Care has been taken to confirm the accuracy of the information presented and to describe generally accepted practices. However, the authors, editors, and publisher are not responsible for errors or omissions or for any consequences from application of the information in this book and make no warranty, expressed or implied, with respect to the currency, completeness, or accuracy of the contents of the publication. Application of this information in a particular situation remains the professional responsibility of the practitioner; the clinical treatments described and recommended may not be considered absolute and universal recommendations.

The authors, editors, and publisher have exerted every effort to ensure that drug selection and dosage set forth in this text are in accordance with the current recommendations and practice at the time of publication. However, in view of ongoing research, changes in government regulations, and the constant flow of information relating to drug therapy and drug reactions, the reader is urged to check the package insert for each drug for any change in indications and dosage and for added warnings and precautions. This is particularly important when the recommended agent is a new or infrequently employed drug.

Some drugs and medical devices presented in this publication have Food and Drug Administration (FDA) clearance for limited use in restricted research settings. It is the responsibility of the health care provider to ascertain the FDA status of each drug or device planned for use in his or her clinical practice.

# About the Authors

 Dr. Judith A. Allender has been a nurse for more than 45 years. For 30 of those years, she taught nursing—first at Good Samaritan Hospital in Cincinnati, Ohio, and later at California State University, Fresno where she retired as a Professor Emerita. Her nursing practice experiences were varied. She worked with surgical patients, in intensive care units, as a school nurse, in-patient hospice, home care, and community health nursing. She has authored five nursing textbooks in addition to this one. During her long career, she received several awards. She was voted RN of the Year in Education for the Central Valley of California in 1998. The fourth edition of this textbook received a Robert Wood Johnson award in 2001 for the end-of-life care content. In 2005, she was inducted into the Central San Joaquin Valley, California Nursing Hall of Fame. Presently, Dr. Allender consults for a nonprofit immigrant and refugee center and writes a weekly health column for a local newspaper. She received her undergraduate nursing degree from the State University of New York in Plattsburgh; a master's degree in guidance and counseling from Xavier University in Cincinnati, Ohio; a master's in nursing from Wright State University in Dayton, Ohio; and a doctorate of education from the University of Southern California. When not busy at home, she can be found traveling around the world. She and her husband have a blended family with five children, 14 grandchildren, and two great-grandchildren.

Dr. Cherie Rector is a native Californian who is currently a Professor at California State University, Bakersfield Department of Nursing, where she teaches community health nursing. She served as director of the School Nurse Credential Program and the RN to BSN Program there and was formerly the coordinator of the School Nurse Credential Program at California State University, Fresno, where she also taught community health nursing. She has served as the director of Allied Health and the Disabled Students Program at College of the Sequoias. She has consulted with school districts and hospitals in the areas of child health, research, and evidence-based practice and has practiced community health and school nursing, as well as neonatal nursing in the acute care setting. She has taught undergraduate and graduate level courses in community health, vulnerable populations, research, and school nursing. Her

grants, research, publications, and presentations have focused largely on child and adolescent health, school nursing, nursing education, and disadvantaged students. She earned an associate's degree in nursing from the College of the Sequoias more than 30 years ago, and a bachelor of science in nursing degree from the Consortium of the California State Universities, Long Beach. She has a master's degree in nursing (clinical specialist, community health) and a School Nurse Credential from California State University, Fresno. Her doctorate of philosophy in educational psychology is from the University of Southern California. Dr. Rector and her husband have three grown sons, five grandsons, and a granddaughter.

Dr. Kristine Warner, also a native Californian, is an associate professor at California State University, Chico with a specialization in public/community health nursing. With more than 3 decades of experience in the field of public/community health, she has taught in nursing programs in both Pennsylvania and California. Undergraduate and graduate courses she has taught include community health nursing, nursing research, program planning and development, and health policy. Her nursing career began in adult and pediatric acute care, and she has practiced home care and public health in rural and urban settings. Her current professional interests include evidence-based practice, nursing education, emergency preparedness, and health needs of vulnerable populations. Her grants, research, publications, and presentations have focused on emergency preparedness, poverty, chronic illness, and nutrition. Dr. Warner is a retired Navy Nurse Corps Captain, having ended a 29-year career of both active and reserve service in 2002. She was recalled to active duty and stationed in the Saudi Arabian desert during the first Gulf War as Assistant Charge Nurse of a 20-bed medical unit. She received her bachelor of science in nursing from Harris College of Nursing, Texas Christian University; master of public health (community health nursing) and master of science (community health nursing and nursing education) from the University of South Florida; and doctorate of philosophy in nursing from the University of Pennsylvania. Dr. Warner has three grown children and one daughter-in-law. She was a resident of Germany for 2 years in the early 1980s and has traveled extensively in Europe.

# Preface

 The seventh edition of *Community Health Nursing: Promoting and Protecting the Public's Health* continues in the tradition of the previous editions of this text, beginning with Barbara Spradley's initial publication in 1981. The purpose of this textbook is to introduce undergraduate nursing students to the stimulating world of nursing outside the acute care setting—whether at a public health department, community health agency, school, or other setting. We hope to share our enthusiasm and devotion to this population-focused, community-oriented form of nursing. Compared with acute care nurses, those working in public or community health are often more autonomous and exert a greater influence on the overall health of their communities by being political advocates for their clients and aggregates.

This book is designed to give students a basic grounding in the principles of public health nursing and introduce them to key populations they may engage while working in the community setting. Entry-level public health nurses may also find it a helpful resource as they begin to familiarize themselves with their unique practice settings and target populations. The nexus of public health nursing lies in the utilization of public health principles along with nursing science and skills in order to promote health, prevent disease, and protect at-risk populations. We use the term *community health nurse* interchangeably with *public health nurse* to describe the practitioner who does not simply “work in the community” (physically located outside the hospital setting, in the community), but rather one who has a focus on nursing and public health science that informs their community-based, population-focused nursing practice.

## ABOUT THE SEVENTH EDITION

This textbook has always strived to be a user-friendly resource for nursing students who are new to public health nursing, and this new edition is no exception. We have attempted to write in a style that is accessible to students, with a conversational quality and minimal use of unnecessary jargon and dry narrative. Throughout the book, we have made liberal use of case studies and highlighted student, practitioner, and instructor perspectives on pertinent issues. This is done to help students more readily grasp and apply necessary information to their real clients and better understand the common issues and problems they will face in this new area of nursing study. At the same time, our goal is to provide the most accurate, pertinent, and current information for students and faculty. We have sought out experts in various fields and specialty areas of public health nursing in order to provide a balanced and complete result. With the addition of more than 20 new contributors from across the country, the content reflects a broad spectrum of views and expertise.

## ORGANIZATION OF THE TEXT

The seventh edition has five fewer chapters than the sixth edition, having been reorganized to combine some related topics while reducing duplication in other areas. We have chosen to continue the emphasis on *Healthy People 2010* goals and objectives throughout the text and to maintain a research emphasis by providing examples of evidence-based practice where applicable.

The book is now organized into eight units, with revised unit titles to better reflect content covered. In addition, some content has shifted to better align with the new units. The eighth unit was added to encompass the various settings for public health nursing practice or community-based nursing.

**Unit 1, Foundations of Community Health Nursing**, describes the core public health functions (Chapter 3), as well as the basic public health concepts of health, illness, wellness, community, aggregate, population, and levels of prevention (Chapter 1). Leading health indicators are introduced, along with *Healthy People 2010* goals and objectives (Chapter 1). The rich history of public health nursing is examined, along with social influences that have shaped our current practice (Chapter 2). Educational preparation is discussed, as well as the roles and functions of public health nurses (Chapters 2 and 3). Common settings for public health nursing are introduced (Chapter 3), and values, ethical principles, and decision making are also considered (Chapter 4). Evidence-based practice and research principles relating to community health nursing are discussed, along with the nurse's role in utilizing current research (Chapter 4). Cultural principles are defined and the importance of cultural diversity and sensitivity in public health nursing are highlighted, as well as cultural assessment and folk remedies (Chapter 5).

**Unit 2, Public Health Essentials for Community Health Nursing**, covers the structure of public health within the health system infrastructure, along with a basic overview of the economics of health care (Chapter 6). Epidemiology and communicable disease are examined, and principles of disease investigation and surveillance are explored from both an historical and practical perspective (Chapters 7 and 8). Chapter 9 focuses on issues of environmental health with particular attention to areas of concern to community health nursing practice. Emphasis is placed on prevention and using an ecological approach when addressing issues of environmental health and safety.

**Unit 3, Community Health Nursing Toolbox**, examines tools used by the public health nurse to ensure effectiveness in his or her practice. Communication and collaboration, as well as contracting with clients, are essential skills that must be mastered by all community health nurses (Chapter 10). Health promotion is examined in Chapter 11 with particular emphasis on achieving behavioral change

through educational methodologies. Chapter 12 focuses on planning and developing community health programs with attention to the practical steps needed to achieve successful outcomes. Social marketing as an emerging tool in community health programs and grant funding are also explored. The community health nurse is an advocate for clients, and a basic knowledge of policy-making, political advocacy, and client empowerment strategies is needed (Chapter 13).

**Unit 4**, The Community as Client, examines the theoretical basis for public health nursing (Chapter 14). Moving the student's focus from the individual patient to the community as their client is emphasized in Chapter 15, as are community assessment strategies and resources. Chapter 16 describes the global community in which we now live, and provides examples of international health problems and practices. The timely topics of disaster and terrorism are covered in Chapter 17, with emphasis on the role of the community health nurse in emergency preparedness, both personally and professionally.

**Unit 5**, The Family as Client, introduces theoretical frameworks for promoting family health and better understanding and working with family dysfunctions (Chapter 18). Family assessment and application of the nursing process are included in Chapter 19. Chapter 20 examines family violence, spousal and child abuse, and effective measures that can be utilized by the community health nurse to provide resources and education.

**Unit 6**, Promoting and Protecting the Health of Aggregates with Developmental Needs, provides information about client groups as they are often delineated by public health departments—maternal-child and infants (Chapter 21), children and adolescents (Chapter 22), adult women's and men's health (Chapter 23), and the elderly (Chapter 24). These particular chapters can be very helpful in targeted health efforts for select population groups and build upon the content presented in Unit 5.

**Unit 7**, Promoting and Protecting the Health of Vulnerable Populations, examines theoretical frameworks, basic principles of vulnerability, and effective methods of working with vulnerable clients (Chapter 25). Clients with chronic illnesses and disabilities are also included (Chapter 26), as well as those with behavioral health problems, such as mental health and substance abuse (Chapter 27). The homeless client and the impact of poverty on these individuals and families are discussed in Chapter 28. Chapter 29 covers the unique challenges of rural and urban health care in terms of health care needs and types of service delivery options. The particular needs of migrant populations and issues of social justice are also explored.

**Unit 8**, Settings for Community Health Nursing, examines public (Chapter 30) and private (Chapter 31) settings in more depth. These chapters provide overviews of a number of practice options available to both new and experienced nurses. There is a vast array of opportunities for practice in public/community health, and this section is designed to enhance understanding of some of those options. Finally, the important roles of home health and hospice nursing are discussed in Chapter 32. With the aging of our population, many nurses are finding this practice area a challenging and satisfying option.

## NEW AND REVISED CHAPTERS

Each of the chapters maintained from the sixth edition has been rigorously updated to provide clear and accurate information. Some content has been maintained, but reorganized into the new chapter format to keep the textbook to a manageable length and to enhance student learning. We are particularly pleased to present seven chapters that have been completely rewritten to reflect changes in nursing knowledge and to provide a fresh approach to valuable content. Chapter 12, on planning and developing community programs, now emphasizes the need for rigorous collaboration with community groups to both identify and solve health problems. Unit 7 contains three completely new chapters focusing on vulnerable populations, including how to work with vulnerable clients (Chapter 25), the unique aspects of behavioral health in the community (Chapter 27), and the homeless (Chapter 28). Chapter 26, dealing with disabilities and chronic illness, was new to the sixth edition, and has been updated and expanded here. Unit 8 is entirely new, with Chapters 30 and 31 focusing on practice settings in the public and private sector. Chapter 32 continues with the vital role of home care and hospice nursing in the aging of our population.

## KEY FEATURES

The seventh edition of *Community Health Nursing: Promoting and Protecting the Public's Health* includes key features from previous editions as well as new ones. Features continued from previous editions include:

- ◆ An emphasis on aggregate-level nursing and the community health nurse's opportunity and responsibility not only to serve individuals and families, but also to promote and protect the health of communities and populations.
- ◆ An emphasis on health promotion, health protection, and illness prevention. This, in addition to the aggregate emphasis, reflects the view set forth in this text that community health nursing is the amalgamation of nursing science with public health science. Public health philosophy, values, knowledge, and skills are an essential part of all community health nursing practice.
- ◆ A balance of theory with application to nursing practice. The seventh edition continues the presentation of theoretical and conceptual knowledge to provide an understanding of human needs and a rationale for nursing actions. At the same time, the text presents practical information on the use of theory to undergird practice.
- ◆ A *Summary* of highlights at the end of each chapter provides an overview of material covered and serves as a review for study.
- ◆ *References* and *Selected Readings* at the end of each chapter provide you with classic sources, current research, and a broad base of authoritative information for furthering knowledge on each chapter's subject matter.
- ◆ A student-friendly writing style has been a hallmark of this text since the first edition. Topics are expressed and concepts explained to enhance understanding and capture interest. Writing style remains consistent throughout the

text (including contributed chapters) to promote an uninterrupted flow of ideas and enhance learning.

- ◆ *Internet Resources* have been improved and are included in nearly every chapter for quick and easy student reference.
- ◆ *Learning Objectives* and *Key Terms* sharpen the reader's focus and provide a quick guide for learning the chapter content.
- ◆ *Activities to Promote Critical Thinking* at the close of each chapter are designed to challenge students, promote critical-thinking skills, and encourage active involvement in solving community health problems. They include Internet activities, where appropriate.
- ◆ Recurring *displays, tables, and figures* throughout the text highlight important content and create points of interest for student learning.
- ◆ *Levels of Prevention Pyramid* boxes enhance understanding of the levels of prevention concept, basic to community health nursing. Each box addresses a chapter topic, describes nursing actions at each of the three levels of prevention, and is unique to this text in its complexity and comprehensiveness.
- ◆ Additional assessment tools can be found throughout the chapters. They are added to enhance assessment skills of aggregates, families, or individuals in unique situations.

## FEATURES NEW TO THIS EDITION

Additional recurring displays new to this edition include:

- ◆ *Evidence-based Practice*—this feature incorporates current research examples and how they can be applied to public/community health nursing practice to achieve optimal client/aggregate outcomes.
- ◆ *From the Case Files*—presentation of a scenario/case study with student-centered, application-based questions. Emphasizing nursing process, students are challenged to reflect on assessment and intervention in typical yet challenging examples.
- ◆ *Perspectives*—this feature is included in most chapters and provides stories (viewpoints) from a variety of

sources. The perspective may be from a nursing student, a novice or experienced public health nurse, a faculty member, a policy maker, or a client. These short features are designed to promote critical thinking, reflect on commonly held misconceptions about public/community health nursing, or to recognize the link between skills learned in this specialty practice and other practice settings, especially acute care hospitals.

- ◆ New art has been added throughout the text to clarify important concepts and enhance interest in and understanding of material.

## RESOURCES FOR INSTRUCTORS

A set of tools to assist you in teaching your course is available at <http://thepoint.lww.com/allender7e>. **thePoint\*** is Lippincott Williams & Wilkins' web-based course and content management system that provides every resource instructors need in one easy-to-use site.

*If, as an instructor, you want help structuring your lessons...*  
We've provided PowerPoint slides, which condense the material into bulleted lists, figures, and tables.

*If you'd like your students to engage in further study of the material, beyond what's provided in the textbook...*

We've provided journal articles and a listing of internet resources to facilitate research.

*If you'd like your students to start applying what they've learned...*

We've provided a set of case studies associated with units of the book to get students thinking about how their nursing knowledge works in real-world scenarios.

*If you're concerned about preparing your students for the NCLEX exams...*

We've provided a Test Generator that includes unique questions for each chapter. These questions are presented in traditional and in alternate-form NCLEX style, so students will become familiar with the format of the exams.

# Acknowledgments

 We are grateful to those who helped with the writing and publication of this text. To the contributors who brought their wealth of knowledge and experience to bear in writing their chapters, we acknowledge our debt and gratitude. We also thank former contributors whose work may remain, in part, in this edition. We appreciate the assistance of many other colleagues and friends who served as “sounding boards” and cheerleaders, and those who contributed ideas and suggestions, among them Linda Olsen Keller from the University of Minnesota; Dr. Linda Hewett from the University of California San Francisco and the Alzheimer’s

& Memory Center; Lieutenant Commander A. Karen Bryant from the U.S. Public Health Service; and Travis Hunter, RN, from the Utah State Prison.

To our managing editors, Katherine Burland and Betsy Gentzler, and acquisitions editor, Margaret Zuccarini, along with other staff at Lippincott Williams & Wilkins, we express our thanks.

We are in debt to our family and friends who “suffered” through this experience with us. We appreciate your flexibility and encouragement.

# The Journey Begins: Introduction to Community Health Nursing

## LEARNING OBJECTIVES

*Upon mastery of this chapter, you should be able to:*

- ◆ Define community health and distinguish it from public health.
- ◆ Explain the concept of community.
- ◆ Diagram the health continuum.
- ◆ Name three of the 10 leading health indicators.
- ◆ Discuss ways that public health nursing (PHN) practice is linked to acute care nursing practice.
- ◆ Discuss the two main components of community health practice (health promotion and disease prevention).
- ◆ Differentiate among the three levels of prevention.
- ◆ Describe the eight characteristics of community health nursing.

*“A generation that acquires knowledge without ever understanding how that knowledge can benefit the community is a generation that is not learning what it means to be citizens in a democracy.”*

—Elizabeth L. Hollander, Author (1817–1885)

Wellness

 **Opportunities** and challenges in nursing are boundless and ever-changing. You have spent a lot of time and effort learning how to care for individual patients in medical-surgical and other acute-care oriented nursing specialties. Now you are entering a unique and exciting area of nursing—community/public health.

As one of the oldest specialty nursing practices, community health nursing offers unique challenges and opportunities. A nurse entering this field will encounter the complex challenge of working with populations rather than just individual clients, and the opportunity to carry on the heritage of early public health nursing efforts with the benefit of modern sensibilities. There is the challenge of expanding nursing's focus from the individual and family to encompass communities and the opportunity to affect the health status of populations. There also is the challenge of determining the needs of populations at risk and the opportunity to design interventions to address their needs. There is the challenge of learning the complexities of a constantly changing health care system and the opportunity to help shape service delivery. Community health nursing is community-based and, most importantly, it is population-focused. Operating within an environment of rapid change and increasingly complex challenges, this field of nursing holds the potential to shape the quality of community health services and improve the health of the general public.

You have provided nursing care in familiar acute care settings for the very ill, both young and old, but always with other professionals at your side. You have worked as part of a team, in close proximity, to welcome a new life, reestablish a client's health, or comfort someone toward a peaceful death. Now, you are being asked to leave the familiarity of the acute care setting and go out into the community—into homes, schools, recreational facilities, work settings, parishes, and even street corners that are familiar to your clients and unfamiliar to you. Here, you will find minimal or no monitoring devices, no charts full of laboratory data, nor professional and allied health workers at your side to assist you. You will be asked to use the nontangible skills of listening, assessing, planning, teaching, coordinating, evaluating, and referring. You will also draw on the skills you have learned through your acute care setting experiences (e.g., psychiatric mental health nursing, maternal child health nursing, medical surgical nursing), and begin to “think on your feet” in new and exciting situations. Often, your practice will be solo, and you will need to combine creativity, ingenuity, intuition, and resourcefulness along with these skills. You will be providing care not only to individuals but also to families and other groups in a variety of settings within the community. Talk about boundless opportunities and challenges! (See Perspectives: Student Voices.)

You may feel that this is too demanding. You may be anxious about how you will perform in this new setting. But perhaps, just perhaps, you might find that this new area is a rewarding kind of nursing—one that constantly challenges you, interests you, and allows you to work holistically with clients of all ages, at all stages of illness and wellness; one that absolutely demands the use of your critical-thinking skills. And you may decide, when you finish your community health nursing course, that you have found your career choice. Even if you are not drawn away from acute care nursing, your community health nursing experience will give you a

deeper understanding of the people for whom you provide care—where and how they live, the family and cultural dynamics at play, and the problems they will face when discharged from your care. You will also discover myriad community agencies and resources to better assist you in providing a continuum of care for your clients. Finding out begins with understanding the concepts of community and health.

This chapter provides an overview of the basic concepts of community and health, the components of community health practice, and the salient characteristics of contemporary community health nursing practice, so that you can enter this field of nursing in concert with its intentions. The opportunities and challenges of community health nursing will become even more apparent as the chapter progresses. The discussion of the concepts and theories that make community health nursing an important specialty within nursing begins with the broader field of community health, which provides the context for community health nursing practice.

## COMMUNITY HEALTH

Human beings are social creatures. All of us, with rare exception, live out our lives in the company of other people. An Eskimo lives in a small, tightly knit community of close relatives; a rural Mexican may live in a small village with hardly more than 200 members. In contrast, someone from New York City might be a member of many overlapping communities, such as professional societies, a political party, a religious group, a cultural society, a neighborhood, and the city itself. Even those who try to escape community membership always begin their lives in some type of group, and usually they continue to depend on groups for material and emotional support. Communities are an essential and permanent feature of the human experience.

The communities in which we live and work have a profound influence on our collective health and well-being (World Health Organization [WHO], 2006a). And, since the beginning, people have attempted to create healthier communities. Here are three recent examples:

- ◆ Asthma currently affects more than 31 million Americans—over three times the number reported in 1980. Worldwide, the number of asthma cases has increased 50% each decade, with over a quarter of a million people dying from asthma in 2005. Asthma-related costs are estimated to exceed those for tuberculosis and HIV/AIDS combined (Associated Press, 2006). Evidence of a connection between asthma attacks and community environments has been demonstrated both in the United States and abroad. In Harlem, 25% of the children were reported to have asthma—twice the expected rate. Public health officials note chronic environmental factors as a possible cause for increased asthma cases; pollution from high-traffic areas, secondhand smoke in homes, as well as poor living conditions characterized by dust mites, mold, industrial air pollution, mouse and cockroach droppings, and animal dander (Krisberg, 2006). In Atlanta, the 1996 Olympics brought an unexpected benefit; a 42% reduction in asthma-related

## PERSPECTIVES STUDENT VOICES

I was really terrified when I got to my community health rotation and found that I had to go to people's homes and knock on their doors! I was going to graduate in a few months, and I felt really comfortable in the hospital. . . .

I knew the routines and the machines well. Now, I had to actually find houses and apartments in an area of the city I would normally never venture into! And, it wasn't clear to me what I was supposed to do! I didn't have much equipment—a baby scale, a blood pressure cuff, a stethoscope, a thermometer, and a paper tape measure—that was all! I was told to go visit this 16-year-old mother who had a 4-month-old baby, and to monitor the baby's progress. I don't even have children! What can I tell her? And, besides, she is a teenager who "knows it all." My clinical instructor told me to "build a relationship with her" and to "gain trust and rapport." That is hard to do when you are scared to death! I was afraid of her responses, of being out in that part of the city alone, and of trying to answer questions without anyone there to turn to. But, I wanted to get through nursing school, so I drove over there and knocked on her door. I was shocked to see the condition of the apartment building in which she lived. Peeling paint, loud music, trash everywhere, and strange characters at every turn. When she answered the door, she seemed uninterested—or maybe a little defensive. I told her who I was and why I was there, and she motioned me inside and pointed toward the baby, propped up on the tattered couch. I spent the next 15 weeks visiting Anna and her baby; weighing and measuring the baby, doing a Denver II and sharing the results with Anna, helping her schedule appointments for immunizations, listening to Anna's story of abuse and abandonment, and

realizing that what I was doing was actually exciting and rewarding. By the end of my rotation, I was truly going to miss Anna and little José! He always smiled at me, and I enjoyed "playing" with him as I instructed her about baby-proofing her apartment, finding resources for food and clothing, and getting birth control. We even talked about how she could finish high school. I thought about Anna and José occasionally, when young mothers would bring their babies into the emergency department, where I worked after graduation. I learned from my community health nursing rotation that I needed to look beyond the bravado of a teenage mother and try to "connect" with her in order to assure that she would follow through with the antibiotics and antipyretics we were prescribing for her baby's dangerously high fever and serious infection. A year and a half after I graduated, one day when it had been particularly hectic but was now calming down, I glanced up to see Anna and José. She looked so relieved to see me! She was frantic with worry about the serious burn José had on his right hand. The other nurses were mumbling about "child abuse" and how "irresponsible teen mothers always were." I learned that Anna had left José with a neighbor for an hour while she visited a nearby high school to see about getting her GED. The older neighbor was not used to dealing with a busy toddler, and she had left the handle of a pan of refried beans where José could reach it. The team treated José's burn, and I gave Anna instructions for follow-up care. The bond we had developed was still there. She trusted me, and I knew that she would follow through with the instructions. I also knew that the other nurses who were making comments about her did not know Anna's circumstances. I feel that I am a more effective ER nurse because of the things I learned in community health. Someday, when I get tired of the hospital, I may try working as a Public Health Nurse. You never know!

*Courtney, Age 25*

emergency room visits. With the Olympic congestion downtown, Atlanta restricted traffic and thus improved air quality. Internationally, Singapore also noticed a reduction in emergency room visits for asthma after it restricted automobile traffic in its central business district (*Milestones in Public Health*, 2006).

- ◆ Before the historic Surgeon General's *Report on Smoking and Health*, it was common to see people smoking on television, at work, in restaurants, and even in physician offices. Since that report linked tobacco to disease and death more than 40 years ago, much has changed in our living spaces. In most states, it is now uncommon to see smoking in public places, and smokers are often relegated to outdoor smoking areas. However, tobacco is still the leading cause of preventable disease and death in the United States (*Milestones in Public Health*, 2006). While U.S. consumption of tobacco

products has dropped by more than half, it is estimated that almost 5 million people die each year because of tobacco-related illnesses (*Morbidity and Mortality Weekly Report* [MMWR], 2006). With our present focus on bioterrorism, it is interesting to note the findings of a recent study showing that the worldwide mortality burden from tobacco averages 5,700 times that of international terrorism; in the United States, tobacco-related mortality is 1,700 times greater than terrorism-related mortality, and in Russia it is 12,900 greater (Thomson & Wilson, 2005). With the assistance of the Master Settlement Agreement negotiated by state attorneys general and the tobacco industry in 1999, \$206 billion has been given to states to promote smoking cessation; create smoke-free environments in the workplace, restaurants, and bars; and develop antismoking public information campaigns (*Milestones in Public Health*, 2006). This is due

to wide acceptance of the research showing deleterious effects of secondhand smoke for nonsmoking bystanders (*MMWR*, 2004).

- ◆ Exercise promotes health, and many people enjoy riding bicycles as a form of recreational exercise. However, risks for bicycle-related injury exist. State laws that require the use of helmets for bicyclists reduce the risk of head injuries (Macpherson, To, Macarthur, Chipman, Wright, & Parkin, 2002). Rodgers (2002, p. 42) found that state helmet laws significantly increased the use of bicycle helmets by children and adolescents. It is estimated that over 100,000 bicycle-related head injuries and over \$81 million in direct health costs and \$2.3 billion in indirect health costs could have been prevented if all bicycle riders wore helmets (Schulman, Sacks, & Provenzano, 2002). In many states, motorcyclists must also wear helmets, and research has found that helmet use decreases the severity of injuries and mortality rates (Hundley, Kilgo, Miller, Chang, Hensberry, Meredith, & Hoth, 2004). This study also showed that riders without helmets “monopolize hospital resources, incur higher hospital charges” and that the cost of caring for them is often borne by the larger community (p. 1091). In Florida, where the universal helmet law was amended to exclude those riders who were insured and over the age of 21, the death rate for motorcyclists increased significantly with a 25% greater likelihood of death (Kyrychenko & McCartt, 2006).

Just as systems theory reminds us that a whole is greater than the sum of its parts, the health of a community is more than the sum of the health of its individual citizens. A community that achieves a high level of wellness is composed of healthy citizens, functioning in an environment that protects and promotes health. Community health, as a field of practice, seeks to provide organizational structure, a broad set of resources, and the collaborative activities needed to accomplish the goal of an optimally healthy community.

When you worked in hospitals or other acute care settings, your primary focus was the individual patient. Patients’ families were viewed as ancillary. Community health, however, broadens the view to focus on families, aggregates, populations, and the community at large. The community becomes the recipient of service, and health becomes the product. Viewed from another perspective, community health is concerned with the interchange between population groups and their total environment, and with the impact of that interchange on collective health. The narrow view of the solitary patient, so common in acute care nursing, is expanded to encompass a much wider vista.

Although many believe that health and illness are individual issues, evidence indicates that they are also community issues; and that the world is a community. The spread of the human immunodeficiency virus (HIV) pandemic, nationally and internationally, is a dramatic and tragic case in point, having spread to the “furthest corners of the world” (Coovadia & Hadingham, 2005, p. 1). Other community, national, and global concerns include the rising incidence and prevalence of tuberculosis (Zumla & Mullan, 2006), cardiovascular disease (WHO, 2006b), antibiotic resistance

(Zhang, Eggleston, Rotimi, & Zeckhauer, 2006), terrorism, and pollution-driven environmental hazards. While the United States fights rising rates of obesity, many countries in Africa battle malnutrition and starvation. Communities can influence the spread of disease, provide barriers to protect members from health hazards, organize ways to combat outbreaks of infectious disease, and promote practices that contribute to individual and collective health (Institute of Medicine [IOM], 1998; American Nurses Association [ANA], 2005).

Many different professionals work in community health to form a complex team. The city planner designing an urban renewal project necessarily becomes involved in community health. The social worker providing counseling about child abuse or working with adolescent substance abusers is involved in community health. A physician treating clients affected by a sudden outbreak of hepatitis and seeking to find the source is engaged in community health practice. Prenatal clinics, meals for the elderly, genetic counseling centers, and educational programs for the early detection of cancer all are part of the community health effort.

The professional nurse is an integral member of this team, a linch-pin and a liaison between physicians, social workers, government officials, and law enforcement officers. Community health nurses work in every conceivable kind of community agency, from a state public health department to a community-based advocacy group. Their duties range from examining infants in a well-baby clinic, to teaching elderly stroke victims in their homes, to carrying out epidemiologic research or engaging in health policy analysis and decision-making. Despite its breadth, however, community health nursing is a specialized practice. It combines all of the basic elements of professional clinical nursing with public health and community practice. Together, we will examine the unique contribution made by community health nursing to our health care system.

Community health and public health share many features. Both are organized community efforts aimed at the promotion, protection, and preservation of the public’s health. Historically, as a field of practice, public health has been associated primarily with the efforts of official or government entities—for example, federal, state, or local tax-supported health agencies that target a wide range of health issues. In contrast, private health efforts or nongovernmental organizations (NGOs), such as those of the American Lung Association or the American Cancer Society, work toward solving selected health problems. The latter augments the former. Currently, public health practice encompasses both approaches and works collaboratively with all health agencies and efforts, public or private, which are concerned with the public’s health. In this text, community health practice refers to a focus on specific, designated communities. It is a part of the larger public health effort and recognizes the fundamental concepts and principles of public health as its birthright and foundation for practice.

In the IOM’s landmark publication, *The Future of the Public’s Health* (1998), the mission of public health is defined simply as “fulfilling society’s interest in assuring conditions in which people can be healthy” (p. 7). Winslow’s classic 1920 definition of **public health** still holds true and forms the basis for our understanding of community health in this text:

Public health . . . is the science and art of preventing disease, prolonging life, and promoting health and efficiency through organized community efforts for the sanitation of the environment, the control of communicable infections, the education of the individual in personal hygiene, the organization of medical and nursing services for the early diagnosis and preventive treatment of disease, and the development of the social machinery to insure everyone a standard of living adequate for the maintenance of health. (Clinton County Health Department, 2006, p. 1)

More recent and concise definitions of public health include “an effort organized by society to protect, promote, and restore the people’s health” (Trust for America’s Health, 2006, p. 27) and “the health of the population as a whole rather than medical health care, which focuses on treatment of the individual ailment” (Public Health Data Standards Consortium, 2006, p. 120). The core public health functions have been delineated as assessment, policy development, and assurance. These will be discussed in more detail in Chapter 3.

Given this basic understanding of public health, the concept of community health can be defined. **Community health** is the identification of needs, along with the protection and improvement of collective health, within a geographically defined area.

One of the challenges community health practice faces is to remain responsive to the community’s health needs. As a result, its structure is complex; numerous health services and programs are currently available or will be developed. Examples include health education, family planning, accident prevention, environmental protection, immunization, nutrition, early periodic screening and developmental testing, school programs, mental health services, occupational health programs, and the care of vulnerable populations. The Department of Homeland Security, for example, is a community health and safety agency developed in the aftermath of the terrorist attack on New York City and Washington, D.C., on September 11, 2001.

Community health practice, a part of public health, is sometimes misunderstood. Even many health professionals think of community health practice in limiting terms such as sanitation programs, health clinics in poverty areas, or massive public awareness campaigns to prevent communicable disease. Although these are a part of its ever-broadening focus, community health practice is much more. To understand the nature and significance of this field, it is necessary to more closely examine the concept of community and the concept of health.

## THE CONCEPT OF COMMUNITY

The concepts of community and health together provide the foundation for understanding community health. Broadly defined, a community is a collection of people who share some important feature of their lives. In this text, the term **community** refers to a collection of people who interact with one another and whose common interests or characteristics form the basis for a sense of unity or belonging. It can be a society of people holding common rights and privileges (e.g., citizens of a town), sharing common interests (e.g., a community of farmers), or living under the same laws and

regulations (e.g., a prison community). The function of any community includes its members’ collective sense of belonging and their shared identity, values, norms, communication, and common interests and concerns (Anderson & McFarlane, 2004). Some communities—for example, a tiny village in Appalachia—are composed of people who share almost everything. They live in the same location, work at a limited type and number of jobs, attend the same churches, and make use of the sole health clinic with its visiting physician and nurse. Other communities, such as members of Mothers Against Drunk Driving (MADD) or the community of professional nurses, are large, scattered, and composed of individuals who share only a common interest and involvement in a certain goal. Although most communities of people share many aspects of their experience, it is useful to identify three types of communities that have relevance to community health practice: geographic, common interest, and health problem or solution.

## Geographic Community

A community often is defined by its geographic boundaries and thus is called a **geographic community**. A city, town, or neighborhood is a geographic community. Consider the community of Hayward, Wisconsin. Located in northwestern Wisconsin, it is set in the north woods environment, far removed from any urban center and in a climatic zone characterized by extremely harsh winters. With a population of approximately 2,200, it is considered a rural community. The population has certain identifiable characteristics, such as age and sex ratios, and its size fluctuates with the seasons: summers bring hundreds of tourists and seasonal residents. Hayward is a social system as well as a geographic location. The families, schools, hospital, churches, stores, and government institutions are linked in a complex network. This community, like others, has an informal power structure. It has a communication system that includes gossip, the newspaper, the “co-op” store bulletin board, and the radio station. In one sense, then, a community consists of a collection of people located in a specific place and is made up of institutions organized into a social system.

Local communities such as Hayward vary in size. A few miles south of Hayward lie several other communities, including Northwoods Beach and Round Lake; these three, along with other towns and isolated farms, form a larger community called Sawyer County. If a nurse worked for a health agency serving only Hayward, that community would be of primary concern; however, if the nurse worked for the Sawyer County Health Department, this larger community would be the focus. A community health nurse employed by the State Health Department in Madison, Wisconsin, would have an interest in Sawyer County and Hayward, but only as part of the larger community of Wisconsin.

Frequently, a single part of a city can be treated as a community. Cities are often broken down into *census tracts*, or neighborhoods. In Seattle, for example, the district near the waterfront forms a community of many transient and homeless people. In New York City, the neighborhood called Harlem is a community, as is the Haight-Ashbury district of San Francisco.

In community health, it is useful to identify a geographic area as a community. A community demarcated by

geographic boundaries, such as a city or county, becomes a clear target for the analysis of health needs. Available data, such as morbidity and mortality figures, can augment assessment studies to form the basis for planning health programs. Media campaigns and other health education efforts can readily reach intended audiences. Examples include distributing educational information on safe sex, self-protection, the dangers of substance abuse, or where to seek shelter from abuse and violence. A geographic community is easily mobilized for action. Groups can be formed to carry out intervention and prevention efforts that address needs specific to that community. Such efforts might include more stringent policies on day care, shelters for battered women, work site safety programs in local hazardous industries, or improved sex education in the schools. Furthermore, health actions can be enhanced through the support of politically powerful individuals and resources present in a geographic community.

On a larger scale, the world can be considered as a global community. Indeed, it is very important to view the world this way. Borders of countries change with political revolution. Communicable diseases are not aware of arbitrary political boundaries. A person can travel around the world in less than 24 hours, and so can diseases. Children starving in Africa affect persons living in the United States. Political uprisings in the Middle East have an impact on people in Western countries. Floods or tsunamis in Southeast Asia have meaning for other national economies. The world is one large community that needs to work together to ensure a healthy today and a healthier and safer tomorrow. **Global health** has become a dominant phrase in international public health circles. Globalization raises an expectation of health for all, for if good health is possible in one part of the world, the forces of globalization should allow it elsewhere (Lopez, Mathers, Ezzati, Jamison, & Murray, 2006; Huynen, Martens, & Hilderink, 2005). Governments need to work together to develop a broader base for international relations and collaborative strategies that will place greater emphasis on global health security. We will learn more about global health issues and the global community in Chapter 16.

### Common-interest Community

A community also can be identified by a common interest or goal. A collection of people, even if they are widely scattered geographically, can have an interest or goal that binds the members together. This is called a *common-interest community*. The members of a church in a large metropolitan area, the members of a national professional organization, and women who have had mastectomies are all common-interest communities. Sometimes, within a certain geographic area, a group of people develop a sense of community by promoting their common interest. Disabled individuals scattered throughout a large city may emerge as a community through a common interest in promoting adherence to federal guidelines for wheelchair access, parking spaces, toilet facilities, elevators, or other services for the disabled. The residents of an industrial community may develop a common interest in air or water pollution issues, whereas others who work but do not live in the area may not share that interest. Communities form to protect the rights of children, stop violence against women, clean up the environment, promote the arts, pre-

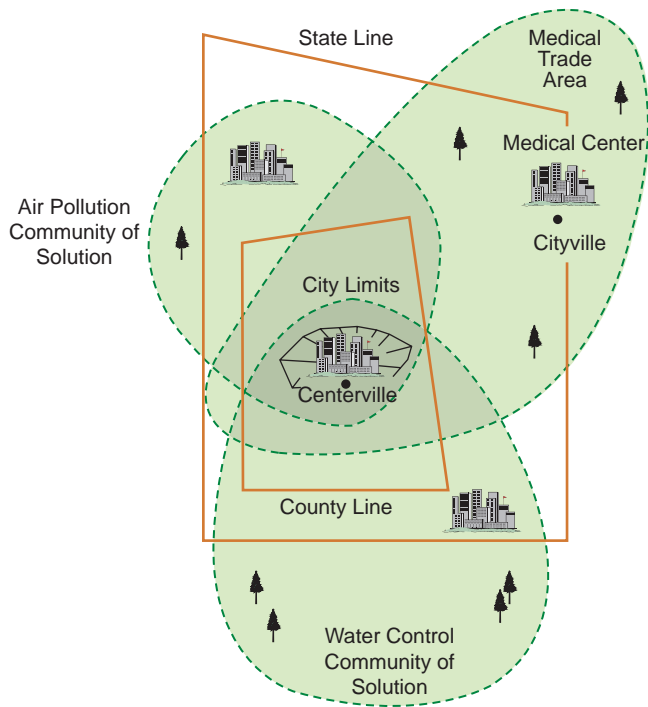

serve historical sites, protect endangered species, develop a smoke-free environment, or provide support after a crisis. The kinds of shared interests that lead to the formation of communities vary widely.

