and increase the risk for HIV transmission through risky sexual behaviors (i.e., lack of condom use) and the sharing of needles or other injection equipment. Community health nurses must be able to talk openly and nonjudgmentally with men about their use of substances and their sexual relationships. These conversations can be challenging, but they have to occur if the number of HIV infections is to be reduced (Blake & Jones Taylor, 2006).

## EVIDENCE-BASED PRACTICE

### The Global Community

A study was implemented to examine the effects of a multifaceted HIV/AIDS educational intervention on the knowledge, attitudes, and willingness of 208 Chinese nurses to care for persons living with human immunodeficiency virus (HIV). A pretest, posttest, quasi-experimental design was employed. The intervention consisted of a 5-day workshop that included lectures interspersed with activities designed to elicit discussion of participants' values and personal feelings about HIV/acquired immune deficiency syndrome (AIDS). The content included HIV epidemiology, natural history, transmission route, and clinical care. In addition, human sexuality, addictive disease, and bereavement were addressed. The outcome variables included HIV/AIDS knowledge, attitude toward persons living with HIV/AIDS, and willingness to provide nursing care. At baseline, HIV/AIDS knowledge was low, and participants were neutral in their attitudes and willingness to care for infected individuals. Knowledge, attitudes toward persons with HIV/AIDS, and willingness to provide nursing care improved at the conclusion of the educational intervention ( $p = 0.001$ ).

The HIV/AIDS epidemic challenges nurses to increase their knowledge about providing effective HIV/AIDS prevention and care. As the epidemic expands, nurses are being called upon to deliver competent and compassionate care to persons living with the disease and their families. Comprehensive and interactive HIV/AIDS educational programs can contribute to international efforts to increase knowledge and improve attitudes toward caring for persons living with HIV/AIDS.

Williams, A.B., Wang, H., Burgess, J., Wu, C., Gong, Y., & Li, Y. (2006). Effectiveness of an HIV/AIDS educational programme for Chinese nurses. *Journal of Advanced Nursing*, 53(6), 710–720.

## Testicular Cancer

The risk for testicular cancer is a health problem that young men should be aware of even before early adulthood. The disease occurs most often in men between 20 and 39 years of age. Men with a personal history of undescended testicles or a family history of testicular cancer have the highest risk of developing this cancer (ACS, 2007; National Cancer Institute, 2005). It is a rare form of cancer and is not on the list of objectives for men in *Healthy People 2010*. However, if detected early, this cancer is highly curable. It is beneficial to the overall health of a young man to know how to do a testicular self-examination (TSE), and teaching men how to perform this exam appropriately is an important role for the community health nurse (see Display 23.6).

The choices a man makes during these years establish healthy eating, work, rest, and exercise habits that will benefit him for a lifetime. Men should follow the diet recommended foods in the U.S. Department of Agriculture's Food

## DISPLAY 23.6

## PERFORMING TESTICULAR SELF-EXAMINATION (TSE)

- TSE should be performed monthly.
- TSE should be done right after a hot shower or bath. The scrotum is most relaxed then, which makes it easier to examine the testicles.
- Examine one testicle at a time. Use both hands to gently roll each testicle (with slight pressure) between your fingers. Place your thumbs over the top of your testicle, with the index and middle fingers of each hand behind the testicle, and then roll it between your fingers.
- The epididymis, which feels soft, rope-like, and slightly tender to pressure, is located at the top of the back part of each testicle. This is a normal lump.
- One testicle (usually the right one) is slightly larger than the other; this is normal.
- When examining each testicle, feel for any lumps or bumps along the front or sides. Lumps may be as small as a piece of rice or a pea.
- If there are any swellings, lumps, or changes in the size or color of a testicle, or if there is any pain or achy area in your groin, let your doctor know right away.
- Lumps or swelling may not be cancer, but a physician should be consulted.

Adapted from Testicular Cancer Resource Center. (2006). *How to do a testicular self-examination*. Retrieved May 14, 2007 from <http://tcrc.acor.org/tcexam.html>.

Guide Pyramid, considering his personal likes and dislikes (2005). He and his family will benefit if he is able to balance work and home, doing his best in both settings. Establishing a pattern of rest that allows his body to recover and refresh from a day full of meaningful activities will help him look forward to each day. He should establish an exercise routine that meets his personal needs, fits his skills and talents, and includes some physical activities that involve his family.

These choices provide him with the knowledge that he is doing everything he can to keep himself healthy and to prevent the two major killers of men—heart disease and cancer. However, there are additional considerations. Typically, young adult clients have few interactions with health care providers in any given year. It is often assumed that young adult males in this age range are not at risk for physical or psychological disease. This is a myth. It is important for people in this age group to have regular health checkups, to be assessed for early signs of disease and discuss health promotion activities.

### Adult Men (35 to 65 Years)

Men in the developmental stage between 35 and 65 years of age are often faced with caring for both their own children

and their aging parents and in-laws. The physical, economic, and emotional demands can be great: older adults may have extended care needs while, simultaneously, the family must bear the economic burdens of putting children through college. Meanwhile, men are adjusting to the reality that their career path is probably set and many of their life choices have been made.

The term “midlife” is applied to the first half of this age period. It is a time when many men focus on a reappraisal of values, priorities, and personal relationships. As the term “midlife crisis” implies, this can be one of the more difficult stages of life. It can be an emotional time of doubt and anxiety when a man becomes uncomfortable with the idea that his life is half over. He may believe that he has not accomplished enough, or he may struggle to find new meaning or purpose in his life. Men may experience boredom with their personal life, job, or partners, and desire to make changes in these areas may occur (Wilcox et al., 2006).

The later years in this stage, ages 50 to 64, involve preparation for retirement. In anticipation of retirement, these years are marked by expanded social relationships and pursuit of new hobbies to fill increased leisure time, along with anticipating finishing of a career and accumulation of the best retirement benefits. The decisions made during these years will play out over the rest of a man’s life and could alter how a spouse or long-term partner lives out their years. Health problems that were left undiagnosed when the man was younger begin to emerge. Peers may be suffering and succumbing to diseases, and a man begins to adjust to the potential loss of loved ones, particularly a spouse or long-term companion (Miner-Rubino, Winter, & Stewart, 2004).

Successful navigation of this stage can be fulfilling but may require a man to enhance his self-care skills. This includes having a positive attitude toward aging, one that examines the benefits of maturity, finds a balance between work and home, and maintains a healthy lifestyle by eating balanced meals and obtaining regular exercise. The community health nurse can provide anticipatory guidance to men approaching this stage and help them with ways to manage life more effectively.

### Reproductive Health

During this stage, especially when a man has decided that his family is complete, he may choose a permanent form of birth control. For men, permanent birth control can be obtained through a surgical procedure called a *vasectomy*. A vasectomy includes removal of all or a segment of the vas deferens, so that sperm cannot be released. The procedure is routinely conducted on an outpatient basis and is minimally invasive. The procedure takes about 30 minutes. Vasectomies are to be considered permanent, however with the advent of microsurgical techniques, vasectomy reversals are now possible. Vasectomies have grown in popularity since development in the 19th century, and about 500,000 men in the United States choose to undergo the procedure each year (Dassow & Bennett, 2006).

Erection problems are common among men of all ages, but especially in men as they age. **Erectile dysfunction (ED)**, sometimes called “impotence,” is the repeated inability to get or keep an erection firm enough for sexual intercourse. The word “impotence” may also be used to describe other

problems that interfere with sexual intercourse, such as lack of sexual desire and problems with ejaculation or orgasm. Using the term *erectile dysfunction* makes it clear that those other problems are not involved (American Urological Association [AUA], 2006b; Wessell, Joyce, Wise, & Wilt, 2007).

Since an erection requires a specific sequence of events, ED can occur when any of the events are disrupted. The sequence includes nerve impulses in the brain, spinal column, and area around the penis, and response in muscles, fibrous tissues, veins, and arteries in and near the corpora cavernosa. Damage to nerves, arteries, smooth muscles, and fibrous tissues, often as a result of disease, is the most common cause of ED. Diseases such as diabetes, kidney disease, chronic alcoholism, multiple sclerosis, atherosclerosis, vascular disease, and neurologic disorders, account for about 70% of ED cases. Between 35% and 50% of men with diabetes experience ED (National Institute of Diabetes and Digestive and Kidney Diseases [NIDDKD], 2005; Sun et al., 2006).

Lifestyle choices that contribute to heart disease and vascular problems also increase the risk of ED. Smoking, being overweight, and lack of exercise are possible causes of ED. Surgery (especially radical prostate and bladder surgery for cancer) can injure nerves and arteries near the penis, causing ED. Injury to the penis, spinal cord, prostate, bladder, and pelvis can lead to ED by harming nerves, smooth muscles, arteries, and fibrous tissues of the corpora cavernosa. In addition, many common medicines—antihypertensives, antihistamines, antidepressants, tranquilizers, appetite suppressants, and cimetidine—can produce ED as a side effect (AUA, 2006b).

In diagnosing ED, the medical history should include whether or not erections occur at other times. If an erection can be achieved with masturbation or upon awakening, the problem is probably not physical and is related to stress or an emotional problem. Treatment for ED usually proceeds from least to most invasive. For some men, making a few healthy lifestyle changes may solve the problem. Smoking cessation, weight loss, and increased physical activity may help some men regain sexual function. Cutting back on any drugs with harmful side effects is considered next. For example, drugs for high blood pressure work in different ways. If a particular drug is causing problems with erection, a different class of blood pressure medicine might work just as well. Psychotherapy and behavior modifications in some men should be considered (AUA, 2006b; Laumann et al., 2007).

Drugs for treating ED can be taken orally, injected directly into the penis, or inserted into the urethra at the tip of the penis. In March 1998, the FDA approved sildenafil citrate (Viagra), the first pill to treat ED. Since that time, vardenafil hydrochloride (Levitra) and tadalafil (Cialis) have also been approved. Viagra, Levitra, and Cialis all belong to a class of drugs called phosphodiesterase (PDE) inhibitors. Taken an hour before sexual activity, these drugs work by relaxing smooth muscles in the penis during sexual stimulation and allow increased blood flow (Shabsigh et al., 2006).

## Heart Disease and Men

**Cardiovascular disease** (CVD) is a term that refers to the broadest category of diseases that affect the heart and blood vessels. More than 37 million men (about one in three) have some form of CVD. The number of deaths among men from

this disease exceeds 300,000 deaths annually. CVD accounts for more deaths in men than cancer, lung disease, accidents, and diabetes combined. Compared to White men, Black men are more likely to die of CVD and Hispanic men are less likely (NCHS, 2007; Rosamond et al., 2007).

In the 44-year follow-up of the Framingham Heart Study participants and the 21-year follow-up of their offspring, researchers found that the average annual rate of a major cardiovascular event among men 35 to 44 years of age was seven per 1,000.

It is estimated that between 70% and 89% of sudden cardiac events occur in men and that 50% of these men had no previous symptoms of disease. The average age of a first heart attack for men is 66 years. Men who have a heart attack before age 65 have an almost 50% chance of dying within 8 years (Rosamond et al., 2007).

Major risk factors for heart disease in men include hypertension, hyperlipidemia, tobacco use, diabetes, lack of physical activity, excessive alcohol consumption, and low daily fruit and vegetable consumption. When working with adult men, the community health nurse should educate men about the importance of modifying factors that increase their risk of developing CVD. Knowing the signs and symptoms of a heart attack and how to access emergency medical treatment are also important topics that the community health nurse should discuss with adult males.

## Prostate Health

Prostate health is another concern that may occur later in this life stage. The **prostate** is a doughnut-shaped cluster of glands located at the bottom of the bladder, about halfway between the rectum and the base of the penis. The prostate encircles the urethra. The walnut-sized gland produces most of the fluid in semen. Men can experience infection (prostatitis), prostate enlargement (benign prostatic hypertrophy), and prostate cancer.

Benign prostatic hypertrophy (BPH) is very common, and affects about one-third of men over age 50. The primary risk factor for developing BPH is age. Symptoms of BPH are caused by an obstruction of the urethra and gradual loss of bladder function, which results in incomplete emptying of the bladder. The symptoms of BPH vary, but the most common ones involve changes or problems with urination, such as hesitant, interrupted, or weak urinary stream; urgency or leaking of urine; and more frequent urination, especially at night. Men often report the symptoms of BPH before the physician diagnoses it through a digital rectal examination (DRE). Treatment for BPH can include medication or surgery to reduce the size of the prostate (AUA, 2006a; Rados, 2006).

Prostate cancer is the most frequently diagnosed cancer in men. The ACS estimated that there were almost 219,000 new cases of the disease and about 27,050 deaths from prostate cancer in 2007. For unknown reasons, the incidence rates are significantly higher in Blacks than in Whites. Age, ethnicity, and family history of the disease are the only well-established risk factors. More than 65% of all prostate cancers are diagnosed in men age 65 years or older. If it is detected early, the cancer may be curable. The ACS recommends that screening of men who are at average risk should begin at age 50 years and should include a blood test to assess levels of prostate specific antigen (PSA) and a DRE.

Individuals at higher risk for developing the disease (Black men or men with a family history) should begin screening at age 45 (ACS, 2007; Constantinou & Feneley, 2006).

Treatment for prostate cancer depends on the man's age, overall health status, and stage of the disease. Treatment options include surgery to remove all or part of the prostate (prostatectomy), radiation, and hormone therapy. Surgery, radiation, and hormone therapy all have the potential to disrupt sexual desire and performance, temporarily or permanently. Urinary dysfunction and urinary incontinence are common side effects that can occur after surgery or radiation. Rather than immediate treatment, watchful waiting or careful observation is an option that may be appropriate for older men with limited life expectancy and/or less aggressive tumors. A community health nurse can reinforce or clarify information shared with the man by his health care provider, discuss his treatment options with him and his family, and provide the support they may need if prostate cancer is diagnosed.

## ROLE OF THE COMMUNITY HEALTH NURSE

The community health nurse works with adults in all age groups using the three levels of prevention—primary, secondary, and tertiary—as a guide. Interventions are conducted at the individual, family, groups, and aggregate levels to make progress toward the *Healthy People 2010* objectives (see Levels of Prevention Pyramid; Display 23.2).

Client teaching by the community health nurse is a major factor in preventing and managing of chronic diseases. The challenge to the nurse is to be prepared to discuss issues, backed up with knowledge of and access to the appropriate community resources, to meet client needs. What the nurse can accomplish can be quite dramatic in terms of reducing days in the hospital because of chronic disease, improving quality of life for the chronically ill person, and preventing a combination of unhealthful habits from becoming causative factors in new cases of chronic disease. A nursing care plan matrix can guide the community health nurse in discussing areas of health promotion and protection with the client. An example of a Nursing Care Plan Matrix for Young Adults can be found in Display 23.4.

### Primary Prevention

Primary prevention activities focus on education to promote a healthy lifestyle. Much of the community health nurse's time is spent in the educator role. When working with individuals, the community health nurse should encourage routine health examinations, healthy eating habits, adequate sleep, moderate drinking, and no smoking. Among aggregates, the community health nurse focuses on community needs for services and programs that will keep that population healthy, such as providing flu clinics, teaching sexual responsibility, and preventing STIs.

The community health nurse may collaborate with community leaders and other stakeholders in designing programs, work with committees to secure funding, or approach the state legislature to lobby for needed changes to state laws and policies governing the health of adults. At other times, the nurse works with small groups of adults who could benefit from making healthy choices in diet, relax-

ation, and physical activity. Likewise, it is not unusual for the community health nurse to work with an individual to promote healthy living.

### Secondary Prevention

Secondary prevention focuses on screening for early detection and prompt treatment of diseases. Throughout the lifespan, screening tests can help adults to identify disease early (see Display 23.2). A significant amount of the community health nurse's time is spent in assessing the need for, planning, implementing, or evaluating programs that focus on the early detection of diseases. This is followed with teaching to prevent further damage from the disease in progress or to prevent the spread of the disease if it is communicable. Examples of secondary prevention programs include establishing mammography clinics, teaching breast and testicular self-examination, and conducting blood pressure, blood glucose, BMI, and cholesterol screenings. Wherever adults gather in groups, this is a good place to provide both primary and secondary health care and prevention services.

### Tertiary Prevention

The tertiary level of prevention focuses on rehabilitation and preventing further damage to an already compromised system. Many adults that a community health nurse works with have chronic diseases, conditions resulting from another disease, or longstanding injuries with resulting disability. Ideally, negative health conditions can be prevented. If not, the next best thing is for them to be diagnosed early, without damage to an individual's health. But if negative health conditions have not been treated or brought under control, then the individual is at a tertiary level of prevention. At this level of prevention, the nurse focuses on maintaining quality of life.

Depending on the client's age, tertiary prevention can be simple or very complicated. A 19-year-old man who breaks his leg while skiing needs information about using crutches safely, a reminder to eat protein foods for bone healing, and a reminder to return to his health care provider to get the cast removed or if he experiences various symptoms. He needs no additional help from others. Tertiary prevention in this case is easy. On the other hand, a 62-year-old woman who is 70 pounds overweight with out-of-control blood glucose levels, symptoms of congestive heart failure, and difficulty walking more than 20 feet has much to accomplish in order to feel healthy. Can the nurse help the woman lose weight? Will weight loss bring her diabetes under control and alleviate congestive heart failure symptoms? With some weight reduction, will she be able to walk more easily? Or, will the woman feel better with physical therapy and a different medication regimen? Is there a quicker, safer, and better approach? On assessment, the nurse discovers that the woman has been as much as 80 pounds overweight for 40 years. Will this information alter the nurse's approach to helping this woman? What additional information does the nurse need?

Caring for people at the tertiary level of prevention can become quite complicated, because so many systems become involved. In addition, all people function within many social systems, which may include family expectations, roles people have within the family, expected behaviors, community

## LEVELS OF PREVENTION PYRAMID

**SITUATION:** Breast Cancer

**GOAL:** Using the three levels of prevention, negative health conditions are avoided or promptly diagnosed and treated, and the fullest potential is restored.

<b>Tertiary Prevention</b>	
<b>Rehabilitation</b>	<b>Primary Prevention</b>
<ul style="list-style-type: none"> <li>Recovery at home with return to activities of daily living within 2 weeks</li> </ul>	<p style="text-align: center;"><i>Health Promotion &amp; Education</i></p> <ul style="list-style-type: none"> <li>Maintains periodic follow-up with health care provider, follow-up mammogram at 6 months and 12 months, and as recommended by health care provider</li> <li>Education regarding risk for other cancers (ovarian, etc.)</li> </ul> <p style="text-align: center;"><i>Health Protection</i></p> <ul style="list-style-type: none"> <li>Continues to practice breast self-exam (BSE) and receive mammograms as required; receives screening for ovarian cancer—transvaginal ultrasonography and blood test for tumor marker CA125</li> </ul>
<b>Secondary Prevention</b>	
<b>Early Diagnosis</b>	<b>Prompt Treatment</b>
<ul style="list-style-type: none"> <li>Identification of lump in left breast; appointment made with health care provider for evaluation</li> <li>Receives mammogram and sonogram</li> </ul>	<ul style="list-style-type: none"> <li>Needle aspiration of lump followed by cytologic studies</li> <li>Lumpectomy with removal of two suspicious lymph nodes</li> <li>Low-dose radiation</li> </ul>
<b>Primary Prevention</b>	
<b>Health Promotion &amp; Education</b>	<b>Health Protection</b>
<ul style="list-style-type: none"> <li>Education regarding how to perform the BSE</li> <li>Education regarding timelines for BSE and mammograms</li> <li>Education regarding environmental exposure and breast cancer (smoking, alcohol, chemicals)</li> <li>Education regarding low-fat diet and maintaining a BMI less than 29</li> </ul>	<ul style="list-style-type: none"> <li>Avoidance of environmental exposures that may contribute to cancer</li> <li>Performs monthly BSE and obtains mammogram as appropriate</li> </ul>

system knowledge and involvement, personal expectations, motivation, and support. Working at the tertiary level involves all of the nurse's skills in addition to community resources and a client who can be or wants to be motivated.

### Summary

The 20th century saw a shift in the leading causes of death, from communicable to noncommunicable diseases. Currently, the five leading causes of death in adults are diseases of the

heart, malignant neoplasms, cerebrovascular diseases, chronic lower respiratory diseases, and unintentional injuries—none of which are communicable. The health care needs of adults are of great concern. Many needs are the same for both women and men, but the important differences were addressed in this chapter.

Adults have health care needs that change as they age. Diet and exercise, obesity, substance use, safety, and healthy lifestyle choices are issues that adults must consider throughout their lives. Heart disease and cancers remain

important concerns for both men and women, and health decisions made as a young adult can have a major impact on a person as he ages.