Common-interest communities whose focus is a health-related issue can join with community health agencies to promote their agendas. A group's single-minded commitment is a mobilizing force for action. Many successful prevention and health promotion efforts, including improved services and increased community awareness of specific problems, have resulted from the work of common-interest communities. Mothers Against Drunk Driving is one example. In 1980, after a repeat drunk-driving offender killed her 13-year-old daughter Cari, Candace Lightner gathered with a group of outraged mothers at a restaurant in Sacramento, California. Across the country, another mother was soon touched by a similar tragedy. Cindi Lamb's five-and-a-half month old infant daughter became a quadriplegic at the hands of a repeat drunk driver. Within a short time, the two women joined forces to form MADD and 2 years later, President Ronald Reagan organized a Presidential Task Force on drunk driving and invited MADD to participate. With media attention and perseverance, MADD quickly grew to over 100 chapters across the United States and Canada and worked to establish a federal legal minimum drinking age and standard blood alcohol levels of 0.08 percent, as well as to defend sobriety checkpoints before the Supreme Court. The National Highway Transportation and Safety Administration credited MADD when they released the 1994 figures showing a 30-year low in alcohol-related traffic deaths. Mothers Against Drunk Driving now claims more than 3 million members worldwide, and is one of the largest and most successful common-interest organizations (*Milestones in Public Health*, 2006).

### Community of Solution

A type of community encountered frequently in community health practice is a group of people who come together to solve a problem that affects all of them. The shape of this community varies with the nature of the problem, the size of the geographic area affected, and the number of resources needed to address the problem. Such a community has been called a *community of solution*. For example, a water pollution problem may involve several counties whose agencies and personnel must work together to control upstream water supply, industrial waste disposal, and city water treatment. This group of counties forms a community of solution focusing on a health problem. In another instance, several schools may collaborate with law enforcement and health agencies, as well as legislators and policy makers, to study patterns of substance abuse among students and design possible preventive approaches. The boundaries of this community of solution form around the schools, agencies, and political figures involved. Figure 1.1 depicts some communities of solution related to a single city.

In recent years, communities of solution have formed in many cities to attack the spread of HIV/AIDS, and have worked with community members to assess public safety and security and create plans to make the community a safer place in which to live. Public health agencies, social service groups, schools, and media personnel have banded together

**FIGURE 1.1** A city's communities of solution. State, county, and city boundaries (solid lines) may have little or no bearing on health solution boundaries (dashed lines).

to create public awareness of dangers that are present and to promote preventive behaviors (e.g., childhood obesity). Former President Bill Clinton organized the Alliance for a Healthier Generation in partnership with the American Heart Association, and they recently announced an agreement with beverage companies such as Coca-Cola and PepsiCo. Vending machines that once stocked calorie-laden sodas will now have supplies of low-calorie soft drinks and sports drinks, juices with no added sugar, tea, low or fat-free milk, and water (American Cancer Society, 2008). Although soft drinks are not the only culprit in the childhood obesity epidemic, this is an important step in helping kids make healthier choices. A community of solution is an important medium for change in community health.

## Populations and Aggregates

The three types of communities just discussed underscore the meaning of the concept of community: in each instance, a collection of people chose to interact with one another because of common interests, characteristics, or goals. The concept of population has a different meaning. In this text, the term **population** refers to all of the people occupying an area, or to all of those who share one or more characteristics. In contrast to a community, a population is made up of people who do not necessarily interact with one another and do not necessarily share a sense of belonging to that group. A population may be defined geographically, such as the population of the United States or a city's population. This designation of a population is useful in community health for epidemiologic study and for collecting demographic data for purposes such as health planning. A population also may be defined by common qualities or characteristics,

such as the elderly population, the homeless population, or a particular racial or ethnic group. In community health, this meaning becomes useful when a specific group of people (e.g., homeless individuals) is targeted for intervention; the population's common characteristics (e.g., the health-related problems of homelessness) become a major focus of the intervention.

In this text, the term **aggregate** refers to a mass or grouping of distinct individuals who are considered as a whole, and who are loosely associated with one another. It is a broader term that encompasses many different-sized groups. Both communities and populations are types of aggregates. The aggregate focus, or a concern for groupings of people in contrast to individual health care, becomes a distinguishing feature of community health practice. Community health nurses may work with aggregates such as pregnant and parenting teens, elderly adults with diabetes, or gay men with HIV/AIDS.

The continuing shift away from acute care settings and toward community-based services as the focus of the health care system, along with a rising emphasis on the managed care of populations, underscores the importance of community health nursing's aggregate focus. In fact, some say it validates the focus of community health nursing as practiced over many decades (Porter-O'Grady, 2001). With the community as central to the health care model, it becomes essential for nurses to understand the meaning of community health and to assume leadership in aggregate-level health care (see What Do You Think?).

Community health workers, including community health nurses, need to define the community targeted for study and intervention: Who are the people who compose the community? Where are they located, and what are their characteristics? A clear delineation of the community or population must be established before the nurse can assess needs and design interventions. The complex nature of communities also must be understood. What are the characteristics of the people in terms of age, gender, race, socioeconomic level, and health status? How does the community interact with other communities? What is its history? What are its resources? Is the community undergoing rapid change, and, if so, what are the changes? These questions, as well as the tools needed to assess a community for health purposes, are discussed in detail in Chapter 15.

## What Do You Think?

According to Porter-O'Grady (2001) during the past 20 to 30 years 70% of nurses worked in hospitals. That percentage has slowly diminished to 50% as we move through the early years of the 21st century. What do you think the continuing trend will be like as we get closer to 2050? Where do you think your career in nursing will take you over the next 25 years?

## THE CONCEPT OF HEALTH

Health, in the abstract refers to a person's physical, mental, and spiritual state; it can be positive (as being in good health) or negative (as being in poor health). Health is extolled as a "dynamic state of well-being" (Bircher, 2005, p. 335) and, in a classic article from 1997, Sarrachi describes health as a "basic and universal human right" (p. 1,409). The World Health Organization (WHO) defines health positively as "a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity" (Ustin & Jakob, 2005). Our understanding of the concept of health builds on this classic definition. **Health**, in this text, refers to a holistic state of well-being, which includes soundness of mind, body, and spirit. Community health practitioners place a strong emphasis on **wellness**, which includes this definition of health, but also incorporates the capacity to develop a person's potential to lead a fulfilling and productive life—one that can be measured in terms of *quality of life*. Today, our health is greatly affected by the lifestyles we lead and the risk behaviors we engage in. An individual's behavioral risk factors, such as smoking, physical inactivity, or substance abuse, can be assessed through the use of various interview techniques and questionnaires or surveys (Glasgow, et al., 2005). The Behavioral Risk Factor Surveillance Survey, Jackson's Smoking Susceptibility Scale, and the Physical Activity and Nutrition Behaviors Monitoring Form are some examples.

There is increasing awareness of the strong relationship of health to environment. This is not a new concept. Almost 150 years ago, Florence Nightingale explored the health and illness connection with the environment. She believed that a person's health was greatly influenced by ventilation, noise, light, cleanliness, diet, and a restful bed. She laid down simple rules about maintaining and obtaining "health," which were written for lay women caring for family members to "put the constitution in such a state as that it will have no disease" (Nightingale, 1859, preface). The "built environment" is a concept under study by public health and other professionals, as the manmade structures and surroundings in a community (e.g., highways and bike paths, parks and open spaces, public buildings and housing developments) have an impact on the health of individuals and populations. Environment's relationship to health will be discussed in more detail in Chapter 9.

In some cultures, health is viewed differently. Some see it as the freedom from and absence of evil. Illness may be seen as punishment for being bad or doing evil (Lipson & Dibble, 2005). Many individuals come from families in which beliefs regarding health and illness are heavily influenced by religion, superstition, folk beliefs, or "old wives' tales." This is not unusual, and encountering such beliefs when working with various groups in the community is common. Chapter 5 explores these beliefs more thoroughly for a better understanding of how health beliefs influence every aspect of a person's life.

Although health is widely accepted as desirable, the nature of health often is ambiguous. Consumers and providers often define health and wellness in different ways. To clarify the concept for nurses who are considering community health practice, the distinguishing features of health are briefly characterized here; the implications of this concept for professionals in the field can then be examined more fully.

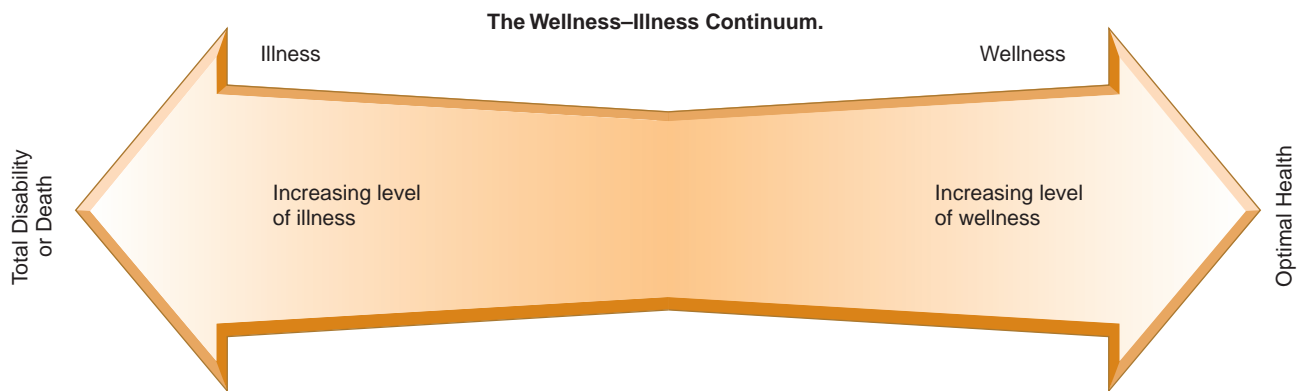

## The Health Continuum: Wellness–Illness

Society suggests a polarized or "either/or" way of thinking about health: people either are well or they are ill. Yet wellness is a relative concept, not an absolute, and **illness** is a state of being *relatively* unhealthy. There are many levels and degrees of wellness and illness, from a robust 70-year-old woman who is fully active and functioning at an optimal level of wellness, to a 70-year-old man with end-stage renal disease whose health is characterized as frail. Someone recovering from pneumonia may be mildly ill, whereas a teenaged boy with functional limitations because of episodic depression may be described as mildly well.

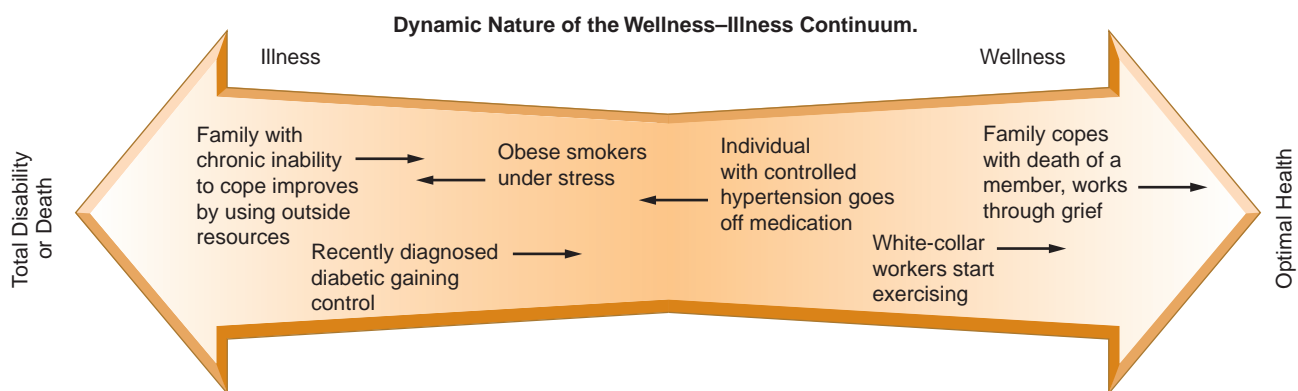

The Human Genome Project, begun in 1990 and completed in 2000, and the genomic era of health care may skew the health continuum toward the healthy end (*Milestones in Public Health*, 2006). **Genomics**, the identification and plotting of human genes and the study of the interaction of genes with each other and the environment, will alter how we view and treat disease (Meadows, 2005). Primary and secondary preventive services will be individually designed based on genetic findings, and client lifestyle modifications will be recommended from birth. **Pharmacogenomics** will permit the design of drugs tailored to a person's genetic makeup or to a targeted disease. The capacity for this kind of health care will be a reality over the next decade, and we must guard against limiting access to this type of care and permitting further disenfranchisement of vulnerable populations (Eisenberg, 2005; Meadows, 2005).

Because health involves a range of degrees from optimal health at one end to total disability or death at the other (Fig. 1.2), it often is described as a continuum. This **health continuum** applies not only to individuals, but also to families and communities. A nurse might speak of a *dysfunctional family*, meaning one that is experiencing a relative degree of illness; or, a healthy family might be described as one that exhibits many wellness characteristics, such as effective communication and conflict resolution, as well as the ability to effectively work together and use resources appropriately. Likewise, a community, as a collection of people, may be described in terms of degrees of wellness or illness. The health of an individual, family, group, or community moves back and forth along this continuum throughout the lifespan. Healthy people make healthy communities and a healthy society. The Declaration of Alma Ata, which took place in 1978, noted that health is a "fundamental human right" and that the level of health must be raised for all countries in order for any society to improve their health (Bryant, 2003).

By thinking of health relatively, as a matter of degree, the scope of nursing practice can be broadened to focus on preventing illness or disability and promoting wellness. Traditionally, most health care has focused on treatment of acute and chronic conditions at the illness end of the continuum. Gradually, the emphasis is shifting to focus on the wellness end of the continuum, as outlined in the government document, *Healthy People 2010* (U.S. Department of Health and Human Services [USDHHS], 2000). The two main goals of Healthy People 2010 are: "1) to increase the quality and years of life, and 2) to eliminate health disparities" (§ 3).

The level (degree) of illness increases as one moves toward total disability or death; the level of wellness increases as one moves toward optimal health. This continuum shows the relative nature of health. At any given time a person can be placed at some point along the continuum.

A person's relative health is usually in a state of flux, either improving or deteriorating. This diagram of the wellness-illness continuum shows several examples of people in changing states of health.

FIGURE 1.2 The health continuum.

These goals overarch the 28 focus areas (see Display 1.1) and the 467 objectives stated in measurable terms that specify targeted incidence and prevalence changes and address age, gender, and culturally vulnerable groups along with improvement in public health systems. Ten major health concerns were also identified as the **leading health indicators** (*Healthy People 2010, 2006*) and these are used in measuring the health of the U.S. population (see Display 1.2 for a list of resources pertaining to each of these health indicators):

- ◆ Physical activity
- ◆ Overweight and obesity
- ◆ Tobacco use
- ◆ Substance use
- ◆ Responsible sexual behavior
- ◆ Mental health
- ◆ Injury and violence
- ◆ Environmental quality
- ◆ Immunization
- ◆ Access to health care

Community health practice ranges across the entire health continuum; it always works to improve the degree of health in individuals, families, groups, and communities. In

particular, community health practice emphasizes the promotion and preservation of wellness and the prevention of illness or disability.

Community characteristics of health have been described by the Centers for Disease Control as health-related quality of life indicators. These include such things as rates of poverty and unemployment, levels of high school education and severe work disability, mortality rates, and the proportion of adolescent births (*MMWR, 2000*). Canada has included such factors as life expectancy at birth, infant mortality, self-rated health, cancer incidence, body mass index (BMI) and dietary practices, life stress, smoking and alcohol use, unemployment rate, leisure-time physical activity, number of health professionals, as well as the total health expenditures in their list of health indicators (Canadian Institute for Health Information, 2006). How does the United States compare to other developed countries on population health indicators? See Chapter 6 for details. *Healthy People in Healthy Communities* is an outgrowth of the *Healthy People 2010* movement (*Healthy People 2010, 2001*). A healthy community is defined as one that:

- ◆ Is characterized by a safe and healthy environment
- ◆ Offers access to health care services, focusing on both treatment and prevention for all members of the community

## DISPLAY 1.1

## ISSUES IN COMMUNITY HEALTH NURSING

**Priority Areas for National Health Promotion and Disease Prevention**

The context in which the document *Healthy People 2010* was developed differs from that in which *Healthy People 2000* was framed—and will continue to evolve through the decade. Advances in preventive therapies, vaccines and pharmaceuticals, assistive technologies, and computerized systems will all change the face of medicine and how it is practiced. New relationships will be defined between public health departments and health care delivery organizations. Meanwhile, demographic changes in the United States—reflecting an older and more radically diverse population—will create new demands on public health and the overall health care system. Global forces—including food supplies, emerging infectious diseases, and environmental interdependence—will present new public health challenges (U.S. Department of Health and Human Services, 2000).

Its report, *Healthy People 2010*, states two broad goals: to (1) increase the quality and years of healthy life, and (2) eliminate health disparities. To accomplish these goals, measurable objectives were established under each of the following 28 priority areas:

**Healthy People 2010 Focus Areas**

1. Access to Quality Health Services
2. Arthritis, Osteoporosis, and Chronic Back Conditions
3. Cancer
4. Chronic Kidney Disease

5. Diabetes
6. Disability and Secondary Conditions
7. Educational and Community-Based Programs
8. Environmental Health
9. Family Planning
10. Food Safety
11. Health Communication
12. Heart Disease and Stroke
13. HIV
14. Immunization and Infectious Diseases
15. Injury and Violence Prevention
16. Maternal, Infant, and Child Health
17. Medical Product Safety
18. Mental Health and Mental Disorders
19. Nutrition and Overweight
20. Occupational Safety and Health
21. Oral Health
22. Physical Activity and Fitness
23. Public Health Infrastructure
24. Respiratory Diseases
25. Sexually Transmitted Diseases
26. Substance Abuse
27. Tobacco Use
28. Vision and Hearing

This national listing is a guide to policy makers and health planners at all levels. It provides a framework for prioritizing and addressing specific health needs in designated communities.

- ◆ Has roads, playgrounds, schools and other services to meet the needs of the population

Another description of a healthy community, first described by Cottrell (1976) as a *competent community*, is one in which the various organizations, groups, and aggregates of people making up the community do at least four things:

1. They collaborate effectively in identifying the problems and needs of the community.
2. They achieve a working consensus on goals and priorities.
3. They agree on ways and means to implement the agreed-on goals.
4. They collaborate effectively in the required actions.

Healthy communities and healthy cities impact the health of their populations and vice versa. In the 1980s, the WHO initiated the Healthy Cities movement to improve the health status of urban populations. A healthy city is defined as “one that is continually creating and improving those physical and social environments and expanding those community resources that enable people to mutually support each other in performing all functions of life and in developing their maximum potential” (WHO, 2004, ¶ 8). The eleven key components of a healthy city are listed in Display 1.3. How many of these are found in your city or community?

**Health as a State of Being**

Health refers to a state of being, including many different qualities and characteristics. An individual might be described in terms such as energetic, outgoing, enthusiastic, beautiful, caring, loving, and intense. Together, these qualities become the essence of a person’s existence; they describe a state of being. Similarly, a specific geographic community, such as a neighborhood, has many characteristics. It might be characterized by the terms congested, deteriorating, unattractive, dirty, and disorganized. These characteristics suggest diminishing degrees of vitality. A third example might be a population, such as workers involved in a massive layoff, who band together to provide support and share resources to effectively seek new employment. This community shows signs of healthy adaptation and positive coping.

Health involves the total person or community. All of the dimensions of life affecting everyday functioning determine an individual’s or a community’s health, including physical, psychological, spiritual, economic, and sociocultural experiences. All of these factors must be considered when dealing with the health of an individual or community. The approach should be holistic. A client’s placement on the health continuum can be known only if the nurse considers all facets of the client’s life, including not only physical and emotional status, but also the status of home, family, and work.

## DISPLAY 1.2

## RESOURCES FOR THE LEADING HEALTH INDICATORS

The Leading Health Indicators will be used to measure the health of the nation over the next 10 years. Each of the 10 Leading Health Indicators has one or more objectives from *Healthy People 2010* associated with it. As a group, the Leading Health Indicators reflect the major health concerns in the United States at the beginning of the 21st century. The Leading Health Indicators were selected on the basis of their ability to motivate action, the availability of data to measure progress, and their importance as public health issues. Corresponding sample resources from the Federal government are listed here. The Federal consumer health information Web site, [www.healthfinder.gov](http://www.healthfinder.gov), is also a good starting point for more information on these topics.

## DISPLAY 1.3

## WHAT ARE THE QUALITIES OF A HEALTHY CITY?

- A clean, safe physical environment of a high quality (including housing quality)
- An ecosystem that is stable now and sustainable in the long term
- A strong mutually supportive and nonexploitative community
- A high degree of participation in and control by the citizens over the decisions affecting their lives, health, and well-being
- The meeting of basic needs (food, water, shelter, income, safety, and work) for all the city's people
- Access by the people to a wide variety of experiences and resources, with the chance for a wide variety of contact, interaction, and communication
- A diverse, vital, and innovative economy
- The encouragement of connectedness with the past, with the cultural and biologic heritage of city dwellers, and with other groups and individuals
- A form that is compatible with and enhances the preceding characteristics
- An optimum level of appropriate public health and sickness care services, accessible to all, and high health status (high levels of positive health and low levels of disease)

(Retrieved from [www.euro.who.int/healthy-cities/introducing/20050202\\_4.](http://www.euro.who.int/healthy-cities/introducing/20050202_4.))

When considering an aggregate or group of people in terms of health, it becomes useful for intervention purposes to speak of the “health of a community.” With aggregates as well as individuals, health as a state of being does not merely involve that group’s physical state but also includes psychological, spiritual, and socioeconomic factors. The health of the Gulf Coast region after hurricane Katrina made landfall in August 2005 is one example. Widespread damage occurred after the deadliest hurricane since the 1920s, and then, only 26 days later, hurricane Rita (the fourth most intense Atlantic hurricane on record) hit near the Texas–Louisiana border. The Centers for Disease Control (CDC) estimated that more than 200,000 people converged on evacuation centers, and the country watched in anguish as the Federal Emergency Management Agency (FEMA) struggled to meet the emergency needs of the survivors. At the same time, over 1,000 deaths have been attributed to Katrina, and the survivors are left with many physical, emotional, and social difficulties. The CDC estimated that almost 2 months after Katrina made landfall, more than 20% of houses did not have water, almost 56% of households had at least one member with a chronic health condition, and almost half of the adults had a level of emotional distress indicating a need for mental health services (*MMWR*, March 10, 2005; *MMWR*, January 19, 2006). Prior to that, on September 11, 2001, thousands of lives were lost in New York City’s World Trade Center towers, in the Pentagon in Washington, DC, and in an airliner that crashed in Somerset County, Pennsylvania. The trauma of these events left our nation shaken. The health of many communities was dangerously poor. Communities needed to be restored, and the entire country needed to heal.

### Subjective and Objective Dimensions of Health

Health involves both *subjective* and *objective* dimensions; that is, it involves both how people feel (subjective) and how well they can function in their environment (objective). Subjectively, a healthy person is one who feels well, who experiences the sensation of a vital, positive state. Healthy

people are full of life and vigor, capable of physical and mental productivity. They feel minimal discomfort and displeasure with the world around them. Again, people experience varying degrees of vitality and well-being. The state of feeling well fluctuates. Some mornings we wake up feeling more energetic and enthusiastic than we do on other mornings. How people feel varies day by day, even hour by hour; nonetheless, how they feel overall is a strong indicator of their overall state of health.

Health also involves the objective dimension of ability to function. A healthy individual or community carries out necessary activities and achieves enriching goals. Unhealthy people not only feel ill, but are limited, to some degree, in their ability to carry out daily activities. Indeed, levels of illness or wellness are measured largely in terms of ability to function (Roach, 2000). A person confined to bed is labeled sicker than an ill person managing self-care. A family that meets its members’ needs is healthier than one that has poor communication patterns and is unable to provide adequate physical and emotional resources. A community actively engaged in crime prevention or policing of industrial wastes shows signs of healthy functioning. The degree of functioning is directly related to the state of health (see Perspectives: Voices from the Community).

The ability to function can be observed. A man dresses and feeds himself and goes to work. Despite financial exigencies, a family nourishes its members through a supportive emotional climate. A community provides adequate resources and services for its members. These performances, to some degree, can be regarded as indicators of health status.

The actions of an individual, family, or community are motivated by their values. Some activities, such as walking and taking care of personal needs, are functions valued by most people. Other actions, such as bird watching, volunteering to help a charity, or running, have more limited appeal. In assessing the health of individuals and communities, the community health nurse can observe people’s ability to function, but also must know their values, which may contrast sharply with those of the professional. The influence of values on health is examined more closely in Chapter 4.

## PERSPECTIVES

### VOICES FROM THE COMMUNITY

“I never thought much about being healthy or not, now that you ask. I keep busy, I cook like I’m expecting company, I have a good appetite. I really think all these so-called healthy things people suggest are fads, just so someone can get rich—like tofu and low fat this and that. Don’t give me margarine, only butter, . . . and skim milk, it’s like drinking water! I work in my garden, I read, and I eat fresh foods, and don’t talk to me about my smoking, it’s the one pleasure I have left.”

*—Betty, age 81*

The subjective dimension (feeling well or ill) and the objective dimension (functioning) together provide a clearer picture of people’s health. When they feel well and demonstrate functional ability, they are close to the wellness end of the health continuum. Even those with a disease, such as arthritis or diabetes, may feel well and perform well within their capacity. These people can be considered healthy or closer to the wellness end of the continuum. Figure 1.3 depicts the relationships between the subjective and objective views of health.

### Continuous and Episodic Health Care Needs

Community health practice encompasses populations in all age groups with birth to death developmental health care needs. These **continuous needs** may include, for example, assistance with providing a toddler-proof home or establishing positive toilet-training techniques, help in effectively dealing with the progressive emancipation of pre-teens and teenagers, anticipatory guidance for reducing and managing the stress associated with retirement, or help coping with the death of an aged parent. These are developmental events experienced by most people, and they repre-

sent typical life occurrences. The community health nurse has the skills to work at the individual, family, and group level to meet these needs. On an individual and family level, a home visit may be the appropriate place for intervention. If the nurse sees that the community has many young and growing families, and several families have similar developmental issues, a class for mothers and babies, parents and teenagers, or preretirement adults may be formed to meet weekly at the library or health clinic waiting room. In these instances, the nurse works with groups ranging from small to large.

In addition, populations may have a one-time, specific, negative health event, such as an illness or injury, that is not an expected part of life. These **episodic needs** might derive from the birth of an infant with Down syndrome, a head injury incurred from an automobile crash, or a diagnosis of HIV/AIDS.

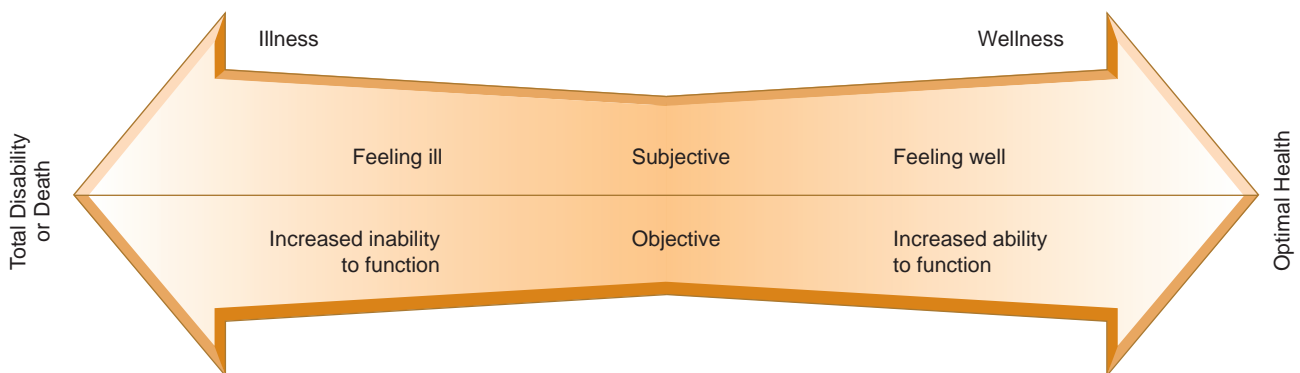

In a given day, the community health nurse may interact with clients having either continuous or episodic health care needs, or both. For example, when can parents expect a child with Down syndrome to begin toilet training? How do middle-aged adults, planning their retirement and preparing for the death of an aged parent, deal with their adult child’s AIDS diagnosis? Complex situations such as these may be positively influenced by the interaction with and services of the community health nurse.

### COMPONENTS OF COMMUNITY HEALTH PRACTICE

Community health practice can best be understood by examining two basic components—promotion of health and prevention of health problems. The levels of prevention are a key to community health practice.

#### Promotion of Health

Promotion of health is recognized as one of the most important components of public health and community health practice (USDHHS, 2000). **Health promotion** includes all efforts that seek to move people closer to optimal well-being or higher levels of wellness. Nursing, in particular, has a social mandate for engaging in health promotion (Pender, Murdaugh & Parsons, 2006). Health promotion programs and activities include many forms of health education—for

**FIGURE 1.3** Subjective and objective views of the wellness–illness continuum.

example, teaching the dangers of drug use, demonstrating healthful practices such as regular exercise, and providing more health-promoting options such as heart-healthy menu selections. Community health promotion, then, encompasses the development and management of preventive health care services that are responsive to community health needs. Wellness programs in schools and industry are examples. Demonstration of such healthful practices as eating nutritious foods and exercising more regularly often is performed and promoted by individual health workers. In addition, groups and health agencies that support a smoke-free environment, encourage physical fitness programs for all ages, or demand that food products be properly labeled underscore the importance of these practices and create public awareness.

The goal of health promotion is to raise levels of wellness for individuals, families, populations, and communities. Community health efforts accomplish this goal through a three-pronged effort to:

1. Increase the span of healthy life for all citizens
2. Reduce health disparities among population groups
3. Achieve access to preventive services for everyone

Specifically, in the 1980s, the U.S. Public Health Service published the Surgeon General's report, *Healthy People*, and continued with *Promoting Health, Preventing Disease: 1990 Health Objectives for the Nation* and *Healthy People 2000*. The third set of health objectives for the nation, *Healthy People 2010* (USDHHS, 2000), built on the previous two decades of success in Healthy People initiatives. These documents provide guidance for promoting health as a nation.

The Surgeon General's report provided vision and an agenda for significantly reducing preventable death and disability nationwide, enhancing quality of life, and greatly reducing disparities in the health status of populations. It emphasized the need for individuals to assume personal responsibility for controlling and improving their own health destiny. It challenged society to find ways to make good health available to vulnerable populations whose disadvantaged state placed them at greater risk for health problems. Finally, it called for an intensified shift in focus from treating preventable illness and functional impairment to concentrating resources and targeting efforts that promote health and prevent disease and disability. The Institute of Medicine's 2001 report, *The Future of the Public's Health in the 21st Century*, notes that the majority of health care spending, "as much as 95%," focuses on "medical care and biomedical research," whereas evidence suggests that "behavior and environment are responsible for over 70% of avoidable mortality" and that health care is only one of many "determinants of health" (p. 2).

The implications of this national agenda for health have far-reaching consequences for persons engaged in health care. For centuries, health care has focused on the illness end of the health continuum, but health professionals can no longer justify concentrating most of their efforts exclusively on treating the sick and injured. We now live in an age when it is not only possible to promote health and prevent disease and disability, but it is our mandate and responsibility to do so (USDHHS, 2000).

## Prevention of Health Problems

Prevention of health problems constitutes a major part of community health practice. Prevention means anticipating and averting problems or discovering them as early as possible in order to minimize potential disability and impairment. It is practiced on three levels in community health: primary prevention, secondary prevention, and tertiary prevention (Neuman, 2001). These concepts recur throughout the chapters of this text, in narrative format and in the Levels of Prevention Pyramids, because they are basic to community health nursing. Once the differences among the levels of prevention are recognized, a sound foundation on which to build additional community health principles can be developed.

**Primary prevention** obviates the occurrence of a health problem; it includes measures taken to keep illness or injuries from occurring. It is applied to a generally healthy population and precedes disease or dysfunction. Examples of primary prevention activities by a community health nurse include encouraging elderly people to install and use safety devices (e.g., grab bars by bathtubs, hand rails on steps) to prevent injuries from falls; teaching young adults healthy lifestyle behaviors, so that they can make them habitual behaviors for themselves and their children; or working through a local health department to help control and prevent communicable diseases such as rubeola, poliomyelitis, or varicella by providing regular immunization programs.

Primary prevention involves anticipatory planning and action on the part of community health professionals, who must project themselves into the future, envision potential needs and problems, and then design programs to counteract them, so that they never occur. A community health nurse who instructs a group of overweight individuals on how to follow a well-balanced diet while losing weight is preventing the possibility of nutritional deficiency (see Levels of Prevention Pyramid). Educational programs that teach safe-sex practices or the dangers of smoking and substance abuse are other examples of primary prevention. In addition, when the community health nurse serves on a fact-finding committee exploring the effects of a proposed toxic waste dump on the outskirts of town, the nurse is concerned about primary prevention. The concepts of primary prevention and planning for the future are foreign to many social groups, who may resist on the basis of conflicting values. The Parable of the Dangerous Cliff (Display 1.4) illustrates such a value conflict. How often does our nation put an ambulance at the bottom of the cliff?

**Secondary prevention** involves efforts to detect and treat existing health problems at the earliest possible stage, when disease or impairment is already present. Hypertension and cholesterol screening programs in many communities help to identify high-risk individuals and encourage early treatment to prevent heart attacks or stroke. Other examples are encouraging breast and testicular self-examination, regular mammograms and Pap smears for early detection of possible cancer, and providing skin testing for tuberculosis (in infants at 1 year of age and periodically throughout life, with increasing frequency for high-risk groups). Secondary prevention attempts to discover a health problem at a point when intervention may lead to its control or eradication.

## LEVELS OF PREVENTION PYRAMID

**SITUATION:** Promotion of community nutritional status through healthy dietary practices.

**GOAL:** Using the three levels of prevention, negative health conditions are avoided, or promptly diagnosed and treated, and the fullest possible potential is restored.

Tertiary Prevention		
Rehabilitation	Health Promotion & Education	Primary Prevention
<ul style="list-style-type: none"> <li>Encourage long-term follow-up for diagnosed eating disorders</li> <li>Reassess client dietary practices as necessary</li> </ul>	<ul style="list-style-type: none"> <li>Encourage healthy meal preparation and consumption</li> </ul>	<ul style="list-style-type: none"> <li>Use vitamin and mineral supplements as needed</li> </ul>
Secondary Prevention		
Early Diagnosis	Prompt Treatment	
<ul style="list-style-type: none"> <li>Provide dietary screening programs for high-risk groups: infants, adolescents, young female adults, elderly individuals</li> <li>Refer clients with eating disorders (underweight/overweight, anorexia, bulimia, compulsive eating) to nutritionist or primary care provider</li> </ul>	<ul style="list-style-type: none"> <li>Initiate educational and incentive programs to improve dietary practices</li> <li>Teach clients (individuals or families) on a one-to-one basis to modify dietary practices</li> </ul>	
Primary Prevention		
Health Promotion & Education	Health Protection	
<ul style="list-style-type: none"> <li>Provide nutrition educational programs to promote awareness at schools, work sites, food stores, etc.</li> <li>Encourage restaurants to offer healthy menu items</li> <li>Complete a kitchen cupboard survey in collaboration with client</li> <li>Recommend nutrition classes offered at neighborhood centers or health care facilities</li> </ul>	<ul style="list-style-type: none"> <li>Supplement diet with vitamins and minerals that offer health protection (e.g., vitamins A, B, C, E)</li> </ul>	

This is the goal behind testing of water and soil samples for contaminants and hazardous chemicals in the field of community environmental health. It also prompts community health nurses to watch for early signs of child abuse in a family, emotional disturbances among widows, or alcohol and drug abuse among adolescents.

**Tertiary prevention** attempts to reduce the extent and severity of a health problem to its lowest possible level, so as to minimize disability and restore or preserve function. Examples include treatment and rehabilitation of persons after a stroke to reduce impairment, postmastectomy exercise programs to restore functioning, and early treatment and management of diabetes to reduce problems or slow their progress. The individuals involved have an existing illness or disability whose impact on their lives is lessened through tertiary prevention. In community health, the need to reduce disability and restore function applies equally to families,

groups, communities, and individuals. Many groups form for rehabilitation and offer support and guidance for those recuperating from some physical or mental disability. Examples include Alcoholics Anonymous, halfway houses for psychiatric patients discharged from acute care settings, ostomy clubs, and drug rehabilitation programs. In broader community health practice, tertiary prevention is used to minimize the effects of an existing unhealthy community condition. Examples of such prevention are insisting that businesses provide wheelchair access, warning urban residents about the dangers of a chemical spill, and recalling a contaminated food or drug product. When a community experiences a disaster such as an earthquake, a fire, a hurricane, or even a terrorist attack, preventing injuries among the survivors and volunteers during rescue is another example of tertiary prevention—eliminating additional injury to those already experiencing a tragedy.

## DISPLAY 1.4

## PARABLE OF THE DANGEROUS CLIFF

Twas a dangerous cliff, as they freely confessed,  
 Though to walk near its crest was so pleasant;  
 But over its terrible edge there has slipped  
 A duke, and full many a peasant.  
 The people said something would have to be done  
 But their projects did not at all tally.  
 Some said, "Put a fence around the edge of the cliff";  
 Some, "an ambulance down in the valley."  
 The lament of the crowd was profound and was loud,  
 As their hearts overflowed with their pity;  
 But the cry of the ambulance carried the day  
 As it spread through the neighboring city.  
 A collection was made to accumulate aid  
 And the dwellers in highway and alley  
 Gave dollars or cents not to furnish a fence  
 But "an ambulance down in the valley."

"For the cliff is all right if you're careful," they said.

"And if folks ever slip and are dropping,  
 It isn't the slipping that hurts them so much  
 As the shock down below when they're stopping."  
 So for years (we have heard), as these mishaps  
 occurred,

Quick forth the rescuers sally,  
 To pick up the victims who fell from the cliff,  
 With the ambulance down in the valley.  
 Said one in his plea, "It's a marvel to me  
 That you'd give so much greater attention  
 To repairing results than to curing the cause;  
 You had much better aim at prevention.  
 For the mischief, of course, should be stopped at its  
 source,

Come neighbors and friends, let us rally.  
 It is far better sense to rely on a fence  
 Than an ambulance down in the valley."  
 "He is wrong in his head," the majority said;  
 "He would end all our earnest endeavor.  
 He's a man who would shirk this responsible work,  
 But we will support it forever.

Aren't we picking up all, just as fast as they fall,  
 and giving them care liberally?  
 A superfluous fence is of no consequence,  
 If the ambulance works in the valley."  
 The story looks queer as we've written it here,  
 But things oft occur that are stranger.  
 More humane, we assert, than to care for the hurt,  
 Is a plan for removing the danger.  
 The very best plan is to safeguard the man,  
 And attend to the thing rationally;  
 To build up the fence and try to dispense  
 With the ambulance down in the valley.  
 Better still! Cut down the hill!

—Author Unknown

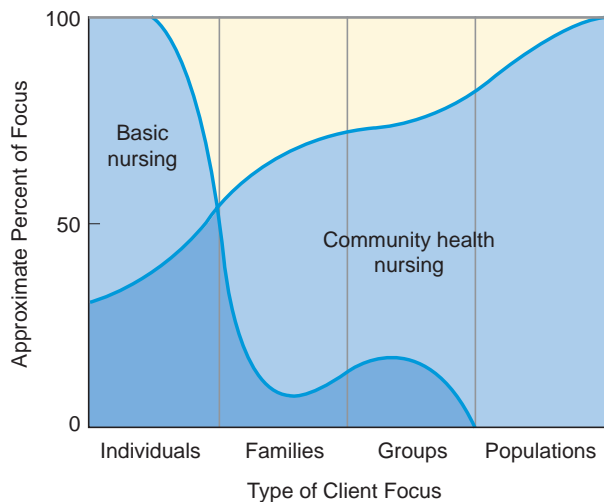

Health assessment of individuals, families, and communities is an important part of all three levels of preventive practice. Health status must be determined to anticipate problems and select appropriate preventive measures. Community health nurses working with young parents who themselves have been victims of child abuse can institute early treatment for the parents to prevent abuse and foster adequate parenting of their children. If the assessment of a community reveals inadequate facilities and activities to meet the future needs of its growing senior population, agencies and groups can collaborate to develop the needed resources.

Health problems are most effectively prevented by maintenance of healthy lifestyles and healthy environments. To these ends, community health practice directs many of its efforts to providing safe and satisfying living and working conditions, nutritious food, and clean air and water. This area of practice includes the field of preventive medicine,

which is a population-focused, or community-oriented, branch of medical practice that incorporates public health sciences and principles (Kriebel & Tickner, 2001).

## CHARACTERISTICS OF COMMUNITY HEALTH NURSING

As a specialty field of nursing, community health nursing adds public health knowledge and skills that address the needs and problems of communities and aggregates and focuses care on communities and vulnerable populations. Community health nursing is grounded in both public health science and nursing science, which makes its philosophical orientation and the nature of its practice unique. It has been recognized as a subspecialty of both fields. Recognition of this specialty field continues with a greater awareness of the important contributions made by community health nursing to improve the health of the public.

**FIGURE 1.4** Difference in client focus between basic nursing and community health nursing.

Knowledge of the following elements of public health is essential to community health nursing (ANA, 2005; Quad Council, 2003; Williams, 1977):

- ◆ Priority of preventive, protective, and health-promoting strategies over curative strategies
- ◆ Means for measurement and analysis of community health problems, including epidemiologic concepts and biostatistics
- ◆ Influence of environmental factors on aggregate health
- ◆ Principles underlying management and organization for community health, because the goal of public health is accomplished through organized community efforts
- ◆ Public policy analysis and development, along with health advocacy and an understanding of the political process

Confusion over the meaning of “community health nursing” arises when it is defined only in terms of where it is practiced. Because health care services have shifted from the hospital to the community, many nurses in other specialties now practice in the community. Examples of these practices include home care, mental health, geriatric nursing, long-term care, and occupational health. Although community health nurses today practice in the same or similar settings, the difference lies in applying the public health principles to large groups and communities of people (Fig. 1.4). For nurses moving into this field of nursing, it requires a shift in focus— from individuals to aggregates. Nursing and other theories undergird its practice (see Chapter 14), and the nursing process (incorporated in Chapter 15 and 19) is one of its basic tools (see the levels of prevention discussed earlier).

**Community health nursing**, then, as a field of nursing, combines nursing science with public health science to formulate a community-based and population-focused practice (Anderson & McFarlane, 2004). “Public health nursing is the practice of promoting and protecting the health of populations using knowledge from nursing, social, and public health sciences” (ANA, 2005, p. 10) (see Display 1.5). For instance, community health nurses are nursing when their concern for homeless individuals sleeping in a park leads to development of a program providing food and shelter for this population. Community health nurses are nursing when they collaborate to institute an AIDS education curriculum in the local school system. When they assess the needs of elderly people in retirement homes to ensure necessary services and provide health instruction and support, they are, again, nursing.

During the first 70 years of the 20th century, community health nursing was known as **public health nursing**. The PHN section of the American Public Health Association’s definition of a public health nurse is a “nursing professional with educational, preparation in public health and nursing science with a primary focus on population-level outcomes” and notes the primary focus for public health nursing is to “promote health and protect disease for entire population

### DISPLAY 1.5 THE ROLE OF PUBLIC HEALTH NURSES

Public health nurses integrate community involvement and knowledge about the entire population with personal, clinical understandings of the health and illness experiences of individuals and families within the population. They translate and articulate the health and illness experiences of diverse, often vulnerable individuals and families in the population to health planners and policy makers, and assist members of the community to voice their problems and aspirations. Public health nurses are knowledgeable about multiple strategies for intervention, from those applicable to the entire population, to those for the family, and the individual. Public health nurses translate knowledge from the health and social sciences to individuals and population groups through targeted interventions, programs, and advocacy. Public health nursing may be practiced by one public

health nurse or by a group of public health nurses working collaboratively. In both instances, public health nurses are directly engaged in the interdisciplinary activities of the core public health functions of assessment, assurance, and policy development. Interventions or strategies may be targeted to multiple levels, depending on where the most effective outcomes are possible. They include strategies aimed at entire population groups, families, or individuals. In any setting, the role of public health nurses focuses on the prevention of illness, injury, or disability; the promotion of health; and the maintenance of the health of populations.

(Public Health Nursing Section, American Public Health Association [1996]. The definition and role of public health nursing. Washington, DC: APHA.)

groups” (1996, p. 2). The later title of community health nursing was adopted to better describe where the nurse practices. As used in this text, the terms are interchangeable.

Eight characteristics of community health nursing are particularly salient to the practice of this specialty:

1. The client or “unit of care” is the population.
2. The primary obligation is to achieve the greatest good for the greatest number of people or the population as a whole.
3. The processes used by public health nurses include working with the client(s) as an equal partner.
4. Primary prevention is the priority in selecting appropriate activities.
5. Selecting strategies that create healthy environmental, social, and economic conditions in which populations may thrive is the focus.
6. There is an obligation to actively reach out to all who might benefit from a specific activity or service.
7. Optimal use of available resources to assure the best overall improvement in the health of the population is a key element of the practice.
8. Collaboration with a variety of other professions, organizations, and entities is the most effective way to promote and protect the health of people. (ANA, 2005, pp. 12–14)

## Population-focused

The central mission of public health practice is to improve the health of population groups. Community health nursing shares this essential feature: it is **population-focused**, meaning that it is concerned for the health status of population groups and their environment. A population may consist of the elderly living throughout the community or of Southeast Asian refugees clustered in one section of a city. It may be a scattered group with common characteristics, such as people at high risk of developing heart disease or battered women living throughout a county. It may include all people living in a neighborhood, district, census tract, city, state, or province. Community health nursing’s specialty practice serves populations and aggregates of people.

Working with individuals and families as aggregates has been common for community health nursing; however, such work must expand to incorporate a population-oriented focus, a feature that distinguishes it from other nursing specialties. Basic nursing focuses on individuals, and community health nursing focuses on aggregates, but the many variations in community needs and nursing roles inevitably cause some overlap.

A population-oriented focus requires the assessment of relationships. When working with groups and communities, the nurse does not consider them separately but rather in context—that is, in relationship to the rest of the community. When an outbreak of hepatitis occurs, for example, the community health nurse does more than work with others to treat it. The nurse tries to stop the spread of the infection, locate possible sources, and prevent its recurrence in the community. As a result of their population-oriented focus, community health nurses seek to discover possible groups with a common health need, such as expectant mothers or groups at high risk for development of a common health problem (e.g., obese children at risk for type 2 diabetes, victims of child abuse).

Community health nurses continually look for problems in the environment that influence community health and seek ways to increase environmental quality. They work to prevent health problems, such as promoting school-based education about nutrition and physical activity or exercise programs for groups of seniors.

## The Greatest Good for the Greatest Number of People

A population-oriented focus involves a new outlook and set of attitudes. Individualized care is important, but prevention of aggregate problems in community health nursing practice reflects more accurately its philosophy and benefits more people. The community or population at risk is the client (see Display 1.6). Furthermore, because community health nurses are concerned about several aggregates at the same time, service will, of necessity, be provided to multiple and overlapping groups. The ethical theory of *utilitarianism* promotes the greatest good for the greatest number. Further discussion of ethical principles in community health nursing can be found in Chapter 4.

## Clients as Equal Partners

The goal of public health, “to increase quality and years of healthy life and eliminate health disparities” (USDHHS, 2000, ¶ 3), requires a partnership effort. Just as learning cannot take place in schools without student participation, the goals of public health cannot be realized without consumer participation. Community health nursing’s efforts toward health improvement go only so far. Clients’ health status and health behavior will not change unless people accept and apply the proposals (developed in collaboration with clients) presented by the community health nurse.

Community health nurses can encourage individuals’ participation by promoting their autonomy rather than permitting a dependency. For example, elderly persons attending a series of nutrition or fitness classes can be encouraged to take the initiative and develop health or social programs on their own. Independence and feelings of self-worth are closely related. By treating people as independent adults, with trust and respect, community health nurses help promote self-reliance and the ability to function independently.

Frequently, consumers are intimidated by health professionals and are uninformed about health and health care. They do not know what information to seek and are hesitant to act assertively. For example, a migrant worker brought her 2-year-old son, who had symptoms resembling those of scurvy, to a clinic. Recognizing a vitamin C deficiency, the physician told her to feed the boy large quantities of orange juice but gave no explanation. Several weeks later, she returned to the clinic, but the child was much worse. After questioning her, the nurse discovered that the mother had been feeding the child large amounts of an orange soft drink, not knowing the difference between that beverage and orange juice. Obviously, the quality of care is affected when the consumer does not understand and cannot participate in the health care process. **Health literacy**, or the ability to “obtain, process, and understand basic health information and services needed to make appropriate health decisions,” is an important concept that will be discussed more fully in Chapter 10 (Parker & Gazmararian, 2003, p. 116).

## DISPLAY 1.6

## PARABLE OF THE TREES: POPULATION-FOCUSED PRACTICE

There were once two sisters who inherited a large tract of heavily forested land from their grandmother. In her will, the grandmother stipulated that they must preserve the health of the trees. One sister studied tree surgery and became an expert in recognizing and treating diseased trees. She also was able to spot conditions that might lead to problems and prevent them. Her work was invaluable in keeping single or small clusters of trees healthy. The other sister became a forest ranger. In addition to learning how to care for individual trees, she studied the environmental conditions that affected the well-being of the forest. She learned the importance of proper ecologic balance between flora and fauna and the impact of climate, geog-

raphy, soil conditions, and weather. Her work was to oversee the health and growth of the whole forest. Although she spent time walking through the forest assessing conditions, her aerial view from their small plane was equally important for spotting fires, signs of disease, or other potential problems. Together, the sisters preserved a healthy forest.

Nursing also has tree surgeons and forest rangers. Various nursing specialties, like the tree surgeons, serve the health needs of individuals and families. Community health nurses, like the forest rangers, study and address the needs of populations. Both are needed and must work together to ensure healthy communities.

When people believe that their health, and that of the community, is their own responsibility, not just that of health professionals, they will take a more active interest in promoting it. The process of taking responsibility for developing one's own health potential is called **self-care**. As people maintain their own lives, health, and well-being, they are engaging in self-care. Some examples of self-care activities at the aggregate level include building safe playgrounds, developing teen employment opportunities, and providing senior exercise programs.

When people's ability to continue self-care activities drops below their need, they experience a **self-care deficit**. At this point, nursing may appropriately intervene. However, nursing's goal is to assist clients to return to or reach a level of functioning at which they can attain optimal health and assume responsibility for maintaining it (Orem, 2001). To this end, community health nurses foster their clients' sense of responsibility by treating them as adults capable of managing their own affairs. Nurses can encourage people to negotiate health care goals and practices, develop their own programs, contact their own resources (e.g., support groups, transportation services), identify and implement lifestyle changes that promote wellness, and learn ways to monitor their own health.

When planning for the health of communities, for example, partnerships must be established and the values and priorities of the community incorporated into program planning, data collection and interpretation, and policy making.

### Prioritizing Primary Prevention

In community health nursing, the promotion of health and prevention of illness are a first-order priority. Less emphasis is placed on curative care. Some corrective actions always are needed, such as cleanup of a toxic waste dump site, stricter enforcement of day care standards, or home care of the disabled; however, community health best serves its constituents through preventive and health-promoting actions (USDHHS, 2000). These include services to mothers and infants, prevention of environmental pollution, school health programs, senior citizens' fitness classes, and "workers' right-to-know" legislation that warns against hazards in the workplace.

Another distinguishing characteristic of community health nursing is its emphasis on positive health, or wellness (Anderson & McFarlane, 2004; Porter-O'Grady, 2001). Medicine and acute care nursing have dealt primarily with

the illness end of the health continuum. With the potential of genomics just around the corner, the wellness end of the continuum will come into greater focus. In contrast, community health nursing always has had a primary charge to prevent health problems from occurring and to promote a higher level of health. For example, although a community health nurse may assist a population of new mothers in the community with postpartum fatigue and depression, the nurse also works to prevent such problems among women of child-bearing age by developing health education programs, establishing prenatal classes, and encouraging proper rest and nutrition, adequate help, and stress reduction.

Community health nurses concentrate on the wellness end of the health continuum in a variety of ways. They teach proper nutrition or family planning, promote immunizations among preschool children, encourage regular physical and dental checkups, assist with starting exercise classes or physical fitness programs, and promote healthy interpersonal relationships. Their goal is to help the community reach its optimal level of wellness.

This emphasis on wellness changes the role of community health nursing from a reactive to a proactive stance. It places a greater responsibility on community health nurses to find opportunities for intervention. In clinical nursing and medicine, the patients seek out professional assistance because they have health problems. As Williams put it decades ago, “patients select themselves into the care system, and the providers’ role is to deal with what the patients bring to them” (1977, p. 251). Community health nurses, in contrast, seek out potential health problems. They identify high-risk groups and institute preventive programs. They watch for early signs of child neglect or abuse and intervene when any occur, often long before a request for help is made. They look for possible environmental hazards in the community, such as smoking in public places or lead-based paint in older housing units, and work with appropriate authorities to correct them. A wellness emphasis requires taking initiative and making sound judgments, which are characteristics of effective community health nursing.

### Selecting Strategies That Create Healthy Conditions in Which Populations May Thrive

With our population focus, it is prudent for community health nurses to design interventions for “education, community development, social engineering, policy development, and enforcement” that “result in laws and rules, policies and budget priorities” (ANA, 2005, p. 13). Advocacy for our clients, whether they be individuals, families, aggregates, communities, or populations, is an essential function of public health nursing. We want to create healthy environments for our clients, so that they can thrive and not simply survive.

### Actively Reaching Out

We know that some clients are more prone to develop disability or disease because of their vulnerable status (e.g., poverty, no access to health care, homeless). Outreach efforts are needed to promote the health of these clients and to prevent disease. In acute care and primary health care settings, like emergency rooms or physician offices, clients come to you for service. However, in community

health, nurses must “focus on the whole population and not just those who present for services” and seek out clients wherever they may be (ANA, 2005, p. 13). Like Lillian Wald and her Henry Street Settlement, community health nurses must learn about the populations they serve and be willing to search out the most at-risk. You will learn more about the rich history of community/public health nursing in Chapter 2. Chapter 25 will cover vulnerable populations.

### Optimal Use of Available Resources

It is our duty to wisely use the resources we are given. For many public health agencies, budgets have been stretched to the limits. Tertiary health care uses up the greatest percentage of our health care dollar, leaving decreased funds for primary and secondary services. Decisions for programs or services are often made on the basis of the “cost-benefit or cost-effectiveness of potential strategies” (ANA, 2005, p. 13). It is vital that community health nurses ground their practice in research, and use that information to educate policy makers about best practices. Utilizing personnel and resources effectively and prudently will pay off in the long run.

### Interprofessional Collaboration

Community health nurses must work in cooperation with other team members, coordinating services and addressing the needs of population groups. This interprofessional **collaboration** among health care workers, other professionals and organizations, and clients is essential for establishing effective services and programs. Individualized efforts and specialized programs, when planned in isolation, can lead to fragmentation and gaps in health services. For example, without collaboration, a well-child clinic may be started in a community that already has a strong Early and Periodic Screening and Developmental Testing (EPSDT) program, yet community prenatal services may be nonexistent. Interprofessional collaboration is important in individualized practice, because nurses need to plan with the client, family, physician, social worker, physical therapist, teacher, or counselor, and must keep them informed of the client’s health status; however, it is a greater necessity when working with population groups, especially those from vulnerable or at-risk segments.

Effective collaboration requires team members who are strong individuals, with various areas of expertise and who can make a commitment to team goals. Community health nurses who think and act interdependently make a great contribution to the team effort. In appropriate situations, community health nurses also function autonomously, making independent judgments. Collaboration involves working with members of other professions on community advisory boards and health planning committees to develop needs assessment surveys and to contribute toward policy development efforts.

Interprofessional collaboration requires clarification of each team member’s role, a primary reason for community health nurses to understand the nature of their practice. When planning a city-wide immunization program with a community group, for example, community health nurses

need to explain the ways in which they might contribute to the program's objectives. They can offer to contact key community leaders, with whom they have established relationships, to build community acceptance of the program. They can share their knowledge of the public's preference about times and locations for the program. They can meet with various local agencies and organizations (e.g., health insurance companies, local hospitals) to gain financial support. They can help to organize and give the immunizations, and they can influence planning for follow-up programs. Another component includes development of policies to promote and protect the health of clients. This can be accomplished by meeting with local legislators and providing testimony to local, state, and national bodies in an effort to promote legislation to mandate helmets for cyclists, ban sugar-laden beverages in school vending machines, or provide funding for specific community-based programs. Collaboration is discussed further in Chapter 10.

Client participation is promoted when people serve as partners on the health care team. An aim of community health nursing is to collaborate with people, rather than do things for them. As consumers of health services are treated with respect and trust and, as a result, gain confidence and skill in self-care—promoting their own health and that of their community—their contribution to health programs becomes increasingly valuable. The consumer perspective in planning and delivering health services makes those services relevant to consumer needs. Community health nurses encourage the involvement of health care consumers by soliciting their ideas and opinions, by inviting them to participate on health boards and committees, and by finding ways to promote their participation in decisions affecting their collective health.

## Summary

Community health nursing has opportunities and challenges to keep the nurse interested and involved in a community-focused career for a lifetime. Community health is more than environmental programs and large-scale efforts to control communicable disease. It is defined as the identification of needs and the protection and improvement of collective health within a geographically defined area. To comprehend the nature and significance of community health and to clarify its meaning for the specialty practice of community health nursing, it is important to understand the concepts of community and of health.

A *community*, broadly defined, is a collection of people who share some common interest or goal. Three types were discussed in this chapter: geographic, common-interest, and health problem-solving communities. Sometimes, a community such as a neighborhood, city, or county is formed by geographic boundaries. At other times, a community may be identified by its common interest; examples are a religious community, a group of migrant workers, or citizens concerned about air pollution. A community also is defined by a pooling of efforts by people and agencies toward solving a health-related problem.

Health is an abstract concept that can be understood more clearly by examining its distinguishing features. First, people are neither sick nor well in an absolute sense but have levels of illness or wellness. These levels may be plotted along a continuum ranging from optimal health to total

disability or death. This is known as the *health continuum*. A person's state of health is dynamic, varying from day to day and even hour to hour.

Second, health is a state of being that includes all of the many characteristics of a person, family, or community, whether physical, psychological, social, or spiritual. These characteristics often indicate the degree of wellness or illness of an individual or community and suggest the presence or absence of vitality and well-being.

Third, health has both subjective and objective dimensions: the subjective involves how well people feel; the objective refers to how well they are able to function. Most often, functional performance diminishes dramatically toward the illness end of the health continuum.

Fourth, health care needs can be either continuing, as in developmental concerns that occur over a person's lifetime, or episodic, occurring unexpectedly once or twice in a lifetime. Community health nursing deals with continuing needs, whereas episodic needs are more often managed in acute care settings.

Community health practice incorporates the elements of promotion of health and prevention of health problems.

The eight important characteristics of community health practice are the client is the population, the greatest good for the greatest number of people, working with clients as equal partners, primary prevention is the priority, select strategies that create healthy environmental, social and economic conditions, reach out to all who might benefit, make optimal use of available resources, and collaborate with a variety of professions, organizations, and entities. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Identify a community of people about whom you have some knowledge. What makes it a community? What characteristics do this group of people share? Work on this activity in a group of peers or family members. Do they think as you do? Is there a difference between the views of family members and those of nursing student peers?
2. Select three populations for whom you have some concern, and place each group on the health continuum. What factors influenced your decision?
3. Describe three preventive actions (one primary, one secondary, and one tertiary) that might be taken to move each of your selected populations closer to optimal wellness.
4. Select a current health problem and identify the three levels of prevention and corresponding activities in which you as a community health nurse would engage at each level.
5. Discuss how you might implement one health-promotion effort with each of your selected populations.
6. Browse the Internet for community health nursing research articles that focus on levels of prevention. Find one focusing on each level. For those involved

in the articles focusing on secondary and tertiary prevention, what could you as a community health nurse have done to keep the clients at the primary level of prevention?

7. Place yourself on the health continuum. What factors influenced your decision?
8. Using the eight characteristics of community health nursing outlined in this chapter, give examples of how a community health nurse might demonstrate meeting each characteristic.

# 2

## History and Evolution of Community Health Nursing

### LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Describe the four stages of community health nursing's development.
- ◆ Recognize the contributions of selected nursing leaders throughout history to the advancement of community health nursing.
- ◆ Analyze the impact of societal influences on the development and practice of community health nursing.
- ◆ Explore the academic and advanced professional preparation of community health nurses.

*“Our basic idea was that the nurse’s peculiar introduction to the patient and her organic relationship with the neighborhood should constitute the starting point for a universal service to the region. . . . we considered ourselves best described by the term ‘public health nurses.’ ”*

—Lillian Wald (1867–1940), pioneer of public health nursing

### KEY TERMS

Causal thinking  
Community-based nursing  
District nursing

 You just left the home of a long-time client who is concerned about a new family who just moved into the building where she lives. The family of six lives in an apartment with barely enough room for two. After years in this neighborhood, you are well aware of the high rents charged for apartments with peeling paint, rodents, and garbage all around the buildings. Your client is concerned that the young mother looks “worn out” and coughs all the time. She said she tried to help, but the family doesn’t speak much English. She describes four young children all under the age of about 5. She’s never seen the husband, but you know that most of the men in this neighborhood leave early in the morning to try to get some day work, so you are not surprised. You assure your client that you will do what you can to help her new neighbors and thank her for being such a kind person. Thinking about how you will prepare for the visit to the family who doesn’t even expect you, your thoughts are racing. At the top of your list is trying to find someone who speaks their language; you only know a few words. You suspect without even seeing the mother what the cough means, although you hope you are wrong. Then you think about the four young children living so close together and creating so much work for a woman who isn’t well. The husband may want to help his wife more, but if he doesn’t work, they can’t get by. You wonder if he has the cough too.

As you read this scenario, what picture did you have in your mind? What language did this family speak? What disease did this young mother likely have? Now, think about when this event might have occurred. If you thought it was now, it certainly could be, but this scenario was actually set in the early 1900s. This family emigrated from Greece and hadn’t yet mastered the English language. The mother likely had consumption (the old name for tuberculosis). Because birth control information was not available to most women, she had no idea how to space out her pregnancies. The filthy and overcrowded housing, often called *tenement housing*, was typical of the time. The husband found work as he could. Few social services were available; no work, no food for the family, and no money to pay the rent. The family came to America with the hope of a new start, but what they found was in many ways worse than what they had left. At least at home in Greece, they had family and friends to count on; here, they were alone. There were others from Greece who lived nearby, but it wasn’t the same. Life was hard, and they worried most about their children, wondering what the future could hold for them.

Community health nurses in the early 20th century had to deal with many of the same issues we face today. We thought for a long time that tuberculosis was a disease of the past; now clients with multidrug-resistant strains are becoming alarmingly more common. Poverty, communicable diseases, poor housing, lack of social services, and limited access to family planning information remain as challenges to improving the health of our populations. As a community health nurse, you will be facing similar challenges to those faced by nurses of the past. History is not always exciting, but without it we often fail to see where we need to go next. The often misquoted saying by George Santayana (1863–1952), “Those who cannot remember the past are condemned to repeat it,” serves to caution us not to “forget” our heritage (Kaplin, 1992, p. 588). As you read through this chapter, think about how your practice has been shaped by the hard work of the nurses who went before.

This chapter examines the international roots of community health nursing as a specialty, exploring the historical and philosophical foundations that undergird the dynamic nature of its practice. The chapter traces community health nursing’s historical development, highlighting the contributions of several nursing leaders, and examining the global societal influences that shaped early and evolving community health nursing practice. The final section of the chapter describes the academic and advanced professional preparation required of community health nurses today. Nursing’s past influences its present, and both guide the future of community health nursing in the 21st century.

## HISTORICAL DEVELOPMENT OF COMMUNITY HEALTH NURSING

Before the nature of community health nursing can be fully grasped or its practice defined, it is necessary to understand its roots and the factors that shaped its growth over time. Community health nursing is the product of centuries of responsiveness and growth. Its practice has adapted to accommodate the needs of a changing society, yet it has always maintained its initial goal of improved community health. Community health nursing’s development, which has been influenced by changes in nursing, public health, and society, can be traced through several stages. This section examines these stages.

The history of public health nursing, since its recognized inception in Europe, and more recently in America, encompasses continuing change and adaptation (Hein, 2001). The historical record reveals a professional nursing specialty that has been on the cutting edge of innovations in public health practice and has provided leadership to public health efforts. A summary of public health nursing made in the early 1900s still holds true:

It is precisely in the field of the application of knowledge that the public health nurse has found her great opportunity and her greatest usefulness. In the nationwide campaigns for the early detection of cancer and mental disorders, for the elimination of venereal disease, for the training of new mothers, and the teaching of the principles of hygiene to young and old; in short, in all measures for the prevention of disease and the raising of health standards, no agency is more valuable than the public health nurse. (Central Hanover Bank and Trust Company, 1938, p. 8)

In tracing the development of public health nursing and, later, community health nursing, the leadership role has been clearly evident throughout its history. Nurses in this specialty have provided leadership in planning and developing programs, in shaping policy, in administration, and in the application of research to community health.

Four general stages mark the development of community health/public health nursing: (1) the early home care nursing stage, (2) the district nursing stage, (3) the public health nursing stage, and (4) the community health nursing stage. It is well worth referring to the Chapter 1 discussion of the interchangeable terms *public health nurse* and *community health nurse*. In the course of the historical evolution of this specialty, there was a definite shift in thinking about the focus of practice, resulting in the broader use of the term *community health nurse*. However, the discussion that follows is

about the practice emphasis, not the title. There are still nurses in practice who use the title public health nurse, in addition to those called community health nurses; some even use the title community/public health nurse. Whether by custom, preference, or established employment title, nurses call themselves by many professional titles. It is important to recognize that the work of the nurse is, as it always has been, to improve the health of the community.

## Early Home Care Nursing (Before Mid-1800s)

The prototype of **community-based nursing** can be seen within the historical development of home-care nursing. For many centuries, the sick were tended at home by female family members and friends. In fact, in 1837, Farrar (p. 57) reminded women, “You may be called upon at any moment to attend upon your parents, your brothers, your sisters, or your companions.” The focus of this care was to reduce suffering and promote healing.

## The Origins of Early Nursing

The early roots of home-care nursing began with religious and charitable groups. Even emergency care was provided. In 1244, a group of monks in Florence, Italy, known as the Misericordia provided first-aid care for accident victims on a 24-hour basis. Another example is the Knights Hospitallers, who were warrior monks in Western Europe. They protected and cared for pilgrims on their way to Jerusalem (“Men, monasteries, wars, and wards,” 2001). These and other men’s contributions to the early practice of nursing have been long overlooked. Further, the lack of attention to these early works “perpetuates the notion of men nurses as anomalies” (Evans, 2004, p. 321).

Medieval times saw the development of various institutions devoted to the sick, including hospitals and nursing orders. In England, the Elizabethan Poor Law, written in 1601, provided medical and nursing care to the poor and disabled. St. Frances De Sales organized the Friendly Visitor Volunteers in the early 1600s in France. This association was directed by Madame de Chantel and assisted by wealthy women who cared for the sick poor in their homes (Dolan, 1978). In Paris in 1617, St. Vincent de Paul started the Sisters of Charity, an organization composed of nuns and lay women dedicated to serving the poor and needy. The ladies and sisters, under the supervision of Mademoiselle Le Gras in 1634, promoted the goal of teaching people to help themselves as they visited the sick in their homes. In their emphasis on preparing nurses and supervising nursing care, as well as determining causes and solutions for clients’ problems, the Sisters of Charity laid a foundation for modern community health nursing (Bullough & Bullough, 1978).

Unfortunately, the years that followed these accomplishments marked a serious setback in the status of nursing and care of the sick. From the late 1600s to the mid-1800s, the social upheaval after the Reformation caused a decline in the number of religious orders, with subsequent curtailing of nursing care for the sick poor. Babies continued to be delivered at home by self-declared midwives, most of whom had little or no training. Concern over high maternal mortality rates prompted efforts to better prepare midwives and medical

students. One midwifery program was begun in Paris in 1720, and another in London by Dr. William Smellie in 1741 (Bullough & Bullough, 1978).

The Industrial Revolution created additional problems; among them were epidemics, high infant mortality, occupational diseases and injuries, and increasing mental illness in both Europe and America. Hospitals were built in larger cities, and dispensaries were developed to provide greater access to physicians. However, disease was rampant; mortality rates were high; and institutional conditions, especially in prisons, hospitals, and “asylums” for the insane, were deplorable. The sick and afflicted were kept in filthy rooms without adequate food, water, cover, or care for their physical and emotional needs (Bullough & Bullough, 1978). Reformers such as John Howard, an Englishman who investigated the spread of disease in hospitals in 1789 (Kalisch & Kalisch, 2004), revealed serious needs that would not be addressed until much later (Bullough & Bullough, 1978).

Both Catholic and Anglican religious nursing orders, although few in number, continued the work of caring for the sick poor in their homes. For example, in 1812, the Sisters of Mercy organized in Dublin to provide care for the sick at home. With the status of women at an all-time low, often only the least respectable women pursued nursing. In 1844, in his novel *Martin Chuzzlewit*, Charles Dickens (1910) portrayed the nurse Sairy Gamp as an unschooled and slovenly drunkard, reflecting society’s view of nursing at the time. It was in the midst of these deplorable conditions and in response to them that Florence Nightingale began her work.

## The Early Nightingale Years

Much of the foundation for modern community health nursing practice was laid through Florence Nightingale’s remarkable accomplishments (Figure 2.1). She has been referred to as a reformer, a reactionary, and a researcher (Palmer, 2001). Born in 1820 into a wealthy English family, her extensive travel, excellent education—including training at the first school for nurses in Kaiserwerth, Germany—and determination to serve the needy resulted in major reforms and improved status for nursing. Her work during the Crimean War (1854–1856) with the wounded in Scutari is well documented (Florence Nightingale Museum Trust, 1997; Woodham-Smith, 1951). Conditions in the military hospitals during the war were unspeakable. Thousands of sick and wounded men lay in filth, without beds, clean coverings, food, water, or laundry facilities. Florence Nightingale organized competent nursing care and established kitchens and laundries that resulted in hundreds of lives being saved. Her work further demonstrated that capable nursing intervention could prevent illness and improve the health of a population at risk—precursors to modern community health nursing practice. Her subsequent work for health reform in the military was supported by implementing another public health strategy: the use of biostatistics. Through meticulously gathered data and statistical comparisons, Miss Nightingale demonstrated that military mortality rates, even in peacetime, were double those of the civilian population because of the terrible living conditions in the barracks. This work led to important military reforms.

Miss Nightingale’s concern for populations at risk included a continuing interest in the population of the sick at

**FIGURE 2.1** Florence Nightingale’s concern for populations at risk, as well as her vision and successful efforts at health reform, provided a model for community health nursing today.

home. Her book, *Notes on Nursing: What It Is, and What It Is Not*, published in England in 1859, was written to improve nursing care in the home. It was also during this period that Nightingale clarified nursing as a woman’s occupation (Evans, 2004). This gender distinction in nursing was due more to the culture of the times than as a direct exclusion of men from the practice; it was consistent with social norms of that period.

Florence Nightingale also became a skillful lobbyist for health care reform. Her exemplary influence on English politics and policy improved the quality of existing health care and set standards for future practice. Furthermore, she demonstrated how population-focused nursing works.

In her work to help establish the first nonreligious school for nurses in 1860 at St. Thomas Hospital in London, she promoted a standard for proper education and supervision of nurses in practice, known as the Nightingale Model. Principles she wrote about in *Notes on Nursing* relate directly to her early education and the notions held by Hippocrates in ancient Greece, which she had studied for years. Specifically, her concern with the environment of patients, the need for keen observation, the focus on the whole patient rather than the disease, and the importance of assisting nature to bring about a cure all reflect Hippocrates’ teachings (Nightingale, 1859/1969; Palmer, 2001).

Another great nurse and healer in her own right was Mary Seacole (1805–1881), who has been called the “Black Nightingale.” She was the daughter of a well-respected “doctress” who practiced Creole or Afro-Caribbean medicine in Jamaica, and began helping her mother at an early age. Spending many years developing her skills, she helped populations who experienced tropical diseases, especially cholera, in Central America, Panama, and the Caribbean. She attempted, through many formal channels, to join Florence Nightingale in Scutari, but was rejected again and again. Undaunted, she went to the Crimea on her own to open a hotel for sick and convalescing soldiers,

where she met Miss Nightingale and many of the troops she had cared for in Jamaica. Many of the military commanders sought her out for her knowledge of healing, and she was affectionately known by the troops as “Mother Seacole.” After the war and into her old age, she continued to provide nursing care in London and when visiting Jamaica. She focused her caregiving among high-risk clients of the day and did so in an innovative, entrepreneurial manner unique for women, especially for women of color in the 1800s (Florence Nightingale Museum Trust, 1997).

## District Nursing (Mid-1800s to 1900)

### *Nightingale’s Continued Influence*

The next stage in the development of community health nursing was the formal organization of visiting nursing, or **district nursing**. In 1859, William Rathbone, an English philanthropist, became convinced of the value of home nursing as a result of private care given to his wife. He employed Mary Robinson, the nurse who had cared for his wife, to visit the sick poor in their homes and teach them proper hygiene to prevent illness. The need was so great that it soon became evident that more nurses were needed. In 1861, with Florence Nightingale’s help and advice, Rathbone opened a training school for nurses connected with the Royal Liverpool Infirmary and established a visiting nurse service for the sick poor in Liverpool. Florence Lees, a graduate of the Nightingale School, was appointed first Superintendent-General of the District Nursing System (Mowbray, 1997). As the service grew, visiting nurses were assigned to districts in the city—hence the name, district nursing. Subsequently, other British cities also developed district nursing training and services. An example is the Nurse Training Institution for district nurses, founded in Manchester in 1864. Privately financed, the nurses were trained and then “dispensed food and medicine” to the sick poor in their homes; they were “closely supervised by various middle and upper class women who collected the necessary supplies” (Bullough & Bullough, 1978, p. 143).

Although Florence Nightingale is best remembered for her professionalization of nursing, she had a full understanding of the need for community health nursing. This was documented in her writings and recorded conversations:

Hospitals are but an intermediate stage of civilisation. At present hospitals are the only place where the sick poor can be nursed, or, indeed often the sick rich. But the ultimate object is to nurse all sick at home. (Nightingale, 1876)

The aim of the district nurse is to give first-rate nursing to the sick poor at home. (Nightingale, 1876 [cited in Mowbray, 1997, p. 24])

The health visitor must create a new profession for women. (conversation with Frederick Verney, 1891 [cited in Mowbray, 1997, p. 25])

For years, Miss Nightingale studied the social and economic conditions of India (Nightingale, 1864). The plight of the poor and ill in India led her to become involved with Frederick Verney in a pioneering “health at home” project in England in 1892. She wrote a series of papers on the need for “home missionaries” and “health visitors,” endorsing the view that prevention was better than cure (Mowbray, 1997).

## TWENTY YEARS IN HISTORY: 1873–1893

1873	First Nightingale-model nursing school established in the U.S. at Bellevue Hospital
1877	Francis Root—First Public Health Nurse hired by the Women’s Branch of the New York Mission
1885	Visiting Nurse Association established in Buffalo, New York
1886	Visiting Nurse Associations established in Philadelphia and Boston
1893	Lillian Wald and Mary Brewster organize a visiting nurses service for the poor in New York, which would be named the Henry Street Settlement in 1906

### Home Visiting Takes Root

In the United States, the first community health nurse, Frances Root, hired by the Women’s Branch of the New York Mission in 1877, pioneered home visits to the poor in New York City. District nursing associations were founded in Buffalo in 1885, and in Boston and Philadelphia in 1886 (Display 2.1). These district associations served the sick poor exclusively, because patients with enough money had private home nursing care. However, the English model with its standards for visiting nurses’ education and practice, established in 1889 under Queen Victoria, was not followed in the United States. Instead, visiting nursing organizations sprang up in many cities without common standards or administration. Twenty-one such services existed in the United States in 1890 (Bullough & Bullough, 1978; Kalisch & Kalisch, 2004).

Although district nurses primarily cared for the sick, they also taught cleanliness and wholesome living to their patients, even during that early period. For example, the Boston program, founded by the Women’s Educational Association, “emphasized the teaching of hygiene and cleanliness, giving impetus to what was called instructive district nursing” (Bullough & Bullough, 1978, p. 144). This early emphasis on prevention and “health” nursing became one of the distinguishing features of district nursing and, later, of public health nursing as a specialty.

The work of district nurses in the United States focused mostly on the care of individuals. District nurses recorded temperatures and pulse rates and gave simple treatments to the sick poor under the immediate direction of a physician. They also instructed family members in personal hygiene, diet and healthful living habits, and the care of the sick. The problems of early home care patients in the United States were numerous and complex. Thousands of European and eastern European immigrants filled tenement housing in the poorest and most crowded slums of the large coastal cities during the late 1800s. Inadequate sanitation, unsafe and unhealthy working conditions, and language and cultural barriers added to poverty and disease. Nursing educational programs at that time did not prepare district nurses to cope with their patients’ multiple health and social problems.

The sponsorship of district nursing changed over time. Early district nursing services in both England and the United States were founded by religious organizations. Later, sponsorship shifted to private philanthropy. Funding came from contributions and, in a few instances, from fees charged to patients on an ability-to-pay basis. Finally, visiting nursing began to be supported by public money. An early example occurred in Los Angeles where, in 1897, a nurse was hired as

a city employee. Although one form of funding dominated, all three types of financing continued to exist, as they still do. Although the government was beginning to assume more responsibility for the public’s health, most district nursing services during this time remained private.

In England, the establishment of “health visitors” in poor areas of London began early in the 19th century. These health care providers enhanced the English model of health visitor/district nurse/midwife as the backbone of the primary health care system in the second half of the 1800s. “The impact of early health visiting was clearly shown by the halving of infant mortality in the areas within two years” (Beine, 1996, p. 59). The main focus of the health visitor’s work was giving advice to poor mothers and teaching hygiene to prevent infant diarrhea (Beine, 1996).

### Public Health Nursing (1900 to 1970)

By the beginning of the 20th century, district nursing had broadened its focus to include the health and welfare of the general public, not just the poor. This new emphasis was part of a broader consciousness about public health. Robert Koch’s demonstration that tuberculosis was communicable led the Johns Hopkins Hospital to hire a nurse, Reba Thelin, in 1903, to visit the homes of tuberculosis patients. Her job was to ensure that patients followed prescribed regimens of rest, fresh air, and proper diet and to prevent possible infection (Sachs, 1908). A growing sense of urgency about the interrelatedness of health conditions and the need to improve the health of all people led to an increased number of private health agencies. These agencies supplemented the often-limited work of government health departments. By 1910, new federal laws made states and communities accountable for the health of their citizens.

### Nurses Making a Difference

Three years before Reba Thelin began her work with Johns Hopkins Hospital, Jessie Sleet was hired by the Charity Organization Society’s (COS) tuberculosis committee as a temporary district nurse in New York City (Mosley, 2007). Her position called for her to visit the city’s black community, which was ravaged by the disease. Jessie Sleet had been trained at the Provident Hospital in Chicago (a hospital for black patients), which had a nurse’s training program for black women. Credited as the first black public health nurse, Ms. Sleet was not eagerly accepted by the COS membership, but they agreed in hope that she would be accepted by the black community. She was so successful in her efforts that, one year later, the society

**FIGURE 2.2** Public health nurses—uniforms and symbols. (Photograph courtesy of Visiting Nurses and Hospice of San Francisco.)

hired her as a permanent employee (Mosley, 2007). Jessie Sleet was a pioneer in early community health nursing practice and forged the way for many.