Chronic illness is an issue of increasing concern for both men and women as life expectancies increase. Community health nurses should use the three levels of prevention to promote health across the lifespan. Primary prevention activities focus on education to promote a healthy lifestyle. Secondary prevention focuses on screening for early detection and prompt treatment of diseases. The community health nurse's role at this stage is to assess the need for, plan, implement, or evaluate programs that focus on the early detection of diseases, and to educate clients to prevent further damage from, or spread of, the disease. The tertiary level of prevention focuses on rehabilitation and prevention of further damage to an already compromised system. At this level of prevention, the nurse focuses on maintaining quality of life. ■

### ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Using the local newspaper, select three articles that relate to a preventable chronic disease. For each article, summarize the content, identify the likely cause, and describe how the disease may have been prevented.
2. You are asked to offer a weight-control program for 12 young adults who are residents in an apartment complex that has monthly programs related to health and wellness. The ages of the intended participants range from 20 to 35. What steps would you take to develop a successful program?
3. Using the Internet and school library, research a chronic disease associated with men aged 35 to 65. Write a two-page paper in which you identify selected concerns and discuss both personal responsibility and societal responsibility regarding management of this health problem.
4. Using the Internet and school library, research a chronic disease associated with women aged 35 to 65. Write a two-page paper in which you identify selected concerns and discuss both personal responsibility and societal responsibility regarding management of this health problem.

# Older Adults: Aging in Place

## LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Describe the global and national health status of older adults.
- ◆ Identify and refute at least four common misconceptions about older adults.
- ◆ Identify four types of elder abuse.
- ◆ Describe characteristics of healthy older adults.
- ◆ Provide an example of primary, secondary, and tertiary prevention practices in the elderly population.
- ◆ Identify four chronic conditions most commonly found in the elderly population.
- ◆ Discuss four primary criteria for effective programs for older adults.
- ◆ Describe various types of living arrangements and care options as older adults age in place.
- ◆ Describe the difference between hospice and palliative care.
- ◆ Describe the future of an aging America and the role of the community health nurse.

*“We are encouraging Americans of all ages to live healthier lives. Healthy living can prevent diseases and certain disabilities, and it can ensure that today’s older persons—as well as future generations—not only live longer, but also better.”*

—Josefina G. Carbonell, Assistant Secretary for Aging, U.S. Department of Health and Human Services (Administration on Aging, 2007a, p. 1).

## KEY TERMS

Ageism  
 Alzheimer’s disease (AD)  
 Assisted living  
 Board and care homes  
 Case management  
 Continuing care retirement communities (CCRCs)  
 Custodial care  
 Elder abuse  
 Elite-old  
 Frail elderly  
 Geriatrics  
 Gerontology  
 Hearty elderly  
 Hospice  
 Intermediate care  
 Long-term care  
 Osteoporosis  
 Palliative care  
 Personal care homes  
 Respite care  
 Senility  
 Skilled nursing facilities

 **Older** Americans constitute a large and rapidly growing population group. If you aren't already part of it, you will be in the future. Perhaps your parents and grandparents are in that group now. Improved medical care, advances in public health standards, and focus on prevention have contributed to dramatic increases in life expectancy in the United States. Average life expectancy at birth rose from 47.3 in 1900 to 76.9 in 2000 (He, Sengupta, Velkoff, & DeBarros, 2005). According to U.S. Census Bureau projections, a substantial increase in the number of older people will occur during the 2010 to 2030 period, due to (1) increasing life spans and (2) aging baby boomers (people born between 1956 and 1964). By 2030, there will be 71 million American older adults, accounting for roughly 20% of the U.S. population (Centers for Disease Control [CDC] & Merck Co. Foundation, 2007).

The future older population is expected to be better educated than the current one. The increased levels of education will most likely accompany better health, higher incomes, more wealth, and consequently a higher standard of living in retirement. As people retire at younger ages and in better health, they will require programs and services that support preventive health measures, and thus provide opportunities for continued wellbeing and enhanced quality of life, and contribute to overall longevity (CDC & Merck Co. Foundation, 2007).

By 2030, the nation's health care spending is expected to increase by 25% due to projected numbers of aging adults that will require care (He et al., 2005). The cost of providing health care for an American 65 years and older is three to five times greater than the cost for someone younger (CDC, 2003a). The number of people over the age of 65 who will require health care services will create challenges, as well as opportunities, for our already overburdened, understaffed, and ever changing health care system. From 1990 to 2001, the U.S. expenditures for home health and nursing home care doubled, and are expected to continue to rise (CDC, 2003a). Although tremendous efforts have been made to develop and promote preventive health programs and services, the outcomes and benefits of these efforts may not be seen for many years (He et al., 2005; Schwappach, Boluarte, & Suhrcke, 2007).

For community health nursing, the growing aging population will present opportunities for nurses to work with communities to strengthen and build programs and services that focus on supporting the aging population's highest functional level. Like other nursing specialty areas, the community health nurse will be in the position to advocate for the needs of an aging population and work with other agencies and organizations involved with health care delivery to ensure that seniors have access to high quality health care and comprehensive services that address their unique and complex problems.

This group's potential for longevity will bring on myriad problems including poor retirement planning and dwindling finances, increased living costs and increasing chronic disease and disability, diminishing functional capacity, and ongoing losses. Despite preventive and supportive services, it is estimated that at least 40% of the population over the age of 75 will require extensive health care services late in their lives (CDC & Merck Co. Foundation, 2007; Lorenz et al., 2004). Those without adequate access to care will suffer

more long-term consequences (Rahimi, Spertus, Reid, Bernheim, & Krumholz, 2007). Significant economic, environmental, and social changes create a demand for greater protective and preventive services for older adults in addition to requiring adjustments in health care provision patterns (He et al., 2005; Martini, Garrett, Lindquist, & Isham, 2007; Lorenz et al., 2004).

This chapter focuses on population-based nursing for the elderly. There are four fundamental requirements for effective nursing of any population:

1. Know the characteristics of the population.
2. Set aside stereotypes based on misconceptions about the population.
3. Know the health needs of the population as a basis for nursing intervention.
4. View the population from an aggregate, public health perspective that emphasizes health protection, health promotion, and disease prevention.

This chapter first examines the characteristics of the aging population in the United States and the global challenge of an aging society. Some myths and misconceptions about the elderly are described, and ageism is discussed. Four types of elder abuse are reviewed along with factors that contribute to the abuse of seniors. Next, the primary, secondary, and tertiary health needs of older adults are explored. Finally, population-based health services and nursing interventions applied to the health of the aging population are discussed in light of cost containment and comprehensive care at the beginning of the new millennium.

## HEALTH STATUS OF OLDER ADULTS

The growth in the number and proportion of older adults living in the United States is unprecedented in our nation's history. The proportion of individuals aged 65 and older is projected to increase from 12.4% in 2000 to almost 20% by the year 2030 (CDC, 2003a). People are living longer as a result of improved health care, eradication and control of many communicable diseases, use of antibiotics and other medicines, healthier dietary practices, safer global water supplies, regular exercise, and accessibility to a better quality of life including education and social services. Increased life expectancy reflects, in part, the success of public health interventions, but public health programs must now respond to new challenges including the growing burden of chronic illness, injuries, disabilities, increasing concerns about future caregiving, and rapidly rising health care costs (CDC & Merck Co. Foundation, 2007; Lorenz et al., 2004; Martin & Sheaff, 2007).

As noted earlier, life expectancy at birth in the United States has increased from age 47.3 in 1900 to 76.9 in 2000 (He et al., 2005). Those born between 1946 and 1964, often referred to as "baby boomers," will begin to reach age 65 in 2011. By the year 2030, it is estimated that 20% of the entire U.S. population will be over age 65 (CDC & Merck Co. Foundation, 2007; U.S. Census Bureau, 2007). During that period, the U.S. population age 19 and under will drop—to 26.2% and 26%, respectively (U.S. Census Bureau, 2007).

The rising number of older adults increases demands on the public health system and on medical and social services

and health care delivery. Chronic diseases, which affect older adults disproportionately, contribute to disability, diminish quality of life, and increase health care costs. As more and more Americans reach age 65, society is increasingly challenged to help them grow old with dignity and comfort (Kapo, Morrison, & Liao, 2007). Chronic diseases and conditions are also a part of aging, and 59% of those over 65 years of age in the United States report arthritis as a leading cause of disability (CDC, 2003b). Diabetes and Alzheimer disease affect one in five and one in 10 of those age 65 and older, respectively, and are expected to have even greater effects on the U.S. health care system in the next few decades (CDC, 2003a). Two key challenges that are new to the public health arena, although they have long been the target of health care and aging services professions, are preventing and treating cognitive decline and addressing end-of-life issues (Kettl, 2007; Richardson, Sullivan, Hill, & Yu, 2007; Mitchell, Teno, Intrator, Feng, & Mor, 2007). Meeting these challenges, along with the increasing number of individuals with chronic conditions, is critical to ensuring that the aging population can look forward to their later years.

## Global Demographics

In 1950, there were 131 million people worldwide over the age of 65. By 1995, that number had increased to 371 million, and it should double again between 2000 and 2025. It is estimated that there could be 1.4 billion elderly worldwide by the year 2050 (International Institute for Applied Systems Analysis [IIASA], 2007). The elderly comprised 5.2% of the world population in 1950, growing only to 6.2% in 1995. But by 2050 one tenth of the population will be over the age of 65 (IIASA, 2007). In most of the world, the population of those over 80 years of age is growing faster than any other population age group (United Nations [UN], 2003a). The largest increases in absolute numbers of older persons will occur in developing countries, with China most likely to have an extraordinary rise in the proportion of elderly as their birth rates decline (IIASA, 2007). By 2050, Asia is predicted to be home to 63% of the world's elderly (UN, 2003a). Because of this demographic shift along with altered societal expectations, changes in attitudes and social policies worldwide are needed; many countries have few or no social programs, pensions, or health care services available for their elderly populations (UN, 2003b).

Life expectancy at birth around the world now ranges from 32.2 to 83.5 years (Central Intelligence Agency [CIA], 2007). Life expectancy has increased in developing countries since 1950, although the amount of increase varies. A higher life expectancy at birth for females compared with males is almost universal, with the average gender differential estimated for 2007 at approximately 4 years worldwide (67.8 years for females, 63.8 for males) (CIA, 2007). These high percentages are in part the result of extended lifespan, but they also reflect low birth rates in many countries. Presently, the world population is at roughly 6.6 billion people, but population projections continue to project increases (7.79 billion by 2025, 8.75 by 2050) despite lower birth rates in many countries (CIA, 2007; IIASA, 2007).

The median age of the world's population is 28 years, and this has been increasing due in part to declining fertility

and a 20-year increase in the average life span during the second half of the 20<sup>th</sup> century (CIA, 2007; UN, 2003b). These factors, combined with elevated fertility in many countries during the 2 decades after World War II (i.e., the Baby Boom), will result in increased numbers of persons aged 65 and over as outlined above (IIASA, 2007). Worldwide, another 10 years will be added to the average lifespan by the year 2050 (CDC, 2003a).

## National Demographics

As a result of demographic transitions including declining infant and childhood mortality, lower fertility rates, and improvements in adult health, the shape of the global age distribution is changing. By 2005, the age distribution in developed countries represented a larger proportion of older to younger populations. For developing countries, age distribution is projected to have similar proportions by 2025-2050 (UN, 2003a).

Estimates for 2007 reveal the average life expectancy at birth for Americans as 78 years (CIA, 2007). However, there are disparities in life expectancy among various subgroups in the population. Life expectancy is highest for White Americans and lowest for Black Americans, who have the highest death rates of any of America's racial and ethnic groups (Gist, 2007). Although life expectancies have been increasing for all Americans in general, a variety of factors have caused those figures to level off in recent years. These include unhealthy lifestyles; societal problems, such as deaths caused by firearms, substance abuse, and human immunodeficiency virus/acquired immunodeficiency syndrome (HIV/AIDS); and the rise of Alzheimer disease (AD) among the elderly (Gist, 2007).

The Hispanic, Black, and Asian populations have been expanding and are projected to grow substantially through 2025 (Campbell, 1996). The health status of racial and ethnic minorities of all ages lags far behind that of nonminority populations. For a variety of reasons, older adults may experience the effects of health disparities more dramatically than any other population group. In an effort to help address these health disparities, the Racial and Ethnic Approaches to Community Health (REACH 2010) Program supports community-based coalitions in the design, implementation, and evaluation of innovative strategies to reduce or eliminate health disparities among racial and ethnic minorities (CDC, 2006a). Methods utilized include "capacity building, targeted actions, community/system change, widespread risk/protective behavior change, (and) health disparity reduction" (p. 2). An example of one of these programs is highlighted in Display 24.1. One of the two goals of *Healthy People 2010*, the comprehensive set of health objectives for the nation, is to eliminate health disparities among different segments of the population, and current research has shown that although many efforts—such as aspirin use for high-risk adults, tobacco-use screening and brief intervention, colorectal cancer screening for adults over age 50, and immunization for pneumococcal disease for those age 65 and older—can be very effective, they are not always implemented or consistently utilized (Maciosek, Coffield, Edwards, Flottemesch, Goodman, & Solberg, 2006).

Nevertheless, older people are healthier than ever before. Increasing numbers of capable elderly people are

## DISPLAY 24.1

RACIAL AND ETHNIC APPROACHES TO COMMUNITY HEALTH (REACH)—  
DETROIT, MICHIGAN

High rates of diabetes-related hospital discharges and diabetes-related mortality were noted in both southwest and eastern areas of Detroit, Michigan. Public health nurses and other officials also checked statistical data and found that 43% of African Americans in Detroit were overweight, whereas 33% of Whites were overweight. Almost half of all residents reported that they had a sedentary lifestyle, and one-third stated that they engaged in no physical activities during their leisure time. Many of these people were older adults and elderly.

It was decided that this problem had to be addressed at multiple levels: with individuals and families (changing behaviors), social support systems, community agencies and services, and by making changes in policies and programs offered by Detroit Community Health & Social Services. They formed a partnership, based upon the principles of community-based participatory research (see Chapter 4). They began by collecting additional data on the prevalence of diabetes, the accessibility of quality health care services, and what community resources were available that promoted healthy lifestyles. They also looked for acceptable models of community-based interventions and gathered per-

spectives from members of the community by holding family focus groups.

They began educating their target population, and conducted diabetes education and self-management classes over a period of 5 to 6 weeks. They had good results with retention of REACH participants (80%), and significant improvements in both physical activity and dietary knowledge and behavior. Self-care behaviors and diabetes problem areas were also significantly improved ( $p < .05$ ), as were levels of hemoglobin A1C. Hypertension was also decreased, from a baseline of 54.1% of REACH participants to 42.4% at the 6-month mark.

This multilevel, community-based intervention made marked improvements on several outcome measures for the targeted population. What type of disease or problem is most prevalent in your area? With whom could you collaborate to design interventions? Which levels would you want to address? How would you measure success (which outcomes would you select)?

Two Feathers, J., Kieffer, E., Palmisano, G., Anderson, M. et al. (2005). Racial and ethnic approaches to community health (REACH). Detroit partnership: Improving diabetes-related outcomes among African American and Latino adults. *American Journal of Public Health, 95*(9), 1552–1560.

living independently, and the **hearty elderly**—people older than 65 years of age who maintain a high level of wellness and activity, well above present expectations for that age—are increasing in number. Most people older than 65 years of age not only maintain independent living but also continue to contribute to society (Ostbye et al., 2006). Many continue to work and stay involved in community programs and activities. Some have become valuable volunteers, helping others in such community activities as hospice and literacy programs for adults, serving as foster grandparents, working in libraries and homeless shelters, or providing services such as Meals on Wheels. Research has shown a connection between positive health effect and community involvement/participation, volunteering, and other forms of social capital (Kim & Kawachi, 2006).

Not only are more people living into old age, but also, once they get there, they are living longer. Eliopoulos (2004) characterizes those between the ages of 65 and 75 as “young-old,” whereas those between 75 and 85 years are labeled “old-old” (p. 5). The number of people living into “older” old age (75 years and older) is increasing. Forty percent of elderly people in the United States are among the “oldest old” (85–100 years)—0.2 million in the year 2000—and more than 200,000 are among the **elite-old**, or centenarians (Eliopoulos, 2004).

Some 72 million people will be entering old age, significantly affecting health care resources, housing options for older adults, and national longevity statistics. As the number of “old-old” people increases, so too will the need for assistance with activities of daily living (ADLs) and other services. Many people will be involved with the care

and disposition of the **frail elderly**, those older than 85 years of age who need assistance in attending to ADLs such as dressing, eating, toileting, and bathing, and researchers are seeking effective methods of providing respite to caregivers and reducing costs (Mason et al., 2007).

In the United States, approximately 80% of all persons aged 65 years and older have at least one chronic condition, and 50% have at least two (CDC, 1999; National Center for Health Statistics, 2002). Death is only part of the picture of the burden of chronic disease among older Americans. These conditions can cause years of pain, disability, and loss of function and independence before resulting in death. In addition to chronic conditions that require ongoing monitoring and management, the community health nurse should anticipate the needs of many older adults who will face the loss of a spouse, helpmate, or companion and who may experience loneliness, social isolation, and depression.

In the total U.S. population, almost twice as many women as men (12.4% versus 7%) live below the poverty level, and this trend continues into old age (Gist, 2007). More than one in ten older Americans (10.1%) are poor, and many live in profound poverty. They are unable to afford clothing, recreation, transportation, or other items that most people consider necessary for mental health, social status, and continued personal growth. The differences among various ethnic groups experiencing poverty in old age are broad. Among White older adults, 8.9% were found to live below the poverty level, whereas 21.9% of African American elders and 21.8% of Hispanic elders live in poverty. Hispanic women who lived alone or with nonrelatives had the highest proportion of poverty at 50.5% (Administration on Aging, 2002a). Those

elderly living barely above the poverty level (“near-poor”) represent even greater numbers: 30% of Whites, 34% of Latinos, 28% of African Americans, 32% of Asian/Pacific Islanders, and 41% of American Indian/Alaska Natives live under 200% of the federal poverty level—proportions much higher than the nonelderly population (The Henry J. Kaiser Family Foundation, 2003).

The education level of the older population is increasing. The percentage of older adults who have completed high school increased between 1970 and 1998 (from 28% to 67%), and this trend is expected to continue to rise to 83% by 2030 (American Geriatric Society, 2007). These figures are predicted to change as the United States witnesses a trend toward a more educated senior population because of the significant numbers of baby boomers who completed high school and entered college during and since the 1960s. The number of seniors with bachelor’s degrees is expected to increase from 15% to 24% (American Geriatric Society, 2007). With higher levels of education should come broader health consumerism and better quality of life.

## DISPELLING AGEISM

Stereotyping older adults and perpetuating false information and negative images and characteristics regarding older adults is called **ageism**. These stereotypes often arise from negative personal experience, myths shared throughout the ages, and a general lack of current information. Ageism is a term that describes negative stereotyping of older adults and discrimination because of older age. Unfortunately health concerns and symptoms in the elderly are often overlooked or dismissed as part of the normal aging process (Moore, 2002). By becoming more aware of myths and realities of aging, community health nurses can improve the health and quality of life of the growing elderly population (Salzman, 2006). Ageism can interfere with effective practice and prevent the kind of comprehensive and interdisciplinary services and care that aging persons need and deserve (Ory, 2003). Ageism has an impact on both society and culture, even though most individuals are not aware of it. Ageism creates needless fear, waste, illness, and misery (Palmore, 2005).

### Misconceptions About Older Adults

Most people know little about aging and may have negative stereotypes about old people. Community health nurses must guard against ageism in their practice by dispelling common misconceptions.

#### **Misconception: Most Older Adults Cannot Live Independently**

Although over 900,000 seniors live in assisted living residences and more than 1.1 million live in some type of senior housing community, most American seniors are below age 85 and live with their spouse (American Geriatric Society, 2007). In fact, 55% of older Americans were reported to be married and living with their spouse in 2000 (Administration on Aging, 2002a; American Association of Homes and Services for the Aging [AAHSA], 2007). Ninety-four percent of elderly individuals live in the community, outside formal facilities or institutions (Ebersole & Hess, 2004). About 30% live alone, and

others live with friends or in the homes of nonrelatives with room and board provided (Administration on Aging, 2002a). In some homes, assistance with ADLs is provided. Over 150,000 are provided services and care through adult day care (AAHSA, 2007). Alternative-housing arrangements are also available—group-living situations for older adults in which many types of housing and care possibilities are offered. This concept is not new, but these centers are being built now in greater numbers to meet the needs of a growing segment of the older adult population. These situations are well suited to those who desire such comprehensive living choices and have the financial means for the housing and care arrangements provided. About 745,000 seniors live in these continuing care retirement communities (AAHSA, 2007). The average waiting list time for an eligible older adult to be placed in an affordable senior housing unit is over 13 months (AAHSA, 2007).