As specialized programs such as infant welfare, tuberculosis clinics, and venereal disease control were developed, there was an increased demand for nurses to work in these areas (Figure 2.2). As Bullough and Bullough commented, “Although the hospital nursing school movement emphasized the care of the sick, a small but growing number of nurses were finding employment in preventive health care” (1978, p. 143). In 1900, there were an estimated 200 public health nurses. By 1912, that number had grown to 3,000 (Gardner, 1936). “This development was important: it brought health care and health teaching to the public, gave nurses an opportunity for more independent work, and helped to improve nursing education” (Bullough & Bullough, 1978, p. 143).

The role of the district nurse expanded during this stage. Lillian D. Wald (1867–1940), a leading figure in this expansion, first used the term *public health nursing* to describe this specialty (Bullough & Bullough, 1978). District nurses, while caring for the sick, had pioneered in health teaching, disease prevention, and promotion of good health practices. Now, with a growing recognition of familial and environmental influences on health, public health nurses broadened their practice even more. Nurses working outside of the hospital increased their knowledge and skills in specialized areas such as tuberculosis, maternal and child health, school health, and mental disorders.

Lillian Wald’s contributions to public health nursing were enormous. A graduate of the New York Hospital Training School, she started teaching home nursing but quickly

changed to a career of social reform and nursing activism (Christy, 1970). Appalled by the conditions of an immigrant neighborhood in New York’s Lower East Side, she and a nurse-friend, Mary Brewster, started the Henry Street Settlement in 1893 to provide nursing and welfare services. Her books, *The House on Henry Street* (1915) and *Windows of Henry Street* (1934), portray her work and views on public health nursing. Nursing visits conducted through her organization were supervised by nurses, in contrast to earlier models, in which nursing services were administered by lay boards and actual care was supervised by lay persons. It was during these early years that Wald asked Jessie Sleet to recommend another black nurse for service at the settlement (Mosley, 2007). Miss Sleet recommended her schoolmate Miss Elizabeth Tyler, a graduate of the Freedmen’s Hospital Training School for Nurses (Washington, D.C.). In 1906, Miss Tyler became the first black nurse hired at the Henry Street Settlement; she would not be the last. This was no small event in the progress of public health nursing and was a clear demonstration of Miss Wald’s commitment to social change.

### **Wald’s Growing Influence**

The work done at the Henry Street Settlement showed clearly that nursing could reduce illness-caused employee absenteeism. She demonstrated this in her early work with the city of New York. She would use this success to address the issue of childhood illness and school absenteeism (Bullough & Bullough, 1978). In the early 1900s, approximately 15 to 20 children per day were sent home from each school in New York City for health-related reasons. Wald suggested that

## DISPLAY 2.2

## TWENTY YEARS IN HISTORY: 1909–1929

1909	Metropolitan Life Insurance Company provided first insurance reimbursement for visiting nursing care
1910	Public Health Nursing program instituted at Teacher's College, Columbia University
1912	National Organization for Public Health Nursing formed, with Lillian Wald as first President
1917	U.S. entry into World War I 18th Amendment passed by Congress (Prohibition)
1918	U.S. Public Health Service establishes Division of Public Health Nursing to aid the war effort World War I Armistice World-wide influenza epidemic begins
1919	19th Amendment passed by Congress (Vote)
1920	Women vote for the first time in a presidential election
1921	Margaret Sanger founds the American Birth Control League to distribute birth control information Bureau of Indian Affairs Health Division created (later to become the Indian Health Service)
1925	Frontier Nursing Service established
1929	Stock Market Crash

placing nurses in the schools would allow for follow-up on recurring cases and home visits during the periods of exclusion. She argued that the nurses could supplement the work done by local physicians, who occasionally examined the children. Offering the services of one nurse for 1 month, Wald hoped to demonstrate how effective a school nurse could be. The work done by this first school nurse, Lina Rogers, was a resounding success (Kalisch & Kalisch, 2004). One year after this initial experiment, the number of children sent home from the New York City schools had dropped dramatically. By September 1903, only 1,101 children needed to be excluded (compared with 10,567 one year earlier); a nearly 10-fold reduction. As a result, the New York Board of Health hired dozens of nurses to work at the schools.

Just 6 years after her efforts with the New York City schools, Wald embarked on another visionary path. In 1909,

she convinced the Metropolitan Life Insurance Company that nurse intervention could reduce death rates (Hamilton, 2007). In collaboration with the Henry Street Settlement, the company organized the Visiting Nurse Department and provided services to policy holders in a section of Manhattan (Display 2.2). The success of this program resulted in expansion to other parts of the city and to 12 other eastern cities within 1 year. By 1912, the company had organized 589 Metropolitan nursing centers and, when possible, contracted with local Visiting Nurses Associations, although they also hired their own nurses (Kalisch & Kalisch, 2004).

The legendary accomplishments of Lillian Wald reflect her driving commitment to serve needy populations. Through her efforts, the New York City Bureau of Child Hygiene was formed in 1908, and the Children's Bureau at the federal level in 1912 (Figure 2.3). Wald's emphasis on illness prevention

**FIGURE 2.3** Examination of infants was part of early health department programs in which district nurses played a major role.

and health promotion through health teaching and nursing intervention, as well as her use of epidemiologic methodology, established these actions as hallmarks of public health nursing practice. She promoted rural nursing and family-focused nursing, and encouraged improved coursework at the Teachers College of Columbia University (New York) to prepare public health nurses for practice. Through her work and influence with the legislature to establish health and social policies, improvements were made in child labor and pure food laws, tenement housing, parks, city recreation centers, immigrant handling, and teaching of mentally handicapped children. In 1912, she helped to found and was first president of the National Organization for Public Health Nursing (NOPHN), an organization that set standards and guided public health nursing's further development and impact on public health (Christy, 1970). Her exemplary accomplishments truly reflect a concern for populations at risk. They further demonstrate how nursing leadership, involvement in policy formation, and use of epidemiology led to improved health for the public.

### Another Nurse—Another Problem

During the same period that Lillian Wald and her contemporaries were working to alleviate the suffering caused by disease and poverty, another nurse, Margaret Sanger, began a different battle. Sanger, who was born in 1879, had seen her own mother die at the age of 48 after a long struggle with tuberculosis. Her 18 pregnancies undoubtedly contributed to her both contracting the disease and eventually succumbing to it. After her mother's death, she was accepted at White Plains Hospital as a nursing probationer (Ruffing-Rahal, 1986). Later, as a visiting nurse Sanger was prevented by the Comstock Act of 1873 from providing any information on contraception to the women she cared for (Draper, 2006). She knew, as did many at the time, that the affluent and educated in American society were the only ones to have reliable contraception. Even discussing the topic was prohibited, placing increased pressure on the poor and uneducated women who were most in need of this basic information. In 1912, Sanger watched helplessly as a 28-year-old mother of three died from abortion-induced septicemia. "A few months earlier, during a similar crisis, this woman had begged Sanger for the 'secret' of preventing future pregnancy" (Ruffing-Rahal, 1986, pp. 247–248). In 1916, Sanger openly offered birth control information in the Brownsville section of Brooklyn. Ten days after opening the

first birth control clinic in America, Sanger was arrested and the clinic was closed. This was not the first nor would it be her last encounter with the legal system. Her open defiance of a law that she saw as unjust eventually resulted in the formation of the International Planned Parenthood Federation.

### The Profession Evolves

By the 1920s, public health nursing was acquiring a more professional stature, in contrast to its earlier association with charity. Nursing as a whole was gaining professional status as a science, in addition to being an art. National nursing organizations began to form during this stage and contributed to nursing's professional growth. The first of these emphasized establishing educational standards for nursing. Called the American Society of Superintendents of Training Schools for Nurses in the United States and Canada, it was started by Isabel Hampton Robb in 1893, and later became known as the National League of Nursing Education in 1912. This was the forerunner of the National League for Nursing (NLN), which was established in 1952 (Ellis & Hartley, 2000). In 1890, a meeting of nursing leaders at the World's Fair in Chicago initiated an alumnae organization of 10 schools of nursing to form the National Associated Alumnae of the United States and Canada in 1896, which was created to promote nursing education and practice standards. In 1899, the group was renamed the Nurses' Associated Alumnae of the United States and Canada. Canada was excluded from the title in 1901, because New York, where the organization was incorporated, did not allow representation from two countries. In 1911, the organization went through a final name change to the American Nurses' Association (ANA), while Canadian nurses formed their own nursing organization (Ellis & Hartley, 2000). The previously mentioned NOPHN, founded by Lillian Wald and Mary Gardner, merged with the NLN in 1952. These three organizations, in particular, strengthened ties between nursing groups and improved nursing education and practice.

As nursing education became increasingly rigorous, collegiate programs began to include public health as essential content in basic nursing curricula. The first collegiate program with public health content to be accredited by the NLN began in 1944 (National Organization for Public Health Nursing, 1944) (Display 2.3). Previously, only postgraduate courses in public health nursing had been offered for nurses

#### DISPLAY 2.3

#### TWENTY YEARS IN HISTORY: 1933–1953

1933	18th Amendment repealed (Prohibition)
1935	Passage of Social Security Act
1937	Birth control information legal in all but two states (Massachusetts and Connecticut)
1941	U.S. entry into World War II
1943	Division of Nursing established at Public Health Service

1945	World War II ends
1946	Hill-Burton Act approved Communicable Disease Center established; forerunner of the Centers for Disease Control and Prevention
1950	U.S. involvement in Korean Conflict
1953	U.S. withdrawal from Korea

choosing this specialty. The first such course had been developed by Adelaide Nutting in 1912, at Teachers College in New York, in affiliation with the Henry Street Settlement. A group of agencies met in 1946 to establish guidelines for public health nursing, and by 1963, public health content was required for NLN accreditation in all baccalaureate nursing programs. The nurse practitioner (NP) movement, starting in 1965 at the University of Colorado, was initially a part of public health nursing and emphasized primary health care to rural and underserved populations. The number of educational programs to prepare NPs increased, with some NPs continuing in public health and others moving into different clinical areas.

During this period, as a result of the influence of Lillian Wald and other nursing leaders, the family began to emerge as a unit of service (Figure 2.4). The multiple problems faced by many families impelled a trend toward nursing care generalized enough to meet diverse needs and provide holistic services. Public health nurses gradually gained more autonomy in such areas as home care and instruction of good health practices to families and community groups. Their collaborative relationships with other community health providers grew as the need to avoid gaps and duplication of services became apparent. Public health nurses also began keeping better records of their services.

Industrial nursing, another form of public health nursing, also expanded during this period. The first known industrial nurse, Philippa Flowerday Reid, was hired in Norwich, England, by J. and J. Colmans in 1878. Her job was to assist the company physician and to visit sick employees and their families in their homes. In the United States, the Vermont Marble Company was first to begin a nursing service in 1895; other companies followed soon after. By 1910, 66 firms in the United States employed nurses. During World War I, the number of industrial nurses greatly increased with the recognition that nursing service reduced worker absenteeism (Bullough & Bullough, 1978). Early industrial nursing was the

forerunner of modern occupational and environmental health nursing.

During this stage, the institutional base for much of public health nursing shifted to the government. By 1955, 72% of the counties in the continental United States had local health departments. Public health nursing constituted the major portion of these local health services and emphasized health promotion, as well as care for the ill at home (Scutchfield & Keck, 2003). Some of the district nursing services, known as *visiting nurse associations* (VNAs), remained privately funded and administered, offering their own home nursing care. In some places, city or county health departments joined administratively and financially with VNAs to provide a combination of services, such as home care of the sick and health promotion to families.

Rural public health nursing, which had already been organized around 1900 in Great Britain, Germany, and Canada, also expanded in the United States (see Chapter 29). Initially, starting in 1912, rural nursing was privately financed and largely administered through the Red Cross and the Metropolitan Life Insurance Company, but responsibility had shifted to the government by the 1940s (Bullough & Bullough, 1978). An innovative example of rural nursing was the Frontier Nursing Service, which was started by Mary Breckenridge (1881–1965) in 1925, to serve mountain families in Kentucky. From six outposts, nurses on horseback visited remote families to deliver babies and provide food and nursing services. Over the years, the service has expanded to provide medical, dental, and nursing care. The Frontier Nursing Service continues today, with its remarkable accomplishments of reducing mortality rates and promoting health among this disadvantaged population, as the parent holding company for the Frontier School of Midwifery and Family Nursing. It is the largest nurse-midwifery program in the United States. In addition, Mary Breckinridge Healthcare, Inc. consists of a home health agency, two outpost clinics,

**FIGURE 2.4** The public health nurse, carrying her bag of equipment and supplies, makes regular home visits to provide physical and psychological care, as well as health lessons to families.

one primary care clinic, and the Kate Ireland Women's Healthcare Clinic (Simpson, 2000).

The public health nursing stage was characterized by service to the public, with the family targeted as a primary unit of care. Official health agencies, which placed greater emphasis on disease prevention and health promotion, provided the chief institutional base.

## Community Health Nursing (1970 to the Present)

The emergence of the term *community health nursing* heralded a new era. By the late 1960s and early 1970s, while public health nurses continued their work, many other nurses who were not necessarily practicing public health were based in the community. Their practice settings included community-based clinics, doctors' offices, work sites, and schools. To provide a label that encompassed all nurses in the community, the ANA and others called them community health nurses.

This term was not universally accepted, however, and many people—including nurses and the general public—had difficulty distinguishing community health nursing from public health nursing. For example, nursing education, recognizing the importance of public health content, required course work in public health for all baccalaureate students. This meant that graduates were expected to incorporate public health principles such as health promotion and disease prevention into nursing practice, regardless of their sphere of service. Consequently, some questioned whether public health nursing retained any unique content. Although leaders such as Carolyn Williams clearly stated that community health nursing's specialized contribution lay in its focus on populations (Williams, 1977), this concept did not appear to be widely understood or practiced.

To distinguish the domains of community and public health nursing, in 1984, the U.S. Department of Health and Human Services, Bureau of Health Professionals, Division of Nursing, convened a Consensus Conference on the Essentials of Public Health Nursing Practice and Education in Washington, D.C. (U.S. Department of Health and Human Services [USDHHS], Division of Nursing, 1984). This group concluded that *community health nursing* was the broader term, referring to all nurses practicing in the community, regardless of their educational preparation. *Public health nursing*, viewed as a part of community health nursing, was described as a generalist practice for nurses prepared with basic public health content at the baccalaureate level and a specialized practice for nurses prepared in public health at the masters level or beyond.

Confusion also arose regarding the question of whether community health nursing is a generalized or a specialized practice. Graduates from baccalaureate nursing programs were inadequately prepared to practice in public health; their education had emphasized individualized and direct clinical care and provided little understanding of applications to populations and communities. By the mid-1970s, various community health nursing leaders had identified knowledge and skills needed for more effective community health nursing practice (Roberts & Freeman, 1973). These leaders valued promoting the health of the community, but both education and practice continued to emphasize direct clinical care to individuals, families, and groups in the community (de Tornay, 1980). Reflecting this view, the ANA's Division of Community Health Nursing developed *A Conceptual Model of Community Health*

*Nursing* in 1980. This document distinguished generalized community health nursing preparation at the baccalaureate level and specialized community health nursing preparation at the masters or postgraduate level. The generalist was described as one who provides nursing service to individuals and groups of clients while keeping "the community perspective in mind" (American Nurses Association, 1980, p. 9).

Finally, confusion also arose regarding the changing roles and functions of community health nurses. Accelerated changes in health care organization and financing, technology, and social issues made increasing demands on community health nurses to adapt to new patterns of practice. Many new kinds of community health services appeared. Hospital-based programs reached into the community. Private agencies proliferated, offering home care and other community-based services. Other community health professionals assumed responsibilities that traditionally had been the domain of public health nursing. For example, some school counselors in Oregon began coordinating home visits previously done by school nurses, and health educators (who were part of a more recently developed discipline) took over large segments of client education. Social workers, too, provided services that overlapped with community health nursing roles. Health educators, counselors, social workers, epidemiologists, and nutritionists working in community health came prepared with different backgrounds and emphases in their practice. Their contributions were and still are important. Their presence, however, forced community health nurses to reexamine their own contribution to the public's health and incorporate stronger interdisciplinary and collaborative approaches into their practice (see Levels of Prevention Pyramid).

The debate over these areas of confusion continued through the 1980s, and some issues are yet unresolved. Still, the direction in which public health and community health nursing must move remains clear: to care *for*, not simply *in*, the community. Public health nursing continues to mean the synthesis of nursing and the public health sciences applied to promoting and protecting the health of populations. Community health nursing, for some, refers more broadly to nursing in the community. In this text, the term *community health nursing* is used synonymously with *public health nursing* and refers to specialized, population-focused nursing practice, which applies public health science and nursing science. A possible distinction between the two terms might be to view community health nursing as a beginning level of specialization and public health nursing as an advanced level. Clarification and consensus on the meaning of these terms help to avoid misconceptions and misuse, and are explored more fully in Chapter 3. Whichever term is used to describe this specialty, the fundamental issues and defining criteria remain the same: (1) Are populations and communities the target of practice? and (2) Are the nurses prepared in public health and engaging in public health practice?

As community health nursing continues to evolve, many signs of positive growth are evident. Community health nurses are carving out new roles for themselves in primary health care. Collaboration and interdisciplinary teamwork are recognized as crucial to effective community nursing. Practitioners work through many kinds of agencies and institutions, such as senior citizen centers, ambulatory services, mental health clinics, and family planning programs. Community needs assessment, documentation of nursing outcomes, program evaluation, quality improvement, public

## LEVELS OF PREVENTION PYRAMID

**GOAL:** Clarify and enhance the community health nurse's role to promote impact.

### Tertiary Prevention

- Promote increasing influence of the nurse through an expanded role in service delivery
- Minimize the impact of community misunderstandings of the nurse's role through education

### Secondary Prevention

- Promote aggregate-level interventions
- Foster nurse involvement on community boards and other political groups

### Primary Prevention

- Participate in policy formation
- Be politically active
- Assist in acquiring funding for community health programs
- Conduct research on health and nursing outcomes to enhance evidenced-based practice
- Collaborate with the news media to publicize current public health issues

policy formulation, and community nursing research are high priorities. This field of nursing is assuming responsibility as a full professional partner in community health.

Internationally, community nursing services are well established in England, Scandinavia, the Netherlands, and Australia. Services, however, are relatively underdeveloped in France and Ireland. Furthermore, relatively few professional nurses are working in the community in central and eastern Europe and in the former Union of Soviet Socialist Republics (USSR). Ivanov and Paganpegara (2003) note that changes have occurred in nursing education subsequent to the collapse of the Soviet Union, but they have not included content in public health nursing. Moreover, the concepts of health promotion and health education are not well understood, with the vast majority of health care provided at the tertiary level. It is concerning that modernization in many countries has not included expansion of public health services in general and community health nursing more specifically. In many of the most populated regions of the world—such as China, Africa,

and India—volunteers, lay providers, and paraprofessionals provide the bulk of community health services.

In 1978, a joint World Health Organization (WHO) and the United Nations Children's Fund International Conference in Alma-Ata, in the Soviet Union, adopted a declaration on primary health care as the key to attaining the goal of health for all by the year 2000. At this conference, delegations from 134 governments agreed to incorporate the concepts and principles of primary health care in their health care systems to reach this goal (WHO, 1978, 1998). This was adopted by the World Health Assembly and endorsed by the United Nations General Assembly in 1981. On paper, at least, everyone acknowledged the crucial need for nurses to be involved in reaching this goal. In practice, support has not been forthcoming in many countries. Policy makers and the public still need to be educated to realize that nursing's most effective contributions to the overall health of the population are based in the community.

Table 2.1 summarizes the most important changes that have occurred during community health nursing's four stages

**TABLE 2.1** Development of Community Health Nursing

Stages	Focus	Nursing Orientation	Service Emphasis	Institutional Base (Agencies)
Early home care (Before mid-1800s)	Sick poor	Individuals	Curative	Lay and religious orders
District nursing (1860–1900)	Sick poor	Individuals	Curative; beginning of preventive	Voluntary; some government
Public health nursing (1900–1970)	Needy public	Families	Curative; preventive	Government; some voluntary
Emergence of community health nursing (1970–present)	Total community	Populations	Health promotion; illness prevention	Many kinds; some independent practice

of development. It shows these changes in terms of focus, nursing orientation, service emphasis, and institutional base.

## SOCIETAL INFLUENCES ON THE DEVELOPMENT OF COMMUNITY HEALTH NURSING

Many factors have influenced the growth of community health nursing. To better understand the nature of this field, the forces that began and continue to shape its development must be recognized. Six are particularly significant: advanced technology, progress in causal thinking, changes in education, demographic changes and the role of women, the consumer movement, and economic factors.

### Advanced Technology

Advanced technology has contributed in many ways to shaping the practice of community health nursing. For example, technologic innovation has greatly improved health care, nutrition, and lifestyle and has caused a concomitant increase in life expectancy. Consequently, community health nurses direct an increasing share of their effort toward meeting the needs of the elderly population and addressing chronic conditions. The advances in technology in the home can be life-altering. For example, homebound elders, disabled persons, and their caregivers found a new sense of camaraderie and friendship through use of a grant-sponsored website with discussion groups and a listserv (Bradley & Poppen, 2003). After 1 year, these individuals expressed increased satisfaction with the amount of contact with others, thus supporting the use of online access for isolated persons.

Online access to health information can provide a critical link to information for all elderly persons, but it is important to recognize that not all websites are reputable. An increasing number of online websites catering to the elderly provide inaccurate information and, in some cases, are designed to defraud (Moore, 2005) or possibly harm those who access the website. It is critical for the community health nurse to check carefully any websites that are recommended for clients. It is important for clients to access only reputable sites and participate in discussion groups that utilize a facilitator or moderator (Moore, 2005).

Advanced technology has been a strong force behind industrialization, large-scale employment, and urbanization. We are now primarily an urban society, with approximately 75% of the world's population living in urban or suburban areas. Population density leads to many health-related problems, particularly the spread of disease and increased stress. Community health nurses are learning how to combat these urban health problems. In addition, changes in transportation and high job mobility have affected the health scene. As people travel and relocate, they are separated from families and traditional support systems; community health nurses design programs to help urban populations cope with the accompanying stress. New products, equipment, methods, and energy sources in industry have also increased environmental pollution and industrial hazards. Community health nurses have become involved in related research, occupational health, and preventive education. Technologic innovation has promoted complex medical diagnostic and treatment procedures, making illness-oriented care more dramatic and desirable, as well

as more costly. Community health nurses face a challenge to demonstrate the physical and economic value of technology for wellness-oriented care.

Finally, innovations in communications and computer technology have shifted America from an industrial society to an "information economy." Our economy is built on information—the production and marketing of knowledge—making it global and active around-the-clock. Community health nurses now are in the business of information distribution, and they use computer technologies to enhance the efficiency and effectiveness of their services. Geographic Information Systems (GIS) is an example of emerging computer technology that the community health nurse can use to design and evaluate population-focused programs (Caley, 2004). GIS technology can be a valuable tool for many purposes, including examining health disparities and outbreaks of disease and for determining health priorities within a community (Riner, Cunningham, & Johnson, 2004). Telenursing, telehealth, and nursing informatics are part of our professional activities as community health nurses. We communicate by e-mail, use computer-based applications to enhance education among peers and with clients, and comfortably use the computers that are found in all areas where nurses function (Saba, 2001). As we move deeper into the 21st century, we move to "mobile care," using handheld, wireless technology tools that are nurse-friendly and compatible with the nurse's role. We have the ability to "tele-visit" our clients, and we regularly use smaller and smaller laptop computers for video conferencing (Saba, 2001). We even have the ability to take a "bird's-eye" view of the distribution of service providers and chronic disease clusters in a community through the use of GIS technology. Access to information is increasing, and the use of the information is limitless. The emerging difficulty is how to manage the sheer volume of information and still meet the needs of our communities.

### Progress in Causal Thinking

Relating disease or illness to its cause is known as **causal thinking** in the health sciences. Progress in the study of causality, particularly in epidemiology, has significantly affected the nature of community health nursing (Fos & Fine, 2000; Thomas & Weber, 2001). The *germ theory* of disease causation, established in the late 1800s, was the first real breakthrough in control of communicable disease. At that time, it was established that disease could be spread or transmitted from patient to patient or from nurse to patient by contaminated hands or equipment. Nurses incorporated the teaching of cleanliness and personal hygiene into basic nursing care.

A second advance in causal thinking was initiated by the tripartite view that called attention to the interactions among a causative agent, a susceptible host, and the environment. This information offered community health nurses new ways to control and prevent health disorders. For example, nurses could decrease the vulnerability of individuals (hosts) by teaching them healthier lifestyles. They could instigate measles vaccination programs as a means of preventing the organism (agent) from infecting children. They could promote proper disinfection of a neighborhood swimming pool (environment) to prevent disease.

Further progress in causal thinking led to the recognition that not just one single agent, but many factors—a multiple causation approach—contribute to a disease or health disorder. A food poisoning outbreak that is associated with a restaurant might be caused not only by the *Salmonella* organism but also by improper food handling and storage, lack of adherence to minimum food preparation standards, and lack of adequate health department supervision and enforcement (see Chapter 7). A chronic condition such as coronary heart disease can be related to other kinds of multicausal factors, such as heredity, diet, lack of exercise, smoking, and personal and work stress.

Community health nurses can control health problems by examining all possible causes and then attacking strategic causal points. Efforts to prevent acquired immunodeficiency syndrome (AIDS) provide a dramatic case in point. Contact reporting, condom use, protection of health workers serving patients infected with the human immunodeficiency virus (HIV), screening for HIV infection, and public education about AIDS are examples of a multifaceted approach.

Current causal thinking has led to a broader awareness of unhealthy conditions; in addition to disease, problems such as accidents and environmental pollution are major targets of concern. Work-related stress, environmental hazards, chemical food additives, and alcohol and nicotine consumption during pregnancy are all examples of concerns in community health nursing practice.

Nursing's contribution to public health adds a further application to causal thinking. That is, nursing seeks to identify and implement the causes, or contributing factors, of wellness. Community health nurses do more than prevent illness; they seek to promote health. By conducting research and applying research findings, community health nurses promote health-enhancing behaviors. Nurses promote healthier lifestyle practices such as eating low-fat diets, exercising, and maintaining social support systems; promote healthy conditions in schools and work sites; and design meaningful activities for adolescents and the elderly.

## Changes in Education

Changes in education, especially those in nursing education, have had an important influence on community health nursing practice. Education, once an opportunity for a privileged few, has become widely available; it is now considered a basic right and a necessity for a vital society. When people's understanding of their environment grows, an increased understanding of health usually is involved. For the community health nurse, health teaching has steadily assumed greater importance in practice. For the learner, education has led to more responsibility. As a result, people believe that they have a right to know and question the reasons behind the care they receive. Community health nurses have shifted from planning for clients to collaborating with clients.

Education has had other effects. Scientific inquiry, considered basic to progress, has created a dramatic increase in knowledge. The wealth of information relevant to community health nursing practice means that nursing students have more content to assimilate, and practicing community health nurses have to make greater efforts to keep abreast of knowledge in their field. In contrast to earlier times, when nurses were trained to work as apprentices in hospitals or health

agencies and to follow orders perfunctorily, today's educational programs, including continuing education, prepare nurses to think for themselves in the application of theory to practice. Community health nursing has always required a fair measure of independent thinking and self-reliance; now, community health nurses need skills in such areas as population assessment, policy making, political advocacy, research, management, collaborative functioning, and critical thinking. As the result of expanding education, community health nurses have had to reexamine their practice, sharpen their knowledge and skills, and clarify their roles.

## Demographic Changes and the Role of Women

The changing demographics in the United States and the changing role of women have profoundly affected community health nursing. In the 20th century, the Women's Rights movement made considerable progress; women achieved the right to vote and gained greater economic independence by moving into the labor force. Today, 145 million people are employed in the United States, 46.6% of whom are female. In the decade between 1998 and 2008, the number of women in the labor force will likely increase by 15%, compared with 10% for men. In the same decade, the percentage of workers aged 45 years or older will increase from 33% to 40% of the workforce (USDHHS, 2004).

Women nurses are aging in a predominantly female profession. In 1996, the average age of a registered nurse was 42.3 years. By 2004, the average age had increased to 46.8 years. Looking back just 25 years, a dramatic shift has occurred in the ratio of younger to older registered nurses. In 1980, 40.5% of registered nurses were under the age of 35. By 2004, only 16.6% of registered nurses fit into that demographic age group (USDHHS, 2004). Although most nursing schools remain full and many have a waiting list, the number of nurses staying active in their profession is dwindling. Those remaining in the profession are "graying" and retiring. Added to this is the aging population of nursing faculty, which raises concern over meeting the increased demand for nurses in the coming decade.

Salaries for nurses compare favorably with those for other workers who have four years of education in fields other than health care, such as education, human services (social work), and business. When compared with other workers in the health care field, however, nurses make a lower salary. For example, among the 2,368,070 practicing registered nurses in the United States in 2005, the average salary was \$56,880. In comparison, the average salary for physical therapists was \$65,350; for dental hygienists, it was \$60,620, and for occupational therapists, it was \$59,100 (U.S. Department of Labor, 2006).

Changing demographics, such as shifting patterns in immigration, varying numbers of births and deaths, and a rapidly increasing population of elderly persons, affect community health nursing planning and programming efforts. Monitoring these changes is essential for relevant and effective nursing services. Equally important is a diverse and representative workforce in nursing. The 2004 findings of the National Sample Survey of Registered Nurses indicated that the vast majority of nurses (81.8%) specifying a racial background selected White (non-Hispanic). With 7.5% of nurses not specifying a racial background, that left 10.6% in one or

more of the groups identified in the survey. Because of a change in the form of questioning, these figures are difficult to compare with earlier surveys. It is concerning, however, that in 2000, 12.3% of the registered nurses identified themselves as being non-White, whereas the 2004 estimate was only 10.6%; clearly, this is a move in the wrong direction if the 2004 estimate is correct. The 2004 data also showed the racial background of the nurses surveyed to be 4.6% Black/African American; 3.3% Asian/Pacific Islander; 1.8% Hispanic; 0.4% American Indian/Alaskan Native; and a further 1.5% indicated two or more racial backgrounds (USDHHS, 2004). Increased racial and ethnic representation in community health nursing is essential and remains one of the major challenges facing the profession in the coming years.

Although the diversity of career options and employment opportunities for women has been a positive social factor, these gains have decreased the number of women entering nursing. As a profession, nursing's contributions and status have improved, but its ability to compete with careers offering higher pay and status remains problematic. Changes resulting from the women's movement continue. Nurses still struggle for equality—equality of recognition, respect, and autonomy, as well as job selection, equal pay for equal work, and equal opportunity for advancement in the health field. If community health nurses are to influence the field of community health, they need status and authority equal to that of their colleagues. This step requires nurses to demonstrate their competence and learn to be assertive in assuming roles as full professional partners. It is worth noting that, in 2002, men held more than one-third of the nursing administrative positions (U.S. Department of Labor, 2002). This is significant because, in that same year, men represented only 5.4% of the total registered nurse population. Despite efforts to recruit more men into nursing, the 2004 data suggest only minimal improvement to 5.7% of registered nurses (RNs) (USDHHS, 2004). The high proportion of leadership positions held by the men may in part reflect a larger proportion of women in nursing who have less than full-time careers. The women's movement has contributed to community health nursing's gains in assuming leadership roles, but a need for greater influence and involvement remains for all nurses.

## Consumer Movement

The consumer movement also has affected the nature of community health nursing. Consumers have become more aggressive in demanding quality services and goods; they assert their right to be informed about goods and services and to participate in decisions that affect them regardless of

sex, race, or socioeconomic level. This movement has stimulated some basic changes in the philosophy of community health nursing. Health care consumers are viewed as active members of the health team rather than as passive recipients of care. They may contract with the community health nurse for family care or group services, represent the community on the local health board, or act as ombudsmen by serving as representatives or advocates for their community constituents (e.g., to investigate complaints and report findings to protect the quality of care in a local nursing home). This assumption of consumers' responsibility for their own health means that the community health nurse often supplements clients' services, rather than primarily supervising them.

The consumer movement has also contributed to increased concern for the quality of health services, including a demand for more humane, personalized health care. Dissatisfied with fragmented services offered by an array of health workers, consumers seek more comprehensive, coordinated care. For example, senior citizens in a high-rise apartment building need more than a series of social workers, nutritionists, recreational therapists, nurses, and other callers ascertaining a variety of specific needs and starting a variety of separate programs. Community health nurses seek to provide holistic care by collaborating with others to offer more coordinated, comprehensive, and personalized services—a case-management approach. One example of the current attention given to the opinions of consumers is exemplified by the 2005 Gallup Poll discussed in Display 2.4. In this poll, nurses are the most highly rated profession with respect to honesty and ethics; not a bad position to be in.

## Economic Forces

Myriad economic forces have affected the practice of community health nursing. Unemployment and the rising cost of living, combined with mounting health care costs, have resulted in numerous people carrying little or no health insurance. With limited or no access to needed health services, these populations are especially vulnerable to health problems and further economic stress. Other economic forces affecting community health nursing are changing health care financing patterns (including prospective payment and diagnosis-related groups); decreased federal, state, and local subsidies of public health programs; pressures for health care cost containment through managed care; and increased competition and managed competition among providers of health services (see Chapter 6).

Global economic forces also influence community health nursing practice. As the United States experiences

### DISPLAY 2.4

## NURSES RANK HIGH IN HONESTY AND ETHICAL STANDARDS

Nurses are again at the top of the list, according to a Gallup Poll taken in 2005. When asked how they would rate the honesty and ethical standards of members of various professions, Americans rated nurses highest. Each year, a random sample of Americans are asked to rate select professions on a five-point scale ranging from “very high” to “very low.” Since being added to the list in 1999, nurses have been at the top of the list each year except 2001, when firefighters took the #1 spot (“Nurses Top

List,” 2006). Here are the results for the top scoring professions:

- Nurses 82%
- Pharmacists 67%
- Medical Doctors 65%
- High School Teachers 64%
- Policemen 61%
- Clergy 54%

increasing interdependence with foreign countries for trade, investment, and production of goods, the population has experienced a growing mobility and increased immigration, particularly among Hispanic and Asian groups. Under these conditions, the spread of communicable diseases poses a serious threat, as do problems associated with unemployment and poverty. Furthermore, the fastest-growing sector of the job market is in technical fields, which require new or retrained workers, and these jobs frequently are accompanied by health problems related to the stresses of ever-changing technology and financial and competitive pressures to produce.

Community health nursing has responded to these economic forces in several ways. One is by assuming new roles, such as health educators in industry or case managers for government and privately sponsored programs for the elderly. Another is by directly competing with other community health service providers, particularly in such areas as ambulatory care or home care. Still another is by developing new programs and service emphases. Elder day care, respite care, senior fall-prevention programs, teen pregnancy and drug prevention projects, and programs for the homeless are a few examples of the response by community health nursing to the changing community needs created by demographic and economic forces. Yet another community health nursing response has been to develop new revenue-generating services, such as workplace wellness or health screening programs, to augment depleted budgets.

Economic factors continue to play a significant role in shaping community health nursing practice. Limited dollars for health promotion services and a continued need for home care have drawn some public health agencies into more illness-oriented rather than wellness-oriented services. Yet, community health nurses continue to be resourceful in finding ways to foster the community's optimal health while adapting to changing economic conditions.

## PREPARATION FOR COMMUNITY HEALTH NURSING

The demands of community health nursing practice are significant, as described in Chapter 1, and are elaborated elsewhere in this textbook. The daily routine of the community health nurse may include organizing a flu clinic for seniors in the community, making home visits, giving a presentation on playground safety at a parent–teacher meeting, participating in a team meeting in the health department office, answering telephone calls, and charting. All of the skills learned in a basic baccalaureate nursing program are needed to effectively manage this type of day. Furthermore, this day may not represent the bigger picture of the community health nurse's role in community advisory panels, grant writing for new programs, or participation in or presentation of in-service programs. Academic preparation for this role is necessary, as is continuous professional development, and this training must meet the requirements of both employers and, in many instances, state regulations.

### Academic Preparation

The minimum preparation for community health nurses in many states has been graduation from a baccalaureate-level nursing program, a nursing major built on 2 years of liberal arts and sciences courses (Ellis & Hartley, 2000). This can be

achieved in a variety of ways. Some students enter a baccalaureate program as their initial higher educational experience after high school or later. Others complete an associate degree program in nursing and continue on to a university to receive the baccalaureate degree. This requires additional courses in liberal arts and sciences, along with selected nursing courses, usually one or more courses in public health nursing, nursing research, and leadership-management courses. In some programs designed to extend an RN to a Bachelor of Science in Nursing (BSN), nurses with years of experience in acute care nursing can “challenge” the previously mentioned courses by taking a test to demonstrate clinical expertise or by presenting a portfolio of experience, or a combination of these. Nevertheless, whatever the initial entry into practice, a comprehensive nursing education that is rich in leadership, management, research, health maintenance and promotion, disease prevention, and community health nursing experience is needed to meet the demands of this specialty.

In some states, meeting criteria for entry into practice as a public health nurse is required by some employers. In California, the State Board of Registered Nursing (BRN) has established specific criteria, including completion of specific coursework (e.g., child abuse and prevention information), which must be documented in undergraduate classes. On graduation, a school transcript, application, and fee are sent to the BRN to receive the public health nursing certificate. After they pass the RN license examination (NCLEX), these nurses can sign “RN, PHN” after their names. Only those who have completed a baccalaureate nursing program can apply for this certificate, and only people with the certificate can take jobs as public health nurses. In California, this means that employment as an RN in settings such as health departments, schools, and Native American health services requires a PHN certificate.

### Professional Development

Completion of a baccalaureate education may not be sufficient educational preparation for the more demanding community health nursing settings. Furthermore, to maintain licensure in most states, it is mandated that nurses participate in continuing education programs and receive continuing education units (Ellis & Hartley, 2000). In the United States, courses on specific topics are offered by employers, nursing associations, nursing journals, and private programs that travel to various cities. These help nurses to remain current on topics covered by the courses; however, a community health nurse may consider more lengthy and formal professional development opportunities such as advanced nursing practice (NP) programs or certification opportunities.

To someone who is just finishing an undergraduate nursing program, the thought of continuing in school may be overwhelming. However, within a few months or years after graduation, continuing in higher education may seem right. It can take time and experience to find a particular focus in nursing and to decide on specializing at an advanced level. When that time comes, a variety of course work and degree options are available. For example, short-term certificate programs specialize in a narrow focus of health care, such as early recognition and prevention of child abuse, research, grant writing, or team management. These may or may not be offered for university credit, but the content enhances a nurse's role in an agency.

Matriculation in an NP program or a master's degree program in nursing is a longer commitment and gives the nurse greater marketability. In some health departments, NPs run well-child clinics, and a school nurse with an NP license can direct a school-based clinic. Advanced practice in community health nursing can open doors into leadership positions in community health agencies. A master's degree in business, public health, education, or epidemiology can lead to management positions, private community health agency ownership, agency teaching, or research positions. A doctoral program may be the next educational step for those wanting tenure-track university teaching, research, or upper-level administrative positions.

The American Nurses Credentialing Center (ANCC) provides other opportunities by offering nurses certification in more than 36 specialty areas (2008). Currently, only one specialty is available in community health nursing: Advanced Public Health Nurse (APHN-BC). A generalist certificate in public/community health nursing had been available but was suspended in 2006, pending an ongoing review. Related certifications as an NP or in nursing administration also exist. Each certificate is awarded after completion of a certain number of years of practice in the specialty, payment of a fee, and passage of an ANCC Certification Examination. Many employers reward the initiative required for certification with promotion or a higher salary, accompanied by additional responsibilities and opportunities.

## Summary

The specialty of community health nursing developed historically through four stages. The early home-care stage (before the mid-1800s) emphasized care to the sick poor in their homes by various lay and religious orders. The district nursing stage (mid-1800s) included voluntary home nursing care for the poor by specialists or "health nurses" who treated the sick and taught wholesome living to patients. The public health nursing stage (1900 to 1970) was characterized by an increased concern for the health of the general public. The community health nursing stage (1970 to the present) includes increased recognition of community health nursing as a specialty field, with focus on communities and populations.

Six major societal influences have shaped the development of community health nursing. They are advanced technology, progress in causal thinking, changes in education, the changing demographics and role of women, the consumer movement, and economic factors such as health care costs, access, limited funds for public health, and increased competition among health service providers.

Academic preparation for community health nursing begins at the baccalaureate level. However, students beginning at the diploma or associate degree level can advance to a BSN completion program and then are prepared to enter this challenging specialty in nursing. The demands of community health nursing require additional courses in liberal arts and science, along with courses in community health nursing practice at the student level. Once students achieve an undergraduate degree, completion of additional educational programs is required to keep current and, in most states, to maintain licensure, advance in practice opportunities, or branch out into administration, teaching, or research. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Select one societal influence on the development of community health nursing and explore its continuing impact. What other events are occurring today that shape community health nursing practice? Support your arguments with documentation. Use the Internet to find your documentation.
2. Using the Internet, seek out information about a historical public health nursing leader. Using this information, determine how this practitioner might deal with current population-based issues such as AIDS, sexually transmitted diseases, or child neglect and abuse.
3. Assume that you have been asked to make a home visit to a 75-year-old man, living alone, whose wife recently died. Besides assessing his individual needs, what additional factors should you consider for assessment and intervention that would indicate an aggregate or population-focused approach? What self-care practices might you encourage or teach?
4. Interview a community health nursing director to determine what population-based programs are offered in your locality. Explore nursing's role in the assessment, development, implementation, and evaluation of these programs. Discuss with the director how community health nurses might expand their population-focused interventions.
5. Go to your university, nursing college, or school and locate brochures for advanced degrees in nursing and related areas. Peruse them and see whether any of the programs appeal to you. Request more information from at least one of these programs through the mail or the Internet.

## Setting the Stage for Community Health Nursing

### LEARNING OBJECTIVES

*Upon mastery of this chapter, you should be able to:*

- ◆ Identify the three core public health functions basic to community health nursing.
- ◆ Describe and differentiate among seven different roles of the community health nurse.
- ◆ Discuss the seven roles within the framework of public health nursing functions.
- ◆ Explain the importance of each role for influencing people's health.
- ◆ Identify and discuss factors that affect a nurse's selection and practice of each role.
- ◆ Describe seven settings in which community health nurses practice.
- ◆ Discuss the nature of community health nursing, and the common threads basic to its practice, woven throughout all roles and settings.
- ◆ Identify principles of sound nursing practice in the community.

*“One good community nurse will save a dozen policemen.”*

—Herbert Hoover

Leader  
Manager  
Policy development  
Researcher

 **Historically**, community health nurses have engaged in many professional roles. Nurses in this professional specialty have provided care to the sick, taught positive health habits and self-care, advocated on behalf of needy populations, developed and managed health programs, provided leadership, and collaborated with other professionals and consumers to implement changes in health services. Although the practice settings may have differed, the essential goal of the community health nurse has always been a healthier community. The home certainly has been one site for practice, but so too have public health clinics, schools, factories, and other community-based locations. Today, the roles and settings of community health nursing practice have expanded even further, offering a wide range of professional opportunities.

This chapter examines how the conceptual foundations and core functions of community health practice are integrated into the various roles and settings of community health nursing. It provides an opportunity to gain greater understanding about how and where community health nursing is practiced. Moreover, it will expand awareness of the many existing and future possibilities for community health nurses to improve the public's health. As you read through this chapter, think about client populations that you may have encountered in the acute care setting and consider your role with these same populations in a community setting. Perhaps you may discover a community health nursing specialty area that you never even considered.

## CORE PUBLIC HEALTH FUNCTIONS

Community health nurses work as partners within a team of professionals (in public health and other disciplines), nonprofessionals, and consumers to improve the health of populations. The various roles and settings for practice hinge on three primary functions of public health: assessment, policy development, and assurance (Institute of Medicine [IOM], 1988). These functions are foundational to all roles assumed by the community health nurse and are applied

at three levels of service: to individuals, to families, and to communities (Display 3.1). Regardless of the role or setting of choice, these three essential responsibilities direct the work of all community health nurses.

## Assessment

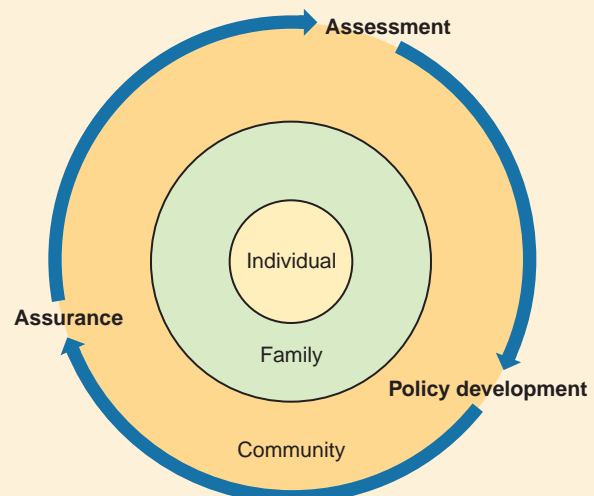

An essential first function in public health, **assessment**, means that the community health nurse must gather and analyze information that will affect the health of the people to be served. As described in Display 3.1, assessment is *the systematic collection, assembly, analysis, and dissemination of information about the health of a community* (U.S. Department of Health & Human Services [USDHHS], Centers for Disease Control & Prevention [CDC], 2006). The nurse and others on the health team need to determine health needs, health risks, environmental conditions, political agendas, and financial and other resources, depending on the individuals, community, or population targeted for intervention. Data may be gathered in many ways; typical methods include interviewing people in the community, conducting surveys, gathering information from public records (many of which are available online), and using research findings.

The community health nurse is typically both trusted and valued by clients, agencies, and private providers. Trust placed in the community health nurse can often be attributed to consistency, honesty, dependability, and an ongoing presence in the community. Although securing and maintaining the trust of others is pivotal to all nursing practice, it is even more critical when working in the community. Trust can afford a nurse access to client populations that are difficult to engage, to agencies, and to health care providers. In the capacity of trusted professional, community health nurses gather relevant client data that enable them to identify strengths, weaknesses, and needs. It is important to recognize that as difficult as it may be for the nurse to gain the trust and respect of the community, if ever lost, these attributes can be difficult if not impossible to regain.

DISPLAY 3.1

### PUBLIC HEALTH NURSING WITHIN THE CORE PUBLIC HEALTH FUNCTIONS MODEL

The model includes assessment, policy development, and assurance surrounding the individual, family, and community. *Assessment* is “the systematic collection, assembly, analysis, and dissemination of information about the health of a community.” *Policy development* uses the scientific information gathered during assessment to create comprehensive public health policies. *Assurance* is the “pledge to constituents that services necessary to achieve agreed-upon goals are provided by encouraging actions of others (private or public), requiring action through regulation, or providing service directly.”

(From U.S. Department of Health and Human Services, Centers for Disease Control & Prevention, retrieved October 31, 2006 from [http://www.cdc.gov/epo/dphsi/AI/what\\_new.htm](http://www.cdc.gov/epo/dphsi/AI/what_new.htm).)

At the community level, assessment is done both formally and informally as nurses identify and interact with key community leaders. With families, the nurse can evaluate family strengths and areas of concern in the immediate living environment and in the neighborhood. At the individual level, people are identified within the family who are in need of services, and the nurse evaluates the functional capacity of these individuals through the use of specific assessment measures and a variety of tools. Assessment of communities and families as the initial step in the nursing process is discussed more fully in Chapters 15 and 19.

## Policy Development

**Policy development** (defined in Display 3.1) is enhanced by the synthesis and analysis of information obtained during assessment. At the community level, the nurse provides leadership in convening and facilitating community groups to evaluate health concerns and develop a plan to address those concerns. Typically, the nurse recommends specific training and programs to meet identified health needs of target populations. This is accompanied by raising the awareness of key policy makers about factors such as health regulations and budget decisions that negatively affect the health of the community (see Chapter 13). With families, the nurse recommends new programs or increased services based on identified needs. Additional data may be needed to identify trends in groups or clusters of families, so that effective intervention strategies can be used with these families. At the individual level, the nurse assists in the development of standards for individual client care, recommends or adopts risk-classification systems to assist with prioritizing individual client care, and participates in establishing criteria for opening, closing, or referring individual cases.

## Assurance

**Assurance** activities—activities that make certain that services are provided—often consume most of the community health nurse’s time. With the shift in emphasis to programmatic funding and direct state reimbursement

through Medicaid programs, community health nurses in many settings have been required to focus on direct service to individuals rather than on population-based services. Nonetheless, community health nurses perform the assurance function at the community level when they provide service to target populations, improve quality assurance activities, maintain safe levels of communicable disease surveillance and outbreak control, and collaborate with community leaders in the preparation of a community disaster plan. In addition, they participate in outcome research, provide expert consultation, promote evidence-based practice, and provide services within the community based on standards of care.

## Essential Services

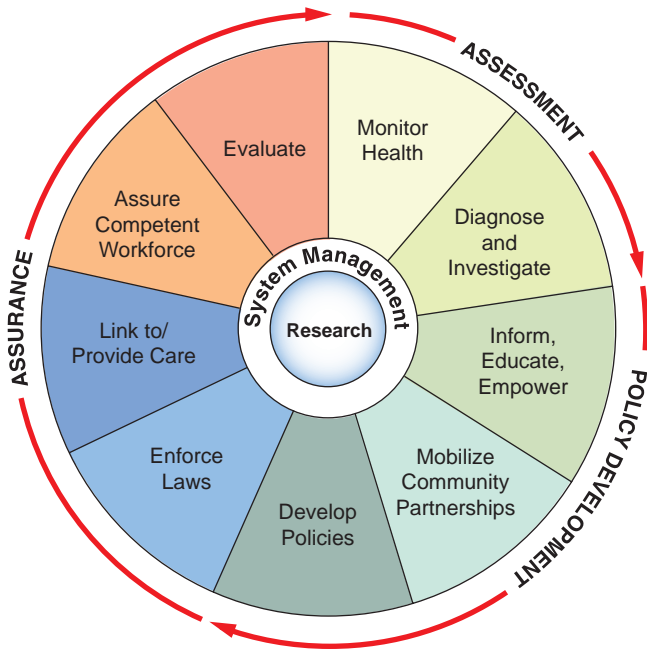

To more clearly articulate the services that are linked to the core functions of assessment, policy development and assurance, a list of 10 essential services was developed in 1994 by the Public Health Functions Steering Committee (USDHHS, 1997) (see Display 3.2). This initial effort to define the service components of the core functions provided an organized service delivery plan for public health providers across the country. A model depicting the relationships between the core functions and the essential services was eventually developed (USDHHS, 1999). The model (Fig. 3.1) shows the types of services necessary to achieve the core functions of assessment, policy development, and assurance. It also emphasizes the circular or ongoing nature of the process. The placement of research at the center of the model is a clear indication of the high priority placed on providing scientific evidence in all areas of service delivery. Research is essential to evidence-based practice and is vital to achieving healthy communities. As you review this model, think about what types of services might be provided in each category, depending on whether you are focusing on an individual, a family, or a community. It is not necessary that the community health nurse provide each of the listed services. Working in collaboration with an interdisciplinary team, the community nurse can support the efforts of others to achieve improved health in the community. What is important is that the team members all recognize their respective roles and are working toward the same goal.

### DISPLAY 3.2

### TEN ESSENTIAL SERVICES OF PUBLIC HEALTH

1. Monitor health status to identify community health problems.
2. Diagnose and investigate health problems and health hazards in the community.
3. Inform, educate, and empower people about health issues.
4. Mobilize community partnerships to identify and solve health problems.
5. Develop policies and plans that support individual and community health efforts.
6. Enforce laws and regulations that protect health and ensure safety.
7. Link people to needed personal health services and assure the provision of health care when otherwise unavailable.
8. Assure a competent public health and personal health care workforce.
9. Evaluate effectiveness, accessibility, and quality of personal and population-based health services.
10. Research for new insights and innovative solutions to health problems.

(From U.S. Department of Health and Human Services, Public Health Functions Project, 1997.)

**FIGURE 3.1** The Core Functions & Ten Essential Services of Public Health. From U.S. Department of Health and Human Services, Office of Disease Prevention & Health Promotion (1999), retrieved July 4, 2008 from <http://www.health.gov/phfunctions/public.htm>.

### STANDARDS OF PRACTICE

In 1998, the American Association of Colleges of Nursing published the document *The Essentials of Baccalaureate Education for Professional Nursing Practice*. This document was a major step in providing clear guidelines as to what constituted professional nursing education. Roles of beginning professional nursing practice were grouped into three broad areas: provider of direct and indirect care to individuals, families, groups, communities, and populations; designer, manager, and coordinator of care; and member of a profession. Although this document describes educational preparation in all areas of nursing practice, the link to community health nursing is quite evident. The document lists seven areas of core knowledge seen as vital to the education of the nurse. Content typically associated with community health nursing is emphasized: health promotion, risk reduction, and disease prevention; global health care; and health care systems and policy. This document clearly articulates the growing need to prepare nurses to assume a variety of roles in the community (both domestic and international).

Community health nursing practice is further defined by specific standards developed under the auspices of the American Nurses Association (ANA) in collaboration with the Quad Council of Public Health Nursing Organizations (ANA, 2007c). The Quad Council is comprised of representatives from the American Nurses Association, Council on Nursing Practice and Economics; the American Public Health Association, Public Health Nursing Section; the Association of Community Health Nursing Educators; and the Association of State and Territorial Directors of Nursing. These four organizations represent academics and professional practitioners, providing a broad spectrum of views regarding professional practice in the field of community health nursing. Public Health Nursing: Scope and Standards of Practice provides guidance as to what constitutes public health nursing and how it can be differentiated from other nursing specialties. Standards of care are consistent with the nursing process and include assessment, diagnosis, outcomes identification, planning, assurance, and evaluation. This document is an important reference for all those practicing in the community. It provides the basis for evaluating an individual’s performance in this field, and is used by many employers to assess job performance.

In addition to their work on the practice standards, the council completed work in 2003 on the *Quad Council Public Health Nursing Competencies*, which is designed as a tool to evaluate community health nursing practice. This guide was developed in conjunction with the more broadly focused *Core Competencies for Public Health Professionals*, with attention to areas specific to public health nursing practice. The list of competencies is applicable to two levels of practice; the staff nurse/generalist role and the manager/specialist/consultant role. Use of the competencies is seen as an appropriate assessment tool for practicing community health nurses and as a guide for agencies and academic programs as they plan educational experiences for both novice and experienced nurses (Association of Community Health Nursing Educators [ACHNE], 2003). General areas covered in the list of competencies include analytic assessment skills, policy development and program planning skills, communication skills, cultural competency skills, community dimensions of practice skills, basic public health sciences skills, financial planning and management skills, and leadership and systems thinking skills. It is also important to recognize that a specific objective in *Healthy People 2010* (23-8) stresses the need for public health agencies to utilize a competency-based assessment of their personnel (Display 3.3). The Quad Council competencies provide the basis for addressing that national objective.

DISPLAY 3.3 HEALTHY PEOPLE 2010—OBJECTIVE 23 PUBLIC HEALTH INFRASTRUCTURE	
Ensure that federal, tribal, state, and local health agencies have the infrastructure to provide essential public health services effectively	23-10 Continuing education and training by public health agencies
<b>Workforce</b>	<b>Prevention Research</b>
23-8 Competencies for public health workers	23-17 Population-based prevention research
23-9 Training in essential public health services	

The community health nurse provides nursing services based on other standards developed by the American Nurses Association (ANA), such as the *Code of Ethics for Nurses with Interpretive Statements* (2001), *Nursing's Social Policy Statement* (2003), and *Nursing: Scope and Standards of Practice* (2004). These three documents provide essential information regarding sound general nursing practice. When combined with *Public Health Nursing: Scope and Standards of Practice* (2007c), they provide the community health nurse with a clear understanding of accepted practice in this nursing specialty. With specific standards of practice and clear competencies to achieve, the community health nurse can integrate the core functions of assessment, policy development, and assurance throughout all of the various roles and community settings of practice.

## ROLES OF COMMUNITY HEALTH NURSES

Just as the health care system is continually evolving, community health nursing practice evolves to remain effective with the clients it serves. Over time, the role of the community health nurse has broadened. This breadth is reflected in the description of public health nursing from the American Public Health Association, Public Health Nursing Section (1996):

Public health nurses integrate community involvement and knowledge about the entire population with personal, clinical understandings of the health and illness experiences of individuals and families within the population. They translate and articulate the health and illness experiences of diverse, often vulnerable individuals and families in the population to health planners and policy makers, and assist members of the community to voice their problems and aspirations. Public health nurses are knowledgeable about multiple strategies for intervention, from those applicable to the entire population, to those for the family, and the individual. Public health nurses translate knowledge from the health and social sciences to individuals and population groups through targeted interventions, programs, and advocacy.

Public health nursing may be practiced by one public health nurse or by a group of public health nurses working collaboratively. In both instances, public health nurses are directly engaged in the interdisciplinary activities of the core public health functions of assessment, assurance, and policy development. Interventions or strategies may be targeted to multiple levels depending on where the most effective outcomes are possible. They include strategies aimed at entire population groups, families, or individuals. In any setting, the role of public health nurses focuses on the prevention of illness, injury or disability, the promotion of health, and maintenance of the health of populations.

Community health nurses wear many hats while conducting day-to-day practice. At any given time, however, one role is primary. This is especially true for specialized roles, such as that of full-time manager. This chapter examines seven major roles: clinician, educator, advocate, manager, collaborator, leader, and researcher. It also describes the factors that influence the selection and performance of those roles.

## Clinician Role

The most familiar role of the community health nurse is that of clinician or care provider. The provision of nursing care, however, takes on new meaning in the context of community health practice. The **clinician** role in community health means that the nurse ensures health services are provided not just to individuals and families, but also to groups and populations. Nursing service is still designed for the special needs of clients, however, when those clients comprise a group or population, clinical practice takes different forms. It requires different skills to assess collective needs and tailor service accordingly. For instance, one community health nurse might visit elderly residents in a seniors' high-rise apartment building. Another might serve as the clinic nurse in a rural prenatal clinic that serves migrant farm workers. These are opportunities to assess the needs of entire aggregates and design appropriate services.

For community health nurses, the clinician role involves certain emphases that are different from those of basic nursing. Three clinician emphases, in particular, are useful to consider here: holism, health promotion, and skill expansion.

## Holistic Practice

Most clinical nursing seeks to be broad and holistic. In community health, however, a holistic approach means considering the broad range of interacting needs that affect the collective health of the "client" as a larger system (Dossey, Keegan, & Guzzetta, 2005). Holistic nursing care encompasses the comprehensive and total care of the client in all areas, such as physical, emotional, social, spiritual, and economic. All are considered and cared for when the client is a large system, just as they should be with individual clients. The client is a composite of people whose relationships and interactions with each other must be considered in totality. Holistic practice must emerge from this systems perspective.

For example, when working with a group of pregnant teenagers living in a juvenile detention center, the nurse would consider the girls' relationships with one another, their parents, the fathers of their unborn children, and the detention center staff. The nurse would evaluate their ages, developmental needs, and peer influence, as well as their knowledge of pregnancy, delivery, and issues related to the choice of keeping or giving up their babies. The girls' reentry into the community and their future plans for school or employment would also be considered. Holistic service would go far beyond the physical condition of pregnancy and childbirth. It would incorporate consideration of pregnant adolescents in this community as a population at risk. What factors contributed to these girls' situations, and what preventive efforts could be instituted to protect other teenagers or these teens from future pregnancies? The clinician role of the community health nurse involves holistic practice from an aggregate perspective.

## Focus on Wellness

The clinician role in community health also is characterized by its focus on promoting wellness. As discussed in Chapter 1, the community health nurse provides service along the entire range of the health continuum, but especially emphasizes promotion of health and prevention of illness. Effective services

include seeking out clients who are at risk for poor health and offering preventive and health-promoting services, rather than waiting for them to come for help after problems arise. The community health nurse identifies people, programs, and agencies interested in achieving a higher level of health, and works with them to accomplish that goal and to sustain the expected changed behavior (Pender, Murdaugh, & Parsons, 2005). The nurse may help employees of a business learn how to live healthier lives or work with a group of people who want to quit smoking. The community health nurse may hold seminars with a men's group on enhancing fathering skills or assist a corporation with the implementation of a health promotion program. Groups and populations are identified that may be vulnerable to certain health threats, and preventive and health-promoting programs can be designed in collaboration with the community (Pender et al., 2005). Examples include immunization of preschoolers, family planning programs, cholesterol screening, and prevention of behavioral problems in adolescents. Protecting and promoting the health of vulnerable populations is an important component of the clinician role and is addressed extensively in the chapters in Unit VII on vulnerable aggregates.

### Expanded Skills

Many different skills are used in the role of the community health clinician. In the early years of community health nursing, emphasis was placed on physical care skills. With time, skills in observation, listening, communication, and counseling became integral to the clinician role as it grew to encompass psychological and sociocultural factors. Recently, environmental and community-wide considerations—such as problems caused by pollution, violence and crime, drug abuse, unemployment, poverty, homelessness, and limited funding for health programs—have created a need for stronger skills in assessing the needs of groups and populations and intervening at the community level. The clinician role in population-based nursing also requires skills in collaboration with consumers and other professionals, use of epidemiology and biostatistics, community organization and development, research, program evaluation, administration, leadership, and effecting change (ANA, 2000; ANA, 2006). These skills are addressed in greater detail in later chapters.

### Educator Role

A second important role of the community health nurse is that of **educator** or health teacher. Health teaching, a widely recognized part of nursing practice, is legislated through nurse practice acts in a number of states and is one of the major functions of the community health nurse (ANA, 2004; ANA, 2007c).

The educator role is especially useful in promoting the public's health for at least two reasons. First, community clients usually are not acutely ill and can absorb and act on health information. For example, a class of expectant parents, unhampered by significant health problems, can grasp the relationship of diet to fetal development. They understand the value of specific exercises to the childbirth process, are motivated to learn, and are more likely to perform those exercises. Thus, the educator role has the potential for finding greater receptivity and providing higher-yield results.

Second, the educator role in community health nursing is significant because a wider audience can be reached. With an emphasis on populations and aggregates, the educational efforts of community health nursing are appropriately targeted to reach many people. Instead of limiting teaching to one-on-one or small groups, the nurse has the opportunity and mandate to develop educational programs based on community needs that seek a community-wide impact. Community-wide antidrug campaigns, dietary improvement programs, and improved handwashing efforts among children provide useful models for implementation of the educator role at the population level and demonstrate its effectiveness in reaching a wide audience (Redman, 2007).

One factor that enhances the educator role is the public's higher level of health consciousness. Through plans ranging from the President's Council on Physical Fitness and Sports to local antismoking campaigns, people are recognizing the value of health and are increasingly motivated to achieve higher levels of wellness. When a middle-aged man, for example, is discharged from the hospital after a heart attack, he is likely to be more interested than before the attack in learning how to prevent another. He can learn how to reduce stress, develop an appropriate and gradual exercise program, and alter his eating habits. Families with young children often are interested in learning about children's growth and development; most parents are committed to raising happy, healthy children. Health education can affect the health status of people of all ages (Bastable, 2006; Pender et al., 2005). Today, in more businesses and industries, nurses promote the health of employees through active wellness-education and injury-prevention programs. The companies recognize that improving the health of their workers, which includes earning a living wage, means less absenteeism and higher production levels, in addition to other benefits (Halls & Rhodes, 2004). Some companies even provide exercise areas and equipment for employees to use and pay for the cost of their participation or allow paid time off for exercise.

Whereas nurses in acute care teach patients with a one-on-one focus about issues related to their hospitalization, community health nurses go beyond these topics to educate people in many areas. Community-living clients need and want to know about a wide variety of issues, such as family planning, weight control, smoking cessation, and stress reduction. Aggregate-level concerns also include such topics as environmental safety, sexual discrimination and harassment at school or work, violence, and drugs. What foods and additives are safe to eat? How can people organize the community to work for reduction of violence on television? What are health consumers' rights? Topics taught by community health nurses extend from personal and family health to environmental health and community organization.

As educators, community health nurses seek to facilitate client learning. Information is shared with clients both formally and informally. Nurses act as consultants to individuals or groups. Formal classes may be held to increase people's understanding of health and health care. Established community groups may be used in the nurse's teaching practice. For example, a nurse may teach parents and teachers at a parent-teacher meeting about signs of mood-modifying drug and alcohol abuse, discuss safety practices with a group of industrial workers, or give a presentation on the importance of early detection of child abuse to a health

planning committee considering funding a new program. At times, the community health nurse facilitates client learning through referrals to more knowledgeable sources or through use of experts on special topics. Client self-education is facilitated by the nurse; in keeping with the concept of self-care, clients are encouraged and helped to use appropriate health resources and to seek out health information for themselves. The emphasis throughout the health teaching process continues to be placed on illness prevention and health promotion. Health teaching as a tool for community health nursing practice is discussed in detail in Chapter 11.

## Advocate Role

The issue of clients' rights is important in health care. Every patient or client has the right to receive just, equal, and humane treatment. The role of the nurse includes client advocacy, which is highlighted in the ANA *Code of Ethics for Nurses with Interpretive Statements* (2001) and *Nursing's Social Policy Statement* (2003). Our current health care system is often characterized by fragmented and depersonalized services, and many clients—especially the poor, the disadvantaged, those without health insurance, and people with language barriers—frequently are denied their rights. They become frustrated, confused, degraded, and unable to cope with the system on their own. The community health nurse often acts as an **advocate** for clients, pleading their cause or acting on their behalf. Clients may need someone to explain which services to expect and which services they ought to receive, to make referrals as needed, and to write letters to agencies or health care providers for them. They need someone to guide them through the complexities of the system, and assure the satisfaction of their needs. This is particularly true for minorities and disadvantaged groups (Sequist, Cullen, & Ayanian, 2005; Traeger, Thompson, Dickson, & Provencio, 2006).

## Advocacy Goals

Client advocacy has two underlying goals. One is to help clients gain greater independence or self-determination. Until they can research the needed information and access health and social services for themselves, the community health nurse acts as an advocate for the clients by showing them what services are available, those to which they are entitled, and how to obtain them. A second goal is to make the system more responsive and relevant to the needs of clients. By calling attention to inadequate, inaccessible, or unjust care, community health nurses can influence change.

Consider the experience of the Merrill family. Gloria Merrill has three small children. Early one Tuesday morning, the baby, Tony, suddenly started to cry. Nothing would comfort him. Gloria went to a neighbor's apartment, called the local clinic, and was told to come in the next day. The clinic did not take appointments and was too busy to see any more patients that day. Gloria's neighbor reassured her that "sometimes babies just cry." For the rest of the day and night, Tony cried almost incessantly. On Wednesday, Gloria and her children made the 45-minute bus ride to the clinic, and waited 3.5 hours in the crowded reception room; the wait was punctuated by interrogations from clinic workers. Gloria's other children were restless, and the baby was crying. Finally, they saw the physician. Tony had an inguinal hernia

that could have strangulated and become gangrenous. The doctor admonished Gloria for waiting so long to bring in the baby. Immediate surgery was necessary. Someone at the clinic told Gloria that Medicaid would pay for it. Someone else told her that she was ineligible because she was not a registered clinic patient. At this point, all of her children were crying. Gloria had been up most of the night. She was frantic, confused, and felt that no one cared. This family needed an advocate.

## Advocacy Actions

The advocate role incorporates four characteristic actions: being assertive, taking risks, communicating and negotiating well, and identifying resources and obtaining results.

First, advocates must be assertive. Fortunately, in the Merrills' dilemma, the clinic had a working relationship with the City Health Department and contacted Tracy Lee, a community health nurse liaison with the clinic, when Gloria broke down and cried. Tracy took the initiative to identify the Merrills' needs and find appropriate solutions. She contacted the Department of Social Services and helped the Merrills to establish eligibility for coverage of surgery and hospitalization costs. She helped Gloria to make arrangements for the baby's hospitalization and the other children's care.

Second, advocates must take risks—go "out on a limb" if need be—for the client. The community health nurse was outraged by the kind of treatment received by the Merrills: the delays in service, the impersonal care, and the surgery that could have been planned as elective rather than as an emergency. She wrote a letter describing the details of the Merrills' experience to the clinic director, the chairman of the clinic board, and the nursing director. This action resulted in better care for the Merrills and a series of meetings aimed at changing clinic procedures and providing better telephone screening.

Third, advocates must communicate and negotiate well by bargaining thoroughly and convincingly. The community health nurse helping the Merrill family stated the problem clearly and argued for its solution.

Finally, advocates must identify and obtain resources for the client's benefit. By contacting the most influential people in the clinic and appealing to their desire for quality service, the nurse caring for the Merrill family was able to facilitate change.

Advocacy at the population level incorporates the same goals and actions. Whether the population is homeless people, battered women, or migrant workers, the community health nurse in the advocate role speaks and acts on their behalf. The goals remain the same: to promote clients' self-determination and to shape a more responsive system. Advocacy for large aggregates, such as the millions with inadequate health care coverage, means changing national policies and laws (see Chapter 13). Advocacy may take the form of presenting public health nursing data to ensure that providers deliver quality services. It may mean conducting a needs assessment to demonstrate the necessity for a shelter and multiservice program for the homeless. It may mean testifying before the legislature to create awareness of the problems of battered women and the need for more protective laws. It may mean organizing a lobbying effort to require employers of migrant workers to provide proper housing and

working conditions. In each case, the community health nurse works with representatives of the population to gain their understanding of the situation and to ensure their input.

## Manager Role

Community health nurses, like all nurses, engage in the role of managing health services. As a **manager**, the nurse exercises administrative direction toward the accomplishment of specified goals by assessing clients' needs, planning and organizing to meet those needs, directing and leading to achieve results, and controlling and evaluating the progress to ensure that goals are met. The nurse serves as a manager when overseeing client care as a case manager, supervising ancillary staff, managing caseloads, running clinics, or conducting community health needs assessment projects. In each instance, the nurse engages in four basic functions that make up the management process. The management process, like the nursing process, incorporates a series of problem-solving activities or functions: planning, organizing, leading, and controlling and evaluating. These activities are sequential, yet also occur simultaneously for managing service objectives (Cherry & Jacob, 2005). While performing these functions, community health nurses most often are participative managers; that is, they participate with clients, other professionals, or both to plan and implement services.

### Nurse as Planner

The first function in the management process is planning. A planner sets the goals and direction for the organization or project and determines the means to achieve them. Specifically, planning includes defining goals and objectives, determining the strategy for reaching them, and designing a coordinated set of activities for implementing and evaluating them. Planning may be strategic, which tends to include broader, more long-range goals (Cherry & Jacob, 2005; USDHHS, 2000). An example of *strategic planning* is setting 2-year agency goals to reduce teenage pregnancies in the county by 50%. Planning may be operational, which focuses more on short-term planning needs. An example of *operational planning* is setting 6-month objectives to implement a new computer system for client record keeping.

The community health nurse engages in planning as a part of the manager role when supervising a group of home health aides working with home care clients. Plans of care must be designed to include setting short-term and long-term objectives, describe actions to carry out the objectives, and design a plan for evaluating the care given. With larger groups, such as a program for a homeless mentally ill population, the planning function is used in collaboration with other professionals in the community to determine appropriate goals for shelter and treatment, and to develop an action plan to carry out and evaluate the program (Burke, 2005). The concepts of planning with communities and families are discussed further in Chapters 15 and 19, respectively.

### Nurse as Organizer

The second function of the manager role is that of organizer. This involves designing a structure within which people and tasks function to reach the desired objectives. A manager

must arrange matters so that the job can be done. People, activities, and relationships have to be assembled to put the plan into effect. Organizing includes deciding on the tasks to be done, who will do them, how to group the tasks, who reports to whom, and where decisions will be made (Cherry & Jacob, 2005). In the process of organizing, the nurse manager provides a framework for the various aspects of service, so that each runs smoothly and accomplishes its purpose. The framework is a part of service preparation. When a community health nurse manages a well-child clinic, for instance, the organizing function involves making certain that all equipment and supplies are present, required staff are hired and are on duty, and that staff responsibilities are clearly designated. The final responsibility as an organizer is to evaluate the effectiveness of the clinic. Is it providing the needed services? Are the clients satisfied? Do the services remain cost-effective? All of these questions must be addressed by the organizer.

### Nurse as Leader

In the manager role, the community health nurse also must act as a **leader**. As a leader, the nurse directs, influences, or persuades others to effect change that will positively impact people's health and move them toward a goal. The leading function includes persuading and motivating people, directing activities, ensuring effective two-way communication, resolving conflicts, and coordinating the plan. Coordination means bringing people and activities together, so that they function in harmony while pursuing desired objectives.

Community health nurses act as leaders when they direct and coordinate the functioning of a hypertension screening clinic, a weight control group, or a three-county mobile health assessment unit. In each case, the leading function requires motivating the people involved, keeping open clear channels of communication, negotiating conflicts, and directing and coordinating the activities established during planning, so that the desired objectives can be accomplished.

### Nurse as Controller and Evaluator

The fourth management function is to control and evaluate projects or programs. A controller monitors the plan and ensures that it stays on course. In this function, the community health nurse must realize that plans may not proceed as intended and may need adjustments or corrections to reach the desired results or goals. Monitoring, comparing, and adjusting make up the controlling part of this function. At the same time, the nurse must compare and judge performance and outcomes against previously set goals and standards—a process that forms the evaluator aspect of this management function.

An example of the controlling and evaluating function was evident in a program started in several preschool day care centers in a city in the Midwest. The goal of the project was to reduce the incidence of illness among the children through intensive physical and emotional preventive health education with staff, parents, and children. The two community health nurses managing the project were pleased with the progress of the classes and monitored the application of the prevention principles in day-to-day care. However, staff

became busy after several weeks, and some plans were not being followed carefully. Preventive activities, such as ensuring that the children coughed into their shirt sleeve and washed their hands after using the bathroom and before eating, were not being closely monitored. Several children who were clearly sick had not been kept at home. Including the quiet or reserved children in activities sometimes was overlooked. The nurses worked with staff and parents to motivate them and get the project back on course. They held monthly meetings with the staff, observed the classes periodically, and offered one-on-one instruction to staff, parents, and children. One activity was to establish competition between the centers for the best health record, with the promise of a photograph of the winning center's children and an article in the local newspaper. Their efforts were successful.

### Management Behaviors

As managers, community health nurses engage in many different types of behaviors. These behaviors or parts of the manager role were first described by Mintzberg (1973). He grouped them into three sets of behaviors: decision-making, transferring of information, and engaging in interpersonal relationships.

#### Decision-Making Behaviors

Mintzberg identified four types of decisional roles or behaviors: entrepreneur, disturbance handler, resource allocator, and negotiator. A manager serves in the entrepreneur role when initiating new projects. Starting a nurse-managed center to serve a homeless population is an example. Community health nurses play the disturbance-handler role when they manage disturbances and crises—particularly interpersonal conflicts among staff, between staff and clients, or among clients (especially when being served in an agency). The resource-allocator role is demonstrated by determining the distribution and use of human, physical, and financial resources. Nurses play the negotiator role when negotiating, perhaps with higher levels of administration or a funding agency, for new health policy or budget increases to support expanded services for clients.

#### Transfer of Information Behaviors

Mintzberg described three informational roles or behaviors: monitor, information disseminator, and spokesperson. The monitor role requires collecting and processing information, such as gathering ongoing evaluation data to determine whether a program is meeting its goals. In the disseminator role, nurses transmit the collected information to people involved in the project or organization. In the spokesperson role, nurses share information on behalf of the project or agency with outsiders.

#### Interpersonal Behaviors

While engaging in various interpersonal roles, the community health nurse may function as a figurehead, a leader, and a liaison. In the figurehead role, the nurse acts in a ceremonial or symbolic capacity, such as participating in a ribbon-cutting

ceremony to mark the opening of a new clinic or representing the project or agency for news media coverage. In the leader role, the nurse motivates and directs people involved in the project. In the liaison role, a network is maintained with people outside the organization or project for information exchange and project enhancement.

### Management Skills

What types of skills and competencies does the community health nurse need in the manager role? Three basic management skills are needed for successful achievement of goals: human, conceptual, and technical. *Human skills* refer to the ability to understand, communicate, motivate, delegate, and work well with people (Cherry & Jacob, 2005). An example is a nursing supervisor's or team leader's ability to gain the trust and respect of staff and promote a productive and satisfying work environment. A manager can accomplish goals only with the cooperation of others. Therefore, human skills are essential to successful performance of the manager role. *Conceptual skills* refer to the mental ability to analyze and interpret abstract ideas for the purpose of understanding and diagnosing situations and formulating solutions. Examples are analyzing demographic data for program planning and developing a conceptual model to describe and improve organizational function. Finally, *technical skills* refer to the ability to apply special management-related knowledge and expertise to a particular situation or problem. Such skills performed by a community health nurse might include implementing a staff development program or developing a computerized management information system.

### Case Management

Case management has become the standard method of managing health care in the delivery systems in the United States, and managed care organizations have become an integral part of community-oriented care. **Case management** is a systematic process by which a nurse assesses clients' needs, plans for and coordinates services, refers to other appropriate providers, and monitors and evaluates progress to ensure that clients' multiple service needs are met in a cost-effective manner. Managed care, the broader umbrella under which case management exists, is a cost-containing system of health care administration (Cohen & Cesta, 2005). Managed care, as an approach to delivering health care, is discussed in detail in Chapter 6. As clients leave hospitals earlier, as families struggle with multiple and complex health problems, as more elderly persons need alternatives to nursing home care, as competition and scarce resources contribute to fragmentation of services, and as the cost of health care continues to increase, there is a growing need for someone to oversee and coordinate all facets of needed service (Cohen & Cesta, 2005; Simpson, 2005). Through case management, the nurse addresses this need in the community.

The activity of case management often follows discharge planning as a part of continuity of care. When applied to individual clients, it means overseeing their transition from the hospital back into the community and monitoring them to ensure that all of their service needs are met. Case management also applies to aggregates. In this context, it

involves overseeing and ensuring that a group's or population's health-related needs are met, particularly for those who are at high risk of illness or injury. For example, the community health nurse may work with battered women who come to a shelter. First, the nurse must ensure that their immediate needs for safety, security, food, finances, and child care are met. Then, the nurse must work with other professionals to provide more permanent housing, employment, ongoing counseling, and financial and legal resources for this group of women. Whether applied to families or aggregates, case management, like other applications of the manager role, uses the three sets of management behaviors and engages the community health nurse as planner, organizer, leader, controller, and evaluator.

## Collaborator Role

Community health nurses seldom practice in isolation. They must work with many people, including clients, other nurses, physicians, teachers, health educators, social workers, physical therapists, nutritionists, occupational therapists, psychologists, epidemiologists, biostatisticians, attorneys, secretaries, environmentalists, city planners, and legislators. As members of the health team, community health nurses assume the role of **collaborator**, which means working jointly with others in a common endeavor, cooperating as partners. Successful community health practice depends on this multidisciplinary collegiality and leadership (Klinedinst, 2005; Umble et al., 2005). Everyone on the team has an important and unique contribution to make to the health care effort. As on a championship ball team, the better all members play their individual positions and cooperate with other members, the more likely the health team is to win.

The community health nurse's collaborator role requires skills in communicating, in interpreting the nurse's unique contribution to the team, and in acting assertively as an equal partner. The collaborator role also may involve functioning as a consultant.

The following examples show a community health nurse functioning as collaborator. Three families needed to find good nursing homes for their elderly grandparents. The community health nurse met with the families, including the elderly members; made a list of desired features, such as a shower and access to walking trails; and then worked with a social worker to locate and visit several homes. The grandparents' respective physicians were contacted for medical consultation, and in each case, the elderly member made the final selection. In another situation, the community health nurse collaborated with the city council, police department, neighborhood residents, and the manager of a senior citizens' high-rise apartment building to help a group of elderly people organize and lobby for safer streets. In a third example, a school nurse noticed a rise in the incidence of drug use in her schools. She initiated a counseling program after joint planning with students, parents, teachers, the school psychologist, and a local drug rehabilitation center.