Over 4% of those age 65 and older in 2000 lived in nursing homes, and the current percentage is still below 5%. By the age of 85 and above in 2000, that percentage increased to 18.2%. By 2020, it is estimated that 12 million seniors will need some form of long-term care (AAHSA, 2007). The average age of older adults in residential care is getting higher and is currently about 85 years. Such facilities typically are not chosen by the hearty elderly or by totally independent young-elders, who prefer to receive services that allow them to remain in their own homes—commonly referred to as Aging in Place (Hill, Thorn, Bowling, & Morrison, 2002; Administration on Aging, 2002b). Despite popular notions, only a small minority of older Americans move to warmer climates after retirement (National Association of Area Agencies on Aging, 2007).

Most elders who are vigorous and functioning independently live in their own homes. Only about 6% live in institutions such as skilled nursing facilities, extended care facilities, supervised living facilities, and AD centers, and not all of these are permanent residents. Many are recovering from illnesses or undergoing rehabilitation after an injury or surgery and will return to their living situation in the community within a matter of weeks (Hill et al., 2002).

#### **Misconception: Chronologic Age Determines Oldness**

The aging process is quite distinct among older people, and they age at widely disparate rates. Some people still play golf, drive a car, and participate in social and community activities at age 85; others are frail and cannot move about well, needing assistance with their ADLs. Some prefer to equate “real age” with biological age, not chronological age; this depends on how well an individual takes care of him- or herself physically and mentally (RealAge, 2007). Exercise, nutrition, vitamins, seat belt use, and other factors are thought to play a role in healthy aging. Physical, social, and mental health parameters, life experiences, and genetic traits all combine to make aging an individualized process (see Levels of Prevention Pyramid).

#### **Misconception: Most Elderly Persons Have Diminished Intellectual Capacity or Are Senile**

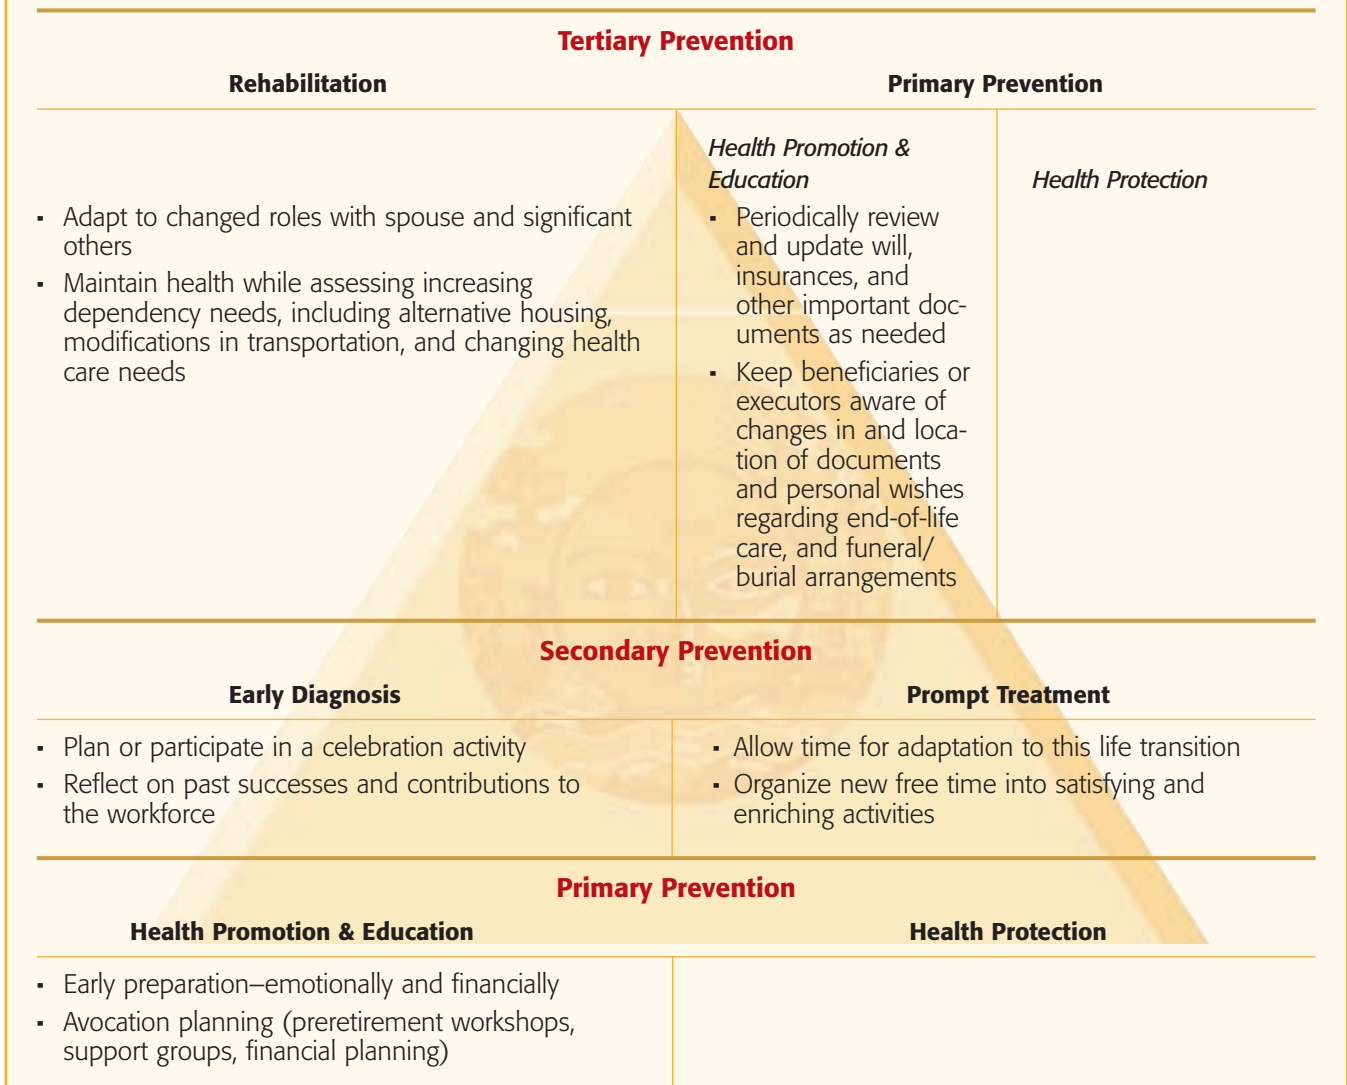

Recent research is proving several myths about cognition to be incorrect, notably the beliefs that aging is a time of irreversible mental decline and that dementia is universal and

## LEVELS OF PREVENTION PYRAMID

**SITUATION:** Making a healthy transition into a satisfying retirement.

**GOAL:** Using the three levels of prevention, negative health conditions are avoided, promptly diagnosed, and treated, and/or the fullest possible potential is restored.

inevitable (Alzheimer's Association Medical and Scientific Advisory Council, 2005). As such, researchers and health professionals have begun to focus on opportunities to maintain or possibly improve cognitive health. Cognitive health is defined as a combination of mental processes we commonly think of as “knowing,” including the ability to learn new things, intuition, judgment, language, and remembering. Studies show that intelligence, learning ability, and other intellectual and cognitive skills do not decline with age. Cognitive deficits are caused by certain risk factors. Nutritional status has been singled out as a physical health variable that influences cognitive functioning, particularly memory performance, regardless of a person's age. Mild cognitive impairment is viewed as “the transitional stage between normal aging and dementia” and can include deficiencies in lan-

guage (slower with words), visual-spatial ability (difficulty with proportions when drawing a box, for instance), executive function (decision making), and memory (recent memory more difficult) (*Medical News Today*, 2006). Generally, older people are capable of making their own decisions; they want and need the freedom to make choices and to be as independent as their limitations will allow.

**Senility**, although not a legitimate medical diagnosis, is a term widely used by the lay public to denote deteriorating mental faculties associated with old age. A recent Mayo Clinic study of close to 4,000 people from a general population in Minnesota found that 12% of 70- to 89-year-olds had mild cognitive impairment—a condition often undiscovered except by close family members living with the elderly person. This increased with age, as only 9% of those 70 to

79 were found to be cognitively impaired whereas 18% of those from 80 to 89 had cognitive impairment. Education mediated those effects, as only 8.5% of those with greater than 16 years were found to have impairment, but 25% of those with up to 8 years of education were mildly cognitively impaired (*Medical News Today*, 2006).

Certainly, Alzheimer disease and arteriosclerosis cause memory loss and altered behavior in the elderly, but many older adults have similar symptoms as a result of anxiety, loss, depression, or grief, or simply from side effects of medications or changes in their routines. These reactions need to be diagnosed by health care providers and differentiated from disease processes, and new research indicates that intellectual stimulation, social engagement, and physical activity may help maintain cognitive functioning in older adults (Butler, 2004). Bernick and colleagues (2005) found a slight decrease in cognitive changes/impairment in a large sample of adults over the age of 65 taking cholesterol-lowering statin drugs, indicating that more research is needed to better understand how to prevent cognitive impairment in older adults.

### **Misconception: All Older People Are Content and Serene**

The picture of Grandma sitting serenely in her rocker with her hands folded in her lap is misleading. It is true that many older people have learned to accept, rather than fight, the hardships and vicissitudes of life. Yet, for most people, advancing age brings increasing physical, social, and financial problems. However, it is important to remember that to attain the status of senior citizen, defined as individuals 65 years or older, one has often exhibited a great deal of strength, tenacity, and capacity for adaptation, as well as a sense of humor about many of the trials, tribulations, and absurdities in life. These people are survivors, and survivors do not always sit contentedly in a rocking chair on the sidelines of life.

Mental health problems continue into old age. Depression, which can affect close to one in five elderly people, is sometimes confused with dementia because of such common symptoms as disorientation, failing memory, and eccentric behavior (National Alliance on Mental Illness [NAMI], 2003). For some, depression has been a lifelong battle, but for others, the first onset of depressive symptoms may occur in old age. The losses and grief experienced by seniors may lead to clinical depression that can be treated with medications and other therapies. Because elderly often do not seek treatment or even recognize that they may be clinically depressed, it is important for public health nurses (PHNs) to monitor their older clients carefully and ask them about changes in appetite, sleep patterns, and behavior. Suicide is not uncommon among the elderly—in fact the highest rates are among older White men (NAMI, 2003).

### **Misconception: Older Adults Cannot Be Productive or Active**

The average American retires at 57.8 years, although the average worker plans to retire at age 61 (Pew Research Center, 2006). Prior to the 1990s, the average age of retirement had been declining. Now, it is moving upward. A recent trend has been for retirees to return to work; 12% in one survey reported they are currently working, most on a part-time basis

(Pew, 2006). A recent AARP survey found that 28% of workers and 12% of current retirees do not feel confident about having sufficient money to pay for medical expenses during retirement; 15% of workers and 9% of retirees are not sure they even have enough money for basic monthly expenses. The survey also noted that 40% of those still working are concerned that their employers will not pay them their full pensions or will abolish retirement health benefits (Holley, 2006).

Labor force participation rates of those over 60 (not retired) have been increasing over the past decade for men and women age 62 to 64 (4% increase for men and 12% increase for women). For those age 70 and above, 15.8% of men and 8.7% of women in 1994 worked full time versus 20.7% of men and 12.8% of women in 2005 (Population Reference Bureau, 2006). Millions of Americans older than 65 years of age work full- or part-time, and many others, who are not included in labor statistics, work but do not report their earnings. An example is the grandmother who chooses to give up full-time employment in an unsatisfying job to baby-sit for three preschool grandchildren and is paid in cash by her two children. The grandmother gets to spend time with growing grandchildren and supplement her retirement income, the parents feel comfortable that their mother is caring for their children, and the grandchildren are experiencing the joy of being with their grandparent. In another situation, active retired older adults assist with their two children's businesses. The mother types legal documents for the son's law practice during busy times, and the father helps out on Saturdays at the daughter's pool supply store. Everyone wins in these situations.

Work remains important to seniors. Healthy older people usually do not disengage or withdraw and isolate themselves from society; rather, they are active and involved. Remaining active—through a daily routine, purposeful behavior, and a positive view of life—produces the best psychological climate.

### **Misconception: All Older Adults Are Resistant to Change**

People at any age can learn new information and skills. Research indicates that older people can learn new skills and improve old ones, including how to use a computer and the Internet. Learning occurs best in a self-paced, supportive environment (American Association of Retired Persons [AARP], 2005). Studies have demonstrated that even those in very old age can still learn new skills. One study from Germany instructed and trained very old adults (mean age of 84 years) in a new skill, and found that they could improve their perceptual speed with training, demonstrating “memory plasticity” (Singer, Lindenberger, & Baltes, 2003). Those between the ages of 60 and 80 performed at a higher level; however, this study demonstrated that the very old were still able to learn and perform a new skill. The elderly have spent a lifetime adapting to change, with varying measures of success. People older than 65 years grew up in an age when having an automobile was a luxury and many did not have a microwave oven, video recorder, or DVDs until they were in middle adulthood. Elders learned to adapt to these changes, and they are becoming increasingly computer literate today. The ability to change does not depend on age, but rather on personality traits acquired throughout life or, sometimes, because of socioeconomic difficulties. For example, elders

living on fixed incomes may be faced with inflationary costs. This may cause them to vote against a school levy that would increase taxes, although they otherwise would be very supportive of schools because they value education.

### **Misconception: Social Security Will Not Be There When I Retire**

The Social Security fund is not yet bankrupt. Although the government has borrowed from it, the trust fund growth is sufficient to keep Social Security solvent and paying full benefits until 2042; after that time, if the current tax cuts are continued and no changes are made, retirees at age 60 in 2040 will have their benefits reduced by 26% and benefits could continue to drop every year (Center on Budget & Policy Priorities [CBPP], 2004; Social Security Administration [SSA], 2006). By 2018, benefit payments will exceed revenues; however, interest earnings on the Social Security Trust Fund will continue to keep it solvent. By 2028, Treasury Bonds will have to be redeemed in order for the government to continue to make full payments to beneficiaries (CBPP, 2007).

Although there are concerns about Social Security, Medicare is in far worse condition. It will stay financially healthy only until 2013 (CBPP, 2007). Money still pours into the Medicare Trust Fund from payroll taxes, and not until 2019 will the administrators have to start tapping the general fund to meet 45% of their obligations to Medicare Part A benefits (Center for Medicare Advocacy, 2007). The large shortfall in Medicare is mostly due to health care costs that continue to rise and the \$10 billion per year overpayments to private insurers (CBPP, 2007). In 2006, a new prescription drug benefit was added to Medicare (Part D), and by 2007, over 39 million people had enrolled in this benefit (Centers for Medicare & Medicaid Services, 2007). Seniors can choose between adding a prescription drug plan to their traditional Medicare Part A and Part B (standard plan) or selecting a Medicare Advantage plan with prescription drug benefits (health maintenance organization [HMO] or preferred provider organization [PPO]), and over 88% have enrolled in these plans (U.S. Department of Health & Human Services, 2006; Centers for Medicare & Medicaid Services, 2007). Premiums average \$22 a month,

and those choosing the standard plan are faced with a coverage gap, termed the “donut hole.” There is a yearly deductible of \$265, and then copayments of 25% up to a limit of \$2,400. After that is reached, seniors pay out of pocket for drugs up to \$3,850, when they reach what is termed the “catastrophic limit” and are only required to pay up to 5% (or a set fee) for medications (Center for Medicare Advocacy, 2007a).

Even though there are reported problems with Social Security and 7 of 10 Americans believe that it will go bankrupt, most do not believe there is a crisis (Morin & Rusakoff, 2005; Center for Medicare Advocacy, 2007b). The system is for the most part secure, and most people who will reach retirement age in the next few decades have experienced a lifestyle well beyond what could be supported by the Social Security benefits they are scheduled to receive. “Social security was never meant to be the sole source of income in retirement” (SSA, 2006, p.16). This system was designed so that current workers pay benefits for current retirees, and investments of their overpayments earn interest. Even though more taxes are currently collected than the amounts paid out, this is changing. The worker-to-beneficiary ratio is now 3.3-to-1, whereas in 1950 it was 16.5-to-1; the ratio is expected to drop to 2-to-1 by 2046 (SSA, 2006). This means that people must plan early and contribute to a retirement fund at work (or establish their own retirement fund if self-employed), invest, and save regularly (Daaleman, 2006). These multiple sources of income at the time of retirement will provide the resources necessary so that decisions about when to start or how to spend one’s retirement can be based on personal preference rather than a restricted and fixed Social Security check.

### **Characteristics of Healthy Older Adults**

No one knows conclusively all of the variables that influence healthy aging, but it is known that a lifetime of healthy habits and circumstances, a strong social support system, and a positive emotional outlook all significantly influence the resources people bring to their later years. Most people recognize a healthy older person when they meet one. See From the Case Files I for an example of healthy aging.

## **From the Case Files I**

I am a PHN and live next door to Minerva Blackstone, affectionately called Minnie by her friends. Minnie is a lively 87-year-old woman who enjoys life. Every day, except in bad weather, she walks a half-mile to visit her granddaughter Karen. There, she works on the quilt—stretched on a frame—that she is making for Karen. In addition, twice a week, Minnie takes the city bus to the senior citizens’ center to join her friends in an exercise class. Although her eyesight has somewhat diminished, Minnie enjoys reading in the evening or crocheting while she watches television. Mysteries and comedies are her favorite kinds of stories.

Minnie is a happy person, but is not content unless she is up on the latest political developments. She always has opinions on current events and expresses them with vigorous shakes of her curly white hair at her monthly group meeting on women and politics. She has a good appetite and generally sleeps well. Minor arthritis does not hamper her activities, nor does the hypertension that she controls by taking her medication with conscientious regularity. Minnie is enjoying a healthy, successful old age.

*Carole Stokes, District PHN*

What is healthy old age? As was mentioned earlier, the vast majority (94%) of our elderly, even those with chronic diseases or other disabilities, are living outside institutions and are relatively independent. Their ability to function is a key indicator of health and wellness and is an important factor in understanding healthy aging. Good health in the elderly means maintaining the maximum possible degree of physical, mental, and social vigor. It means being able to adapt, to continue to handle stress, and to be active and involved in life and living. In short, healthy aging means being able to function, even when disabled, with a minimum of help from others (CDC & Merck Co. Foundation, 2007).

Wellness among the older population varies considerably. It is influenced by many factors, including personality traits, life experiences, current physical health, and current societal supports and personal health behaviors including smoking, obesity, and excessive alcohol use. One way to measure healthy aging on a large scale is the degree to which states have met or exceeded targets on 11 of the *Healthy People 2010* older adult health indicators. For instance, we have already exceeded the goal of 70% of the population receiving mammograms within the past two years (75%). Colorectal screenings and checks for cholesterol have also been exceeded (63% versus 50% and 90% versus 80%, respectively). The number of people who currently smoke has also been reduced (CDC & Merck Co. Foundation, 2007). Other actions that can increase healthy aging include addressing health disparities among older adults, encouraging people to plan for end-of-life care and communicate their wishes through advance directives, improving oral health and increasing physical activity among seniors by promoting environmental changes, increasing adult immunization levels, and preventing falls (CDC & Merck Co. Foundation, 2007). Some elderly people demonstrate maximum adaptability, resourcefulness, optimism, and activity. Others, often those from whom we tend to draw our stereotypes, have disengaged and present a picture of dependence and resignation. Most of the elderly population fall somewhere in between these two extremes. Although the level of wellness varies among the elderly, that level can be raised. The goals in community health nursing are to maximize the wellness potential of elderly clients and to support their highest level of functional ability enabling them to remain independent. Nurses must analyze and build on an older person's strengths rather than focus on the difficulties or deficits. The goal for an aging population is to enable older people to thrive and have the highest quality of life for as long as possible, not merely to survive (Eliopoulos, 2004).

## ELDER ABUSE

Elder abuse has reached epidemic proportions in the United States. Although estimates vary, it is believed that 4 to 6% of the elderly become victims of some form of abuse. One study estimated the frequency at between 2 to 10%. Recognition of elder abuse has been a relatively recent phenomenon (Dong, 2005; Lach & Pillemer, 2004). Some of the difficulty lies in the lack of national definitions of elder abuse or official statistics. There is also no uniform reporting law nationally (National Center on Elder Abuse, 2005). Elders are at increased risk for abuse due to social isolation, mental impairment, and dependency on others. **Elder abuse** is defined as the intentional or unintentional hurting, either

physical or emotional, of a person who is age sixty or over. A recent large-scale survey of adult protective services (APS) revealed that there are 8.3 reports of abuse for every 1,000 American seniors (National Center on Elder Abuse, 2006). There are four general categories of elder abuse: (1) physical abuse, (2) psychological abuse, (3) neglect, and (4) financial abuse. It is important to note that financial abuse often accompanies one of the other forms of abuse. The financial abuse of seniors is a growing problem, often called the "Crime of the 21st Century." It is one of the most sinister forms of abuse. A senior can be financially stable and living independently one day, and become destitute and forced to live in a facility the next as a result of any one of the four types of abuse or a combination of abuses.