## Leadership Role

Community health nurses are becoming increasingly active in the leadership role, separate from leading within the manager role mentioned earlier. The leadership role focuses on

effecting change (see Chapter 11); thus, the nurse becomes an agent of change. As leaders, community health nurses seek to initiate changes that positively affect people's health. They also seek to influence people to think and behave differently about their health and the factors contributing to it.

At the community level, the leadership role may involve working with a team of professionals to direct and coordinate such projects as a campaign to eliminate smoking in public areas or to lobby legislators for improved child day care facilities. When nurses guide community health decision-making, stimulate an industry's interest in health promotion, initiate group therapy, direct a preventive program, or influence health policy, they assume the leadership role. For example, a community health nurse started a rehabilitation program that included self-esteem building, career counseling, and job placement to help women in a halfway house who had recently been released from prison.

The community health nurse also exerts influence through health planning. The need for coordinated, accessible, cost-effective health care services creates a challenge and an opportunity for the nurse to become more involved in health planning at all levels: organizational, local, state, national, and international. A community health nurse needs to exercise leadership responsibility and assert the right to share in health decisions (Cherry & Jacob, 2005). One community health nurse determined that there was a need for a mental health program in his district. He planned to implement it through the agency for which he worked, but certain individuals on the health board were opposed to adding new programs because of the cost. The nurse's approach was to gather considerable data to demonstrate the need for the program and its cost-effectiveness. He invited individual, key board members to lunch to convince them of the need. He prepared written summaries, graphs, and charts, and at a strategic time, he presented his case at a board meeting. The mental health program was approved and implemented.

A broader attribute of the leadership role is that of visionary. A leader with *vision* develops the ability to see what can be and leads people on a path toward that goal. A leader's vision may include long- and short-term goals. In one instance, it began as articulating the need for stronger community nursing services to an underserved population in an inner-city neighborhood served by a community health nurse. In this densely populated, tenant-occupied neighborhood, drugs, crime, and violence were commonplace. One summer, an 8-year-old boy was shot and killed. The enraged immigrant families in the neighborhood felt helpless and hopeless. Several families were visited by the nurse, and they shared their concerns with her. The nurse felt strongly about this blighted community and offered to work with the community to effect change. She gathered volunteers from neighborhood churches, and together they began to discuss the community's concerns. Together they prioritized their needs and began planning to make theirs a healthy community. The nurse organized her work week to provide health screening and education to families in the basement of a church on one morning each week. Initially, only a few families accessed this new service. In a matter of months, it became recognized as a valuable community service, and it expanded to a full day; the expanding volunteer group soon outgrew the space. The community health nurse worked closely with influential community members and the families

being served. They determined that many more services were needed in this neighborhood, and they began to broaden their outreach and think of ways to get the needed services.

Within a year, the group had written several grants to the city and to a private corporation in an effort to expand the voluntary services. The funding that they obtained allowed them to rent vacant storefront space, hire a part-time nurse practitioner, contract with the health department for additional community health nursing services, and negotiate with the local university to have medical, nursing, and social work students placed on a regular basis. The group, under the visionary leadership of the community health nurse, planned to add a one-on-one reading program for children, a class in English as a second language for immigrant families, a mentoring program for teenagers, and dental services. Even the police department had opened a substation in the neighborhood, making their presence more visible. This community health nurse's vision filled an immediate, critical need in the short term and developed into a comprehensive community center in the long term. Violence and crime diminished, and the neighborhood became a place where children could play safely.

## Researcher Role

In the **researcher** role, community health nurses engage in the systematic investigation, collection, and analysis of data for solving problems and enhancing community health practice. But how can research be combined with practice? Although research technically involves a complex set of activities conducted by persons with highly developed and specialized skills, research also means applying that technical study to real-practice situations. Community health nurses base their practice on the evidence found in the literature to enhance and change practice as needed. For example, the work of several researchers over 15 years supports the value of intensive home visiting to high-risk families (Olds, 2006). The outcomes of this research are changing practice protocol to high-risk families in many health departments today.

Research is an investigative process in which all community health nurses can become involved in asking questions and looking for solutions. Collaborative practice models between academics and practitioners combine research methodology expertise with practitioners' knowledge of problems to make community health nursing research both valid and relevant. The ongoing need for evidence-based practice is supported by Healthy People 2010, which stresses the importance of population-based prevention research to our national health goals (Display 3.3).

## The Research Process

Community health nurses practice the researcher role at several levels. In addition to everyday inquiries, community health nurses often participate in agency and organizational studies to determine such matters as practice activities, priorities, and education of public health nurses (Grumbach, Miller, Mertz, & Finocchio, 2004). Some community health nurses participate in more complex research on their own or in collaboration with other health professionals (Elliott, Crombie, Irvine, Cantrell, & Taylor, 2004). The researcher

role, at all levels, helps to determine needs, evaluate effectiveness of care, and develop a theoretic basis for community health nursing practice. Chapters 4 and 12 will explain community health research in greater detail.

Research literally means to *search again*—to investigate, discover, and interpret facts. All research in community health, from the simplest inquiry to the most complex epidemiologic study, uses the same fundamental process. Simply put, the research process involves the following steps: (1) identify an area of interest, (2) specify the research question or statement, (3) review the literature, (4) identify a conceptual framework, (5) select a research design, (6) collect and analyze data, (7) interpret the results, and (8) communicate the findings (see Chapter 4).

Investigation builds on the nursing process, that essential dynamic of community health nursing practice, using it as a problem-solving process (Burns & Grove, 2007). In using the nursing process, the nurse identifies a problem or question, investigates by collecting and analyzing data, suggests and evaluates possible solutions, and either selects a solution or rejects them all and starts the investigative process over again. In a sense, the nurse is gathering data for health planning—investigating health problems to design wellness-promoting and disease-preventing interventions for community populations.

## Attributes of the Researcher Role

A questioning attitude is a basic prerequisite for good nursing practice. A nurse may have revisited a patient many times and noticed some change in her condition, such as restlessness or pallor; consequently, the nurse wonders what is causing this change and what can be done about it. In everyday practice, numerous situations challenge the nurse to ask questions. Consider the following examples:

- ◆ A newspaper reports that another group of children has been arrested for using illegal drugs. Is there an increase in the incidence of illegal drug use in the community?
- ◆ Children attending a day care center appear to have excessive bruises on their arms and legs. What is the incidence of reported child abuse in this community? What could be done to promote earlier detection and improved reporting?
- ◆ Elderly persons are living alone and without assistance in a neighborhood. How prevalent is this situation, and what are this population's needs?
- ◆ Driving through a particular neighborhood, the nurse notices not a single playground. Where do the kids play?

Each of these questions places the nurse in the role of investigator. They demonstrate the fundamental attitude of every researcher: a spirit of inquiry.

A second attribute, careful observation, also is evident in the examples just given. The nurse needs to develop a sharpened ability to notice things as they are, including deviations from the norm and subtle changes suggesting the need for nursing action. Coupled with observation is open-mindedness, another attribute of the researcher role. In the case of the bruises seen on day care children, a community health nurse's observations suggest child abuse as a possible

cause. However, open-mindedness requires consideration of other alternatives, and, as a good investigator, the nurse explores these possibilities as well.

Analytic skills also are used in this role. In the example of illegal drug use, the nurse already has started to analyze the situation by trying to determine its cause-and-effect relationships. Successful analysis depends on how well the data have been collected. Insufficient information can lead to false interpretations, so it is important to seek out the needed data. Analysis, like a jigsaw puzzle, involves studying the pieces and fitting them together until the meaning of the whole picture can be described.

Finally, the researcher role involves tenacity. The community health nurse persists in an investigation until facts are uncovered and a satisfactory answer is found. Noticing an absence of playgrounds and wondering where the children play is only a beginning. Being concerned about the children's safety and need for recreational outlets, the nurse gathers data about the location and accessibility of play areas, as well as expressed needs of community residents. A fully documented research report may result. If the data support a need for additional play space, the report can be brought before the proper authorities.

## SETTINGS FOR COMMUNITY HEALTH NURSING PRACTICE

The previous section examined community health nursing from the perspective of its major roles. The roles can now be placed in context by viewing the settings in which they are practiced. The types of places in which community health nurses practice are increasingly varied and include a growing number of nontraditional settings and partnerships with non-health groups. Employers of community health nurses range from state and local health departments and home health agencies to managed care organizations, businesses and industries, and nonprofit organizations. For this discussion, these settings are grouped into seven categories: homes, ambulatory service settings, schools, occupational health settings, residential institutions, faith communities, and the community at large (domestic and international). This section of the chapter provides a brief overview of the various settings. Chapters 30 and 31 will provide much more detail on specific roles and settings, including both public and private practice settings.

### Homes

Since Lillian Wald and the nurses at the Henry Street Settlement first started their practice at the beginning of the last century, the most frequently used setting for community health nursing practice was the home. In the home, all of the community health nursing roles are performed to varying degrees. Clients who are discharged from acute care institutions, such as hospitals or mental health facilities, are regularly referred to community health nurses for continued care and follow-up. Here, the community health nurse can see clients in a family and environmental context, and service can be tailored to the clients' unique needs.

For example, Mr. White, 67 years of age, was discharged from the hospital with a colostomy. Doreen Levitz, the community health nurse from the county public health nursing agency, immediately started home visits. She met with Mr.

White and his wife to discuss their needs as a family and to plan for Mr. White's care and adjustment to living with a colostomy. Practicing the clinician and educator roles, she reinforced and expanded on the teaching started in the hospital for colostomy care, including bowel training, diet, exercise, and proper use of equipment. As part of a total family care plan, Doreen provided some forms of physical care for Mr. White as well as counseling, teaching, and emotional support for both Mr. White and his wife. In addition to consulting with the physician and social service worker, she arranged and supervised visits from the home health aide, who gave personal care and homemaker services. She thus performed the manager, leader, and collaborator roles.

The home is also a setting for health promotion. Many community health nursing visits focus on assisting families to understand and practice healthier living behaviors. Nurses may, for example, instruct clients on parenting, infant care, child discipline, diet, exercise, coping with stress, or managing grief and loss.

The character of the home setting is as varied as the clients served by the community health nurse. In one day, the nurse may visit a well-to-do widow in her luxurious home, a middle-income family in their modest bungalow, an elderly transient man in his one-room fifth-story walk-up apartment, and a teen mother and her infant living in a group foster home. In each situation, the nurse can view the clients in perspective and, therefore, better understand their limitations, capitalize on their resources, and tailor health services to meet their needs. In the home, unlike in most other health care settings, clients are on their own "turf." They feel comfortable and secure in familiar surroundings and often are better able to understand and apply health information. Client self-respect can be promoted, because the client is host and the nurse is a guest.

Sometimes, the thought of visiting in clients' homes can cause anxiety for the nurse. This may be the nurse's first experience outside the acute care, long-term care, or clinic setting. Visiting clients in their own environment can make the nurse feel uncomfortable. The nurse may be asked to visit families in unfamiliar neighborhoods, and she must walk through those neighborhoods to locate the clients' homes. Frequently, fear of the unknown is the real fear—a fear that often has been enhanced by stories from previous nurses. This may be the same feeling as that experienced when caring for your first client, first entering the operating room, or first having a client in the intensive care unit. However, in the community, more variables exist, and basic safety measures should be used by all people when out in public. General guidelines for safety and making home visits are covered in detail in Chapter 19. Nevertheless, the specific instructions given during the clinical experience should be followed, and everyday, common-sense safety precautions should be used.

Changes in the health care delivery system, along with shifting health economics and service delivery (discussed in Chapter 6), are changing community health nursing's use of the home as a primary setting for practice. Many local health departments are finding it increasingly difficult to provide widespread home visiting by their public health nurses. Instead, many agencies are targeting populations that are most in need of direct intervention. Examples include families of children with elevated blood lead levels, low-birth-weight babies, clients requiring directly observed administration of

tuberculosis medications, and families requiring ongoing monitoring due to identified child abuse or neglect. With limited staff and limited financial resources, the highest-priority clients or groups are targeted.

With skills in population-based practice, community health nurses serve the public's health best by focusing on sites where they can have the greatest impact. At the same time, they can collaborate with various types of home care providers, including hospitals, other nurses, physicians, rehabilitation therapists, and durable medical equipment companies, to ensure continuous and holistic service. The nurse continues to supervise home care services and engage in case management. The increased demand for highly technical acute care in the home requires specialized skills that are best delivered by nurses with this expertise. Chapter 32 further examines the nurse's role in the home health and hospice settings. The ANA documents *Home Health Nursing Scope and Standards of Practice* (2007a) and *Hospice and Palliative Nursing: Scope and Standards of Practice* (2007b) offer additional insight on these specialty areas.

### Ambulatory Service Settings

Ambulatory service settings include a variety of venues for community health nursing practice in which clients come for day or evening services that do not include overnight stays. A community health center is an example of an ambulatory setting. Sometimes, multiple clinics offering comprehensive services are community based or are located in outpatient departments of hospitals or medical centers. They also may be based in comprehensive neighborhood health centers. A single clinic, such as a family planning clinic or a well-child clinic, may be found in a location that is more convenient for clients, perhaps a church basement or empty storefront. Some kinds of day care centers, such as those for physically disabled or adults with behavioral health issues, use community health nursing services. Additional ambulatory care settings include health departments (city, county, or state) and community health nursing agencies, where clients may come for assessment and referral or counseling. An increasing number of nurse-managed health centers have also been formed over the past decade, often as a community service component of schools of nursing. The mission of these centers varies, but they are typically used to enhance student clinical experiences while providing identified community needs in the areas of primary health care and health promotion (see Chapter 31).

Offices are another type of ambulatory care setting. Some community health nurses provide service in conjunction with a medical practice; for example, a community health nurse associated with a health maintenance organization sees clients in the office and undertakes screening, referrals, counseling, health education, and group work. Others establish independent practices by seeing clients in community nursing centers, as well as making home visits.

Another type of ambulatory service setting includes places where services are offered to selected groups. For example, community health nurses practice in migrant camps, on Tribal lands, at correctional facilities, in children's day care centers, through faith communities, and in remote mountain and coal-mining communities. In each ambulatory setting, all of the community health nursing roles are used to varying degrees (see Student Voices).

## PERSPECTIVES STUDENT VOICES

### A Graduating Student Viewpoint on Postgraduation Employment

Before entering nursing school, I spent 6 years on active duty as a corpsman in the Navy. I remembered seeing some nurses who visited our hospital wearing what looked like Navy uniforms, but was told that they worked for the federal government and weren't in the Navy. I didn't think much of it until I was looking up information on the U.S. Public Health Service and the Surgeon General. Only then did it dawn on me that those nurses were part of the Commissioned Corps of the Public Health Service. I didn't even know they existed, much less what they did, so I looked around the section of the website dealing with nursing. It turns out that they do quite a bit—respond to disasters, provide health services to Native Americans, and even work with the federal prisons. It surprised me to find out that they hire new graduates for many of their positions. I still haven't decided what I want to do after I graduate, but I may seriously consider this option. They even have an extern program available while I'm still in school—who knows, I may be in uniform again.

Matt, Age 24

### Schools

Schools of all levels make up a major group of settings for community health nursing practice. Nurses from community health nursing agencies frequently serve private schools at elementary and intermediate levels. Public schools are served by the same agencies or by community health nurses hired through the public school system. The community health nurse may work with groups of students in preschool settings, such as Montessori schools, as well as in vocational or technical schools, junior colleges, and college and university settings. Specialized schools, such as those for the developmentally disabled, are another setting for community health nursing practice.

Community health nurses' roles in school settings are changing. School nurses, whose primary role initially was that of clinician, are widening their practice to include more health education, interprofessional collaboration, and client advocacy. For example, one school had been accustomed to using the nurse as a first-aid provider and record keeper. Her duties were handling minor problems, such as headaches and cuts, and keeping track of such events as immunizations. This nurse sought to expand her practice and, after consultation and preparation, collaborated with a health educator and some of the teachers to offer a series of classes on personal hygiene, diet, and sexuality. She started a drop-in health counseling center in the school and established

a network of professional contacts for consultation and referral.

Community health nurses in school settings also are beginning to assume managerial and leadership roles and to recognize that the researcher role should be an integral part of their practice. The nurse's role with school-age and adolescent populations is discussed in detail in Chapter 22. The *ANA School Nursing: Scope and Standards of Practice* (2005a) provides additional information on this important specialty.

## Occupational Health Settings

Business and industry provide another group of settings for community health nursing practice. Employee health has long been recognized as making a vital contribution to individual lives, the productivity of business, and the well-being of the entire nation. Organizations are expected to provide a safe and healthy work environment, in addition to offering insurance for health care. More companies, recognizing the value of healthy employees, are going beyond offering traditional health benefits to supporting health promotional efforts. Some businesses, for example, offer healthy snacks, such as fruit at breaks, and promote jogging during the noon hour. A few larger corporations have built exercise facilities for their employees, provide health education programs, and offer financial incentives for losing weight or staying well.

Community health nurses in occupational health settings practice a variety of roles. The clinician role was primary for many years, as nurses continued to care for sick or injured employees at work. However, recognition of the need to protect employees' safety and, later, to prevent their illness led to the inclusion of health education in the occupational health nurse role. Occupational health nurses also act as employee advocates, assuring appropriate job assignments for workers and adequate treatment for job-related illness or injury. They collaborate with other health care providers and company management to offer better services to their clients. They act as leaders and managers in developing new health services in the work setting, endorsing programs such as hypertension screening and weight control. Occupational health settings range from industries and factories, such as an automobile assembly plant, to business corporations and even large retail sales systems. The field of occupational health offers a challenging opportunity, particularly in smaller businesses, where nursing coverage usually is not provided. Chapter 31 more fully describes the role of the nurse serving the working adult population.

## Residential Institutions

Any facility where clients reside can be a setting in which community health nursing is practiced. Residential institutions can include a halfway house in which clients live temporarily while recovering from drug addiction or an inpatient hospice program in which terminally ill clients live. Some residential settings, such as hospitals, exist solely to provide health care; others provide a variety of services and support. Community health nurses based in a community agency maintain continuity of care for their clients by collaborating with hospital personnel, visiting clients in the hospital, and planning care during and after hospitalization.

Some community health nurses serve one or more hospitals on a regular basis by providing a liaison with the community, consultation for discharge planning, and periodic in-service programs to keep hospital staff updated on community services for their clients. Other community health nurses with similar functions are based in the hospital and serve the hospital community.

A continuing care center is another example of a residential site providing health care that may use community health nursing services. In this setting, residents usually are elderly; some live quite independently, whereas others become increasingly dependent and have many chronic health problems. The community health nurse functions as advocate and collaborator to improve services. The nurse may, for example, coordinate available resources to meet the needs of residents and their families and help safeguard the maintenance of quality operating standards. Chapter 24 discusses the community health nurse's role with elders aging in place. Chapter 32 discusses nursing services needed by clients after hospitalization through home care services or by families and clients in hospice programs. Sheltered workshops and group homes for mentally ill or developmentally disabled children and adults are other examples of residential institutions that serve clients who share specific needs.

Community health nurses also practice in settings where residents are gathered for purposes other than receiving care, where health care is offered as an adjunct to the primary goals of the institution. For example, many nurses work with camping programs for children and adults offered by religious organizations and other community agencies, such as the Boy Scouts, Girl Scouts, or the YMCA. Other camp nurses work with children and adults who have chronic or terminal illnesses, through disease-related community agencies such as the American Lung Association, American Diabetes Association, and American Cancer Society. Camp nurses practice all available roles, often under interesting and challenging conditions.

Residential institutions provide unique settings for the community health nurse to practice health promotion. Clients are a "captive audience" whose needs can be readily assessed and whose interests can be stimulated. These settings offer the opportunity to generate an environment of caring and optimal-quality health care provided by community health nursing services.

## Faith Communities

Faith community nursing finds its beginnings in an ancient tradition. The beginnings of community health nursing can be traced to religious orders (see Chapter 2), and for centuries, religious and spiritual communities were important sources of health care. In faith community nursing today, the practice focal point remains the faith community and the religious belief system provided by the philosophical framework. Faith community nursing may take different names, such as church-based health promotion (CBHP), parish nursing, or primary care parish nursing practice (PCPNP). Whatever the service is called, it involves a large-scale effort by the church community to improve the health of its members through education, screening, referral, treatment, and group support.

In some geopolitical communities, faith community nurses are the most acceptable primary care providers. The role of the nurse can be broad, being defined by the needs of the members and the philosophy of the religious community. However, the goal is to enhance and extend services available in the larger community, not to duplicate them.

The ANA has written standards of care for faith community nursing practice in collaboration with Health Ministries Association, Inc. (ANA, 2005b). The standards act as guidelines for faith communities that plan to offer or are offering faith community nursing services. This specialty area of practice is guided by a variety of standards set up by several groups. Together, these standards provide guidance and direction for caregiving within the faith community.

When community health nurses work as faith community nurses, they enhance accessibility to available health services in the community while meeting the unique needs of the members of that religious community, practicing within the framework of the tenets of that religion. A nurse working within a faith community must be cognizant of the basic principles and practices of the religious group served. In most situations, the nurse is a

practitioner of the same religious belief system. Chapter 31 provides more detailed information about this specialty area of practice.

### Community at Large

Unlike the six settings already discussed, the seventh setting for community health nursing practice is not confined to a specific philosophy, location, or building. When working with groups, populations, or the total community, the nurse may practice in many different places (Display 3.4). For example, a community health nurse, as clinician and health educator, may work with a parenting group in a church or town hall. Another nurse, as client advocate, leader, and researcher, may study the health needs of a neighborhood's elderly population by collecting data throughout the area and meeting with resource people in many places. Also, a nurse may work with community-based organizations such as an AIDS organization or a support group for parents experiencing the violent death of a child. Again, the community at large becomes the setting for practice for a nurse who serves on health care planning committees, lobbies for health legislation at the state capital, runs for a school board

**DISPLAY 3.4**

**INNOVATIVE COMMUNITY HEALTH NURSING PRACTICE**

In some community health nursing courses, students do not have access to an established agency such as a health department or community center from which to establish a client base. Student nurses and practicing community health nurses can provide outreach services and do case-finding in innovative settings such as these:

Settings	Clients	Roles of the Community Health Nurse
1. Senior centers when flu shots are given or commodities are distributed	Older adults	Educator, Clinician, Advocate
2. Outside of grocery stores, department stores, movie theaters, large pharmacies	People of all ages and families	Educator, Clinician, Advocate
3. At PTA meetings, sporting events, dances, and school registration (in collaboration with school nurses)	Young adults, children, and teenagers	Educator, Clinician, Advocate
4. Outside of concerts, plays, the circus, etc.	People of all ages	Educator, Clinician, Advocate
5. Other public gatherings: farmers markets, neighborhood yard sales, etc.	People of all ages	Educator, Clinician, Advocate
6. Conferences or seminars	People of all ages	Leader, Educator, Clinician
7. "On the street"	Homeless persons, passersby, transients, low-income urban dwellers	Educator, Clinician, Advocate
8. Truck stops	Predominantly employed men	Educator, Clinician, Advocate

**Leader Role**—initiate, plan, strategize, collaborate, and cooperate with community groups to present programs that are focused on specific population's needs.

**Educator Role**—teach nutrition, stress management, safety, exercise, prevention of sexually transmitted diseases, and other mens' and womens' health issues, child home/school/play and stranger safety, and child growth and development, and provide anticipatory guidance. Have pamphlets available to support verbal information on health and safety topics, specific diseases, Social Security, Medicare, and Medicaid.

**Clinician Role**—perform blood pressure screening, height, weight, blood testing for diabetes and cholesterol, occult blood test, hearing and vision tests, scoliosis measurements, and administration of immunizations.

**Advocate Role**—provide information regarding community resources as needed, cut "red tape" for those who need it, answer questions, and guide people to additional resources, such as Internet Web sites and "800" phone numbers.

position, or assists with flood relief in another state or another country.

Although the term “setting” implies a place, remember that community health nursing practice is not limited to a specific site. Community health nursing is a specialty of nursing that is defined by the nature of its practice, not its location, and it can be practiced anywhere. As you read through this chapter, perhaps an area of practice or a particular population captured your attention. If you are interested in Tribal health, you might consider working as a Public Health Service nurse, or if you find that you are more interested in providing comprehensive health promotion programs to rural individuals, a nurse-managed health center may be of interest. Opportunities for community health nursing include the American Red Cross, state and local health departments, the Peace Corps, and various international aide groups. Both private and public health agencies are actively seeking nurses with an interest in improving the health of their communities. Take some time to read over Chapters 30 and 31; perhaps you will find an opportunity that supports your professional goals.

## Summary

Community health nurses play many roles, including that of clinician, educator, advocate, manager, collaborator, leader, and researcher. Each role entails special types of skills and expertise. The type and number of roles that are practiced vary with each set of clients and each specific situation, but the nurse should be able to successfully function in each of these roles as the particular situation demands. The role of manager is one that the nurse must play in every situation, because it involves assessing clients’ needs, planning and organizing to meet those needs, directing and leading clients to achieve results, and controlling and evaluating the progress to ensure that the goals and clients’ needs are met. A type of comprehensive management of clients that has become known as *case management* is an integral part of community health nursing practice.

As a part of the manager role, the nurse must engage in three crucial management behaviors: decision-making, transferring information, and relationship building. Nurses must also use a comprehensive set of management skills: human skills that allow them to understand, communicate, motivate, and work with people; conceptual skills that allow them to interpret abstract ideas and apply them to real situations to formulate solutions; and technical skills that allow them to apply special management-related knowledge and expertise to a particular situation or problem.

There also are many types of settings in which the community health nurse may practice and in which these roles are enacted. “Setting” does not necessarily refer to a specific location or site, but rather to a particular situation. These situations can be grouped into seven major categories: homes; ambulatory service settings, where clients come for care but do not stay overnight; schools; occupational health settings, which serve employees in business and industry; residential institutions such as hospitals, continuing care facilities, halfway houses, or other institutions in which people live and sleep; faith communities, where care is based on the philosophy of the religious organization; and the community at large, which encompasses a variety of expected and innovative locations. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Discuss ways for a community health nurse to make service holistic and focused on wellness with
  - a. preschool-age children in a day care setting.
  - b. a group of chemically dependent adolescents.
  - c. a group of elders living in a senior high-rise building.
2. Select one community health nursing role and describe its application in meeting the needs of your friend or next-door neighbor.
3. Describe a hypothetical or real situation in which you, as a community health nurse, would combine the roles of leader, collaborator, and researcher (investigator). Discuss how each of these roles might be played.
4. If your community health nursing practice setting is the community at large, will your practice roles be any different from those of the nurse whose practice setting is the home? Why? What determines the roles played by the community health nurse?
5. Interview a practicing community health nurse and determine which roles are part of the nurse’s practice during 1 month of caregiving. Describe the ways in which each role is enacted. How many instances of this nurse’s practice were aggregate focused? In which of the settings does the nurse mostly practice? If you were a public health consultant, what suggestions might you make to expand this nurse’s role into aggregate-level practice?
6. Search the Internet or go to the library and find two sources of health-related information for consumers. Was the information accurate?
7. Search the Internet or go to the library and find two research articles on community health nursing. In what settings did the research take place? Did the nursing authors collaborate with interdisciplinary team members on this research? If so, how do you think this collaboration helped the research? If you were to conduct research in the community, would you conduct it with only nurses on the team, or would your team be interdisciplinary? Why? What would be the benefits or limits of each approach?

# 4

## Evidence-based Practice and Ethics in Community Health Nursing

### LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Discuss the concept of evidence-based practice (EBP).
- ◆ List the necessary steps in the process of EBP.
- ◆ Explain the difference between quantitative research and qualitative research.
- ◆ List the nine steps of the research process.
- ◆ Analyze the potential impact of research on community health nursing practice.
- ◆ Identify the community health nurse's role in conducting research and using research findings to improve his or her practice.
- ◆ Describe the nature of values and value systems and their influence on community health nursing.
- ◆ Articulate the impact of key values on professional decision-making.
- ◆ Discuss the application of ethical principles to community health nursing decision-making.
- ◆ Use a decision-making process with and for community health clients that incorporates values and ethical principles.

*“Doing good to others is not a duty. It is a joy, for it increases your own health and happiness.”*

—Zoroaster

As a new student in community health nursing, you may ask, “Can I really do something to make a difference in the lives of my clients?” You may often feel shocked and discouraged by the crushing poverty and overwhelming sense of helplessness many of your clients experience, and by the continual recurrence of substance abuse, domestic violence, job failure, and criminal activity. For the first time, you may truly confront the inequalities and injustices of our health care system. You will face many ethical dilemmas in community health nursing. You may ask, “Why should I bother to make home visits to pregnant teens? Why should I offer smoking cessation classes at the local homeless shelter? Why should I teach clients about the importance of taking their antituberculosis medications? Will it really matter?”

This chapter discusses current research as it relates to and impacts community health nursing practice. The steps of the research process are identified and discussed, and evidence-based practice (EBP) is emphasized. The chapter includes information on constructing a clinical question and incorporating client considerations and clinical guidelines, and helpful resources for finding and analyzing research studies. Ethics and values are also examined, as they relate to both research and community health nursing practice. This chapter explores the nature and function of values and value systems, the role of values and value systems in ethical decision-making, the central values related to health care choices and their potential conflicts, and the implications of values and ethics for community health nursing decision-making and practice.

Recent community health nursing research validates that nursing care *does* matter and that you really *can* make a difference in the lives of your clients. For example, nurse–family partnership programs, based on research conducted by David Olds and his colleagues, are reaping results in many communities across the United States (Nurse–Family Partnership, 2008). In a classic longitudinal study by Olds and his research team (1997), conducted with a primarily White sample in a semi-rural setting over a 15-year period, regular visits by public health nurses (PHNs) to poor, unmarried women and their first-born children resulted in dramatic differences when compared with similar mothers and children in a control group. Many of the women in the study were younger than 19 years of age, and nurses made an average of nine prenatal visits and 23 child-related visits (up to age 2 years). Statistically significant differences were noted in the following outcomes:

- ◆ Fewer subsequent pregnancies and increased percentage of live births
- ◆ Longer intervals between first and second births
- ◆ Fewer incidences of reported child abuse and neglect
- ◆ Fewer months on public assistance and food stamps
- ◆ Fewer arrests and convictions
- ◆ Less reported impairment by alcohol or other drug use

The effects of the intervention continued for up to 15 years after the birth of the first child. This is powerful evidence for the effectiveness of a program of regular community/PHN visits to this vulnerable group. The costs of community health nurse visits are more than offset by the large savings in both dollars and human suffering. The Rand

Corporation estimates that programs of this type “generate a return to society ranging from \$1.80 to \$17.07 for each dollar spent” (2005, p. 1). Rand also noted that “stronger impacts” occurred when a nurse provided home visits “as opposed to a paraprofessional or lay professional home visitor” (2005, p. 2). So, community/PHNs really *do* make a difference!

The nurse–family partnership model was based on theory and research. Numerous other studies of public nursing practice have been done, across different locales and with different populations. For instance, David Olds and his colleagues (Kitzman et al., 2000) examined the enduring effects of a nurse home visitation program on a different population—a group of primarily Black urban women—and found that 3 years after visits ended, when compared with the women in the control group, the participants had:

- ◆ Fewer subsequent pregnancies
- ◆ Longer intervals between the births of their first and second children
- ◆ Fewer closely spaced subsequent pregnancies
- ◆ Fewer months of using welfare and food stamps

Women in the home visitation program had an average of only seven visits during their pregnancies and approximately one visit per month during the first 2 years of their children’s lives—a relatively small investment of time and resources with potentially priceless returns.

In a follow-up study, the effects of this nurse visitation program were found to continue 4 years after the program ended (Olds et al., 2004). Mothers had fewer subsequent pregnancies and births, longer intervals between the births of first and second children, longer relationships with current partners, and fewer months of using food stamps and welfare. In addition, the children who were visited by community health nurses had fewer behavior problems and higher math achievement test scores, and they demonstrated less incoherence and aggression.

Child maltreatment and the early onset of problem behaviors were outcomes also examined by Olds, Eckenrode, and colleagues (1997). They reexamined the group of low-income unmarried women and their first-born children as the children were turning 15 years old; these researchers concluded that a 2-year program of nurse home visitation had moderated the risk of child maltreatment.

Do community health nurses really make the difference, or can other health care workers also get results? Olds and colleagues (2004) have examined differences between nurse and paraprofessional visitation in a large study of mostly Mexican American low-income first-time mothers. Initially, no statistical differences were noted between control and paraprofessional subjects. Two years after the end of the program, participants visited by paraprofessionals had fewer low-birth-weight babies and had better results than control subjects on measures of mastery and mental health, and home environments conducive to early learning—these benefits were only noticeable 2 years after the visits ended. However, mothers visited by nurses showed immediate as well as long-term benefits. They had longer intervals between first and second births, less domestic violence, and home environments conducive to early learning. Children of those mothers had better behavioral adaptation during testing, more advanced language scores, and better executive

functioning. Olds and his fellow researchers are convinced that public/community health nurses are the key to success.

Other researchers have noted benefits of community health nurse visitation in nurse–family partnerships in California for Hispanic adolescent mothers and babies (Nguyen, Carson, Parris, & Place, 2003). Even using different protocols than the tightly controlled Olds’ model, intense PHN visitation for Latina and African American adolescent mothers and infants was found to be more effective than traditional PHN care (Koniak-Griffin et al., 2003).

This evidence about the effectiveness of public health nursing visits can be gleaned only through conducting formal nursing research. **Research** is the systematic collection and analysis of data related to a particular problem or phenomenon. Research that is properly conducted and analyzed has the potential to yield valuable information that can affect the health of large groups of people. Indeed, it should guide our practice of community health nursing, and it often serves as the basis for changes in health care policies and programs. In the current national atmosphere of managed care and obstinately rising health care costs, the importance of valid research on how health care dollars can be spent to benefit the greatest number of people is vitally important.

## EVIDENCE-BASED PRACTICE

Dr. Archie Cochrane, a British epidemiologist, is widely regarded as the force behind evidence-based clinical practice in medicine (The Cochrane Collaboration, 2008). We certainly have ample evidence of the need for a shift to **evidence-based practice** (EBP) in health care: the Institute of Medicine has been studying the issues of health care quality and effectiveness over the past decade and has called for widespread and systematic changes through their reports—*To Err Is Human: Building a Safer Health System* (2000), *Crossing the Quality Chasm: A New Health System for the 21st Century* (2001), and *Priority Areas for National Action: Transforming Health Care Quality* (2003). These reports draw attention to the fact that we spend “billions in research to find appropriate treatments,” and more than a trillion dollars are spent annually on health care, but “we repeatedly fail to translate that knowledge and capacity into clinical practice” (2003, p. 2). In response, the federal Agency for Healthcare Research and Quality (AHRQ) has established EBP centers across the United States and Canada. Schools of nursing, such as Arizona State University, University of Texas Health Science Center at San Antonio, Case Western Reserve, and the University of Rochester, also have established centers for EBP.

According to Melnyk and Fineout-Overholt (2005), EBP in nursing means just that—using evidence (or research findings), along with clinical judgment and patients’ wishes, in making decisions about how to care for patients. Clinical reasoning is an important component. Higgs, Burn, and Jones (2001) reiterate that the practice knowledge of expert clinical nurses is vital to the process. For Porter-O’Grady (2006), EBP is the “integration of the best possible research” evidence with clinical knowledge and expertise, along with patient preferences and needs (p. 1). Thinking critically about practice problems is an important component of EBP. Reflecting on why we do things a particular way, and critically thinking through a problem in a purposeful, systematic way are vital steps in the process. For instance,

Porter O’Grady (2006) finds commonalities between EBP and critical thinking:

- ◆ Exploring a problem
- ◆ Addressing a purpose or goal
- ◆ Making assumptions about the problem derived from an assessment of the problem and its elements
- ◆ Clarifying the problem around central concepts or indicators
- ◆ Accessing data, evidence, information, and sources to better explain the problem
- ◆ Interpreting accumulated evidence about the specific situation or problem
- ◆ Using reasoning, processing, defining, planning, and documenting to guide subsequent actions in addressing the issue
- ◆ Acting on the problem, consistent with protocols and parameters, and “assessing process, impact, and effect” (p. 6)
- ◆ Evaluating, adjusting, generalizing, and applying to a broader problem set (indicative of a successful problem-solving process)

The effective practitioner utilizes his clinical judgment and expertise to reflect on the practice of community health nursing and determine if safe, effective, quality, and cost-efficient care is being delivered. Problems or situations that need clarification can then be identified, and current research can be reviewed to guide needed changes in practice. Although acknowledged barriers exist, they can be overcome utilizing available resources (Ciliska, Pinelli, DiCenso, & Cullum, 2001; Morris, Scott-Findlay, & Estabrooks, 2001). Melnyk and Fineout-Overholt (2005) stress the importance of systematically searching for all relevant research on a clinical question of interest and critically analyzing the evidence (Fig. 4.1). They argue that this is not merely research utilization, in which new interventions may be tried based on the results of one or two good studies, but “systematic reviews of randomized clinical trials (RCTs)” and critical reviews of both quantitative and qualitative studies pertinent to a particular question of interest (p. 7). While doing this, the nurse must keep in mind the unique needs and wants of the clients served, as well as current practice standards, guidelines, and ethical considerations. Sanares and Heliker (2006, p. 33) note that “nationally recognized clinical

### Five Steps of Evidence-based Practice

1. Ask the burning clinical question.
2. Collect the most relevant and best evidence.
3. Critically appraise the evidence.
4. Integrate all evidence with one’s clinical expertise, patient preferences, and values in making a practice decision or change.
5. Evaluate the practice decision or change.

**FIGURE 4.1** Five steps of evidence-based practice. From Melnyk, B., & Fineout-Overholt, E. (2005). *Evidence-based practice in nursing and healthcare*, p. 9, with permission.

practice guidelines” should be reviewed (e.g., National Guideline Clearinghouse at [www.guideline.gov](http://www.guideline.gov)), and expert clinicians could be interviewed for their opinions on the problem at hand. In fact, Thompson and colleagues (2004) note that nurses rely on colleagues as “experiential sources of information”; well-seasoned nurses and clinical nurse specialists can be “the most useful (and accessible) information sources” (p. 7).

Although expert nurses are a good starting point in collecting evidence, clinically relevant research that is both medically sound and patient-centered must be reviewed. Good places to begin are **integrative** or **systematic reviews** that compile all recent studies and summarize what is known about the problem or situation. The Cochrane Collaboration ([www.cochrane.org](http://www.cochrane.org)) lists systematic reviews on various topics of interest to both physicians and nurses. For instance, a community health nurse working with a group of adults who have diabetes might be interested in the systematic review on the importance of exercise for type 2 diabetes clients. This review is based on 14 RCTs that compared the use of exercise in a group of 377 participants over periods of between 8 weeks to 12 months. When compared with those who got no exercise intervention, the results indicated decreased body fat and triglyceride levels and improved blood sugar control for those exercising (even for those who did not lose any weight). Although a community health nurse may certainly have a “hunch” that exercise is good for his or her clients, this systematic review of current studies provides solid evidence on which to base recommendations (Thomas, Elliott, & Naughton, 2006). A review on promoting adherence to antiretroviral therapy for human immunodeficiency virus (HIV)/acquired immune deficiency syndrome (AIDS) clients might be helpful to a PHN supervisor in designing an AIDS case management program utilizing community health nurses. Over 2,159 participants in 19 RCTs were part of this review, which found that interventions such as “practical medication management skills . . . administered to individuals vs. groups and . . . delivered over 12 weeks or more” had improved medication adherence (Rueda et al., 2006, ¶ 6). From this evidence, a community health nurse case manager can conclude that medication compliance can be effectively assured through development of a nurse–client relationship based on the nurse’s consistent availability to the client—through home visits or individual appointments at clinics—and a focus on teaching medication management skills.