Sadly, most elder abuse occurs in the elder's home, and the abuser is usually a family member. Over 89% of alleged abuse occurs in a domestic setting, although abuse can occur in board and care or nursing home settings (National Center on Elder Abuse, 2005). In states reporting on the *2004 Survey of State Adult Protective Services*, almost half of all cases investigated were substantiated. Most victims of elder abuse are White (77.1%), and the majority of victims are reported to be over age 80 and female (National Center on Elder Abuse, 2006). The most common perpetrators of elder abuse are spouses or partners of elders. The next most frequent abuser is the adult child of the elder. An elder person in immediate danger should be removed from her environment (Gorbien & Eisenstein, 2005); however, elder abuse does not often come to the attention of PHNs or other providers of services to the elderly. It is estimated that five occurrences of neglect, abuse, exploitation, or self-neglect go unreported for every case that is reported. Financial exploitation is reported in only about 1 of 25 cases (National Center on Elder Abuse, 2005). Therefore, nurses working in the community with older adults must be vigilant for signs of elder abuse and knowledgeable about reporting laws.

Various state, local, and county agencies investigate and enforce elder abuse laws. The first agency to respond to a report of elder abuse in most states is APS. In some states, certain professionals are required or encouraged to report elder abuse. The people required to report elder abuse are generally doctors and nurses, psychologists, police officers, social workers, and employees of banks and other financial institutions. All elder abuse hotlines are free and anonymous (Gorbien & Eisenstein, 2005).

## HEALTH NEEDS OF OLDER ADULTS

Effective nursing among any population requires familiarity with that group's health problems and needs. Aging, in and of itself, is not a health problem. Rather, aging is a normal, irreversible physiologic process. Its pace, however, can sometimes be slowed, as researchers are discovering, and many of the problems associated with aging can be prevented (Ebersole & Hess, 2004). The aging process is subtle, gradual, and lifelong. One can see remarkable differences among individuals in the rate of aging. Even in a single individual, various systems of the body age at different rates (Eliopoulos, 2004). Therefore, chronologic age cannot readily be a reliable indicator of health needs. However, the proportion of people with health problems increases with age, and as a group older

adults are more likely than younger ones to suffer from multiple, chronic, and often disabling conditions requiring ongoing care and management.

The elderly, like any age group, have certain basic needs: physiologic and safety needs, as well as the needs for love and belonging, self-esteem, and self-actualization. Their physical, emotional, and social needs are complex and interrelated (Eliopoulos, 2004; Miller, 2003). The following sections discuss these needs according to primary, secondary, and tertiary prevention activities.

## Primary Prevention

As discussed previously in this text, primary prevention activities involve those actions that keep one healthy. Such primary prevention activities as health education, follow-through of sound personal health practices (e.g., flossing, seat belt use, exercise), recommended routine screenings, and maintenance of an appropriate immunization schedule ensure that older adults are doing all that they can to maintain their health. The list in Display 24.2 includes strategies for successful aging. Taken from a variety of sources, it provides primary prevention activities the community health nurse can use when working with elders, either individually or in groups.

### DISPLAY 24.2

### STRATEGIES FOR SUCCESSFUL AGING

- Do at least 30 minutes of sustained, rhythmic, vigorous exercise four times a week.
- Eat “like a bushman” (a healthy diet of fruits, whole grains, vegetables, and lean meat).
- Get as much sleep and rest as needed.
- Maintain a sense of humor and deflect anger.
- Set goals and accept challenges that force you to be as alive and creative as possible.
- Don’t depend on anyone else for your well-being.
- Be necessary and responsible; live outside yourself (give to others, become involved).
- Don’t slow down. Stick with the mainstream. Avoid the shadows. Stay together. Maintain energy flow in a purposeful direction; aging need not be characterized by losses. Maintain contacts with family and friends, and stay active through work, recreation, and community.
- Get regular check-ups.
- Don’t smoke—it’s never too late to quit.
- Practice safety habits at home to prevent falls and fractures. Always wear seat belts when traveling by car.
- Avoid overexposure to the sun and the cold.
- If you drink, moderation is the key—when you drink, let someone else drive.
- Keep personal and financial records in order to simplify budgeting and investing—plan long-term housing and financial needs.
- Keep a positive attitude toward life—do things that make you happy.

## Nutrition Needs

People who have maintained sound dietary habits throughout their life have little need to change in old age. Many have not established such habits, but may be required to do so because of disease processes such as diabetes or cardiovascular disease. It is generally believed that older people need to maintain their optimal weight by eating a diet that is low in fats, moderate in carbohydrates, and high in proteins with a daily calorie count of 1,200 to 1,600. Foods with “empty calories,” such as salty snacks, candy, fatty foods, and alcohol, should be limited; they meet hunger needs by satisfying appetite only, while providing little nutrition. Cereals and whole grains, dried beans, and nuts can provide fiber needed by seniors, and eating colorful fruits and vegetables (rather than fruit juice) also contributes to fiber and may help to prevent macular degeneration (Center for the Advancement of Health, 2004). Another important thing to remind older adults to do is to drink adequate amounts of liquids, especially water. Eight glasses a day are recommended, and many older adults have a diminished feeling of thirst and can easily become dehydrated if they do not purposefully plan their fluid intake. Elders need less vitamin A, but more calcium and vitamin D (for healthy bones), more folic acid, and more vitamin B<sub>6</sub> and B<sub>12</sub> (for cognitive health) than younger adults (Center for the Advancement of Health, 2004). Many communities offer meals to seniors, either at Senior Centers or by way of Meals on Wheels, through grants provided by the Elderly Nutrition Program (Administration on Aging, 2007b).

Major advances in the field of oral health including community water fluoridation, advanced dental technology, better oral hygiene, and more frequent use of dental services have had a substantial impact on the number of older adults who retain their natural teeth. Before the time of widespread fluoride use, it was common for people to lose most or all of their teeth by midlife (Ahluwalia, 2004). Most people can keep their natural teeth for a lifetime with preventive practices. Oral health is integral to general health and well being throughout one’s life. A good deal of research has demonstrated the connection between oral health and general health due to chronic inflammation releasing cytokines and C-reactive protein causing endothelial damage and cholesterol plaque attachment in cardiovascular disease and stroke; poor oral health has also been associated with peripheral vascular disease, diabetes, and risk for death caused by pneumonia in nursing homes (Ahluwalia, 2004; Meurman, Sanz, & Janket, 2004; Rubinstein, 2005; Jurasek, 2002). Even those with dentures must be vigilant in maintaining oral health, as they are still at risk from inflammatory processes leading to diseases like pneumonia (Jurasek, 2002).

The oral health of older adults, however, is often neglected. Many older adults, especially those with limited or fixed incomes or cognitive limitations, are not able to maintain their oral health or visit a dentist on a regular basis. Medicare does not cover routine dental services. Maintaining oral health during the senior years is more difficult for many reasons: lack of dental insurance after retirement, economic disadvantages and limited incomes, decreased nutritional and fluid intake, changes in gums and increased periodontal disease, as well as a higher incidence of dry mouth (Gupta, Epstein, & Sroussi, 2006). “Over 400 commonly used medications can be the cause of a dry mouth,” and certain disease

processes produce dry mouth symptoms, but the elderly also have a natural decrease in saliva flow (Gupta et al., 2006; CDC, 2006b, p. 9). Saliva contains minerals for rebuilding of tooth enamel as well as “antimicrobial components” (CDC, 2006b, p. 9). Fluid intake and oral hygiene are appropriate topics for anticipatory guidance from PHNs for older adults.

We are very close to achieving the goal specified in Health People 2010 to reduce the number of adults with complete tooth loss to 20%. The percentage of U.S. adults aged 65 to 74 who experience complete tooth loss has declined from 55% (1957–1958) to 24% (1999–2002) (U.S. Department of Health & Human Services [USDHHS], 2000). Oral health and hygiene needs do not decrease with age. Eating, chewing, and swallowing should be an uncomplicated and natural process. Eating should remain a pleasurable social experience, preferably taking place in the company of others. Community health nurses can assist older adults with meal management by following the suggestions outlined in Display 24.3 and Figure 24.1.

In addition to maintaining a healthy diet, older adults are cautioned to limit the use of alcohol, avoid tobacco, drink fluoridated water or use fluoride toothpaste, and practice good oral hygiene and have regular dental checkups

(CDC, 2006b). They should also avoid the habitual use of laxatives, instead adding more fiber and bulk to their diet with fresh fruits and vegetables. Also inadequate fluid intake can contribute to bowel and bladder problems. Following a diet that includes eight or more 8-oz glasses of fluid (water, juices, tea) each day assists the gastrointestinal and genitourinary system in their functions. Increased physical activity and exercise helps keep an older adult’s bowel patterns regular (Center for the Advancement of Health, 2004).

### Exercise Needs

Older adults need to exercise; in fact, they thrive when exercise is incorporated into their daily routine (Burbank & Riebe, 2002). Research demonstrates that exercise and increased physical activity can slow the loss of bone density and increase the size and strength of muscles, including the heart, as well as increase the action of insulin and improve sleep and functional abilities of the elderly (Ballard, McFarland, Wallace, Holiday, & Roberson, 2004; Fahlman, Morgan, McNevin, Topp, & Boardley, 2007; Sato, Nagasaki, Kubota, Uno, & Nakai, 2007; USDHHS, 2000; Woo, Hong, Lau, & Lynn, 2007). Aging does not and should not involve passivity; instead, physical activity and movement contribute to the quality of intellectual and physical performance in old age. Exercise, such as a daily walk, can keep muscles in good tone, enhance circulation, and promote mental health and adequate sleep (Chen, Li, & Lin, 2007; Sato et al., 2007). Exercise may occur in connection with such activities as homemaking chores, gardening, hobbies, or recreation and sports. Often, such physical outlets are enjoyed in the company of other people, meeting social and emotional needs as well as physical ones. Even among the very old, an exercise routine that includes activities that improve strength, flexibility, and coordination may indirectly, but effectively, decrease the incidence of osteoporotic fractures by lessening the likelihood of falling (Ballard et al., 2004; Fahlman et al., 2007; Ettinger, 2003). Resistance training (with small dumbbells or resistance bands), along with either Tai Chi or regular walking, has been shown to increase muscle strength, stability, and functional ability among seniors (Fahlman et al., 2007; Woo et al., 2007).

Public health nurses can encourage exercise among elderly clients and examine factors that prevent them from regularly exercising (Kressig & Echt, 2002). A recent study found that physical ailments were the most common barrier to exercise, whereas health concerns were the strongest motivators for older adults (Newsom & Kemps, 2007).

### Economic Security Needs

Economic security is another major need for older adults. Worrying about finances is often one of the most debilitating factors of old age. Fearing the potential cost of major illness and not wanting to be a burden on family or friends, many older people conserve their limited finances by establishing frugal eating patterns, using health resources sparingly, not taking their medications or only taking medications in partial doses, reducing costs for home heating and cooling, and, in general, spending little on themselves (Eliopoulos, 2004). Elderly people sometimes have to choose between food, housing, and medications. Another factor that is driving up the cost of health care for the aging population is that many elderly clients wait

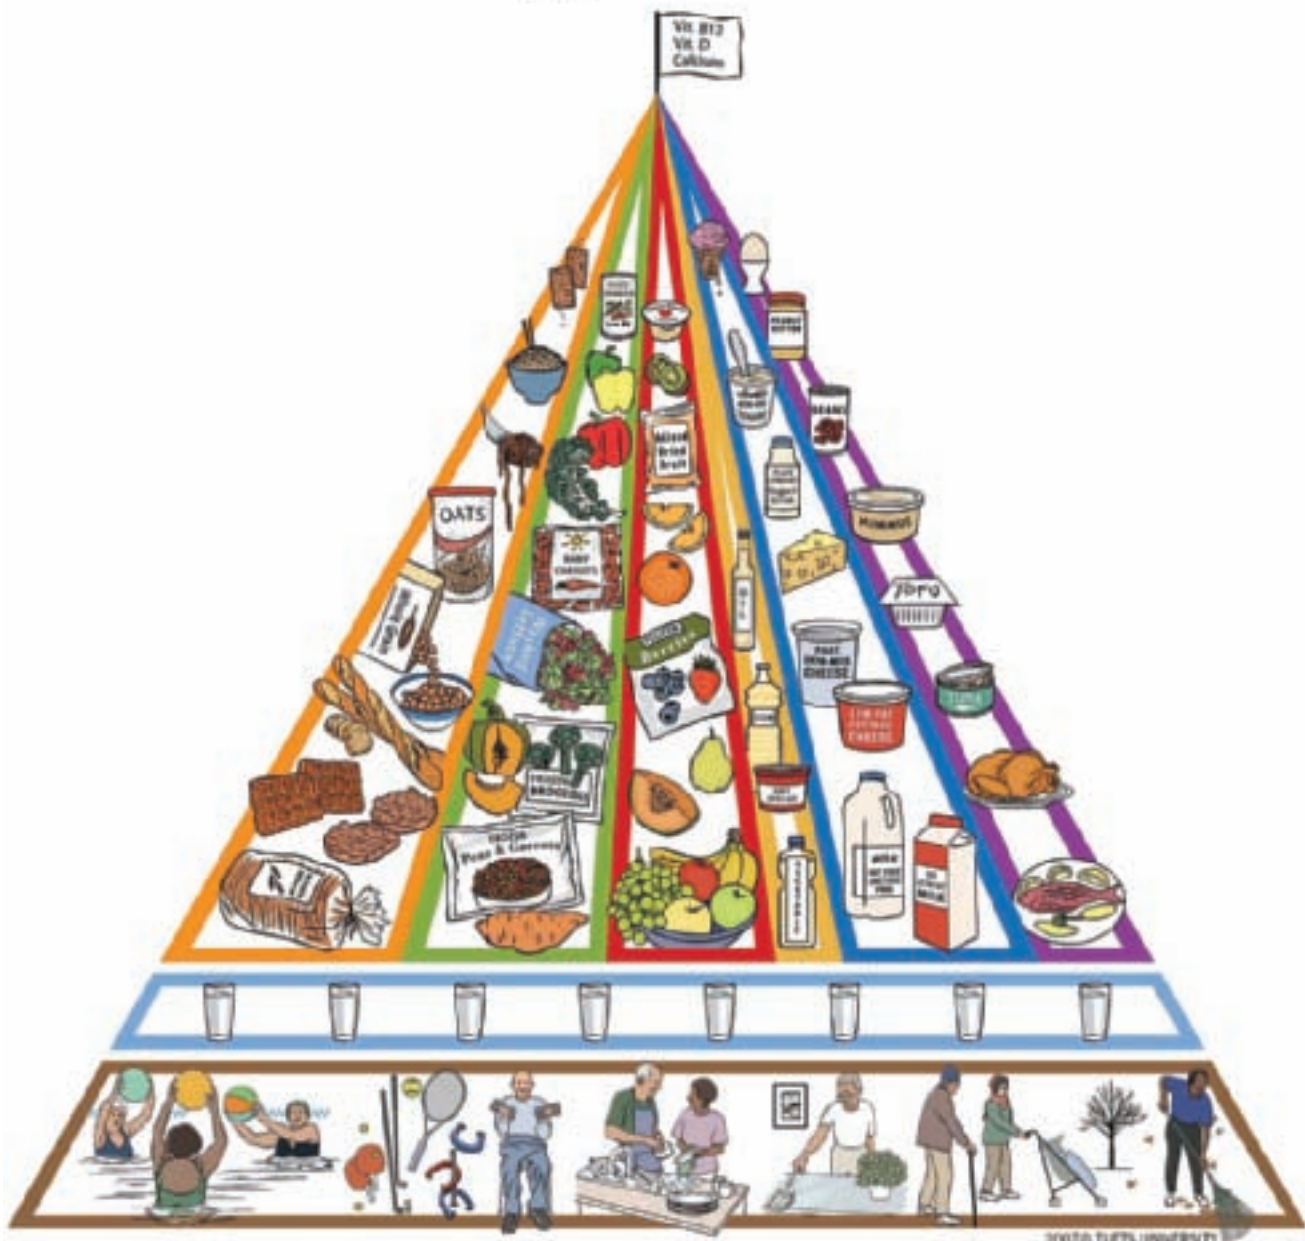

#### DISPLAY 24.3

#### MEAL MANAGEMENT CONSIDERATIONS

- Complete a safety check with the older adult to assess the ability to operate stoves and microwave ovens. Include the elder’s ability to reach, and put things on and off stove burners.
- Arrange cupboards so commonly used items can be reached from an easy standing level.
- Suggest use of turntables and long-handled “grabbers” while discouraging use of step stools or ladders.
- Assess the elder’s typical meal for quality and availability—can be accomplished for all meals by doing a 24-hour dietary recall—begin with the most recent meal and work backwards.
- To ensure that elders eat an appropriate number of times a day, suggest that they “eat by the clock” or with a certain TV show.
- Help older adults build support system for sharing grocery shopping, cooking, and meals.
- Suggest they bake once a week for an activity or shop with another elder.
- Suggest buying convenience foods, making sure they have nutritional value, such as frozen vegetables or dinners.
- Consider community resources to assist with shopping, transportation, or meal preparation as needed. Keeping a continuous shopping list helps elders to remember needed grocery items, and provides a reference if someone offers to assist with shopping.
- Help elders consider increasing socialization by eating together with friends—rotating among three to four friends each week or eating out with friends, selecting restaurants that are physically and financially accessible.

## Modified MyPyramid for Older Adults

**FIGURE 24.1** Modified MyPyramid for older adults. Copyright 2007 Tufts University. Reprinted with permission from Lichtenstein, A.H., Rasmussen, H., Yu, W.W., Epstein, S.R., Russell, R.M. Modified MyPyramid for Older Adults. *J Nutr.* 2008; 138:78–82.

until they are truly ill before seeking health care. In waiting for conditions to improve or go away, the elderly often miss out on important preventive health measures and community based programs that can maximize function and help the client maintain health at a higher level (Ezekowitz, Straus, Majumdar, & McAlister, 2003). Too often, the fear—let alone the reality—of financial difficulties prevents older adults from leading full and active lives (Stoller, 2003).

For older adults today who have lived many years past retirement and perhaps have not planned for sufficient financial security to maintain them throughout these additional, unexpected years, the fears are not unfounded. Putting older people in touch with appropriate community resources can do much to relieve the source of that stress and anxiety. The com-

munity health nurse can also provide information about potential consumer fraud (e.g., telemarketing schemes) targeted to the elderly. This is a form of financial abuse perpetrated by criminals who have no personal relationship with the victims, and seniors with retirement income, savings accounts, or property are disproportionately targeted (Cohen, 2006). Losses from this type of fraud can wipe out a lifetime of savings, and leave the older adult feeling foolish and helpless.

### *Psychosocial Needs*

All human beings have psychosocial needs that must be met for their lives to be rich and fulfilling. Without healthy

relationships with other people, life can be very lonely and lacking in quality. With advancing age, the psychosocial issues are many. A major issue that confronts the majority of our aging population is coping with multiple losses (Chong, 2007). In addition, maintaining independence, social interaction, companionship, and purpose is necessary for a healthy old age. Older adults who have maintained good health and have developed a supportive system of family and friends have more fulfilled lives (Owen, 2007). Programs such as Friendly Visitors, where volunteers regularly meet with isolated seniors either in their homes or long-term care facilities, can be an effective method of increasing social support for those who have no family members nearby (The Senior Source, 2007).

### Coping with Multiple Losses

Elders experience multiple losses, including loss of income and prestige from a career once practiced or the economic stability of an enjoyable job; loss of space due to replacement of a larger residence by a much smaller home or apartment; and reductions in health and vitality that may result in limited movement or pain as a daily concern or may necessitate another move to a more dependent living environment. Repetitive losses occur as elders' significant others, relatives, friends, and acquaintances die; the "bereavement burden" may sometimes be hard to bear (Eliopoulos, 2004; Williams, Sawyer-Baker, Allman, & Roseman, 2007, p. 313).

Inadequate coping with the compounding losses can make an older person believe that life holds no meaning. Depression may be a difficult problem for older adults. Social and emotional withdrawal can often occur, as can suicide. Although older populations have a much lower rate of suicide attempts than younger age groups do, the rate of completed suicide is high. As mentioned earlier, elderly White men have the highest rate of suicide death. Concern for the increased suicide rates among older White men led to a key health objective in *Healthy People 2010*: to reduce the suicide rate to 38.9 per 100,000 people, from the 1987 baseline of 46.1 per 100,000 (USDHHS, 2000). By 1997, for White men aged 65 years or older, the suicide rate was 35.5 per 100,000, thus exceeding the 2010 goal. Because most elderly persons who commit suicide have visited their primary care provider in the last month of their lives, recognition and treatment of depression in health care settings is a promising way to prevent suicide in this age group.