The AHRQ EBP centers also provide evidence reports that are easily accessible online ([www.ahrq.gov/clinic/epcindex.htm](http://www.ahrq.gov/clinic/epcindex.htm)). These can be searched by topical index, clinical area, or health care services (e.g., bioterrorism) and technical areas (e.g., community-based participatory research). Other sources for systematic or integrative reviews include:

- ◆ *Worldviews on Evidence-Based Nursing* from Sigma Theta Tau International ([www.nursingsociety.org](http://www.nursingsociety.org))
- ◆ *Evidence-Based Nursing*, a British online journal ([www.ebn.bmjournals.com](http://www.ebn.bmjournals.com))
- ◆ RAND Corporation research briefs ([www.rand.org](http://www.rand.org))

## ASKING THE QUESTION

Melnyk and others suggest that the first step to solving the problem is “asking the burning clinical question” (2005, p. 8). This question may be about client care or effective interventions, such as:

- ◆ What methods are most effective in assuring client medication compliance with antiretroviral therapy for HIV/AIDS?
- ◆ What is the best information I can give new mothers about preventing sudden infant death syndrome (SIDS)?

It could also be about systems approaches to population health:

- ◆ What is the most effective method of immunizing toddlers?
- ◆ How can PHNs better collaborate with families, physicians, and hospitals in preventing complications of high levels of bilirubin in newborns coming home within 24 to 48 hours after birth?

There are some specific methods of phrasing or structuring questions (Fig. 4.2). The Association of Women’s Health, Obstetric, and Neonatal Nurses (AWHONN) asked a “burning clinical question” when they wanted to find a scientific basis for the development of standards of practice for their members regarding counseling pregnant women on smoking cessation. The project, *Setting Universal Cessation Counseling, Education, and Screening Standards* (SUCCESS), was an attempt to integrate best practices in primary care settings where women of childbearing age receive care. They did extensive searches in the Cumulative Index on Nursing and Allied Health Literature (CINAHL) and MEDLINE for research studies relating to low-birth-weight infants, effects of prenatal smoking on infants, and effects of smoking cessation intervention on premature labor and birth weight with both pregnant women and those seeking care prior to conception (Albrecht, Maloni, Thomas, Jones, Halleran, & Osborne, 2004). They critically analyzed 98 articles, and found evidence of a higher incidence of many complications, including preterm labor, premature rupture of membranes, lower birth weight and length, spontaneous abortion, and placenta previa or abruption in women using tobacco. Infants and children exposed to secondhand smoke had a higher risk for ear infections, asthma and other respiratory problems, SIDS, and learning disorders. Significant evidence suggested that this was a problem that needed to be addressed. They also concluded “office-based assessment, client-specific tobacco counseling, skill development, and support programs serve as an effective practice guideline” for their members, so they developed protocols and began piloting them in 13 states (p. 298). They are currently continuing to collect evaluation research to determine the effectiveness of the protocols.

Critical analysis of the literature is a necessary step in EBP. Systematic reviews should be carefully examined to determine validity by asking these questions (University of Alberta Medical School, 2006):

- ◆ Did the review concentrate on a “focused clinical question” (¶ 1)?
- ◆ Were there appropriate inclusion criteria for articles?

PICO		
<b>Patient population/disease</b>	The patient population or disease of interest, for example: <ul style="list-style-type: none"> <li>• Age</li> <li>• Gender</li> <li>• Ethnicity</li> <li>• With certain disorder (e.g., hepatitis)</li> </ul>	(e.g., adolescent females ages 12–20)
<b>Intervention</b>	The intervention or range of interventions of interest, for example: <ul style="list-style-type: none"> <li>• Exposure to disease</li> <li>• Prognostic factor A</li> <li>• Risk behavior (e.g., smoking)</li> </ul>	(e.g., sexuality education program)
<b>Comparison</b>	What you want to compare the intervention against, for example: <ul style="list-style-type: none"> <li>• No disease</li> <li>• Placebo or no intervention/therapy</li> <li>• Prognostic factor B</li> <li>• Absence of risk factor (e.g., nonsmoking)</li> </ul>	(e.g., no intervention)
<b>Outcome</b>	Outcome of interest, for example: <ul style="list-style-type: none"> <li>• Risk of disease</li> <li>• Accuracy of diagnosis</li> <li>• Rate of occurrence of adverse outcome (e.g., death)</li> </ul>	(e.g., fewer unplanned pregnancies)

**FIGURE 4.2** PICO: Components of an answerable, searchable question. Adapted from Melnyk, B., & Fineout-Overholt, E. (2005). *Evidence-based practice in nursing and healthcare*, p. 30.

- ◆ Were any important, relevant studies overlooked?
- ◆ Was the validity of all included studies taken into consideration?
- ◆ Were there similar results found in all studies?
- ◆ How reliable are the results?
  - Were sample sizes large enough?
  - Were results statistically significant?
  - Were there confounding factors (outside influences that make you doubt the results)?

Next, it is important to decide if incorporating this information into your practice will be helpful by asking:

- ◆ How can I apply these results to my community health nursing practice?
  - Will it benefit my clients?
  - Are my clients similar to the population studied?
  - Do I have the necessary resources?

To effectively practice evidence-based research, community health nurses must know how to correctly compose a clinical question, find an appropriate database to search for systematic reviews, critically review the evidence, consult practice guidelines and expert practitioners, and work with their clients to develop an appropriate plan of action. A clear understanding of basic research principles is needed to systematically review and incorporate research into community health nursing practice.

## QUANTITATIVE AND QUALITATIVE RESEARCH

Scientific inquiry through research is generally pursued by means of two different approaches: quantitative research and qualitative research. **Quantitative research** concerns data that can be quantified or measured objectively. This could be as simple as counting the number of children receiving vaccination for varicella in immunization clinics during the past month and noting the number of reported cases of postvaccination complications. Another example of a rather simple quantitative study uses telephone survey methods to determine older rural adults' use of complementary health care (e.g., acupuncture, herbal remedies). Shreffler-Grant and colleagues (2005) picked a random sample of 325 older adults from rural communities in two states and found that, whereas only 17.5% had used complementary providers, over 45% had used some form of complementary health care—many of them finding out about these methods by word-of-mouth. They noted that this figure was similar to findings in larger national studies. This has implications for nurses working with rural older adults, who may think that this population doesn't have access to alternative forms of health care, thus risking the potential for possible drug interactions or side effects of these treatments in their clients.

Another study by Valente (2005) examined staff nurses' perceptions of improved knowledge with the use of

research-based fact sheets. Concise, well-researched fact sheets on common topics (e.g., hypertension, heart failure, pressure ulcers, depression) were developed at a Veterans Administration hospital in an effort to improve nursing care. Over 93% of nurses felt that the use of the fact sheets improved their knowledge level. This led to other questions, such as the perceived quality of the fact sheets and the perceived areas needing improvement. The majority of nurses rated them as “excellent” and noted that they used them to improve patient “education, assessment, intervention, and follow-up care” (p. 171).

More variables can be added to quantitative studies. An example is a study by Remington (2002) that was also reported in an integrative review on the use of preferred music to decrease agitated behavior in elderly clients with dementia (Sung & Chang, 2005). The review concluded that music has “positive effects on decreasing agitated behaviours in older people with dementia” (p. 1,133), but the Remington study employed 10-minute periods of either calming music, hand massage, combined music and massage, or no treatment (control) to determine whether all of the three treatment groups had demonstrated benefits. By adding the variable of hand massage, another effective method of calming agitated clients with dementia was discovered—one that may be more appropriate for hearing-impaired elders.

Quantitative research is helpful in identifying a problem or a relationship between two or more variables, such as type of treatment (e.g., calming music) and an outcome (agitated behaviors in nursing home residents with dementia). In so doing, quantitative studies tend to examine isolated parts of problems or phenomena and do not generally pay attention to the larger context or overall health of individuals. Quantitative research involves a reductionistic tendency (focusing on the parts rather than the whole) and, if used exclusively, can limit nursing knowledge, because many of the important aspects of client services (e.g., quality of life, grieving, spirituality) cannot be measured objectively.

A more subjective or qualitative approach is needed to study those areas that need a broader focus or that do not lend themselves to objective measurement. **Qualitative research** emphasizes subjectivity and the meaning of experiences to individuals. An example of this type of research is a study examining the experiences of individuals who were quarantined because of severe acute respiratory syndrome (SARS) in Toronto (Cava, Fay, Beanlands, McCay, & Wignall, 2005). Quantitative research can tell us the number of people who were quarantined, but qualitative research is needed to understand the feelings and experiences of those affected. Interviews conducted with a sample of quarantined adults revealed that a variety of responses to the initial quarantine order ranged from “acceptance to fear, shock, disbelief, and anger” (p. 401). While in quarantine, many felt isolated and noted a sense of rejection, stigmatization, and scrutiny. A universal response of “relief” was noted when quarantine ended, and suggestions were made to prompt public health officials to improve communication in future episodes. “Timely and trustworthy information about SARS and quarantine” were recommended to decrease levels of confusion and frustration (p. 403).

It is not uncommon to find research studies in which both quantitative and qualitative approaches are used. A

study examining the experiences of Hurricane Katrina evacuees in Houston shelters combined both survey and interview techniques to gather information about the demographics of the evacuees, their experiences during evacuation and emergency response to the storm, and their current well-being and future plans (Brodie, Weltzein, Blendon, & Benson, 2005). The results of the study indicated that those hardest hit by the storm were poor, working, uninsured, long-term residents of New Orleans, mostly African American, and reliant on safety-net providers for medical care. They were unlikely to have their own car or funds to pay for transportation, and were unlikely to have sources of alternative shelter once evacuated. Implications for policy makers, disaster planners, and health care providers were noted in an attempt to learn from past mistakes and deficiencies.

Another method of analyzing research in community health uses a statistical procedure known as **meta-analysis** to evaluate the results of many similar quantitative research studies in an attempt to integrate the findings and combine the sample sizes of many small studies to obtain a “single-effect measure” (Melnik & Fineout-Overholt, 2005, p. 115). By combining the results of many similar studies, meta-analysis affords greater statistical power and can give the researcher a more complete general perspective, especially when research on a certain issue may seem inconclusive. An example of this type of research is highlighted in *Nursing Research* by Wewers, Sarna, and Rice (2006). In addition to discussing barriers to nursing research related to tobacco cessation and future directions to be taken, the authors cited a meta-analysis done by Rice and Stead (2004), in which 29 RCTs examining the effectiveness of nurses as cessation interventionists were analyzed. Both low- and high-intensity interventions were included (i.e., advice given at a single visit lasting less than about 10 minutes and a longer initial visit with follow-up visits that included additional strategies or materials). Through complex statistical measurements, the authors found that “nurse-delivered interventions were more effective than usual care in achieving abstinence at 6 months or longer” (p. 513). The statistical effect was found consistently in both high- and low-intensity nurse interventions. The moral of this meta-analysis is that even short discussions with your clients about smoking cessation, along with information on accessing support groups or other resources, may prove beneficial.

## STEPS IN THE RESEARCH PROCESS

All effective research follows a series of predetermined, highly specific steps. Each step builds on the previous one and provides the foundation for the eventual discussion of findings. It is important to understand basic research principles in order to effectively implement EBP. Alone or in collaboration with others, community health nurses use the following nine steps to complete a research project:

1. Identify an area of interest.
2. Formulate a research question or statement.
3. Review the literature.
4. Select a conceptual model.
5. Choose a research design.
6. Obtain Institutional Review Board or Human Subjects Committee approval.

7. Collect and analyze data.
8. Interpret results.
9. Communicate findings.

Clear research questions, thorough review of the literature, human subjects protection, and a sound research design are factors to consider when evaluating the results of studies for incorporation into your practice.

## Identify an Area of Interest

Identifying the problem or area of interest is frequently one of the most difficult tasks in the research process. The problem needs *specificity* (i.e., it must be specific enough to direct the formulation of a research question). For example, concern about child safety is too broad a problem; instead, the focus could be on a narrower subject, such as the use of child restraints and car seat availability and use in a particular community.

The problem must also be *feasible*. Feasibility concerns whether the area of interest can be examined, given available resources. For example, a statewide study of the needs of pregnant adolescents might not be practical if time or funding is limited, but a study of the same group in a given school district could be more easily accomplished.

The *meaning* of the project and its *relevance* to nursing must also be considered, such as exploring the implications for nursing practice in the study of pregnant adolescents. Areas for study often evolve from personal interests, clinical experience, or philosophical beliefs. The nurse's specialty influences the selection of a problem for study and also the particular perspective or approaches used. The community health nurse functions within a context that emphasizes disease prevention, wellness, and the active involvement of clients in the services they receive. Clients' physical and social environments, as well as their biopsychosocial and spiritual domains, are of major concern. Community health nurses think in terms of the broader community; their research efforts are developed with the needs of the community or specific populations in mind.

Problems recently identified and studied within community health nursing include:

- ◆ Cardiovascular health promotion in aging women: validating a population health approach (Sawatzky & Naimark, 2005)
- ◆ Childhood immunization refusal: provider and parent perceptions (Fredrickson, Davis, Arnould, Kennen, Hurniston, Cross, & Bocchini, 2004)
- ◆ Process evaluation of a nurse-delivered smoking relapse prevention program for new mothers (Groner, French, Ahijevych, & Wewers, 2005)
- ◆ The impact of just-in-time e-mail "reminders" on patient outcomes in home health care (Feldman, Murtaugh, Pezzin, McDonald, & Peng, 2005)
- ◆ Mothers' ranking of clinical intervention strategies used to promote infant health (Gaffney & Altieri, 2001)
- ◆ Racial differences in parenting dimensions and adolescent condom use at sexual debut (Cox, 2006)
- ◆ The volunteer potential of inactive nurses for disaster preparedness (Fothergill, Palumbo, Rambur, Reinier, & McIntosh, 2005)
- ◆ Public health nursing practice change and recommendations for improvement (Zahner & Gredig, 2005)

Each of these problem areas provides direction for the formulation of related research questions.

## Formulate a Research Question or Statement

The research question or statement reflects the kind of information desired and provides a foundation for the remainder of the project. The manner in which the question or statement is phrased suggests the research design for the project. For example, the question "What are nurses' attitudes toward pregnant women who use methamphetamine?" determines that the design will be simple, nonexperimental, and exploratory (see later discussion). In contrast, the question "What is the effect of an educational program on nurses' attitudes toward drug-abusing pregnant women?" suggests an experiment that will evaluate changes in nurses' attitudes toward pregnant women who abuse drugs after receiving an educational intervention. The first research question suggests a broad, open-ended conversation with nurse participants, asking them to discuss their attitudes toward pregnant women who abuse drugs, such as methamphetamine. From the data obtained, general themes and patterns will emerge, leading the researcher to some overall conclusions. The second question examines the effects that an educational program may have on nurses' attitudes about pregnant women who abuse crack cocaine, for instance. This is most likely a quantitative, evaluative study that may involve pretesting to determine the nurses' attitudes, conducting one or more classes, and then posttesting to determine whether any change occurred in attitude or beliefs.

Well-formulated research questions identify the population of interest, the variable or variables to be measured, and the interventions (if any). It is very important when formulating research questions that specific terms be used to clearly represent the variables being studied. For example, if "stress" is identified as the variable measured in the research question, then it is important to note how stress is being defined. The researcher who wants to measure stress experienced by clients waiting for HIV test results must be careful not to measure other related variables, such as trait anxiety (a general personality trait) or depression. Consistency of terms used is crucial to the success of a project, so investigators must formulate the research question carefully. One must be clear about the variable and what is being measured to ensure validity of the results.

Formulation of a PICO question (*patient problem, intervention, comparison, outcome*), related to EBP, is a similar process, especially in its specificity. Good examples of research questions addressed recently by community health nurses include:

- ◆ Are there differences in how rural and urban families [*population of interest*] view death and end-of-life care [*variables*] for their elderly family members with dementia residing in nursing homes (Gessert, Elliott, & McAlpine, 2006)?
- ◆ What is the effect of rural residence [*variable*] on unmet dental care [*variable*] for children with special

health care needs [*population of interest*] (Skinner, Slifkin, & Mayer, 2006)?

- ◆ What is the lived experience [*variable*] of adults being diagnosed with Lyme disease [*population of interest*] (Drew & Hewitt, 2006)?
- ◆ Are parents of low-income Ohio toddlers [*population of interest*] receiving information on lead poisoning prevention [*variable*], and how would they prefer to receive this information [*variable*] (Polivka, 2006)?
- ◆ Can father's clubs [*intervention variable*] improve the health of rural Haitian children [*population of interest*] (Sloand & Gebrian, 2006)?

## Review the Literature

A review of the literature consists of two phases. The first phase consists of a cursory examination of available publications related to the area of interest. Although several nursing research journals publish studies reflecting all areas of nursing practice, most specialty areas have dedicated journals. *Public Health Nursing, Family and Community Health, Journal of Community Health Nursing, American Journal of Public Health, Journal of School Health, Nursing and Health Sciences*, and *Journal of School Nursing* are some of the journals that publish studies of particular interest to community health nurses. In this phase, the investigator develops knowledge about the area of interest that is somewhat superficial but sufficient to make a decision about the value of pursuing a given topic. If considerable research has already been conducted in the area, the investigator may decide to ask a different question or to pursue another area of interest.

The second phase of the literature review involves an in-depth, critically evaluated search of all publications relevant to the topic of interest. The goal of this phase is to narrow the focus and increase depth of knowledge. Journal articles describing research conducted on the topic of interest provide the most important kind of information, followed by clinical opinion articles (information on the topic described by experts in the field) and books. Journal articles provide more up-to-date information than do books, and systematic investigations provide a foundation for other studies. Prior research that has already been done on the topic of interest provides a solid foundation for later replication studies.

Criteria for compiling a good review of the literature include (a) using articles that closely relate to the topic of interest (relevancy); (b) using current articles that provide up-to-date and recent information—usually within the past 5 years (although earlier articles may be included based on their importance to the area of interest); and (c) using both primary and secondary sources. A *primary source* is a publication that appears in its original form. A *secondary source* is an article in which one author writes about another author's work; reviews fall into this category. Primary sources historically were preferred over secondary sources because they afford the investigator a more accurate and first-hand account of the study from which personal conclusions can be drawn. Secondary sources, however, are now seen as more helpful in guiding practice decisions, as integrative reviews of current research are a critical element of EBP.

A major component of a review of literature is the investigator's critical evaluation of the information collected. The conceptual base and research methods of studies must be critically assessed regarding the appropriateness of the methods used and the conclusions drawn, as well as how carefully the research was conducted.

After a careful, critical, and comprehensive review of the literature, the investigator writes a clear description of the information related to the area of interest, including conflicting findings and referencing each study or article. This review provides the basis for the proposed study or the clinical decision to be made. The conclusions from the literature review become the basis for the new study's assumptions and methodology. Rather than making a "leap of knowledge," the hypothesis or research question must be created by basing assumptions on previous research studies.

## Select a Conceptual Model

In relation to research, a **conceptual model** is a framework of ideas for explaining and studying a phenomenon of interest. A conceptual model conveys a particular perception of the world; it organizes the researcher's thinking and provides structure and direction for research activities. Models are like a framework on which to "hang" concepts or variables, and they should be used to guide the design and methods for collecting research data.

All fields of study identify their major areas of concerns or boundaries. Nursing, since the early work of Florence Nightingale, is concerned with the interaction between humans and the environment in relation to health (Blais, Hayes, Kozier, & Erb, 2006). Widely used classic nursing conceptual models such as Orem's (1985) self-care model or King's (1989) open systems model reflect the boundaries and major concerns of nursing as a profession. Although nurse investigators frequently and successfully use conceptual models developed within other fields, the advantage of using nursing models is that they provide an understanding of the world in terms of nursing's major concerns (see Chapter 14).

The investigator can become familiar with various conceptual models by reviewing the literature in the area of interest and by reading any of the many texts available on conceptual models. A thorough understanding of the major concepts of a potential model and their relationships is necessary before one attempts to use a model as a framework for a study.

## Choose a Research Design

The design of a research project represents the overall plan for carrying out the study. This overall plan guides the conduct of the study and, depending on its effectiveness, can influence investigators' confidence in their results. A major consideration in selecting a particular design is to try to control as much as possible those factors that are not included in the study but can influence the results. For example, in a classic study by Douglas and co-workers (1999), researchers wanted to discover the percentage of homes with functioning smoke alarms. They initially conducted a telephone survey, a commonly used method of survey research in community health, and found that 71% of households reported functioning smoke alarms. Concerned that this might be an inflated number, they conducted an on-site survey to confirm the results.

After face-to-face interviews, they found that only 66% of householders reported having functioning alarms. However, when researchers actually tested the smoke alarms in those homes, only 49% were fully functioning. By having researchers actually test the smoke alarms, this design controlled for inflated results of the more commonly conducted, convenient, and economical telephone survey. Is self-report always unreliable? A small study of working middle-aged women revealed that self-reported weekly physical activity was strongly associated with pedometer data, indicating that, in this case, self-report yielded reasonably reliable data (Speck & Looney, 2006). This is evidence that the community health nurse must determine the most efficacious method of obtaining necessary data.

In another example, researchers themselves controlled the variables to ensure true results. Kerr and colleagues (2001) knew from their review of the literature that posters encouraging exercise at the point of choice between stairs and escalators in public shopping areas could be effective in promoting greater use of stairs. They incorporated this fact into the design of their study. They used a control site and a study site (both shopping malls) and collected baseline data and a first observation 2 weeks after placing posters. Then, they followed up with stair-riser banners containing multiple messages placed on alternate stairs. Both sites were equal at baseline and the first observation; however, at the second observation time (at 4 weeks), there was a 6.7% increase in use of the stairs at the site with stair-riser banners. This simple yet novel approach motivated more people to use the stairs.

Complete descriptions of various research designs and specific methodologies are available in basic nursing research texts. For the purposes of this chapter, a few important considerations underlying design selection are described. First, quantitative approaches use two major categories of research design: experimental and nonexperimental (or descriptive).

**Experimental design** requires that the investigators institute an intervention and then measure its consequences. Investigators hypothesize that a change will occur as a result of their intervention, and then they attempt to test whether their hypothesis was accurate. Experimental design requires investigators to randomly assign subjects to an **experimental group** (those receiving the intervention) and a **control group** (those not receiving the intervention). This process, called **randomization**, is the systematic selection of research subjects, so that each one has an equal probability of selection.

Another important distinction made within the experimental category of research is between true experiments and quasi-experiments. **True experiments** are characterized by instituting an intervention or change, assigning subjects to groups in a specific manner (randomization), and comparing the group of subjects who experience the manipulation to the control group (those not receiving the intervention). **Randomized control trials (RCTs)** are generally considered the gold standard of experimental research—they are commonly used to determine the safety and efficacy of new medications or to test the effectiveness of one intervention over another, and they are a foundation of EBP (Melnyk & Fineout-Overholt, 2005). **Quasi-experiments** lack one of these elements, such as the randomization of subjects. Community health nurses conduct quasi-experiments more often than true experiments because it is often difficult (and some-

times impossible) to use randomization. For instance, a nurse may conduct a nutrition education intervention with fifth grade students at a particular school. Although the nurse can have one classroom participate in the intervention and another remain the control group, he or she cannot randomly assign the children to classrooms (i.e., intervention or control). Therefore, this research would be characterized as quasi-experimental in nature.

**Nonexperimental designs** (also called *descriptive designs*) are used in research to describe and explain phenomena or examine relationships among phenomena. Examples of this approach include examining the relationship between gender and smoking behaviors among adolescents, describing the emotional needs of families of clients with Alzheimer disease, and determining the attitudes of parents in a given community toward sex education in the schools. In each of these instances, the focus of the research is on the relationships observed or the description of what exists. Such nonexperimental designs are often the precursors of experiments. Once such an intervention is developed, further research can evaluate its appropriateness and, ultimately, its effectiveness. Other lines of clinically based research can also be designed. The choice of research design influences the ability to generalize the results, and the attention given to the details of the study affects the value of the knowledge derived. Research done with larger numbers of participants drawn from a geographically diverse area is more complete than small scale, exploratory studies done in an isolated area with a small, homogeneous sample. Valid tools or instruments and appropriately applied statistical methods lead to greater confidence in the results of the study.

## Obtain Institutional Review Board or Human Subjects Committee Approval

Whenever research is to be conducted that involves human subjects, prior approval must be gained from either an Institutional Review Board or a Human Subjects Committee. The reason for this approval is to safeguard the rights of prospective study participants. Each health department should have a committee or a gatekeeper, such as the health officer, who understands the federal guidelines for protecting subjects involved in research studies.

One of the most egregious examples of exploitation of human subjects was a study carried out by the U. S. Public Health Service. The Tuskegee study, begun in 1932 and ended in 1972, sought to learn more about syphilis and to justify treatment services for Blacks in Alabama (Centers for Disease Control and Prevention [CDC], 2008). The 399 men with syphilis who participated in the study had agreed to be examined and treated. However, they were misled about the exact purpose of the study and were not given all of the facts; therefore, they were unable to give truly informed consent. Even after penicillin became the drug of choice for treatment of syphilis in 1947, the researchers failed to offer this treatment to the infected participants. Because of this experiment and earlier Nazi atrocities, the Nuremberg Code and the Declaration of Helsinki were adopted by the world scientific community, then revised in 1975, as a means of assuring ethical research practices (Blais, Hayes, Kozier, & Erb, 2006; CDC, 2003) (see Evidence-Based Practice: Ethics in Action).

## EVIDENCE-BASED PRACTICE

### Ethics in Action

Today, safeguards are in place to ensure that studies are stopped when either potential harm or insufficient benefit are noted. In January 2006, a major international study of a drug-conserving protocol for AIDS medication was stopped because those who were in the on-again, off-again group got sicker than those taking continuous medication therapy (Associated Press, 2006). More than 5,000 HIV patients in 33 countries participated in this study, which was halted by the National Institutes of Health. This large-scale study was initiated after several smaller studies had suggested a possible benefit from the on-and-off medication

strategy. It was hoped that this strategy of only taking medications when immune cell levels dropped would not only cut costs, it would decrease medication side effects for patients. What researchers found was that this episodic strategy actually increased side effects related to the heart, liver, and kidney. Researchers say that the results are difficult to explain, but because of patient safety, it was best to stop the clinical trial. What ethical principles are involved here? Is there an ethical dilemma here? Consider the rights of a few versus the rights of many. Apply Iserson's (1999) three tests (see p. 80 of this text).

The following ethical principles are widely viewed as basic protections for research participants (U.S. Department of Health & Human Services, 2006a). Freedom from harm or exploitation encompasses several aspects. First, no research can be done that may inflict permanent or serious harm. Second, the research study must be stopped if it becomes evident that harm may come to participants. Debriefing, or allowing participants to ask questions of the researcher at the conclusion of the study, as a means of protecting them from any unseen psychological harm, is also a component. There should be some identified benefits from participation in the research study, and any costs or risks should be clearly enumerated, so that participants can more easily determine the cost–benefit ratio (referred to as *full disclosure*). Subjects should also be told that they may withdraw from the study at any time without prejudice or penalty (known as *self-determination*). Consent forms should include full disclosure of the nature of the study, the time and commitment required of subjects, the researcher's contact information, and a pledge of confidentiality (assurance of privacy).

Vulnerable subjects, determined by federal guidelines, include children, mentally or emotionally disabled people, physically disabled people, institutionalized people, pregnant women, and the terminally ill. Special care must be taken to ensure protection of vulnerable subjects. Once approval has been obtained from the proper entities, data collection can begin (U.S. Department of Health & Human Services, 2006b).

### Collect and Analyze Data

The value of the data collected in any research project depends largely on the care taken when measuring the concepts of concern or variables. The specific tool used to measure the variables in a study, often a questionnaire or interview guide, is called an **instrument**. The accuracy of the instrument used and the appropriateness of the choice of instruments can clearly influence the results. For instance, Spielberger's State-Trait Anxiety Inventory is a well-researched questionnaire used in studying anxiety levels in adults. It has been

shown to accurately measure state anxiety and the more stable tendency toward anxious personality—*trait anxiety*. One could infer that more accurate measurements of anxiety could be found using this instrument than a researcher-developed questionnaire that has never been tested for validity and reliability.

### Validity and Reliability

Two tests are used to evaluate instrument accuracy: validity and reliability. **Validity** is the assurance that an instrument measures the variables it is supposed to measure. If a written questionnaire is being used in the study, the questions included would be evaluated to make certain that they are appropriate to the subject (content validity) and that the variable of interest is actually being measured (construct validity).

**Reliability** refers to how consistently an instrument measures a given research variable within a particular population. Test–retest reliability ensures that similar results are obtained using the same instrument with the same population at two separate testing times. If similar results are obtained on two separate occasions, the test can be considered reliable.

Statistical tests and measurements are often used to analyze subjects' responses to questionnaires to evaluate internal consistency. A questionnaire is internally consistent to the extent that all of its subparts measure the same characteristic. Cronbach's alpha ( $\alpha$ ) is often cited as a measure of internal consistency and is reported as a correlation coefficient, so that the closer the value is to +1.0, the greater the degree of internal consistency. Results higher than .7 are generally regarded as desirable.

Within the area of community health nursing research, instruments appropriate to the measurement of nursing concepts (e.g., caring) are often not available. Researchers may use questionnaires that have been designed and tested by other investigators, or they may begin the tedious task of developing their own. Both approaches to measuring the variables of interest are acceptable; however, using available instruments of known reliability and validity saves considerable time.

## Methods of Collecting Data

A variety of methods can be used to collect data, including self-report (subjects report their own experience verbally or in written form), observation (investigators observe subjects and document their observations), physiologic assessment (investigators use measures of physical evidence, such as blood pressure or impaired mobility), and document analysis (investigators review and analyze written materials, such as health records). For example, using these four methods, investigators examining the stress level of the caregiver when a family member chooses to die at home might do the following:

1. Design or use an existing written questionnaire or interview schedule (self-report).
2. Outline a schema, such as a list of potential stress-induced behaviors, for observing caregivers as they function in the home (observation).
3. Measure various physiologic indicators of stress, such as hypertension, insomnia, or poor diet (physiologic assessment).
4. Ask caregivers to keep a diary of their activities and feelings for 2 weeks, and analyze the diaries for evidence of stress (document analysis).

In most instances, the nature of the data to be collected dictates the best method of collection. One or more methods may be appropriate, given the topic of concern. In the example mentioned, a combination of the first three methods would probably be appropriate, or the diary could be substituted for the questionnaire.

## Methods of Analyzing Data

Once collected, data must be analyzed so that a meaningful interpretation can be made. Statistical procedures reduce great amounts of information to smaller chunks that can be easily interpreted. When deciding on an appropriate statistical procedure, it is helpful to consider the two major categories of statistical analysis: descriptive and inferential statistics.

**Descriptive statistics** portray the data collected in quantitative or mathematical terms. Commonly used descriptive statistical methods include calculating the average number (or *mean*) of a particular set of occurrences and calculating *standard deviations* (how much each score on the average deviates from the mean) and percentages. For example, an investigator analyzing data collected from 50 clients with chronic pain might find their mean pain score to be 4.96 (on a scale from 0 [no pain] to 10 [worst pain]), with a standard deviation of 0.83. These descriptive statistics suggest that clients are grouped around the middle of the pain scale and differ very little in the amount of pain they experience. The investigator may also report that more than 95% of the female clients experience pain rated between 4 and 6 on the 10-point pain scale. These descriptive statistics can be reported graphically (using graphs or charts) or in written form as shown in Table 4.1.

**Inferential statistics** involve making assumptions about features of a population based on observations of a sample. For example, the Gallup Poll, which surveys a sample of the population to determine what opinion they hold on a particular topic (e.g., favorite presidential candidate), uses inferential

TABLE 4.1 Pain Ratings

Value	Frequency	Percent (%)
3.00	1	2.0
4.00	11	22.0
5.00	30	60.0
6.00	6	12.0
7.00	1	2.0
8.00	1	2.0
MEAN 4.96	STANDARD DEVIATION 0.83	

statistics to estimate the proportion of the total population that favors a particular candidate (McKenzie & Smeltzer, 2001). The potential for **generalizability**, the ability to apply the research results to other similar populations, has great value to health professionals. It allows researchers to test their hypotheses on smaller groups before instituting widespread changes in methods, programs, and even national health policies.

Inferential statistics are also used to test hypotheses in research; they provide information about the likelihood that an observed difference between two or more groups could have happened just by chance or might be the result of some intervention or manipulation. These statistical procedures provide a determination of the extent to which changes or differences between sets of data are attributable to chance fluctuations and estimate the confidence with which one can make generalizations about the data.

It is appropriate to use both descriptive and inferential statistics to analyze the data from a study. For example, in a study designed to examine the effects of prenatal education on the health status of pregnant women, investigators might use inferential statistics to find a significant difference in health status between the group who experienced the educational program (experimental group) and the group who did not (control group). The investigators might also use descriptive statistics to report the percentage of women from the experimental group who attended all classes and the means and standard deviations for the women's health status scores.

## Interpret Results

The explanation of the findings of a study flows from the previously formulated research plan. The findings need to be a logical conclusion, based upon the building blocks of the literature review, conceptual framework, research question, and methodology. You can't jump to a conclusion for which you have not laid a foundation. Findings need to make sense, to be reasonable and logical. When findings support the directions developed in the research plan, their interpretation is relatively straightforward. For example, a group of community health nurse investigators might design a study to determine the effect of parenting classes on the self-esteem of single welfare mothers between 21 and 35 years of age. They could use Coopersmith's (1967) ideas on self-esteem as their conceptual model, hypothesize that self-esteem will improve

as a result of the classes, and design an experiment to test their idea. If self-esteem does, in fact, increase, their finding flows logically from their framework.

If the findings do not support the hypothesis of the study, investigators question various aspects of the research to develop an explanation. In this instance, a number of questions could be posed. Coopersmith posited that self-esteem would relate to feelings of success in a given endeavor. Can that position be inaccurate? Could the parenting classes have been ineffective? Perhaps they did not enhance feelings of success. Could the intervention have been too weak to show a statistical difference (not enough sessions)? Were there problems with the methodology used: were there too few subjects, or intervening, confounding factors that affected the results? All of these questions and more should be considered in an attempt to explain the results.

If the study is descriptive in nature (i.e., one that was designed to describe particular characteristics of a population), the direction of the findings is not a concern. A detailed, accurate report of the results and their implications alone is appropriate. Given either an experimental or a descriptive design, the importance of accuracy cannot be overemphasized. Leaps of faith when reporting the results of a study are not appropriate unless labeled as such. For example, one could not conclude from the study on parenting classes that these classes develop expert parenting skills, given that parenting skills were not assessed.

A valuable contribution can be made to the advancement of nursing knowledge when investigators use their results to make suggestions for future research. The investigators' knowledge of a particular area and their experience in conducting a specific study give them an excellent background for identifying future research possibilities.

## Communicate Findings

The findings of nursing research projects need to be shared with other nurses, regardless of the studies' outcomes. Negative as well as positive findings can make a valuable contribution to nursing knowledge and influence nursing practice. Whether or not the hypothesis was verified is not the most important part of research; it is equally important to know about results that are inconclusive or not statistically significant, because this information is also necessary to build the science of nursing. For instance, in the study by Eckenrode and colleagues (2000) cited at the beginning of this chapter, researchers found that participants who received nurse home visitation during pregnancy and through the child's second birthday had significantly fewer child maltreatment reports with the mother as perpetrator or the study child as subject than did participants not receiving nurse home visitation. However, for mothers reporting more than 28 incidents of domestic violence, no significant reductions were noted. This is important information, because ongoing domestic violence may limit the effectiveness of these types of programs. In the future, researchers may want to elicit more information about domestic violence when trying to evaluate the effectiveness of this type of intervention.

The research report should include the key elements of the research process. The research problem, methodology used, results of the study, and the investigators' conclusions and recommendations are presented. Whether investigators

are presenting their findings verbally or writing for publication, they need to discuss the implications of their findings for nursing practice.

## IMPACT OF RESEARCH ON COMMUNITY HEALTH AND NURSING PRACTICE

Research has the potential to have a significant impact on community health nursing in three ways, by affecting public policy and the community's health, the effectiveness of community health nursing practice, and the status and influence of nursing as a profession. Community health nurses have been involved in research addressing all three of these dimensions.

### Public Policy and Community Health

Research, with policy implications for addressing the health needs of aggregates, has been conducted on numerous topics. Many studies done by nurses and others have examined issues related to prevention, lifestyle change, quality of life, and health needs of specific at-risk populations (see Evidence-Based Practice: A Change of Position).

Often both quantitative and qualitative methods are useful when conducting **health policy evaluation** studies to determine whether existing health services are appropriate and accessible, as well as effective. Remler and Glied (2003) wanted a better understanding of why many Americans who qualify for health insurance programs do not participate in them. They examined more than 100 articles about health insurance and other health policy-driven programs and found similar patterns and themes across all areas. The most consistent predictor of client participation was the size of the benefit measured over time, and they suggested that longer periods of coverage might promote greater participation. They noted that Medicare, Part A, had the highest percentage of participation (99%), whereas participation in Medicaid for eligible uninsured children ranged between 50% and 70%.

The results of health policy studies can influence public policy, the quality of services, and, in turn, the public's health. As an example, several studies conducted by a researcher at the University of Miami could lead to further policy changes regarding cigarette smoking. One study examined the projected health benefits and cost savings of raising the legal age for smoking in the United States to 21 (Ahmad, 2005a). Using a computer simulation model, the researcher concluded that changing the policy would net total savings of \$212 billion in the United States and reduce the prevalence of cigarette smoking substantially. A similar study, looking only at the state of California, found that raising the legal smoking age to 21 would yield an 82% drop in prevalence in teen smoking and would save \$24 billion over 50 years' time (Ahmad, 2005b). Taxes are another disincentive for smokers. California raised excise taxes on cigarettes in 1999, but Ahmad (2005c) used another computer simulation to reveal that an additional "20% tax-induced cigarette price increase would reduce smoking prevalence from 17% to 11.6% . . . and reduce smoking-related medical costs by \$188 billion" (p. 276). Raising cigarette taxes again would both decrease the number of smokers and increase the tax revenue that could be used to further reduce smoking in California. But, other effective methods of reducing cigarette smoking may exist. Levy, Nikolayev, and Mumford (2005)

noted that smoking prevalence declined between 1997 and 2003, and, although most of the change could be explained by price increases, researchers also found that clean air laws, widespread media campaigns, and more easily accessible smoking cessation interventions also played a part. They encouraged lawmakers to continue with tax increases and to strengthen clean air laws that ban smoking in public places. In a Minnesota study, smoke-free workplaces were found to be more effective than free nicotine replacement therapy (Ong & Glantz, 2005). Other researchers have found that antismoking advertising focusing on the addictive nature of cigarettes and the dangers of environmental tobacco smoke to children increased the chances of quitting among adult smokers who have children living in their homes (Netermeyer, Andrews, & Burton, 2005). Consistent and wide-ranging antismoking media campaigns that emphasize social unacceptability and easier access to smoking cessation classes were also emphasized to policy makers (Alamar & Glantz, 2006).

## Community Health Nursing Practice

A primary purpose for conducting community health research is to gain new knowledge that will improve health services and

promote the public's health. Consequently, most nursing research has implications for nursing practice. Many studies focus on a specific health need or at-risk population, then suggest nursing actions to be taken based on study findings. An example is a study examining effective approaches to take in promoting cardiovascular health in aging women (Sawatzky & Naimark, 2005). Historically, most care has focused on individual-level prevention and the treatment of risk factors such as hypertension and obesity. However, these nurse researchers found that a survey questionnaire, the Cardiovascular Health Promotion Profile, measured population-level determinants of health (i.e., income, social status, social support networks, employment and working conditions, level of education, utilization of health services, and biology and genetic factors) and could be a valuable method of promoting cardiovascular health in women. Individual-level measures are not thought to be as effective as population-based approaches in improving the health of a nation (Edelman & Mandel, 2006).