Mortality after bereavement is high and can sometimes be prevented through nursing intervention. Loss and the mourning process among elders have been examined in many studies. It has been found that the ability to mourn prior states of one's self and the past is crucial to successful aging. Life review can be liberating and can provide energy for current living, including planning for the future; in one study higher levels of self-affirmation, confidence, self-esteem, and life satisfaction were noted (Chiang, Lu, Chu, Chang, & Chou, 2007). Although men and women experience similar levels of depression during early bereavement, it is often more difficult for men to seek and receive social support. One Israeli study found that more highly educated men had the greatest difficulty with bereavement (Manor & Eisenbach, 2003). Depression has been found to increase the risk of death for elderly who have lost a spouse, independent of age or bereavement.

The death of a spouse has effects upon the health of the surviving spouse, and depression can exacerbate these effects (Williams, 2005). In addition, grief over the loss of a spouse can continue for many years, as one study revealed. A large study of widows revealed that they "continued to talk, think, and feel emotions about their lost spouse decades later" — even as much as 20 years after their loss—indicating that the time course for grief is extensive (Carnelley, Wortman, Bolger, & Burke, 2006, p. 476).

In addition to preventing early deaths after the loss of a spouse, the greater goal for the nurse in promoting successful aging can be accomplished when the nurse recognizes the significance of accepting all the losses of aging. The loss of a spouse is much more frequent for women than for men (Eliopoulos, 2004; Carnelley et al., 2006). With this knowledge, a woman can age more successfully by planning for the future through anticipatory guidance, with the help of a community health nurse. Many women can expect to live alone for up to 20 years at the end of their life, because of a longer life expectancy and the fact that women in most cultures marry men older than themselves. The nurse can help to make these years meaningful and as healthy as possible.

### Maintaining Independence

Older people need independence, and those who stay independent are happier. As much as possible, the elderly need to make their own decisions and manage their own lives. Even those with activity limitations because of disability can still exercise decision-making options about many, if not most, aspects of their daily living. Unfortunately, because many older adults have chronic diseases, it can be more difficult for them to maintain their independence. It is estimated that 75% of those over age 65 have one chronic illness, and 50% have at least two chronic illnesses (Agency for Healthcare Research & Quality [AHRQ], 2002). The need for autonomy—to be able to assert oneself as a separate individual—is important for all people. For the elderly person, with restrictions of life ever increasing, this need is even more pronounced (Eliopoulos, 2004; Miller, 2003). Independence helps to meet the need for self-respect and dignity. A self-management program, developed by a federal agency, is being utilized to prevent or delay disability among the elderly. The Chronic Disease Self-Management Program teaches patients to better manage their medications and symptoms, and to maintain greater functional ability. Those who have participated in this program have shown better communication with their physicians (and fewer MD visits and hospitalizations) and better coping and symptom management, along with more energy and increased exercise six months later. The reduced numbers of physician visits and emergency room visits, along with improvements in health status, energy, self-efficacy, and no further increases in disability, were noted at one year and two years postintervention (AHRQ, 2002). The good news is that the percentage of older adults becoming severely disabled has been gradually declining for over a decade, thought to be due to better awareness of the dangers of smoking, the need for better diet and exercise, new medications for cardiovascular and other diseases, and advances in eye surgery (Freudenheim, 2001).

The elderly need to have their ideas and suggestions heard and acted upon, and they ought to be addressed by

their preferred names in a respectful tone of voice. Respect for the older adult is not a strong value in American society, but it is highly valued in Asian, Italian, Hispanic, and Native American cultures (Spector, 2004). Older people represent a rich resource of wisdom, experience, and patience that is often unacknowledged in the United States.

### Social Interaction, Companionship, and Purpose

Older people need companionship and social interaction, particularly if they live alone. The company of other people and the companionship of a household pet offer avenues for expression and response and add meaning to life (Owen, 2007). Many studies of mortality patterns demonstrate that older adults living together have a greater survival rate and retain their independence longer than do those who live alone (Eliopoulos, 2004). As people age, their social networks weaken and community health nurses and others can help to improve their psychosocial health by working at individual, family, and community levels (Chong, 2007). The problem is of greatest significance for women, who outnumber men considerably in the later years and who live alone more frequently.

It is also important for older adults without companions to discover and develop a friendship with someone who can be considered a *confidante*, someone in whom the older adult can confide, share reflections on the past, and trust (Yang, 2006). It could be a close friend, a sibling, a son or daughter, or an acquaintance. This person is usually seen daily or talked with on the telephone each week. In particular, mothers and daughters form confidant bonds. Many women consider a sibling a confidant, especially if that person lives close by; this is especially true for childless and single women.

Meaningful activity is another need of the elderly that adds purpose to life. Some kind of active role in community life is essential for mental health, satisfaction, and self-esteem (Warburton, McLaughlin, & Pinsky, 2006). These activities can range from involvement in hobbies, such as gardening or crafts, to volunteer work or even full-time employment. Examples include the federally supported Foster Grandparents and Senior Companions programs, which engage the help of more than 20,000 seniors (Corporation for National & Community Service, 2007). These older adults work part-time offering companionship and guidance to handicapped children, the terminally ill, and other people in need.

Additional volunteering opportunities abound. Internationally, many older professionals join the Peace Corps, which was initiated in the early 1960s. In this program, people of all ages work for 2-year periods in global communities that are in need of services to improve personal health, education, environment, and the larger community (Peace Corps, 2007). On the national level, the newer AmeriCorps\*VISTA (Volunteers in Service to America) programs are similar, but with a 1-year commitment; the volunteer lives among and at the economic level of the low-income people in the United States served by its projects. Retired people can volunteer to help others, donating their skills at a time in their lives when they are in transition from employment to retirement or to fill active retirement years (AmeriCorps, 2007). The Retired and Senior Volunteer Program (RSVP) engages seniors in a bevy of activities designed to improve people's lives and the environment (Senior Corps, 2007). Environmental Alliance for

Senior Involvement (EASI) is a nonprofit coalition of aging, volunteer, and environmental organizations that began in 1991. It sponsors various environmentally focused programs, such as assisting the Hawk Mountain Sanctuary to protect birds of prey, or monitoring streams and other waterways for cleanliness (EASI, 2007).

Many older adults choose not to engage in long-term volunteering, and other programs are more appropriate for them. Elderhostel is a nonprofit organization with more than 25 years of experience providing high-quality, affordable, educational adventures for adults who are 55 years of age and older. It is the nation's first and the world's largest education and travel organization for older adults, offering "more than 8,000 learning adventures in all 50 states and more than 90 countries" (Elderhostel, 2007). Their theme-based, short-term (3 days to 3 weeks) educational programs are infused with a spirit of camaraderie and adventure. The success of this program is based on the fact that learning is a lifelong process that is rewarding at any age—and it is learning without any test or term papers! Elderhostel is inspired by the youth hostels and folk schools of Europe, but guided by the needs and interests of older citizens.

### Safety Needs

People of all ages have safety needs, and safety issues are a major concern for older adults and the community health nurses who work with them. Several areas of focus are discussed here: personal health and safety, home safety, and community safety.

Personal health and safety includes three major areas: immunizations, prevention of falls, and drug safety. Immunizations are not just for children. Older adults are at risk not only of contracting influenza or pneumonia but of dying from them. During the last decade pneumococcal disease and influenza accounted for close to 40,000 annual deaths among those age 65 and above (CDC, 2003c). Other estimates put the annual death rate from influenza alone at over 41,000 (Dushoff, Plotkin, Viboud, Earn, & Simonsen, 2005). Although the overall influenza immunization rate among elders has steadily increased "from between 15% and 20% before 1980 to 65% in 2001," exceeding the *Healthy People 2000* target as early as 1997, some seniors still refuse to have yearly vaccinations (CDC, 2003c). Reasons most often cited by those 65 years and older for not getting flu shots are lack of knowledge that it is necessary, and concern that the flu shot might give them the flu or result in other side effects (CDC, 2004). Though steady increases have been shown overall, there remain racial and ethnic disparities in senior vaccination rates (Simonsen, Reichert, Viboud, Blackwelder, Taylor, & Miller, 2005, p. 265; CDC, 2003c). These racial and ethnic disparities were found even in groups who are usually most likely to avail themselves of health care services (e.g., those with higher education levels, those who have more frequent visits to health care providers). The reasons for the continuing disparity are not well understood, but are thought to be related to differences in care settings (lower vaccination rates with particular providers), lack of trust in providers, and communication problems, especially with those who do not speak English well. It appears that this problem can be solved with increased attention and consistency; the disparities are absent in Veterans Administration clinics where there are standing

orders for influenza vaccination and systems that prompt providers to offer necessary vaccinations (Fiscella, 2005; CDC, 2004). When PHNs work with seniors, it is important to include outreach efforts, such as culturally targeting communication, reaching out to those providers serving this population, and offering vaccination clinics in underserved sections of the community (CDC, 2004).

Although pneumococcal vaccine coverage rates have also increased steadily from 38.4% in 1995 to 54.9% in 1999, improvement is still needed (Johnson, 2003). Only 16% of states met the *Healthy People 2000* goal of 60% vaccine coverage for a disease that is thought to result in over 175,000 hospitalizations annually (National Foundation for Infectious Diseases [NFID], 2002). Some question the validity of self-reported pneumococcal vaccination because this is, for most, a one time vaccination sometimes given many years before the survey is done, and it is often given with an influenza vaccine, causing confusion (Johnson, 2003). Despite the increases, coverage rates for certain racial and ethnic groups remain substantially below those of the general population (30% for Hispanics, 31% for African Americans) (NFID, 2002). Attempts to improve immunization coverage involve changing provider knowledge, attitudes, and behavior through reminders and standing orders, so that “missed opportunities” when seeing clients are prevented. One simple method is to ask clients about their beliefs and fears related to immunizations and then to address them directly and honestly (Fiscella, 2005). Additional opportunities for vaccinating people exist beyond the primary care setting, as community health nurses are well aware. People can be reached during emergency department visits, at neighborhood and senior centers, at religious facilities, and in other settings where elders may gather. Regardless of the site, a method for tracking and communicating vaccinations is needed so that vaccination information may be documented and shared with the elder’s primary care provider. Some studies have reported that clinicians often fail to document immunizations for adult patients (Johnson, 2003). Immunizations protect more than the at-risk population; they protect society as a whole. People of any age with a chronic illness, such as heart disease, diabetes, or chronic respiratory disease, and people older than 65 years of age, should be encouraged to receive the flu vaccine each year and the pneumonia vaccine every 5 years.

Each year, approximately one-third of people older than 65 years of age who are independent and living on their own experience a fall, and falls occur for half of those over 80 years of age and for those individuals residing in long-term care settings (RAND Health, 2003; Hill-Westmoreland, Soeken, & Spellbring, 2002). Falls and the resulting injuries can have a dramatic impact on self-confidence and independence, often leading to decreased mobility, increased debility, and diminished quality of life as well as additional strain on health services. The injuries received from a fall can result in death, disability, nursing home admission, and direct medical costs. In 2003, a total of 1,700 persons aged 65 and older died from falls, and 1.8 million were treated in emergency departments for nonfatal injuries from falls. The average cost of health care due to a fall for a person 72 years and older has been estimated at close to \$20,000. Falls cause the majority of hip fractures, which can often result in long-term functional impairments that may require admission to a nursing home for up to a year or more (CDC, 2007a; Stevens,

Corso, Finkelstein, & Miller, 2006). In 2000, medical costs were over \$19 billion, and by 2020, the total cost of fall injuries could reach \$43.8 billion (CDC, 2007a; Stevens et al., 2006). Causative factors involve both environmental hazards (e.g., lack of handrails and nonslip surfaces) and host issues (e.g., cognition, vision). Fall prevention, which involves education, strengthening and balance exercises, medication evaluation, and environmental improvements, is an important function of the community health nurse. Research has identified interventions that can reduce falls, but development and implementation of community-based programs remains limited (National Council on Aging, 2005; RAND Health, 2003; Rose, 2003). Use of a home safety checklist can give the nurse a baseline of information from which to begin teaching and providing interventions to ensure continued safety for many independent seniors who choose to remain in their homes (Display 24.4).

A significant safety issue for the older adult arises from adverse drug effects. Older people may need to take several medications to control the effects of chronic conditions, and their bodies can react differently than those of younger people (on whom most new drugs are tested). Absorption time is usually slower, distribution changes as drugs may stay in the body longer due to a higher percentage of fat stores, and reduced liver and kidney function affect clearance time for medications in elderly clients (Wooten & Galavis, 2005). Also, it is not unusual for older people to be taking four to six medications daily and filling 13 prescriptions or more each year. It is estimated that people over age 65 (13% of population) receive 30% of prescriptions and over half of all over the counter medications purchased (Wooten & Galavis, 2005; Bushardt & Jones, 2005). Elders often receive multiple prescriptions from multiple providers, and sometimes from multiple pharmacies, and are in danger of receiving double doses of the same or similar medications. This can happen, for instance, when one health care provider prescribes a name-brand medication and a second one writes a prescription for the same medication, but in generic form. Often, the elderly person has no idea that they are taking two doses of the same medication (Bushardt & Jones, 2005). Also, common medications like acetaminophen can be found in a variety of over the counter and prescription medications (e.g., cold remedies, arthritis topical ointments) and inadvertent overdosing can be a real problem (Bushardt & Jones, 2005). Most adverse drug events (ADEs) are due to drug interactions. The greater number of medications taken, the more likely there will be side effects (Wooten & Galavis, 2005). Multiple medications or complicated drug regimens for many older people can lead to unexpected and dangerous drug interactions or drug–disease interactions; sometimes medications are prescribed for symptoms that may actually be a side effect of an original medication, leading to a “prescribing cascade” (Wooten & Galavis, 2005). Medication side effects or drug interactions can lead to falls and further disability. Elderly clients need education about the drugs they take and their possible effects. They also need proper supervision of their overall medication intake, including complementary and alternative therapies (e.g., herbal treatments) and over the counter drugs. It is also important for all seniors to keep a list of their current medications and doses and to have this available in the event of an emergency. However, many hospitals and providers prefer the “brown bag method” of determining accurate medication information, in which they

## DISPLAY 24.4

## GUIDELINES FOR ASSESSING THE SAFETY OF THE ENVIRONMENT

**Illumination and Color Contrast**

- Is the lighting adequate but not glare producing?
- Are the light switches easy to reach and manipulate?
- Can lights be turned on before entering rooms?
- Are night lights used in appropriate places?
- Are there working flashlights close by (bedroom, kitchen, bath, living room)?
- Is color contrast adequate between objects such as a chair and floor?

**Hazards**

- Are there throw rugs, highly polished floors, or other hazardous floor coverings?
- If area rugs are used, do they have a nonslip backing and are the edges tacked to the floor?
- Are there cords, clutter, or other obstacles in pathways?
- Is there a pet that is likely to be running underfoot?

**Furniture**

- Are chairs the right height and depth for the person?
- Do the chairs have arm rests?
- Are tables stable and of the appropriate height?
- Is small furniture placed well away from pathways?

**Stairways**

- Is lighting adequate?
- Are there light switches at the top and bottom of the stairs?
- Are there securely fastened handrails on both sides of the stairway?
- Are all the steps even?
- Are the treads nonskid?
- Should colored tape be used to mark the edges of the steps, particularly the top and bottom steps?

**Bathroom**

- Are grab bars placed appropriately for the tub and toilet?
- Does the tub have skid proof strips or a rubber mat in the bottom?
- Has the person considered using a tub seat?
- Is the height of the toilet seat appropriate?
- Has the person considered using an elevated toilet seat?
- Does the color of the toilet seat contrast with surrounding colors?
- Is toilet paper within easy reach?

**Temperature**

- Is the temperature of the room(s) comfortable?
- Can the person read the markings on the thermostat and adjust it appropriately?
- During cold months, is the room temperature high enough to prevent hypothermia?
- During hot weather, is the room temperature cool enough to prevent hyperthermia?

**Overall Safety**

- How does the person obtain objects from hard-to-reach places?
- How does the person change overhead light bulbs?
- Are doorways wide enough to accommodate assistive devices?

- Do door thresholds create hazardous conditions?
- Are telephones easily accessible, especially for emergency calls?
- Would it be helpful to use a cordless portable phone or a cellular phone?
- Would it be helpful to have some emergency call system available?
- Does the person wear sturdy shoes with nonskid soles?
- Are smoke alarms present and operational?
- Is there a carbon monoxide detector (if the house has gas appliances)?
- Does the person keep a list of emergency numbers by the phone?
- Does the person have an emergency exit plan in the event of fire?

**Bedroom**

- Is the height of the bed appropriate?
- Is the mattress firm at the edges to provide enough support for sitting?
- If the bed has wheels, are they locked securely?
- Would side rails be a help or a hazard?
- When side rails are in the down position, are they completely out of the way?
- Is the pathway between the bedroom and bathroom clear of objects and adequately illuminated, particularly at night?
- Would a bedside commode be useful, especially at night?
- Does the person have sufficient physical and cognitive ability to turn on a light before getting out of bed?
- Is furniture positioned to allow safe use of assistive devices for ambulation?
- Is a telephone situated near the bed?

**Kitchen**

- Are storage areas used to the best advantage (e.g., are objects that are most frequently used in the most accessible places)?
- Are appliance cords kept out of the way?
- Are nonslip mats used in front of the sink?
- Are the markings on stoves and other appliances clearly visible?
- Does the person know how to use the microwave oven and other appliances safely?

**Assistive Devices**

- What assistive devices are used?
- Is a call light available, and does the person know how to use it?
- Would the person benefit from any assistive devices that are not being used?
- Are assistive devices being used safely and properly, or do they present additional hazards?

Adapted from Miller, C.A. (2003). *Nursing care of older adults: Theory and practice* (4th ed.). Philadelphia: Lippincott, Williams & Wilkins.

Environmental assessments and modifications are only part of an effective multifactorial fall prevention program. Medication assessment and medical evaluation (e.g., gait, balance, strength, vision, orthostatic blood pressure, and cognitive and functional status) need to be done, and an exercise program instituted (RAND, 2003).

are asked to bring everything they take with them (Wooten & Galavis, 2005). This is an area in which the community health nurse can intervene very effectively and with much success (see Display 24.5).

Safety in the community is an additional concern. Safety can involve many things, such as pedestrian and driving issues, crime and fear of crime against elders, and environmental factors such as sun exposure, pollution, heat, and cold.

Because of age-related changes in vision, hearing, mobility, and the effects of polypharmacy, elders are at risk in the community as pedestrians and as drivers. Automobile crashes and pedestrian injuries can be life-threatening events

when elders are involved. As pedestrians, elders must be increasingly vigilant to traffic patterns, sidewalk irregularities, and the possibility of being a victim of street crime. Often out of necessity and pride, elders drive longer than their abilities permit. As people age, they are more prone to lapses in memory and attention, problems with depth perception and gauging distance of cars in traffic, reduced manual dexterity and reaction time, and impairment of other skills critical to driving safety (The Raw Story, 2007). Older adults age 65 and older have the second highest rate of death in car accidents, after those in the 15 to 24 age-range group. As the Baby Boomers age, this rate is expected to climb. The risk of death for a driver over the age of 85 is four times higher than for those 21 and younger (Agence France-Presse, 2007). Most accidents for people 65 years and older involve a seat-belted, sober driver, “pulling into the path of an oncoming vehicle during the day and dying several days after” the moderately severe collision (University of Virginia News, 2006, p.1). Because they generally have chronic diseases and are often frail, they are more susceptible to injury than younger drivers. Stopping driving is usually a difficult and painful decision for the elder to make. Some communities offer specialized driving classes for elders who want to continue to drive for as long as possible. At times, the car keys may have to be taken from the elder for her own safety and that of others. This may be necessary especially with elders who have dementia, AD, uncorrectable vision problems, or stroke-related physical or cognitive aftereffects. Only ten states require mandatory eye testing for drivers over 65 years of age, just five states require seniors to renew their drivers’ licenses in person, and only two states require a mandatory road test (Agence France-Press, 2007). Public health nurses may need to consult with older adults and their families about determining when it is time for elders to stop driving.

Actual crime against elders in the community is lower than any other age group of the population: 2.8 per 1,000 cases for 65 and over versus 12 to 48.4 for those 50 to 64 years old and 20 to 24 years old, respectively (U.S. Department of Justice, 2006). However, the fear of crime among elders is often perceived as a major issue by the general public, and some research has shown both increased and decreased levels of fear in older adults (Acierno, Rheingold, Resnick, & Kilpatrick, 2004; Ziegler & Mitchell, 2003). Some researchers believe that the disposition to fear is more related to personality characteristics and other factors such as social isolation, depressive symptoms, and race (Acierno et al., 2004). Display 24.6 lists client-centered nursing interventions designed to reduce fear among older adults and empower them to feel safer in their communities.

Environmental factors can have an effect on the health and safety of elders when they are outside. Sun exposure, pollution, and exposure to heat and cold can have negative effects on older adults. They are vulnerable, as are infants and children, to climatic changes and should take a variety of preventive measures, including using sun block when gardening, reading, or walking outside for longer than 10 minutes, even on days with an overcast sky. Other measures include staying indoors on days when the air quality is poor or there is an air safety alert, drinking additional fluids, wearing protective covering, and limiting outdoor activities and exposure on days with elevated temperatures; and, conversely, limiting outdoor exposure and wearing appropriate

#### DISPLAY 24.5

### PROMOTING POLYPHARMACY SAFETY IN THE ELDERLY THROUGH MEDICATION REVIEW

- Ask the client to bring all of her medications for you to examine.
- List all medications, along with dosage and time taken.
- Note the pharmacy or pharmacies where each prescription originates. Has more than one physician prescribed medications for the client?
- Ask about medical conditions and diseases for which she takes medications. Does the client have a clear understanding of each medication and its benefits and potential side effects?
- Ask the client for which condition or disease each medication is prescribed. Does the client understand the basic disease process and how the prescribed medication works?
- Are there duplicate medications (e.g., contain the same active ingredient, both a generic and a proprietary form)?
- What are the most common side effects of each medication?
- Is the dosage prescribed within the recommended range?
- Is the client experiencing any symptoms of potential drug interactions (e.g., nausea, headaches, dizziness)?
- Is one medication being used to treat possible side effects of another medication?
- Ask the client if she takes all medications as prescribed. Does she skip doses or medications?
- Does she use a daily/weekly pill box? Does she have some system of checking off when she has taken her medications each day?
- Is the client taking any medications that were prescribed for someone else?
- Is the client taking any over-the-counter or herbal remedies?

## DISPLAY 24.6

## REDUCING THE FEAR OF CRIME

- Allow elder adults time to discuss their fears of crime.
- Facilitate a realistic self-assessment of their ability to avoid crime and to defend themselves.
- Teach basic safety and security techniques.
- Correct the elder's sensory losses if possible, such as by getting a hearing aid or glasses.
- Correct a physical disability if possible, such as by treating the pain of arthritis or obtaining physical therapy.
- Facilitate access to safe, reliable, and affordable transportation.
- Identify family members, friends, neighbors, or caregivers who can support efforts to leave the home on a more regular basis.
- Encourage an elder to make a daily telephone or e-mail contact with at least one supportive person.
- Encourage the elder to get to know his or her neighbors.
- Encourage elders to travel and conduct community activities and errands together.
- Encourage participation in local senior centers and other community-based programs.
- Refer to alternative housing options available for older adults.
- Provide information on local services that assist and support crime victims.

winter clothing, especially layers of clothes, on cold, snowy, or icy days (CDC, 2006c). Although sun exposure is beneficial in vitamin D production, older adults need to be careful about limiting their exposure. Teaching geographically and seasonally appropriate safety precautions is the responsibility of the community health nurse providing services to groups of elders in the community.

### ***Spirituality, Advance Directives, Hospice, Palliative Care, and Preparing for Death***

A final need of the elderly is preparing for a dignified death. In her classic work, Elisabeth Kübler-Ross (1975) described death as the final stage of growth and one that deserves the same measure of quality as other stages of life. Although death is a natural part of life, many older people fear death as an experience of pain, humiliation, discomfort, or financial concern for their loved ones. Sometimes, very aggressive and heroic medical treatments are offered to those near the end of their lives, often at the urging of family members (Richardson et al., 2007). Planning for a dignified death is an important issue for many older people, and PHNs can facilitate conversations among family members and provide necessary information and resources.

A commonly used option that takes a multidisciplinary approach to end of life care and needs is **hospice**. Hospice has been available in the United States since the mid-1970s. Hospice is more a concept of care than a specific place,

although some hospice organizations provide individuals with a place to die with dignity if they have no home or choose not to die at home. Hospice is an option for people with a “projected” life expectancy of six months or less and often involves palliative care (pain and symptom relief) as opposed to ongoing curative measures. Hospice enables many elderly clients to live their end days to the fullest, with purpose, dignity, grace, and support; in fact, one recent large scale study found that hospice patients survived 29 days longer than nonhospice patients (National Hospice & Palliative Care Organization, 2007). Hospice care focuses on all aspects of an individual's life and well being: physical, social, emotional, and spiritual (O'Brien, 2003). Individuals are permitted to go on and off hospice care as needed, or if they change their mind and decide to return to curative treatment. Some community health nursing agencies offer hospice programs staffed by their nurses. It is a service that has been well received by elders, meets important needs, and is growing in use. (See Chapter 32 for more.)

**Palliative care** consists of comfort and symptom management and does not provide a cure. For most chronic ongoing health conditions—such as diabetes, high blood pressure, congestive heart failure, arthritis, and chronic obstructive pulmonary disease—there are no cures, only symptom relief. Relative to the elderly population, which suffers from more chronic conditions than the rest of the population, palliative care should not be viewed as synonymous with hospice or end-of-life care. Rather, palliative care should be viewed as any care primarily intended to relieve the burden of physical and emotional suffering that often accompanies the illnesses associated with aging. Palliative care should be a major focus of care throughout the aging process, regardless of whether death is imminent within six months (Jerant, Azari, Nesbitt, Edwards-Goodbee, & Meyers, 2006).

Many seniors are now “pre-planning” their funerals. This option is gaining momentum in the senior population and allows individuals to make arrangements with a funeral home of their choice, selecting interment or cremation, a memorial service or a celebration of life gathering, music to be played, and other personal details. All options are chosen by the senior rather than leaving these choices and decisions solely to their family members. Other older adults may place less emphasis on the rituals, as was demonstrated by one elder who left these choices to her children by telling them, “Surprise me!”

Living wills and advance health care directives (AHCD), sometimes referred to as *advance directives*, are legal documents that instruct others about end-of-life choices should an individual be unable to make decisions on their own. An AHCD only becomes effective under the circumstances specified in the document. This document allows for appointment of a health care agent who will have the legal authority to make health care decisions on behalf of the patient, and for specific written instructions for future health care in the event of any situation in which the patient can no longer speak for herself. Having such documents prepared and making them known to significant others can ensure that wishes will be honored. These documents can provide clear directions for families and health care professionals and are gaining more recognition and importance as a result of increasing ethical dilemmas and challenges brought on by advances in technology (MedlinePlus, 2007a). Advance directives can be revoked or replaced at any time as long as the individual in question is

capable of making her own decisions. It is recommended that these documents be reviewed every two years or so, or in the event of a change in health status, and revised to ensure that they continue to accurately reflect an individual's wishes (MedlinePlus, 2007a).

## Secondary Prevention

Secondary prevention focuses on early detection of disease and prompt intervention (see Chapter 1). Much of the community health nurse's time is spent in educating the community on preventive measures and positive health behaviors. This includes encouraging individuals to obtain routine screening for diseases such as hypertension, diabetes, or cancer, which, if identified early, can be treated successfully (AHRQ, 2002). Many nurses, working in collaboration with community agencies, are in positions to establish screening programs based on the desires and demographics of the community and agency focus, making them accessible to the population being served.

Older adults need to be encouraged to follow the routine health-screening schedule prescribed by their clinic or health care provider. The health screening schedule described in Table 24.1 is based on the recommendations of Kaiser Permanente, *Healthwise Handbook* (2006), the largest Health Maintenance Organization in the world, that serves millions of clients, and is presented here as a guide. The United States Preventive Services Task Force (USPSTF) (AHRQ, 2007) proposed a more comprehensive view of interventions and recommendations for the periodic health examination of people older than 65 years of age. They identified age-specific, evidence-based preventive services guidelines that are outlined in Display 24.7.

## Tertiary Prevention

Tertiary prevention involves follow-up and rehabilitation after a disease or condition has occurred or been diagnosed and initial treatment has begun. Chronic diseases that are common among older adults, such as heart failure, stroke, diabetes, cognitive impairment, or arthritis, cannot always be prevented, but can frequently be postponed into the later years of life through a lifetime of positive health behaviors (AHRQ, 2002). However, when they occur, the debilitating symptoms and damaging effects can be controlled through healthy choices encouraged by the community health nurse and recommended by the primary care practitioner (Hazard, 2003).

Although many older adults are considered generally healthy, 80% have at least one chronic condition and 50% have at least two (CDC, 2003b). A small proportion suffer more disabling forms of disease, such as chronic obstructive pulmonary disease (COPD), cerebral vascular accidents (CVAs), cancer, or diabetes mellitus (DM), the latter two requiring extensive care and ongoing medical management. The most common health problems of older people in the community are arthritis, reduced vision, hearing loss, heart disease, peripheral vascular disease, and hypertension. In 2002, the top three causes of death for U.S. adults aged 65 or older were heart disease (32% of all deaths), cancer (22%), and stroke (8%). These accounted for 61% of all deaths in this age group. The tragedy of these leading killers is that they are often preventable. Although the risk for disease and disability clearly increases with advancing age, poor health is not always an inevitable consequence of aging. Three behaviors—smoking, poor diet, and physical inactivity—were the root causes of almost 35% of U.S. deaths in 2000 (Mokdad, Marks, Stroup, & Gerberding,

**TABLE 24.1 Recommended Health Screening/Immunizations—Older Adults**

Test	Age 50–64	Age 65+	Comments
<b>Men and Women</b>			
Blood pressure	1–3 years	Yearly	More often if elevated
Total cholesterol	5 years	5 years	More often if elevated
Flexible sigmoidoscopy	10 years	10 years	—
Vision	4 years	2 years	—
Hearing	Not recommended	Once	Evaluate at regular health care practitioner visits
Pneumonia vaccine	Not recommended	Once	—
Influenza vaccine	Yearly	Yearly	—
Tetanus and diphtheria	10 years	10 years	After a closed/dirty wound if it has been >5 years
<b>Women</b>			
Breast self-examination	Monthly	Monthly	—
Pap test	2 years (after age 40)	2 years (after age 40)	After a hysterectomy by health care practitioner evaluation
Clinical breast examination	1–2 years	1–2 years	—
Mammogram	1–2 years	1–2 years	Frequency decided on an individual basis

## DISPLAY 24.7

## HEALTH MAINTENANCE PROGRAMS AND SERVICES FOR OLDER ADULTS

## Resources for Community Health Nurses to Utilize With Clients

- Communication services (phones, emergency access to health care)
- Dental care services
- Dietary guidance and food services (such as Meals on Wheels, commodity programs, or group meal services)
- Escort and protective services
- Exercise and fitness programs
- Financial aid and counseling
- Friendly visiting and companions
- Health education
- Hearing tests and hearing-aid assistance
- Home health services (including skilled nursing and home health aide services)
- Home maintenance assistance (housekeeping, chores, and repairs)
- Legal aid and counseling
- Library services (including tapes and large-print books)
- Medical supplies or equipment
- Medication supervision
- Podiatry services
- Recreational and education programs (community centers, Elderhostel)
- Routine care from selected health care practitioners
- Safe, affordable, and ability-appropriate housing
- Senior citizens' discounts (food, drugs, transportation, banks, retail stores, and recreation)
- Social assistance services offered in conjunction with health maintenance
- Speech or physical therapy
- Spiritual ministries
- Transportation services
- Vision care (prescribing and providing eye glasses; diagnosis and treatment of glaucoma and cataracts)
- Volunteer and employment opportunities (Vista, RSVP)

Adapted from U.S. Preventive Services Task Force. (2000–2003). *Guide to clinical preventive services* (3rd ed.). Retrieved January 30, 2004 from <http://www.upstf.gov>

2004). The costs of chronic illness are high: one study found per capita Medicare expenditures increased from \$211 (no chronic illness) to \$13,973 with four or more chronic conditions and another study reported that someone age 65 and above with one serious chronic illness would spend between \$1,000 and \$2,000 more per year on health care (Wolff, Starfield, & Anderson, 2002; Joyce, Keeler, Shang, & Goldman, 2005). Although most elderly people experience relatively good health, almost all may expect to be chronically ill for an extended amount of time at the end of their lives (RAND Health, 2003). Chapter 26 expands on clients with disabilities and chronic illnesses and the role of the commu-

nity health nurse working with these populations in the community.

**Alzheimer's Disease**

**Alzheimer's disease** (AD) was first described by Dr. Alois Alzheimer in a German medical journal in 1907. It is estimated that close to 5 million Americans suffer from Alzheimer's disease, and that the numbers of people developing this disease doubles every 5 years as people live beyond the age of 65 (National Institute on Aging, 2006a). With no cure in sight, this rate is expected to increase 27% by 2020, 70% by 2030, and it will more than triple by 2050 (Science Blog, 2003; National Institute on Aging, 2006a).

The occurrence of Alzheimer's disease is not a normal development in the aging process. It is characterized by a gradual loss of memory, decline in ability to perform routine tasks, disorientation, difficulty in learning, loss of language skills, impaired judgment and ability to plan, and personality changes. As the disease progresses these changes become so severe that they interfere with the individual's daily functioning, resulting in total dependence on others for care and eventually in death. Although the disease can last from 8 to 10 years, some people live 20 years after the onset of symptoms, and the current costs to Americans total \$61 billion annually and Medicare costs for AD are expected to rise 54% by 2010 (Science Blog, 2003). Alzheimer disease is the fourth leading cause of death among the very old in the United States. Most people diagnosed with AD are older than 65 (called late-onset AD), and the incidence increases in the over-85 population. However, it is possible for the disease to occur in people between the ages of 30 and 60, but early-onset AD is usually considered an inherited form of the disease (National Institute on Aging, 2006a).

There is a simple way to describe the difference between the normal forgetfulness of aging and AD. From time to time, we all forget where we have put our keys, but people with early stage AD may notice that they tend to forget things more often—especially recent activities or events, or names of familiar things or people (National Institute on Aging, 2006a). Although these symptoms are bothersome, they are usually not serious enough to cause alarm. As the disease advances, the symptoms become serious enough to cause people with AD or their family members to recognize that things are not right and that help is needed. In the middle stages of AD, people eventually forget how to do simple tasks like brushing their teeth or combing their hair, and they begin to no longer be able to think clearly. They eventually have problems speaking, understanding, reading or writing, or recognizing people they have known for years. People who suffer from AD may become anxious or aggressive, and may wander away from home, thus requiring the need for total care (National Institute on Aging, 2006a).

There is no single test to identify AD. It is recommended that health care providers offer a comprehensive exam including a complete health history; physical exam; lab tests; neurologic, functional, and mental status assessments; and possible brain scans (National Institute on Aging, 2006a; Cherry, Vickrey, Schwankovsky, Heck, Plauche, & Yep, 2004). A comprehensive assessment is needed because many conditions, including some that are treatable or reversible (e.g., thyroid disease, depression brain tumors, drug reactions), may

cause dementia-like symptoms. Physicians are now able to accurately diagnose 80% to 90% of people who show symptoms, but the only definitive diagnosis of AD is done at autopsy by the examination of brain tissue (National Institute on Aging, 2006a).

Probable causes of AD are many. Promising leads involve the role of neurotransmitters, proteins, metabolism, environmental toxins, and genes. Research has shown links between some genes and AD, with three gene variants identified for early-onset AD and one that boosts risk for late-onset. A recent study found that a new genetic link for late-onset AD, a variation in the gene *SORL1*, may be tied to levels of production of amyloid beta fragments that lead to plaques in the brains of AD patients (National Institute on Aging, 2007). Discovering the cause and a means of preventing AD, as well as better methods of earlier diagnosis, will be a significant achievement that may be realized in this century (National Institute on Aging, 2006b). Currently, 16 different agents are under study relative to AD, compared with 90 for cardiovascular disease; the medical community is not putting the same amount of effort into research for AD as it does for other diseases. This lack of research interest today affects what will be available for those in need tomorrow (Alzheimer's Association Medical and Scientific Advisory Council, 2005).

Medications may be prescribed, but many are largely experimental (National Institute on Aging, 2006a). At best, available medications “turn back the clock somewhat” with the disease worsening at a slower rate, or the drugs control some of the client's behaviors that jeopardize safety, thereby promoting caregiver management.

How does this disease affect the role of the community health nurse? Often, the person with AD is cared for at home until very late in the disease course. The intense care given these clients can be a constant drain on the emotional and physical reserves of their families and highlights the need for respite care (Mason et al., 2007). The client exhibits depression, agitation, sleeplessness, and anxiety, which can greatly upset the family's normal routine. In many situations, the main caregiver is an aged spouse. The stress of providing care puts the caregiver's health at risk, as well. The intensity of caregiving is aptly described in a book written for AD family members, *The 36-Hour Day* (Mace & Rabins, 2001). Another good book is *Staying Connected While Letting Go: The Paradox of Alzheimer's Caregiving* (Braff & Olenik, 2003). (See What Do You Think?)

Because so many elders afflicted with AD reside at home with their family members providing care, it is important for the community health nurse to monitor and assess the levels of stress on family members. The nurse can intervene as necessary and provide caregivers with methods to cope and adapt as needed, making applicable referrals. Most communities have resources for clients and their families. They may provide family and caregiver support groups, respite care, counseling, and legal or financial consultation. These services are available through local agencies, such as the Area Agency on Aging, but there are also government-sponsored national resources that offer information, referral services, and educational materials (e.g., Alzheimer's Association) all of which can be accessed by the community health nurse or the families in need. Some may find online support groups helpful. The nurse needs to know what resources are available in order to guide families to them (see Using the Nursing Process).

## What Do You Think?

Have you heard of the *Best Friends* approach to Alzheimer's care? The approach has changed the caregiving approach to Alzheimer disease (AD) and is changing the lives of caregivers, families, and clients. It improves the quality of life not only for clients with AD but also for those providing care. *Best Friends* is a groundbreaking and up-lifting method for the care of people with AD. It builds on the essential elements of friendship: respect, empathy, support, trust, and humor. These are the building blocks of a care model that is both effective and flexible enough to adapt to each person's remaining strengths and abilities. The *Best Friends* approach does not just prevent catastrophic episodes; it makes every day consistently reassuring, enjoyable, and secure.

(1997). *The Best Friends approach to Alzheimer's care*. Baltimore: Health Professions Press. (*Best friends* is a trademark of Health Professions Press, Inc.)

## Arthritis

Arthritis encompasses more than 100 diseases and conditions that affect joints, surrounding tissues, and other connective tissues, and is the leading cause of disability for adults in the United States (CDC, 2007b). Common forms include osteoarthritis, rheumatoid arthritis, gout, and fibromyalgia. Arthritis is a disease of both young and old, with two-thirds of sufferers younger than age 65. However, it is common among women and older adults, and over half of adults with heart disease or diabetes also have arthritis (CDC, 2007b). By 2030, it is estimated that 20% of Americans older than 65 will have osteoarthritis (OA) (National Institute of Arthritis & Musculoskeletal & Skin Diseases [NIAMS], 2006a).

Osteoarthritis is the most common form of arthritis. In this type of arthritis, the number of cartilage cells diminishes, cartilage becomes ulcerated and thinned, subchondral bone is exposed, and bony surfaces rub together resulting in joint destruction. This disease is no longer considered to be only a normal consequence of aging. Risk factors include obesity, repetitive mechanical overuse of a joint, and heredity. Classic symptoms include aching, stiffness, and limited motion of the involved joint. Discomfort increases with overuse and during damp weather. Acetaminophen is the first drug of choice; however, clients often find a combination of medications and daily routines that helps them the most. The nurse can best assist these clients by assessing the safety of a particular regimen and suggesting treatment changes as new research becomes available, including new medications, surgical options for joint replacement, and dietary changes (e.g., vitamins, foods high in essential fatty acids) (NIAMS, 2006a).

Rheumatoid arthritis (RA) is a progressive chronic condition that begins during young adulthood and becomes disabling as the disease continues, attacking tissues of the joints and causing systemic damage in the later years. It

## USING THE NURSING PROCESS WHEN WORKING WITH OLDER ADULTS

### Assessment

Mr. and Mrs. Boxwell are in their late 70s and have lived modestly on a fixed income since Mr. Boxwell's retirement. However, their budget has been strained this year as they have had \$300 to \$400 a month in out-of-pocket expenses for prescription medications. Mrs. Boxwell confessed to you (the community health nurse visiting them after receiving a referral from the coordinator of the senior center they attend) that at times they will skip medication doses to make "ends meet" some months. They both take drugs for high blood pressure, and Mrs. Boxwell is diabetic and Mr. Boxwell has heart failure. They live in a small, older home, and their older model car is seldom driven as they report "the traffic is getting worse" and they have "come close to having a car crash two times" while they were driving in the past 3 months. They are receptive to your suggestions, and are trying to stay healthy and independent.

### Nursing Diagnoses

1. The clients are at risk for an alteration in their health status due to insufficient finances to purchase needed medications for chronic diseases.
2. The clients are at risk for altered safety when driving related to chronic health problems, diminished driving skills, and a history of near automobile crashes.

### Plan/Implementation

#### Diagnosis 1

The community health nurse will explore the clients' eligibility for Medicare Part D and Medicaid. It is possible these clients are eligible, yet unaware of these programs. The community health nurse will consult with the clients' primary health care provider and ask for a change in pre-

scriptions from brand names to generic. Also, ordering some medications in larger doses that come in scored tablets may be less expensive, and the client can safely break the larger pills in half. Mrs. Boxwell will check with her present distributor of diabetic supplies about getting larger quantities, generic brands of syringes, alcohol pads, etc.

#### Diagnosis 2

Mr. Boxwell will look into selling their car, and exploring the bus schedule and other senior shuttle services that can be used to travel to the doctor and grocery store. Mr. and Mrs. Boxwell's daughter spends a day with them monthly and takes them wherever they want to go, as long as it is "a fun outing," and they will look into coordinating errands with her.

### Evaluation

The couple is eligible for Medicare Part D, and this will help defray the out-of-pocket costs for medications. They have reduced medication costs as much as possible and report not missing any prescribed medications.

They sold their car and are negotiating the bus in good weather and using a taxi in the winter or when it is raining (they figured they save \$1,000 a year in auto insurance, auto maintenance, and gasoline while the bus and taxi costs them about \$22 a month).

Since the couple is receptive to the help you have provided, you initiate a discussion regarding their long-term plans for housing needs as they get older. They are not opposed to a senior housing option, and have been talking about it with their daughter. They are going to talk with a realtor about selling their house, explore some senior apartments with their daughter on her monthly visits, and review their budget.

affects diarthrodial (synovial-line) joints. This form of arthritis is an autoimmune disease that causes inflammation, deformity, and crippling. RA is treated with anti-inflammatory agents, corticosteroids, antimalarial agents, gold salts, and immunosuppressive drugs. Joint discomfort is often relieved by gentle massage, heat, and range-of-motion exercises (NIAMS, 2006b).

The community health nurse needs to be aware of the major differences between these two prevalent forms of arthritis. Recommended treatments, including physical therapy, diet, and medication, change as more evidence-based research is conducted on arthritis. It is important to keep up-to-date on treatments, as these conditions are treated in the community and affect a large portion of the midlife and older populations a PHN may serve.

### Cancer

Cancers, which are characterized by the uncontrolled growth and spread of abnormal cells, steadily increase in incidence in aging adults. Leukemia and cancers of the digestive

system, breast, prostate, and urinary tract increase with age (Ebersole & Hess, 2004). One popular theory is that as the body ages, the immune system declines, losing its ability to serve as a buffer against abnormal cancer cells that have been forming in the body throughout life. Other identified causes of cancer involve personal health behaviors such as tobacco and excessive alcohol use (American Cancer Society, 2002).

It is particularly important for the community health nurse to be aware of the increased incidence of cancer in older clients, because older people often under report symptoms that may be early signs of cancer. It is vital for PHNs, through assessments at clinics, on home visits, or during participation in screening programs, to encourage clients to report untoward symptoms in order to promote early detection, which gives clients their best chance of survival. Adherence to the health care practitioner's recommended schedule for health screening should be encouraged. In addition, being aware of and educating clients about the American Cancer Society's seven warning signals of cancer can possibly save their lives (Display 24.8).

## DISPLAY 24.8

## CAUTION

The seven warning signals of cancer can be remembered through the use of the mnemonic device, *CAUTION*, as follows:

1. Change in bowel or bladder habits
2. A sore throat that does not heal
3. Unusual bleeding or discharge
4. Thickening or lump in breast or elsewhere
5. Indigestion or difficulty in swallowing
6. Obvious change in wart or mole
7. Nagging cough or hoarseness

(Source: The American Cancer Society)

### Depression

Depression is one of the most common, and most treatable, of all the mental disorders in older adults. It is a major health concern in this population and can be life threatening if unrecognized and untreated. Biological, psychological, and social changes place older adults at high risk for the development and recurrence of depression. It is frequently related to multiple losses, such as retirement, a health change, or the death of a significant other. Depression is reported to be more common in women than in men (Ebersole & Hess, 2004). However, as mentioned earlier in this chapter, depression in men is more severe, resulting in suicide at a higher rate than among women. Higher levels of perceived social support are related to lower instances of depression among all people, especially the elderly, and women seem to make these supportive connections throughout life more effectively than men do. The nurturance, reassurance, and support women get from intimate relationships with other women are not often as highly developed in men, and for this reason, men display more symptoms of depression after a loss.

Community health nurses can help elders prevent the overwhelming signs and symptoms of depression related to losses by working with aggregates of elders in the community. Through senior centers, adult housing units, senior day care centers, or men's and women's groups at religious centers, the community health nurse can meet with seniors to offer support, teach strategies to improve the quality and quantity of support systems, invite mental health speakers to discuss the topic of depression prevention, and generally assess the holistic health status of the elders in that setting. The increased years added to life through the advances of the past few decades in medications and treatment should lead to healthy and happy later life for seniors, filled with activities that bring joy and contentment. Years lost to depression are a wasted resource that could be prevented through early intervention and medical management.

### Diabetes

Diabetes mellitus (DM) affects the health of older people and limits their ability to perform activities. Among people 65 years and older in 1999-2000, 15.1% of men and 13.0% of women reported having diabetes. The prevalence of diabetes

tends to be higher among Hispanics and non-Hispanic Blacks. The number of people with DM has increased six fold since 1958, and 95% of these have type 2 diabetes. Type 2 diabetes can often be prevented with adherence to proper diet and regular exercise with the addition of oral medications, when needed (Shashikiran, Vidyasagar, & Prabhu, 2004).

More Americans than ever suffer from various forms of DM, and the resulting rates of death and serious complications, such as adult blindness, kidney disease, and foot or leg amputations, are especially high for elders and racial and ethnic minority populations (Nwasuruba, Khan, & Egede, 2007). In the past, DM was not always managed effectively; fear and misinformation about the disease may hinder today's elders from getting an early diagnosis or from participating in effective teaching and instruction on how to manage DM.

Being diagnosed with DM can cause depression or anger, and the community health nurse must tailor educational programs to meet individual client needs. The plan should be comprehensive, with special emphasis placed on the areas in which each client needs information. For example, a spouse may be concerned about preparing meals that meet her husband's needs, whereas the husband may be more concerned with how the disease will affect his long days on the golf course or sexual functioning; in contrast, a single older woman may worry whether she can see well enough to draw up her insulin or can afford to pay for diabetic supplies and special foods. All newly diagnosed diabetics need a comprehensive overview of the disease process followed by an individualized approach for ongoing control and management of the disease.

Self-care behaviors (e.g., appropriate diet, glucose monitoring, medication management, foot care) are not often consistently practiced, yet they are necessary to promote good health and fewer complications (Nwasuruba et al., 2007). Community health nurses are ideally situated to meet group and individual needs. They have the resources and skills to plan and implement diabetic education classes for groups of elders, in addition to making home visits to address specific learning deficits that impact an individual's ability to manage their diabetes properly. The group setting allows elders to share their experiences, learn from each other, and benefit from the support of the group. Home visits permit the nurse to focus on an assessment of the client, home, family support, diabetic supplies and technique, and overall health management.

### Cardiovascular Disease

Following arthritis and hearing impairment, hypertension is the third most frequent chronic condition for people older than 65 years. About 70% of those 65 and older have been diagnosed with hypertension, as have about 80% of those 75 years and older (CDC, 2006d). Hypertension increases with age and affects men more frequently than women. Hypertension is more prevalent and is less well controlled with medication in African Americans than in Whites (Kramer et al., 2004). Elders have difficulty managing ADLs if antihypertensive medications lower their blood pressure too dramatically. Hypotension leads to problems of safety, including a higher risk of falls, and blood pressure should be monitored by the PHN. Both hypertension and hypotension can have significant detrimental effects on the health of older adults.

Heart disease is the leading cause of death for both men and women in the United States (CDC, 2006e). Risk factors in the aging population associated with cardiovascular disease include tobacco use or exposure to tobacco smoke, inappropriate nutritional patterns, diabetes, high cholesterol, and lack of exercise. There are also regional differences in the pattern of deaths from heart disease: the southeastern coastal plains (Appalachia) and lower Mississippi River Valley (southern parts of Georgia and Alabama) have the highest death rates, and Blacks and Whites generally have higher rates of heart disease death than Hispanics or Asians and other races/ethnicities (CDC, 2006e).

Disease prevention is an important role for the community health nurse. Based on the knowledge of the prevalence of hypertension in older adults, the community health nurse can provide primary prevention by teaching community groups and individuals about this condition and ways to prevent its occurrence, and can provide secondary prevention by screening seniors on a regular basis.

### **Osteoporosis**

**Osteoporosis** is a disease of bone in which the amount of bone is decreased and the strength is reduced. Osteoporosis is a generalized, persistent, and disabling disease that can overshadow every facet of an elder's overall functional level and independence. It causes acute and chronic pain, subsequent fractures, decreased physical activity, limited mobility, changes in body image, role changes, a reduction in ability to perform ADLs, and depression.

According to researchers, by 2025 osteoporosis related fractures and the associated costs are expected to increase by 48%, to more than 3 million fractures at a cost of \$25.3 billion (Kuehn, 2005). In osteoporosis, calcium leaches from the bone mass and results in small holes forming in the bones. These empty spaces within the bone increase susceptibility to fractures of hip, wrist, or vertebra (McKeon, 2002). The risk of osteoporosis increases with age. As the disease progresses, other characteristics show up; e.g., compression of the vertebrae results in loss of height and the hunched back deformity known as dowager's hump.

Proper diet and exercise throughout life are now recognized as the most effective measure to maintain bone health. There is growing evidence that vitamin D supplementation can prevent fractures in the elderly (Bischoff-Ferrari et al., 2004); calcium supplementation is also critical. There are many FDA approved drugs to treat osteoporosis that can be prescribed by the primary care provider. Therefore, identification of risk factors and regular screenings is essential to prevent the progression of this debilitating disease.

Community health nurses can focus their teaching on primary prevention and ensure that people eat diets that are rich in vitamin D and calcium, and include calcium supplements as needed. Not smoking, maintaining a healthy weight, participating in weight bearing activities, and receiving ongoing bone density screenings are positive health behaviors that can contribute to strong bones throughout life. The value of hormone replacement therapy (HRT) in women—its benefits and possible long-term side effects—must be considered on the advice of the primary care provider, whose judgment should be based on the latest research findings along with the individual woman's needs.

## **APPROACHES TO OLDER ADULT CARE**

In general, nursing service to seniors can be divided into two approaches: geriatrics and gerontology. In addition, healthy older adults can be effectively cared for in the community through case management approaches, which focus on all three types of services: primary, secondary and tertiary. The ultimate goal of community based case management for the aging population is to enhance the quality of care by decreasing fragmentation, maximizing resources, and providing the highest quality of care possible (Brickner, 2006; RAND Health, 2003b).

### **Geriatrics and Gerontology**

**Geriatrics** is the medical specialty that deals with the health and social care of the elderly. A geriatrician is a medical doctor who has received specialized training in geriatrics. Geriatrics includes the physiology of aging, diagnosis and treatment of diseases affecting the aged and resulting from the aging process, and the complex psychosocial issues associated with the aging population. Geriatrics, like other medical specialties, with the exception of palliative care, focuses on abnormal conditions and the treatment and cure of those conditions (Eliopoulos, 2004). In the past, geriatric nursing focused primarily on the sick aged. As the profession of nursing has grown, the scope has broadened. Many nurses choose to be involved with community based nursing, focusing on prevention and improved health behaviors for the growing aging population.

**Gerontology** refers to the study of all aspects of the aging process, including economic, social, clinical, and psychological factors, and their effects on the older adult and on society. Gerontology is a broad, multidisciplinary practice, and gerontologic nursing concentrates on promoting the health and maximum functioning of older adults (Eliopoulos, 2004).

Community health nurses work with many types of older people. In one instance, the nurse may work to promote and maintain the health of a vigorous 80-year-old man who lives alone in his home. As another example, the nurse may give post surgical care at home to a 69-year-old woman, teaching her husband how to care for her, and helping them contact community resources for assistance with shopping, meals, housekeeping, and transportation services. Perhaps nursing intervention focuses on teaching nutrition and maintaining a healthful lifestyle for an extended family that includes a 73-year-old grandmother. The nurse may also lead a bereavement support group for senior citizens whose spouses have recently died. The possibilities are limitless and ever expanding.

A community health nurse works with older adults at the individual, family, and group levels. However, a community health perspective must also concern itself with the aggregate of older adults. There are many groups of seniors the PHN may choose to work with, such as those who attend an adult day care center, belong to a retirement community, live in a nursing home, or use Meals on Wheels. Others groups include residents of a senior citizens' apartment building, retired business and professional women, older post-cataract surgery patients at risk for glaucoma, the older poor, AD sufferers, and the homeless elderly. Work with elderly clients can also involve political advocacy.

## Case Management and Needs Assessment

**Case management** involves assessing needs, planning and organizing services, and monitoring responses to care throughout the length of the care giving process, condition, or illness. This concept, which has been practiced by community health nurses for many years, focuses primarily on the health needs of clients. Social workers use case management to address their clients' social needs, including their financial problems. Some HMOs provide a coordinated system of services for their enrolled clients. However, many communities provide no such advocate for their older residents, and a more comprehensive, community-wide system needs to be developed to serve the entire older population. Such a system might be based in an agency specifically designed to serve as case manager or "agent" to assess clients' needs and assemble existing agencies and services to meet those needs (Mullin & Kelley, 2006; Barba et al., 2007).

Various techniques or tools are available to assess the needs of older adults:

- ◆ The Older Americans Resources and Services Information System (OARS), developed by Duke University Center for the Study of Aging and Human Development, utilizes two sections of one tool—OARS Multidimensional Functional Assessment Questionnaire (OMFAQ)—to determine levels of functioning in five areas (mental health, physical health, economic resources, social resources, and ability to perform ADLs), along with the extent and intensity of utilization, as well as perceived need, of services (Duke University, 2007). Administration time is about 45 minutes, and this tool is commonly used in research and to determine effectiveness of services, as well as assessment of functional status.
- ◆ The Barthel Index assesses functional independence and is often used to determine levels of disability or dependence of stroke victims with respect to ADLs. The Modified Rankin Scale (MRS) is another common tool used for this purpose (Sulter, Steen, & DeKeyser, 1999).
- ◆ The Katz Index of Activities of Daily Living is based on an evaluation of the functional independence or dependence of clients with respect to bathing, dressing, toileting, and related tasks. The Instrumental Activities of Daily Living Scale looks at an older adult's ability to perform such activities as using the telephone, shopping, doing laundry, and handling finances (Wallace, Shelkey, & The Hartford Institute for Geriatric Nursing, 2007; Ward, Jagger, & Harper, 1998).
- ◆ Other tools sometimes used with elderly clients include the Stanford 7-day Physical Activity Recall questionnaire (PAR), the Human Activity Profile (HAP), and the Physical Activity Scale for the Elderly (PASE). All of these tools measure physical activity and functioning (Johansen et al., 2001).

A frequently overlooked area of assessment is an elderly client's spiritual needs (Moberg, 2001; Hoffert, Henshaw, & Myududu, 2007). Religious dedication and spiritual concern often increase in later years. Limited ability or lack of trans-

portation may prevent older people from attending religious services or engaging in spiritually enhancing activities. Self-health ratings, including clients' reports on their spiritual needs, provide another useful assessment technique.

## HEALTH SERVICES FOR OLDER ADULT POPULATIONS

How well are the needs of older adults being met? To answer this question, other questions must be raised. Do health programs for the elderly encompass the full range of needed services? Are programs both physically and financially accessible? Do they encourage elderly clients to function independently? Do they treat senior citizens with respect and preserve their dignity? Do they recognize older adults' needs for companionship, economic security, and social status? If appropriate, do they promote meaningful activities instead of overworked games or activities such as bingo, shuffleboard, and ceramics? Are health care services and other social services provided based on evidence and research?

### Criteria for Effective Service

Several criteria help to define the characteristics of an effective community health service delivery system for the elderly. Four, in particular, deserve attention.

For the delivery system of a community health service to be effective, it should be *comprehensive*. Many communities provide some programs, such as limited health screening or selected activities, but do not offer a full range of services to meet the needs of their senior citizens more adequately. Gaps and duplication in programs most often result from poor or nonexistent community-wide planning. Furthermore, such planning should be based on thorough assessment of the needs of the elderly population in that community. A comprehensive set of services should provide the following:

- ◆ Adequate financial support
- ◆ Adult day care programs
- ◆ Access to high quality health care services (prevention, early diagnosis and treatment, rehabilitation)
- ◆ Health education (including preparation for retirement)
- ◆ In-home services
- ◆ Recreation and activity programs that promote socialization
- ◆ Specialized transportation services

A second criterion for a community service delivery system is *coordination*. Often, older people go from one agency to the next. After visiting one place for food stamps, they go to another for answers to Medicare questions, another for congregate dining, and still another for health screenings. Such a patchwork of services reflects a system organized for the convenience of providers rather than consumers. It encourages misuse and discourages effective use. Instead, there should be coordinated, community-wide assessment and planning (Mollica, 2003). Communities must consider alternatives that can meet many needs in one location, such as multiservice agencies and interdisciplinary collaborative programs (AHRQ, 2002; RAND Health, 2003).

A coordinated information and referral system provides another link. Most communities need this type of

information network, which contains a directory of all resources and services for the elderly and includes the name and telephone number of a contact person with each listing. Such a network is available in many communities and should be developed in those without one. A simplified information and referral system that includes one number, such as an 800 number, that can connect seniors with available resources and services is particularly helpful to older people. In an effort to better meet the needs of the elderly, a system of case-finding and referral services was instituted at four emergency departments in the Midwest, using screening assessments by the triage nurse and follow up, when needed, by a geriatric clinical nurse specialist (Mion, Palmer, Anetzberger, & Meldon, 2001).

In most communities, coordination is not present, or it is not done with any regularity or thoroughness. Many agencies in a given community do not coordinate services, but instead deliver their own services to the elderly in a patchwork and uncoordinated fashion (Mollica, 2003). Collaboration among those who provide services to seniors can provide vital information for planning and implementing needed programs. Even within the same health care system, collaboration and coordination of services are not always present. Kaiser-Bellflower, in Southern California, sought to improve end-of-life care by establishing improved connections between palliative and hospice care teams, along with staff members from disease management (RAND Health, 2003).

A third criterion is *accessibility*. Too often, services for the elderly are not conveniently located or are prohibitively expensive. Some communities are considering multiservice community centers to bring programs and services for the elderly closer to home (Artis, 2005). The Program of All-Inclusive Care of the Elderly (PACE) is one example of this. Comprehensive services are offered to eligible nursing home patients, including personal, health care, and housing services: e.g., adult day care, meals, social workers, nurses, primary care physicians, dentists, podiatrists, optometrists, prescriptions, medical specialists, and acute and nursing home care (RAND Health, 2003). More convenient and perhaps specialized transportation services and more in-home services, such as home health aides, homemakers, and Meals on Wheels, may further solve accessibility problems for many older adults. Federal, state, and private funding sources can be tapped to ease the burden on the economically pressured elderly population.

Finally, an effective community service system for older people should *promote quality programs*. This means that services should truly address the needs and concerns of a community's senior citizens and be based on scientific evidence (American Geriatric Society, 2006). Evaluation of the quality of a community's services for the elderly is closely tied to their assessed needs. What are the needs of this specific population group in terms of nutrition, exercise, economic security, independence, social interaction, meaningful activities, and preparation for death? Planning for quality community services depends on having adequate, accurate, and current data. Periodic needs assessment is a necessity to ensure updated information and initiate and promote quality services.

## Services for Healthy Older Adults

Maintaining functional independence should be the primary goal of services for the older population. Assessment of

needs and the ability to function and use of techniques such as OARS, the Instrumental Activities of Daily Living Scale, or other previously mentioned tools form the basis for determining appropriate services. Although many of the well elderly can assess their own health status, some are reluctant to seek needed help (Nussbaum, 2006). Therefore, outreach programs serve an important function in many communities. They locate elderly people in need of health or social assistance and refer them to appropriate resources.

Health screening is another important program for early detection and treatment of health problems among older adults. Conditions to screen for include hypertension, glaucoma, hearing disorders, cancers, diabetes, anemias, depression, mild cognitive impairment, and nutritional deficiencies (Eliopoulos, 2004; Miller, 2003). At the same time, assessment of elderly clients' socialization, housing, and economic needs, along with proper referrals, can prevent further problems from developing that would compromise their health status (Mion et al., 2001).

Health maintenance programs may be offered through a single agency, such as an HMO, or they may be coordinated by a case management agency with referrals to other providers. These programs should cover a wide range of services needed by the elderly, such as those listed in Display 24.7.

## Living Arrangements and Care Options

Three types of living arrangements and care options are available for elders. Some living arrangements are based on levels of care—from independent to skilled nursing care, and all levels of assistance in between. At times, seniors who remain in their own homes or apartments need home care services brought to them. Other seniors live with family members and go to an adult day care center during the day. The third category of living arrangements includes those that are short term. It may be a rehabilitation hospital for recovery and physical therapy related to a hip fracture, or respite care, which gives the usual caregiver a much-needed rest from 24-hour-a-day care giving and helps prevent “burnout.” Families of terminally ill clients and those with severe dementia cared for at home often use respite services (Mason et al., 2007).

To meet the multiple housing and care giving needs of today's elders and in anticipation of the larger numbers to come, many options are becoming available. A range of housing types, from luxurious retirement communities with all amenities for the active and healthier senior to secure and more modestly priced or low-income apartments for independent senior living, are being built in most communities.

## Day Care and Home Care Services

The majority of older adults want to remain in their own homes for the remainder of their lives and be as independent and in control of their lives as possible (AARP, 2007). Some struggle to appear to be doing well in maintaining their independence. Often, they fear that their children or others will make decisions for them that include leaving their homes. Home, whatever form it takes, is where these people believe they are the happiest (Eliopoulos, 2004; Miller, 2003).

There is increased emphasis on providing needed services for elders at home. This trend started several years ago when it became evident that people improved more quickly

and at lower cost when they were cared for as outpatients in their own homes. Today's heightened emphasis on health care cost control gives added support for providing services at home. Given the increase in longevity, the potential for cost savings appears significant if dependent older people can be maintained at home. Doing so encourages functional independence as well as emotional wellbeing (AHRQ, 2002).

Home care provides services such as skilled nursing care, psychiatric nursing, physical and speech therapies, home-maker services, social work services, and dietetic counseling (see Chapter 32). Day care services offer a place where older adults can go during the day for social activities, nutrition, nursing care, and physical and speech therapies. Both services are useful for families who are caring for an elderly person, especially if the caregivers work and no one is at home or available during the day. One disadvantage to those remaining in their homes is that services for the dependent elderly in the community are often fragmented, inadequate, and inaccessible, and at times they operate with little or no maintenance of standards or quality control (Eliopoulos, 2004).

The dependent elderly need someone in the community to assess their particular needs; assemble, coordinate, and monitor the appropriate resources and services; and serve as their advocate. Some communities have Ombudsmen to serve this role. But, community health nurses can easily fill the role of case manager for elderly clients. This case management approach tailors services to the long-term needs of clients and enables them to function longer outside of institutions (Brickner, 2006).

### **Living Arrangements Based on Levels of Care**

Although only 6% of the elderly population lives in **skilled nursing facilities**, such organizations remain the most visible type of health service for older adults (AAHSA, 2007). These facilities provide skilled nursing care along with personal care that is considered nonskilled or **custodial care**, such as bathing, dressing, feeding, and assisting with mobility and recreation. Currently, approximately 2 million elderly people are receiving nursing home care.

**Long-term care** services include those services that provide care for people at different stages of dependence for extended periods of time (Miller, 2003). New choices are now available and provide housing for larger numbers of elders than nursing homes do. There are currently roughly 7 million people with long-term care insurance policies, and the average premium for someone under age 65 is \$1,337 a year (AAHSA, 2007). These policies will pay for skilled nursing care and long-term care facilities, as currently almost 40% of costs are paid by private funds and 40% by Medicaid (AAHSA, 2007).

Nursing home reform was promoted in 1987 with passage of the Omnibus Budget Reconciliation Act (OBRA), which put increased demands on facilities to provide competent resident assessment, timely care plans, quality improvement, and protection of resident rights starting in 1990 (Miller, 2003). This increased complexity of services has resulted in increased costs in these facilities. Staffing needs increase as care becomes more complex and the resident population grows. Licensed personnel must be knowledgeable decision-makers, managers of unskilled staff, staff educators, and role models, and efficient and effective administrators in an essen-

tially autonomous practice setting. And, as the elderly population grows, the need for greater numbers of both licensed and attendant staff becomes more evident. Because many of these jobs offer low pay and are without substantial benefits or a career ladder, it is projected that it will be difficult to find enough staff to meet the demands (RAND Health, 2003).

In the past, nursing homes had stigmas attached to them. Many people saw them as places that enforced dehumanizing and impersonal regulations, such as segregation of sexes, strict social policies, and sometimes overuse of chemical and physical restraints. Media attention to such conditions, together with current licensing regulations, should make these types of practices the rare exception. Gradually, the fear and despair associated with such facilities will begin to dissipate (National Citizen's Coalition for Nursing Home Reform, 2007). In addition, as competition comes from facilities offering lower levels of care (e.g., assisted living centers), residents in nursing homes who are receiving more minimal care may be attracted to move to other types of housing.

Even in institutions in which the quality of care is outstanding, costs are so high that family resources are soon depleted if not planned for long in advance of the need. Although Medicaid pays for skilled nursing costs if the client meets low income and asset requirements, and Medicare pays for a limited period of care, clients and families pay more than half of the total costs (Eliopoulos, 2004). Life savings that older parents had hoped to leave to their children may be quickly consumed, forcing them into indigence. It is estimated that average annual costs for nursing home care range from \$75,000 for a private room and \$65,000 for a semiprivate room (AAHSA, 2007).

**Intermediate care** facilities are less costly and still provide health care, but the amount and type of skilled care given are less than that provided in skilled nursing facilities. Frequently, older adults need **assisted living**, which generally means that they need assistance with everyday tasks such as bathing, eating, dressing, or using the bathroom (Medline Plus, 2007b). This is a less intense level of care than skilled nursing facilities provide. The average yearly cost of this type of care ranges from over \$32,000 to \$35,000 (AARP, 2007; AAHSA, 2007). Medicare and Medicaid generally pay only for care in skilled nursing facilities. Medicaid may pay for care in intermediate care facilities, but only after the client meets income and asset tests that leave them essentially indigent. Medicaid coverage of assisted living services is available in a few states that can grant Medicaid waivers. The average length of time a senior remains in an assisted living facility is 2 years (Bradford, 2001). Due to licensing restrictions, when someone becomes bedridden or needs additional assistance or skilled nursing care, they generally must move from assisted care into another facility.

**Personal care homes** (sometimes called board and care homes) offer 24-hour basic custodial care, such as bathing, grooming, and social support, but provide no skilled nursing services. Boarding homes, board and care homes, and residential care facilities often house a smaller number of elderly people in a residential home (often between five and eight) or a larger number in apartment type housing. These residents need only meals and housekeeping and can manage most of their own personal care, including medications (HelpGuide, 2007a). Costs can range from \$350 to \$3,500 per month, depending upon the amenities and services (HelpGuide, 2007a). Medicare

only pays for medical care, not housing costs. Medicaid may help pay some assisted living costs and limited custodial home care, but not generally for housing costs related to personal care homes. Payment may come from private funds, Social Security, or Supplemental Security Income (aid to the aged, disabled, and blind) in some limited cases (HelpGuide, 2007b). Long-term care insurance usually covers only nursing home care, but some companies are expanding policy guidelines to include assisted living and personal care homes (HelpGuide, 2007b). Homes can serve special populations. Those focusing on the care of people with AD are physically designed with clients' safety and individual needs considered and are staffed with paraprofessionals trained to meet each person's needs.

The concept of **continuing care retirement communities (CCRCs)**, sometimes referred to as total life centers, allow seniors to “age in place,” with flexible accommodations designated to meet their health and housing needs as these needs change over time. CCRCs are the most expensive long-term-care solution available to seniors; however, they provide all levels of living, from total independence to the most dependent, and are designed to meet the continuous living needs of older aging adults. Residents entering CCRCs sign a long-term contract that provides for housing, services, and nursing care, usually all in one location. Many seniors enter into CCRC contracts while they are healthy and active, knowing they will be able to stay in the same community and receive nursing care should this become

necessary. Seniors who invest in a CCRC have adequately planned for housing and care for the remainder of their life, and have the financial means to support it; entrance fees can range from \$20,000 to \$400,000 and monthly fees from \$200 to \$2,500 (AARP, 2007b). Others may choose to remain in their own home because they do not desire consolidated living arrangements that include only older adults, or because they have not planned adequately for the expense. Nevertheless, demand is increasing for this type of housing option. Adults nearing retirement today are investigating this concept as a viable option as they actively plan for their retirement. Because of the demand, many of these centers have waiting lists, so older adults need to seek them out long before they intend to live there (AARP, 2007b).

### Respite Care Services

**Respite care** is a service that is receiving increasing attention. It provides time off for caregivers, including family members, who care for someone who is ill, injured, or frail. An increasing number of older people are cared for in their home by a spouse or other family member on an unpaid basis. Almost 75% of persons receiving care at home rely exclusively on informal caregivers, usually women between the ages of 45 and 64 (AAHSA, 2007). The demands of such care can be exhausting unless the caregiver gets some relief (see Chapter 32). Respite care can take place in an adult day

## PERSPECTIVES VOICES FROM THE COMMUNITY

### Continuing Care Centers— A Solution for Aging Adults

I am really sold on continuing care retirement communities! We have one in our area that is a big hit with our middle and upper income folks. The Otterbein-Lebanon Retirement Community is a model continuing care center and is one of five Otterbein Homes located in Ohio. With housing options for 1200 residents on a 1,500-acre campus in rural southeastern Ohio, older adults can choose housing options that include free-standing two- and three-bedroom homes, one-bedroom cottages, or apartment-style one- or two-bedroom or one-room studio units, where they live independently.

They are licensed for 296 beds, including assisted living options from one-room studio apartments (with limited facilities for meal preparation) to semiprivate rooms in which nurses oversee medication and staff is available to assist with personal care. If caregiving needs become greater, additional services are available. Both skilled nursing services and a freestanding 30-bed Alzheimer's living unit exist for the frailest older adults. This is a real advantage for my clients who want to remain in the same place, even as their physical condition may worsen.

Regardless of the living arrangement, the residents are free to come and go as they wish and all have access to

congregate dining in their large and attractive restaurant-style dining room.

The retirement community is expanding. One hundred and ten patio homes were built in 1999–2000 with additional expansion planned.

The Otterbein-Lebanon Retirement Community also provides a health clinic, adult day care, and the other usual services found in a community: a bank, post office, ice cream parlor, a small convenience store, hairdresser, library, a church (with a 70-member choir, a bell choir, and men's and women's clubs), a thrift shop, and an arts and crafts shop open to the public. Because of the popularity of this Otterbein-Lebanon community, there is a waiting list for some independent living areas.

Many of the assisted living and skilled nursing beds are occupied by residents who moved into the independent living areas 10 to 15 years ago while they were in their 70s or 80s. Their ages now range from the late 80s to older than 100, and care needs have increased. This is wonderful because, in this type of setting, frail elderly people do not have to leave their community to get the care they need, and longtime friends are nearby to care for them or for companionship. It is not unusual to see many of the independent seniors volunteering to help feed frail elderly in the skilled nursing care units. In fact, residents volunteer more than 85,000 hours a year to the Otterbein-Lebanon Retirement Community. They know that when they need the care, a senior friend will be there for them.

Judy, 2008 PHN

center, in the home of the person being cared for, or even in a residential setting such as an assisted living facility or nursing home. Although there are different approaches to respite care, all have the same basic objective: to provide caregivers with *planned* temporary, intermittent, substitute care, allowing for relief from the daily responsibilities of caring for the care recipient (Eldercare, 2005). Respite care is sometimes available through agencies that provide volunteers to relieve caregivers; neighbors, churches, or volunteer organizations may be potential sources of assistance. Some skilled nursing facilities or **board and care homes** provide an extra room to give temporary institutional housing for the elderly while caregivers take a break over a weekend, for instance. Elderly clients may also need a change from the constant interaction with their caregivers. Long-term care insurance may cover some costs of respite care. The 2000 Older Americans Act Amendments provided funding for states to work through the National Family Caregiver Support Program (NFCSP) to address respite care specifically on the local level (Eldercare, 2005).

## THE COMMUNITY HEALTH NURSE IN AN AGING AMERICA

Community health nurses can make a significant contribution to the health of older adults. Because these nurses are in the community and already have contact with many seniors,

they are in a prime position to begin needs assessments and mutual planning for the health of this group. Case management is often a critical aspect of the nurse's role, because the community health nurse must know what resources are available and when and how to make referrals for these older clients (see From The Case Files II).

The availability and scope of health care services for the elderly are changing dramatically. The numbers and types of home care services, for example, are mushrooming. Many entrepreneurs, including nurses, who recognize the potential of this growing market, have begun offering goods and services targeted to older adults. Community health nurses must keep abreast of new developments, programs, regulations, and social and economic forces, along with their potential impacts on the provision of health services.

More importantly, community health nurses need to be proactive, designing interventions that maximize nursing's resources and provide the greatest benefit to elderly clients. For example, community health nurses might develop a case management program for older adults that comprises a community-wide assessment, information, and referral service. Such a program might contract with existing agencies to serve as a clearinghouse for the elderly and to channel clients to appropriate services. Financing of such a program might be based on tax dollars (if it is a public agency), grants, or some innovative fee-for-service reimbursement system.

### From the Case Files II

Johnny Jessup is 94 years old and lives with his wife, age 86, in a small mobile home on some acreage in a rural area of our county. He had mastoiditis as a child and lost a good deal of hearing. His vision is good, though, and he only wears glasses for reading. He was diagnosed with prostate cancer 20 years ago and still suffers from the radiation treatments he had at that time. He wears a protective “diaper” because he is often bowel incontinent. He is generally in good health, with no hypertension or evidence of heart disease. He spends most of his days outside, watering his berries, flowers, and fruit trees. He worked as a farmer and laborer—always outside—and he enjoys being in the sun and away from the television that his wife, Maude, likes to watch. He has difficulty hearing it, and when he turns up the volume, it “hurts her ears” and they argue over that. They have one son who lives in the same town, but who works long hours at his job. They speak by phone every other day, and he comes by to visit when he can. Their three grandsons are all away at college and they rarely see them.

As a young man, Johnny liked to dance, and he occasionally will go to the local senior center dances. Maude does not like to dance and will not accompany him there. This sometimes is a source of stress. Johnny likes to drink an “occasional cold beer,” but he never drinks “hard liquor.” He quit smoking 25 years ago, but he had been a heavy smoker from the age of 20. His appetite has usually been good, but he sometimes has difficulty eating fresh fruit or nuts because of his bowel problems. Maude has recently been having memory lapses and some difficulty remembering to turn off the stove and close the refrigerator door. She has trouble with a number of daily tasks. She likes to have someone bring them fast food as a treat every week, and they now require assistance with errands and most housekeeping tasks.

Recently, Johnny noticed that he was having more difficulty doing his outside chores. He seems more “weak” and “tired” and he has recently had quite a bit of “nausea and vomiting.” Maude and Johnny's son took them for an appointment with his urologist and it was determined that his prostate-specific antigen (PSA) was slightly elevated.

You are a district PHN and have recently been assigned to the Jessup family to assess their functional limitations and provide them with information on resources they might need over the next few months. How would you begin your visit? How can you best determine their functional and physical limitations? What other assessments could be helpful (social, spiritual, mental/cognitive, etc.)? What resources and services might be helpful to them?

Many of the older population's health problems can be prevented and their health promoted. Changing to a healthier lifestyle is one of the most important preventive measures the nurse can emphasize. Education and support are key to the success of these changes.

The role of the community health nurse as a teacher is an important one. Educating the elderly about their health conditions, safety, and use of medications is another important way to prevent problems. Influenza and pneumonia can be prevented through regular health maintenance, which includes immunizations. Other problems associated with environmental conditions and the aging process, such as arthritis, diabetes, and some cancers, can be diagnosed and treated early, thereby minimizing their deleterious effect on functional independence.

Many types of accidents that frequently happen to older adults are preventable. Community health nurses can make a difference through their work with individuals, families, and aggregates in promoting and teaching safety measures to prevent such accidents. As discussed earlier, falls are a leading cause of injury and death for the elderly and result from a combination of internal factors (e.g., diseases, effects of medicines) and external factors (e.g., lighting, area rugs, lack of handrails) that are preventable or controllable (RAND, 2003; Australian Government Department of Health & Aging, 2004). Nurses can make a difference in the lives of older clients by using available materials and their own resources when teaching safety.

Community health nurses face a serious challenge in addressing the needs of the growing and aging elderly population. At the same time, nursing can be at the forefront of developing innovative health services for seniors, rising to meet the opportunity and the challenge.

## Summary

The number of older adults (age 65 years and older) is increasing, and becoming a larger percentage of the overall population. Women commonly outlive men by a number of years, making women a larger part of this older population. With improved medicines and medical technology, many people are now living into their 80s and 90s in relatively good health. They are able to enjoy these later years and still make contributions to their families and society. This extended life expectancy is, of course, good news; however, it has also created a myriad of new health needs and concerns, not only for the older population, but also for health care facilities and professionals who deliver services to older adults.

Healthy longevity is the goal for the aging population and is a focus of *Healthy People 2010*. This means being able to function as independently as possible; maintaining as much physical, mental, and social vigor as possible; and adapting to life's changes while coping with the stresses and losses and still being able to engage in meaningful activity.

To promote and maintain health and prevent illness, older people need to be educated about their own health care needs. In particular, they should understand the potential hazards of drug interactions if they are taking multiple medications. They also need good nutrition and adequate exercise; they need to be as independent and self-reliant as possible; they need coping skills to face the possibility of

financial insecurity and the loss of a spouse or other loved ones; they need social interaction, companionship, and meaningful activities; and they need to resolve anxieties regarding their own eventual death.

The most common health problems of older adults are chronic and often progressive conditions such as arthritis, vision and hearing loss, heart disease, hypertension, and diabetes, all of which can become disabling conditions. Other major causes of death or disability are cancer, cerebral vascular accidents, AD, and accidents and injuries resulting from falls, fires, or automobile crashes. Older adults also often suffer adverse side effects from taking multiple medications prescribed for various chronic conditions, and polypharmacy is a danger. Many of these health problems associated with old age are preventable to some extent, and early diagnosis and treatment of some conditions can minimize their adverse effects. Many accidents and injuries that render older adults unable to live independently are preventable.

Too frequently, older adults suffer from the emotional side effects of aging, such as feelings of distress and anxiety regarding their future; loneliness and social isolation when loved ones or friends die; and even depression, feeling that life is over and they have no purpose or meaningful function in life. However, older people can also enter this phase of life determined to keep physically and mentally healthy, interacting with others and making viable contributions to others and society.

Many programs are available to older adults, both for those who are healthy, hearty, and active, and for those who need some level of dependent or semi dependent care. Programs for hearty older people include health maintenance programs that cover a wide range of health services, wellness programs, health screening, outreach programs, social assistance programs, and information about volunteering and educational opportunities in the community. A variety of living arrangements and care options are available from which to choose, and can be tailored to the older person's desires and needs. These include the newest concepts of continuing care centers, which offer a full range of living arrangements—from totally independent living to skilled nursing services—all within one community. There are also facilities that provide skilled nursing and custodial care, assisted living, home care, day care, respite care, and hospice.

The community health perspective includes a case management approach that offers a centralized system for assessing the needs of older people and then matching those needs with the appropriate services. The community health nurse should also seek to serve the entire older population by assessing the needs of the population, examining the available services, and analyzing their effectiveness. The effectiveness of programs can be measured according to four important criteria (targeted to the specific needs of the population): comprehensiveness, effective coordination, accessibility, and quality.

The community health nurse can make significant contributions to the health of the older population as a whole by being aware of new developments and programs that become available, new regulations, and innovative social and economic forces and their impacts on the provision of health services. More importantly, the community health nurse can design interventions that maximize nursing resources and provide the greatest benefit to the older adult population. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Picture an elderly person who you know well or know a great deal about. Make a list of characteristics that describe this person. How many of these characteristics fit your picture of most senior citizens? What are your biases (ageisms) about the elderly?
2. If you were Minnie Blackstone's community health nurse (see From the Case Files I), what interventions would you consider using to maintain and promote her health? Why?
3. As part of your regular community health nursing workload, you visit a senior day care center one afternoon each week. You take the blood pressures of several people who are taking antihypertensive medications and do some nutrition counseling. The center accommodates 60 senior clients, and you would like to serve the health needs of the aggregate population. What are some potential health needs of this group? What actions might you consider taking at an aggregate level? With whom would you consult as you plan programs at the center?
4. Assume that you have been asked by your local health department to determine the needs of the elderly population in your community. How would you begin conducting a needs assessment? What data might you want to collect? How would you find out what services are already being offered and whether they are adequate?
5. Visit a continuing care center in your community. Assess the housing options, services, and health care provisions. Would you live here when you are older? How would you feel about a family member living here? What would you change if you could?
6. Using the Internet, locate innovative programs for elders in the community at the primary, secondary, and tertiary levels of care. Determine whether such programs could work in your community.