## Nursing's Professional Status and Influence

The third way in which research has a significant impact on community health nursing is in its potential to enhance

### EVIDENCE-BASED PRACTICE

#### A Change of Position

A good number of mothers today place their infants in a supine position—on their backs—to sleep. However, for most of us writing this textbook, the opposite was true—we were placed as sleeping infants in the prone position, on our stomachs. For generations, mothers were told that babies would be at risk of aspiration if they were put to sleep on their backs. Why did this change? In the late 1980s, research indicated that prone positioning of infants was related to greater incidences of sudden infant death syndrome (SIDS), according to a group at the National Institute of Child Health and Human Development (NIH) who conducted an epidemiologic study examining SIDS risk factors (Hoffman, Damus, Hillman, & Krongrad, 1988). In the early 1990s, an expert panel from the same institute and the American Academy of Pediatrics concluded that infant sleeping positioning was an important factor in prevention of SIDS and a recommendation was made for parents to place their infants on their backs when sleeping. The *Back to Sleep* campaign began in 1994 (First Candle, 2006). Since then, the incidence of SIDS has continued to drop steadily in the U.S. (Malloy & Freeman, 2000) and in other countries (Mitchell, Tuohy, et al., 1997)—as much as 50%. Despite this, SIDS is still the leading cause of death in infants between the ages of 1 month and 1 year (American Academy of Pediatrics, 2005). More recent research has focused on the use of side sleeping positions (considered to be as risky as prone positions), bed-sharing (not recommended), prenatal maternal smoking (a major risk factor), and genetic factors as additional variables to consider with SIDS

(Li, Petitti, Willinger, et al., 2003; Thogmartin, Siebert, & Pelian, 2001; Opdal & Rognum, 2004). Current recommendations from the American Academy of Pediatrics (2005) include continuing the *Back to Sleep* campaign and advising parents to:

- Place their sleeping infants in a supine position (not on side or stomach)
- Use a firm sleeping surface (no pillows or quilts under the baby)
- Keeping soft objects (e.g., stuffed animals) and loose bedding (e.g., extra quilts or loose bedding) out of baby's crib
- Not smoke during pregnancy and avoid baby's exposure to secondhand smoke
- Not share the bed with baby—put baby in a separate crib or bassinet with parents in the same room
- Offer a pacifier at sleep time throughout the first year of life (it has been shown to reduce the risk of SIDS)
- Avoid overheating (keep room temperature comfortable for lightly clothed adults—do not overbundle babies)
- Encourage “tummy time” to avoid development of positional plagiocephaly (uneven head)
- Avoid the use of apnea monitors (not shown to be effective) and other commercial devices marketed as effective in reducing SIDS cases (not sufficient proof of efficacy)

Do your community health clients put their babies to sleep on their backs? If not, how can you convince them that it is beneficial?

nursing's status and influence. As community health nursing research sheds light on the critical health needs of at-risk populations, exposes deficiencies in the health care system, demonstrates more efficient and cost-effective methods for delivering services, and documents the effectiveness of nursing interventions, the profession will gain a stronger voice and have a greater impact on health policy and programs. After all, PHNs have always been advocates for their clients and promoted policies that improved health.

An example of community-oriented research was conducted by Rothman and associates (2002). Community-developed strategies were used in a program to reduce lead poisoning in a poor area of Philadelphia. Four census tracts were selected for intervention, on the basis of pre-1950 built housing, poverty level, and percentage of Black citizens. Matching control census tracts were also studied. Adult block parties (using educational and motivational strategies) and interactive educational sessions for children (e.g., puppet shows) were used over the 3 years of study. Approximately 1,200 children and 900 adults participated. Initially, overall lead poisoning awareness was low. Testing of homes revealed that more than 90% were positive for lead. After the first intervention year, a 27% increase occurred in the number of children tested for lead in the intervention census tracts, and only a 10% increase in the control census tracts. An 11% reduction occurred in the percentage of children with excess blood lead levels in the intervention group, and only a 3% reduction in the control group. Participants readily accepted this community-developed and community-based intervention by nurses and a physician from Temple University. This research enhanced nursing's role in the community by engaging with community members on their turf and demonstrating nurses' roles in research.

Strong documentation supports the effectiveness of community health nursing interventions. Nurses in the community setting must provide empiric proof of their worth as professionals, as well as serve the needs of their clients. This kind of information must be made visible if it is to influence legislators, planners, administrators, and other decision-makers in health care. As visibility increases, nursing's status and influence will increase.

## THE COMMUNITY HEALTH NURSE'S ROLE IN RESEARCH

The advantages of community health nursing include a focus on health promotion and disease prevention; provision of services across the lifespan where people live, work, and learn; development of community capacity building for health; and working with partnerships, coalitions, and policy makers to promote a healthier environment. Community health nurses have two important responsibilities with respect to research in community health: to apply research findings to practice (EBP) and to conduct or participate in nursing research. Because research results provide essential information for improving health policy and the delivery of health services, community health nurses must be knowledgeable consumers of research. That is, they need to be able to critically examine research reports and apply study findings to improve the public's health.

Many research textbooks describe the steps one can take to thoroughly assess a research study. Begin by looking

carefully at the title and the journal in which the article is found. Abstracts afford an opportunity to quickly preview the article. The quality of the journal (based on its history, circulation, and caliber of editorial board, among other factors) is another consideration. Authors' educational and affiliative credentials give clues to their credibility and could reveal any financial interest they may have in relation to their research outcomes. For instance, authors whose research studies are funded by drug companies may have a conflict of interest, and the results of those studies could be questioned. Examine the currency of references and the extensiveness of the authors' literature review. When reading the article, keep in mind the steps in the research process and note how carefully the authors followed each one. Ask the following questions:

- ◆ Was the research question clearly stated?
- ◆ Was the literature review complete and current?
- ◆ Was an appropriate conceptual framework in place?
- ◆ How was the sample selected?
- ◆ Did the methodology follow logically from the research question and the conceptual framework?
- ◆ Were the instruments used valid and reliable and described in sufficient detail?
- ◆ Were the methods of data collection and data analysis clearly identified?
- ◆ Did the authors give ideas for future nursing research based on this study?

Review the findings and discussion sections of the research article carefully to determine what implications this study might have for nursing practice. Talk with colleagues and peers about the implications of the study and ways in which it might be replicated or its line of research extended.

Community health nurses have many opportunities to apply the results of other investigators' research, but a necessary prerequisite is to be informed about research findings. As an essential part of their role, community health nurses must read the journals focusing on public health and community health nursing. Subscribing to some of these journals enables nurses to make a regular review of research an ongoing part of their professional practice. Nursing agencies and employment sites in community health can encourage nurses to become more knowledgeable about research findings by subscribing to journals and circulating them among staff, by holding seminars to discuss recent research results, and by promoting nurses' application of research findings in their practice.

Second, although the amount of health nursing research is expanding, and its quality improving, many more community health nurses need to conduct research themselves. An increasing number of nurses have developed skill in research through advanced preparation, and they are conducting investigations related to aggregate health needs. Other community health nurses work collaboratively with trained investigators on a variety of research projects affecting community health. Whether initiated by the nurse or involving the nurse as a team member, these projects are an opportunity to influence the types of research questions that are addressed and the ways in which the research is carried out, factors that ultimately affect the community's health.

## VALUES AND ETHICS IN COMMUNITY HEALTH NURSING

Health care is replete with ethical questions, and the field of bioethics continues to expand as new discoveries are made (Beauchamp & Childress, 2001). Community health nurses face an expanding number of ethical dilemmas every day. Imagine, for example, that you are providing health care to a population of migrant farm workers whose housing lacks adequate toilets, bathing facilities, heating, and equipment for cooking and refrigerating food. You recognize that this is a valid health and safety issue. However, when you report the situation to your supervisor, you are told to ignore the conditions because the wineries that employ the workers contribute heavily to a high-profile clinic for all low-income children in your area. What would you do?

What if you were working in a homeless shelter and were told to evict someone who would not agree to take a tuberculin skin test. You agree that residents should comply with this demand, but would you hesitate to implement the eviction if the resident were elderly or the teenage mother of a newborn?

Within the United States, many marginalized people are failed by the public health care system or go without any health care at all. At the same time, affluent individuals enjoy a plethora of health care options, including preventive screenings and health promotion classes. Community health nurses often are confronted by this disparity when making ethical decisions about client care.

In addition to these dilemmas within U.S. borders, progress in the United States often is linked to the exploitation of people in less-developed countries, and this contributes to widening disparities in health, wealth, and human rights. Failure to respond to such global challenges only leads to greater poverty and deprivation, continuing conflict, escalating migration, and the spread of infectious disease, all further adding to our ethical dilemmas.

Advances in technology also contribute to ethical dilemmas. For example, electronic health records make client information readily accessible, thus raising issues of confidentiality, clients' rights, and informed consent (Ries & Moysa, 2005). Technology also forces nurses to confront the issues of genetic testing and stem cell research, as well as assisted suicide and euthanasia (Burroughs, 2005; Yoshimura, 2006; Hurst & Mauron, 2006). Further ethical questions arise regarding organ, tissue, and limb transplants and the decisions about who is to receive them (Delmonico, 2006). Underlying every issue and influencing every ethical and professional decision are *values*. Ethics and values are inextricably intertwined in professional decision-making, because values are the criteria by which decisions are made.

### Values

What are values? A **value** is something that is perceived as desirable or a personally held abstract belief “about the truth and worth of thoughts, objects, or behavior” (Guido, 2006, p. 2). A value motivates people to behave in certain ways that are personally or socially preferable. Values are usually derived from societal norms, as well as from family and/or religious beliefs. We develop our value system as a result of our experiences with others (e.g., family, peers, schools,

churches, jobs). As seen in Chapter 5, a group's culture often is defined by its members' common or shared values.

### Standards for Behavior

In general, values function as standards that guide actions and behavior in daily situations or act as a code of conduct for living one's life. Once internalized by an individual, a value, such as honesty, becomes a criterion for that individual's personal conduct. Values may function as criteria for developing and maintaining attitudes toward objects and situations or for justifying a person's own actions and attitudes. Values also may be the standard by which people pass moral judgments on themselves and others.

Values have a long-term function in giving expression to human needs. Values motivate people in their work setting, in their personal lives, and in dealing with their health, as well as with the larger society. In addition, values are used as standards to guide presentation of the self to others, to ascertain personal morality and competency, and to persuade and influence others by indicating which beliefs, attitudes, and actions of others are worth trying to reinforce or change. As a practitioner, values act as a compass to direct the nurse when working with clients.

### Qualities of Values

The nature of values can be described according to five qualities: endurance, hierarchical arrangement, prescriptive-prescriptive belief, reference, and preference.

#### Endurance

Values remain relatively stable over time, persisting to provide continuity to personal and social existence. Enduring religious beliefs, for example, offer stability to many people. This is not to say that values are completely stable over time; values do change throughout a person's life. Certainly, the values of children are different from adults. Moral development generally follows a prescribed path, according to Lawrence Kohlberg (Colby & Kohlberg, 1987) and Carol Gilligan (1982), researchers studying changes in moral behavior and judgment from childhood to adulthood. Yet social existence in the community requires standards within the individual as well as an agreement about standards among groups of individuals. As Kluckhohn (1951, p. 400) once pointed out, without values, “the functioning of the social system could not continue to achieve group goals; individuals . . . could not feel within themselves a requisite measure of order and unified purpose.” A group's culture provides such a set of enduring values. By adding an element of collective purpose in social life, values most often guarantee endurance and stability in social existence.

#### Hierarchical System

Isolated values usually are organized into a hierarchical system in which certain values have more weight or importance than others. For instance, in a team sport such as baseball, values regarding individual performance, batting and running records, speed, and throwing and catching all fall into a hierarchy, with the values of team and winning being at the

top. As an individual confronts social situations throughout life, isolated values learned in early childhood come into competition with other values, requiring a weighing of one value against another. Concern for others' welfare, for instance, competes with self-interest. Through experience and maturation, the individual integrates values learned in different contexts into systems in which each value is ordered relative to other values (Glasser, 1998).

### Prescriptive–Proscriptive Beliefs

Rokeach (1973) described values as a subcategory of beliefs. He argues that some beliefs are *descriptive* or capable of being true or false (e.g., the chair on which I am sitting will hold me up). Other beliefs are *evaluative*, involving judgments of good and bad (e.g., that was an excellent lecture). Still other beliefs are *prescriptive–proscriptive*, determining whether an action is desirable or undesirable (e.g., this music is too loud, those baseball fans shouldn't yell when the pitcher is winding up). Values, Rokeach says, are prescriptive–proscriptive beliefs. They are concerned with desirable behavior or “what ought to be.” For example, parents' values about child behavior determine how they choose to discipline their children, using either corporal punishment or a time-out. Some parents believe that their 2-year-old child has the capacity to control his bladder, and when the child wets his pants they are being “rebellious” and should be punished. Values have cognitive, affective, and behavioral components. According to Rokeach, to have a value, it is important to know the correct way to behave or the correct end state for which to strive (cognitive component); to feel emotional about it—to be affectively for or against it (affective component); and to take action based on it (behavioral component).

### Reference

Values also have a reference quality. That is, they may refer to end states of existence called **terminal values**, such as

spiritual salvation, peace of mind, or world peace, or they may refer to modes of conduct called **instrumental values**, such as confidentiality, keeping promises, and honesty. The latter can have a moral focus or a nonmoral focus, and these values may conflict. For example, a nurse may experience a conflict between two moral values, such as whether to act honestly (tell a client about a fatal diagnosis) or to act respectfully (honor the family's request not to tell the client). Similarly, the nurse may experience conflict between two nonmoral values, such as whether to plan logically (design a traditional group intervention for mental health clients) or to plan creatively (design an innovative field experience). The nurse also may experience conflict between a nonmoral value and a moral value, such as whether to act efficiently or to act fairly when establishing priorities for funding among community health programs.

Adults generally possess only a few—perhaps no more than 20—terminal values, such as peace of mind or achievement. These are influenced by complex physiologic and social factors. The needs for security, love, self-esteem, and self-actualization, proposed by Maslow (1969), are believed to be the greatest influences on terminal values. Although an individual may have only a few terminal values, the same person may possess as many as 50 to 75 instrumental values. Any single instrumental value, or several instrumental values combined, also may help to determine terminal values. For example, the instrumental values of acceptance, taking it easy, living one day at a time, and not being concerned about the future can shape the terminal value of peace of mind; whereas the instrumental values of hard work, driving oneself to compete, and not letting anyone get in the way can influence the terminal value of achievement. Figure 4.3 illustrates the influence of instrumental values and human needs on the development of terminal values.

### Preference

A value may show preference for one mode of behavior over another, such as exercise over inactivity, or it may show a

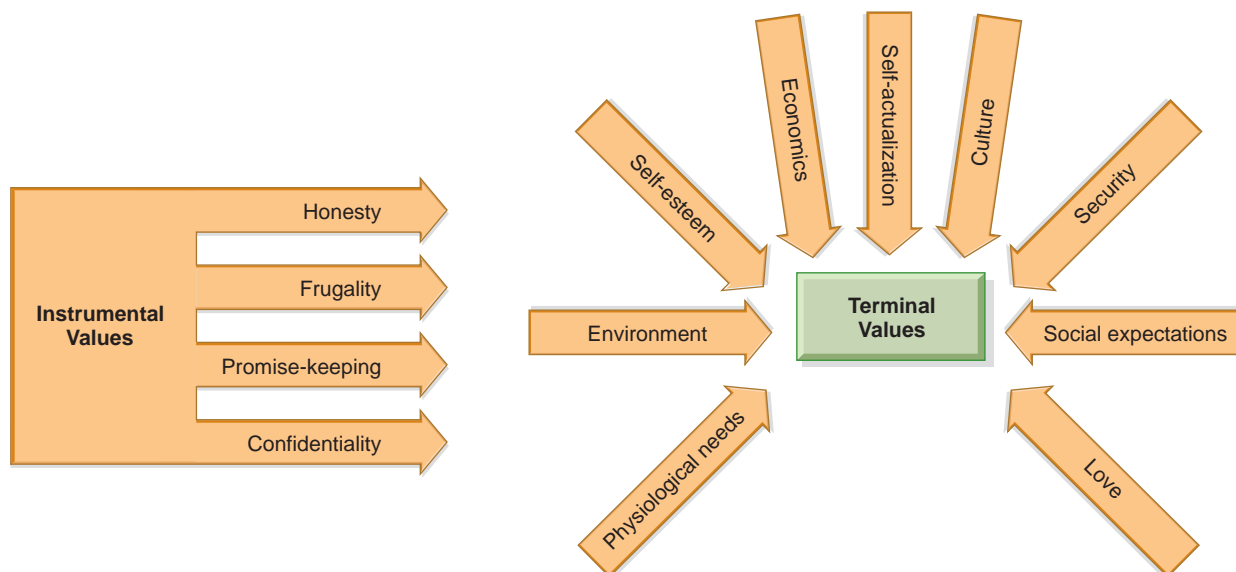

FIGURE 4.3 Factors influencing personal values.

preference for one end state over another, such as physical fitness and leanness over sedentary lifestyle and obesity. The preferred end state, or mode of behavior, is located higher in the personal value hierarchy.

## Value Systems

**Value systems** generally are considered organizations of beliefs that are of relative importance in guiding individual behavior (Rokeach, 1973). Instead of being guided by single or isolated values, however, behavior at any point in time (or over a period of time) is influenced by multiple or changing clusters of values. Therefore, it is important to understand how values are integrated into a person's total belief system, how values assume a place in a hierarchy of values, and how this hierarchical system changes over time.

### Hierarchical System of Values

Learned values are integrated into an organized system of values, and each value has an ordered priority with respect to other values (Rokeach, 1973). For example, a person may place a higher value on physical comfort than on exercising. This system of ordered priority is stable enough to reflect the continuity of someone's personality and behavior within culture and society, yet it is sufficiently flexible to allow a reordering of value priorities in response to changes in the environment or social setting (e.g., society's emphasis on physical fitness and youth) or changes based on personal experiences (e.g., diagnosis of type 2 diabetes). Behavioral change would be regarded as the visible response to a reordering of values within an individual's hierarchical value system.

### Conflict Between Values in a System

When an individual encounters a social situation, several values within the person's value system are activated, rather than just a single value. Because not all of the activated values are compatible with one another, conflict between values occurs. This conflict between values is a part of the decision-making process, and resolving these value conflicts is crucial to making good decisions. Community health nurses face conflicting values when they seek to promote the well being of certain individuals, a result that may come at the expense of the public good. Even within a single community agency, nurses may find that they prioritize client service or programming values differently.

Some values seem to consistently triumph over others, persisting as stronger directives for individual behavior; an example is the value placed on high achievement in the United States. It is this persistence on the part of some values (e.g., individualism versus community) that makes universal coverage and other issues so controversial in health care reform (Axtell-Thompson, 2005). Other values lose their positions of importance in a value hierarchy (e.g., resuscitation of all hospital patients versus do not resuscitate orders [DNRs]). It is this changing arrangement of values in a hierarchical system that determines, in part, how conflicts are resolved and how decisions are made. In this way, people's value systems function as a learned organization of principles and rules that help them

to choose among alternative courses of action to reach decisions.

## Values Clarification

One way to understand the influence and priority of values in your own behavior, as well as in that of community health clients, is to use various values clarification techniques in decision-making. **Values clarification** is a process that helps to identify the personal and professional values that guide your actions, by prompting you to examine what you believe about the worth, truth, or beauty of any object, thought, or behavior and where this belief ranks compared with your other values (Feldman-Stewart, Brennenstuhl, Brundage, & Roques, 2006). Because individuals are largely unaware of the motives underlying their choices, values clarification is important for understanding and shaping the kind of decisions people make. Only by understanding your values and their hierarchy can you ascertain whether your choices are the result of rational thinking or of external influences, such as cultural or social conditioning. Values clarification by itself does not yield a set of rules for future decision-making and does not indicate the rightness or wrongness of alternative actions. It does, however, help to guarantee that any course of action chosen by people is consistent and in accordance with their beliefs and values (Redman, 2001; Guido, 2006).

### Process of Valuing

Before values clarification can take place, it must be understood how the process of valuing occurs in individuals. In 1977, Uustal listed the following seven steps, which remain useful today:

1. Choose the value freely and individually.
2. Choose the value from among alternatives.
3. Carefully consider the consequences of the choice.
4. Cherish or prize the value—feel good about the choice.
5. Publicly affirm the chosen value.
6. Incorporate the value into behavior, so that it becomes a standard or a pattern of behavior.
7. Consciously use the value in decision-making.

These steps provide specific actions for the discovery and identification of people's values. They also assist the decision-making process by explicating the process of valuing itself. For example, some people may choose to value honesty in a presidential candidate. They choose this over other values, such as knowledge of foreign affairs or public speaking ability, because, considering the consequences, they want a leader who will deliver on promises made, who will continue to be the person represented to the public during the campaign. They prize this value of honesty, affirm it publicly, and consciously use it as a standard when deciding on whom to vote into office or to reject.

### Values Clarification Strategies

In 1978, Uustal offered several values clarification strategies that are ultimately useful to the decision-making process in community health nursing practice today. Strategy 1 is a way

### Name Tag

Take a piece of paper and write your name in the middle of it. In each of the four corners, write your responses to these four questions:

1. What two things would you like your colleagues to say about you?
2. What single most important thing do you do (or would you like to do) to make your nurse–client relationships positive ones?
3. What do you do on a daily basis that indicates you value your health?
4. What are the three values you believe in most strongly?

In the space around your name, write at least six adjectives that you feel best describe who you are.

Take a closer look at your responses to the questions and to the ways in which you described yourself. What values are reflected in your answers?

**FIGURE 4.4** Values clarification strategy 1.

for nurses to come to know themselves and their values better (Fig. 4.4). Strategy 2 assists in discovering value clusters and the priority of values within personal value systems (Fig. 4.5). Strategy 3 can be used to examine personal responses to selected issues in nursing practice. Each response helps to establish priorities of values by asking the nurse to choose among the alternatives presented or to

### Patterns

Which of the following words describe you? Draw a circle around the seven words that best describe you as an individual. Underline the seven words that most accurately describe you as a professional person. (You may circle and underline the same word.)

ambitious	reserved	assertive	opinionated
concerned	generous	independent	
easily hurt	outgoing	reliable	indifferent
capable	self-controlled	fun-loving	
suspicious	solitary	likable	dependent
intellectual	argumentative	dynamic	unpredictable
compromising	thoughtful	affectionate	obedient
logical	imaginative	self-disciplined	
moody	easily led	helpful	slow to relate

Reflect on the following questions:

1. What values are reflected in the patterns you have chosen?
2. What is the relationship between these patterns and your personal values?
3. What patterns indicate inconsistencies in attitudes or behavior?
4. What patterns do you think a nurse should cultivate?

**FIGURE 4.5** Values clarification strategy 2.

indicate degree of agreement or disagreement (Fig. 4.6). Other values clarification strategies are included in the critical thinking activities at the end of this chapter to assist in understanding personal ordering of values and when considering directions for change. These strategies also help the nurse to assist community health clients to become clearer about their own values.

All of these strategies can be used to analyze and understand how values are meaningful to people and ultimately influence their choices and behavior. Clarification of a person's values is the first step in the decision-making process, and it affects the ability of people to make ethical decisions. Values clarification also promotes understanding and respect for values held by others, such as community health clients and other health care providers. As pointed out by Uustal (1977, p. 10), "Nurses cannot hope to give optimal, sensitive care to any patient without first understanding their own opinions, attitudes, and values." This values clarification process provides a backdrop for next exploring the role of values in ethical decision-making.

## ETHICS

Values are central to any consideration of ethics or ethical decision-making. Yet, it is not always obvious at first what constitutes an ethical problem in health care or in the practice of community health nursing. Most nurses easily recognize the moral crisis in some kinds of decisions—for example, whether to let seriously deformed newborn infants die, whether to terminate pregnancies resulting from rape, or whether to provide universal health care coverage. However, other, less obvious moral dilemmas often found in the routine practice

### Forced Choice Ranking

How do you order the following alternatives by priority? (There is no correct set of priorities.) What values emerge in response to each question?

1. With whom on a nursing team would you become most angry? The nurse who
  - \_\_\_ never completes assignments.
  - \_\_\_ rarely helps other team members.
  - \_\_\_ projects his or her feelings on clients.
2. If you had a serious health problem, you would rather
  - \_\_\_ not be told.
  - \_\_\_ be told directly.
  - \_\_\_ find out by accident.
3. You are made happiest in your work when you use
  - \_\_\_ your technical skills in caring for adults with complex needs.
  - \_\_\_ your ability to compile data and arrive at a nursing diagnosis.
  - \_\_\_ your ability to communicate easily and skillfully with clients.
4. It would be most difficult for you to
  - \_\_\_ listen to and counsel a dying person.
  - \_\_\_ advise a pregnant adolescent.
  - \_\_\_ handle a situation of obvious child abuse.

**FIGURE 4.6** Values clarification strategy 3.

of community health nursing are not always considered to be ethical in nature.

What is *ethics* and what is *ethical*? The *Merriam Webster Online Dictionary* (2006) defines **ethics** as “a set of moral principles; a theory or system of moral values; the principles of conduct governing a group; a guiding philosophy; a consciousness of moral importance” (§ 1). Ethics are often idealized as “what ought to be.” **Ethical decision-making**, then, means making a choice that is consistent with a moral code or that can be justified from an ethical perspective. Of necessity, the decision-maker must exercise moral judgment. Remember that the term **moral** refers to conforming to a standard that is right and good. Community health nurses become “moral agents” by making decisions that have direct and indirect consequences for the welfare of themselves and others. **Bioethics** refers to using ethical principles and methods of decision-making in questions involving biologic, medical, or health care issues. The next section examines how a nurse makes these moral decisions.

### Identifying Ethical Situations

Ethics involves making evaluative judgments. To be ethically responsible in the practice of community health nursing, it is important to develop the ability to recognize evaluative judgments as they are made and implemented in nursing practice. Nurses must be able to distinguish between evaluative and nonevaluative judgments. Evaluative statements involve judgments of value, rights, duties, and responsibilities. Examples are, “Parents should never strike their children,” and “It is the duty of every citizen to vote.” Among the words to watch for are verbs such as *want*, *desire*, *refer*, *should*, or *ought* and nouns such as *benefit*, *harm*, *duty*, *responsibility*, *right*, or *obligation*.

Sometimes, the evaluations are expressed in terms that are not direct expressions of evaluations but clearly are

functioning as value judgments. For example, the American Nurses Association (ANA) *Code for Nurses with Interpretive Statements* (2001), in its nine statements, has several that actually refer to “the nurse’s obligation” or “owing the same duties to self as to others” and “nursing values” (see Code of Ethics for Nurses—Provisions).

Another important step is to distinguish between moral and nonmoral evaluations. **Moral evaluations** refer to judgments that conform to standards of what is right and good. Moral evaluations assess human actions, institutions, or character traits rather than inanimate objects, such as parks or architectural structures. They are prescriptive–proscriptive beliefs having certain characteristics separating them from other evaluations such as aesthetic judgments, personal preferences, or matters of taste. Moral evaluations also have distinctive characteristics (Thompson, Melia, & Boyd, 2000):

- ◆ *The evaluations are ultimate.* They have a preemptive quality, meaning that other values or human ends cannot, as a rule, override them.
- ◆ *They possess universality or reflect a standpoint that applies to everyone.* They are evaluations that everyone in principle ought to be able to make and understand, even if some individuals, in fact, do not.
- ◆ *Moral evaluations avoid giving a special place to a person’s own welfare.* They have a focus that keeps others in view, or at least considers one’s own welfare on a par with that of others.

### Resolving Moral Conflicts and Ethical Dilemmas

When judgments involve moral values, conflicts are inevitable. In clinical practice, the nurse may be faced with moral conflicts, such as the choice between preserving the welfare of one set of clients over that of others. For example, the nurse may

## CODE OF ETHICS FOR NURSES PROVISIONS, APPROVED AS OF JUNE 30, 2001

1. The nurse, in all professional relationships, practices with compassion and respect for the inherent dignity, worth, and uniqueness of every individual, unrestricted by considerations of social or economic status, personal attributes, or the nature of health problems.
2. The nurse’s primary commitment is to the patient, whether an individual, family, group, or community.
3. The nurse promotes, advocates for, and strives to protect the health, safety, and rights of the patient.
4. The nurse is responsible and accountable for individual nursing practice and determines the appropriate delegation of tasks consistent with the nurse’s obligation to provide optimum patient care.
5. The nurse owes the same duties to self as to others, including the responsibility to preserve integrity and safety, to maintain competence, and to continue personal and professional growth.
6. The nurse participates in establishing, maintaining, and improving health care environments and conditions of employment conducive to the provision of quality health care and consistent with the values of the profession through individual and collective action.
7. The nurse participates in the advancement of the profession through contributions to practice, education, administration, and knowledge development.
8. The nurse collaborates with other health professionals and the public in promoting community, national, and international efforts to meet health needs.
9. The profession of nursing, as represented by associations and their members, is responsible for articulating nursing values, for maintaining the integrity of the profession and its practice, and for shaping social policy.

have to choose whether to keep a promise of confidentiality to persons who are infected by HIV when these individuals continue to have unprotected sex with unknowing partners. Nurses may have to choose between protecting the interests of colleagues or the interests of the employing institution by reporting a nurse who makes phone visits rather than home visits, so that she can spend more time shopping online from work. They may have to decide whether to serve future clients by striking for better conditions or to serve present clients by refusing to strike. Often, nurses' values are at odds with their employers' values and procedures. The moral values of a nurse may conflict with the policies and practices of a particular bureaucracy. Each decision involves a potential conflict between moral values and is called an **ethical dilemma**. An ethical dilemma occurs when morals conflict with one another, causing the nurse to face a choice with equally attractive or equally undesirable alternatives (Kelly, 2006; Thompson, Melia, & Boyd, 2000). When "two or more seemingly equivalent principles or values seem to compel different actions," you are faced with an ethical dilemma (Iserson, 1999, p. 298). It can create a decision-making problem, even in ordinary nursing situations.

## Decision-making Frameworks

To resolve ethical dilemmas or the conflict between moral values in community health nursing practice, and to provide morally accountable nursing service, several frameworks for ethical decision-making have been proposed. Among these frameworks, three key steps are considered as fundamental to choosing alternative courses of action that reflect moral reasoning: separate questions of fact from questions of value, identify both clients' and nurse's value systems, and consider ethical principles and concepts.

The identification of clients' values and those of other persons involved in conflict situations is an important part of ethical decision-making. In the example given in From the Case Files I, what are Mr. Bell's values? What are the values of neighbors who are concerned about him, but feel that they can no longer care for him? What are the nurse's values? What are the values of the nurse's employing agency? What are society's values?

An ethical decision-making framework referred to as the DECIDE model is a practical method of making prudent value judgments and ethical decisions (Thompson, Melia, & Boyd, 2000). It includes the following steps:

- D**—*Define the problem (or problems)*. What are the key facts of the situation? Who is involved? What are their rights and duties and your rights and duties?
- E**—*Ethical review*. What ethical principles have a bearing on the situation, and which principle or principles should be given priority in making a decision?
- C**—*Consider the options*. What options do you have in the situation? What alternative courses of action exist? What help, means, and methods do you need to use?
- I**—*Investigate outcomes*. Given each available option, what consequences are likely to follow from each course of action open to you? Which is the most ethical thing to do?
- D**—*Decide on action*. Having chosen the best available option, determine a specific action plan, set clear objectives, and then act decisively and effectively.
- E**—*Evaluate results*. Having initiated a course of action, assess how things progress, and when concluded, evaluate carefully whether or not you achieved your goals.

## From the Case Files I

### Mr. Bell

Community health nurses encounter value differences every day, and value differences, in turn, create ethical problems. Consider, for example, the dilemma faced by one nurse in Seattle on her first home visit to an elderly man, Mr. Bell, referred by concerned neighbors, this 82-year-old gentleman was homebound and living alone with severe arthritis under steadily deteriorating conditions. Overgrown shrubs and vines covered the yard and house, making access impossible except through the back door. A wood-burning stove in the kitchen was the sole source of heat, and that room, plus a corner of the dining room, were Mr. Bell's living quarters. The remainder of the once-lovely three-bedroom home, including the bathroom, was layered with dust, unused. His bed was a cot in the dining room; his toilet, a two-pound coffee can placed under the cot. Unbathed, unshaven, and existing on food and firewood brought by neighbors, Mr. Bell seemed to be living in deplorable conditions. Yet he prized his independence so highly that he adamantly refused to leave.

The conflict of values between Mr. Bell's choice to live independently and the nurse's value of having him in a safer living situation raises several ethical questions. When do health practitioners or family members have the right or duty to override an individual's preferences? When do neighbors' rights (Mr. Bell's home was an eyesore and his care was a source of anxiety for his neighbors) supersede one homeowner's rights? Should the nurse be responsible when family members can help but won't take action? Mr. Bell had one son living in a neighboring state.

In this case, the nurse entering Mr. Bell's home applied her values of respect for the individual and his right to autonomy even at the risk of public safety. Not until he fell and broke a hip did he reluctantly agree to be moved into a nursing home.

## DISPLAY 4.1

## A FRAMEWORK FOR ETHICAL DECISION-MAKING

1. *Clarify the ethical dilemma:* Whose problem is it? Who should make the decision? Who is affected by the decision? What ethical principles are related to the problem?
2. *Gather additional data:* Have as much information about the situation as possible. Be up to date on any legal cases related to the ethical question.
3. *Identify options:* Brainstorm with others to identify as many alternatives as possible. The more options identified, the more likely it is that an acceptable solution will be found.
4. *Make a decision:* Choose from the options identified and determine the most acceptable option, the one more feasible than others.
5. *Act:* Carry out the decision. It may be necessary to collaborate with others to implement the decision and identify options.
6. *Evaluate:* After acting on a decision, evaluate its impact. Was the best course of action chosen? Would an alternative have been better? Why? What went right and what went wrong? Why?

Other frameworks can be used. The framework for ethical decision-making shown in Display 4.1 helps to organize thoughts and acts as a guide through the decision-making process. The steps help to determine a course of action, with heavy responsibility at the evaluation level: here the outcomes need to be judged and decisions repeated or rejected in future situations. Figure 4.7 summarizes several views in the field on ethical decision-making. This framework advocates keeping multiple values in tension before resolution of conflict and action on the part of the nurse. It suggests that value conflict is not capable of resolution until all possible alternative actions have been explored. Iserson (1999) advocates the use of three tests: the impartiality test (e.g., Would you be willing to have this done to you?—the “golden rule”), the universalizability test (e.g., If every nurse in similar circumstances did the same as you, would you be comfortable with that “universal rule?”), and the interpersonal justifiability test (e.g., Can you state a reason for your choice and justify your actions to your peers, supervisors, and society?). Final resolution of the ethical conflict occurs through a conscious choice of action, even though some values would be overridden by other stronger, presumably moral values.

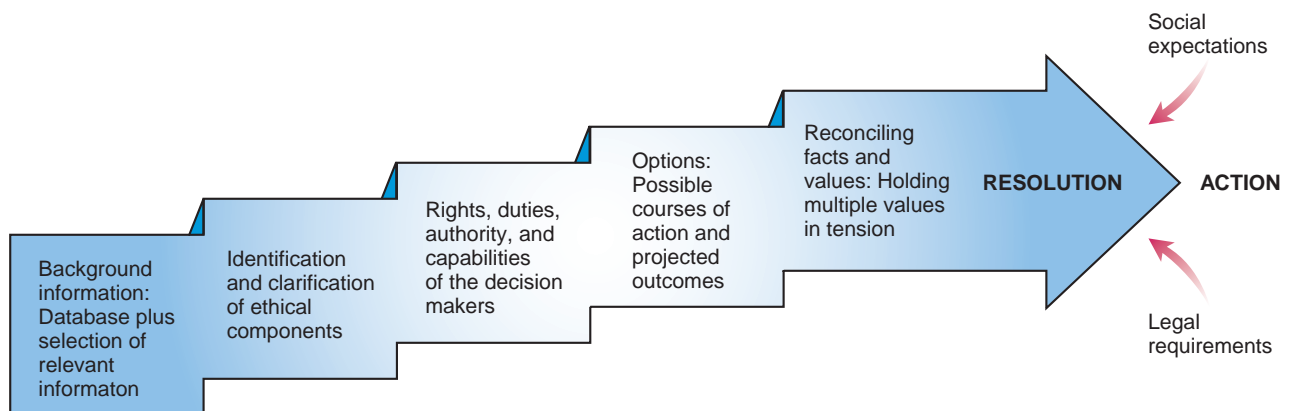

The triumphant values would be those located higher in the decision-maker’s hierarchy of values.

### Basic Values That Guide Decision-making

When applying a decision-making framework, certain values influence community health nursing decisions. Three basic human values are considered key to guiding decision-making in the provider–client relationship: self-determination, well-being, and equity.

### Self-determination

The value of **self-determination** or individual autonomy is a person’s exercise of the capacity to shape and pursue personal plans for life (Guido, 2006). Self-determination is instrumentally valued because self-judgment about a person’s goals and choices is conducive to an individual’s sense of well-being. Informed consent derives from self-determination. When one respects self-determination, it is based on the belief that better outcomes will result when autonomy is held in high regard. The outcomes that could be maximized

**FIGURE 4.7** An ethical decision-making framework. Although legal requirements or social expectations may sway a decision one way or another, they are extrinsic to the ethical analysis and should not be confused with right and wrong. What is legal and what is expected are not necessarily right and wrong.

by respecting self-determination or autonomy include enhanced self-concept, enhanced health-promoting behaviors, and enhanced quality of care. Self-determination is a major value in the United States, but does not receive the same emphasis in all societies or ethnic groups.

In health care contexts, the desire for self-determination has been of such high ethical importance in U.S. society that it overrides practitioner determinations in many situations. Client empowerment is an approach that differs from the paternalistic approach to health care in which decisions are made for, rather than with, the client; instead, it enables patients and professionals to work in partnerships (Gagnon, Hibert, Dube, & Dubois, 2006; Aston, Meagher-Stewart, Sheppard-Lemoine, Vukic, & Chircop, 2006). Many physicians and other health providers, including community health nurses, fail to recognize the high value attributed to self-determination by many consumers or the differences in views of self-determination among ethnic groups.

The conflict between provider and consumer may be broader. When self-determination deteriorates into self-interest, it poses a major roadblock to equitable health care. **Self-interest** is the fulfillment of one's own desires, without regard for the greater good. Consumers mostly have to fend for themselves when they encounter the world of for-profit health care, just as they do in other commercial markets, where "buyer beware" is the standard (Darke & Chaiken, 2005).

When providing health care, self-determination and taking personal responsibility for health care decisions should be nurtured. This includes informing clients of options and the reasoning behind all recommendations. Yet self-determination and personal autonomy at times are impermissible or even impossible. For example, society must impose restrictions on unacceptable client choices, such as child abuse and other abusive behaviors, or situations in which clients are not competent to exercise self-determination, as is true for certain levels of mental

illness or dementia. There are two situations in which self-determination should be restricted: when some objectives of individuals are contrary to the public interest or the interests of others in society (e.g., endangering others with a communicable disease), and when a person's decision-making is so defective or mistaken that the decision fails to promote the person's own values or goals. When a person cannot fully comprehend the options, the consequences of actions related to the options, and the true costs and benefits, he may not have adequate capacity for making health care decisions. In these situations, self-determination is justifiably overridden on the basis of the promotion of one's own well-being or the well-being of others—another important value in health care decision-making (Guido, 2006; Kelly, 2006).

### **Well-being**

**Well-being** is a state of positive health. Although all therapeutic interventions by health care professionals are intended to improve clients' health and promote well-being, well-intended interventions sometimes fall short if they are in conflict with clients' preferences and needs. Determining what constitutes health for people and how their well-being can be promoted often requires knowledge of clients' subjective preferences. It is generally recognized that clients may be inclined to pursue different directions in treatment procedures based on individual goals, values, and interests. Community health nurses, who are committed not only to helping clients but also to respecting their wishes and avoiding harming them, must understand each client group's needs and develop reasonable alternatives for service from which clients may choose (see From the Case Files II). In addition, when individuals are not capable of making a choice, the nurse or other surrogate decision-maker is obliged to make health care decisions that promote the value of well-being. This may mean that the alternatives presented

## **From the Case Files II**

### **Andrea Vargas, PHN—A Family Living in Poverty**

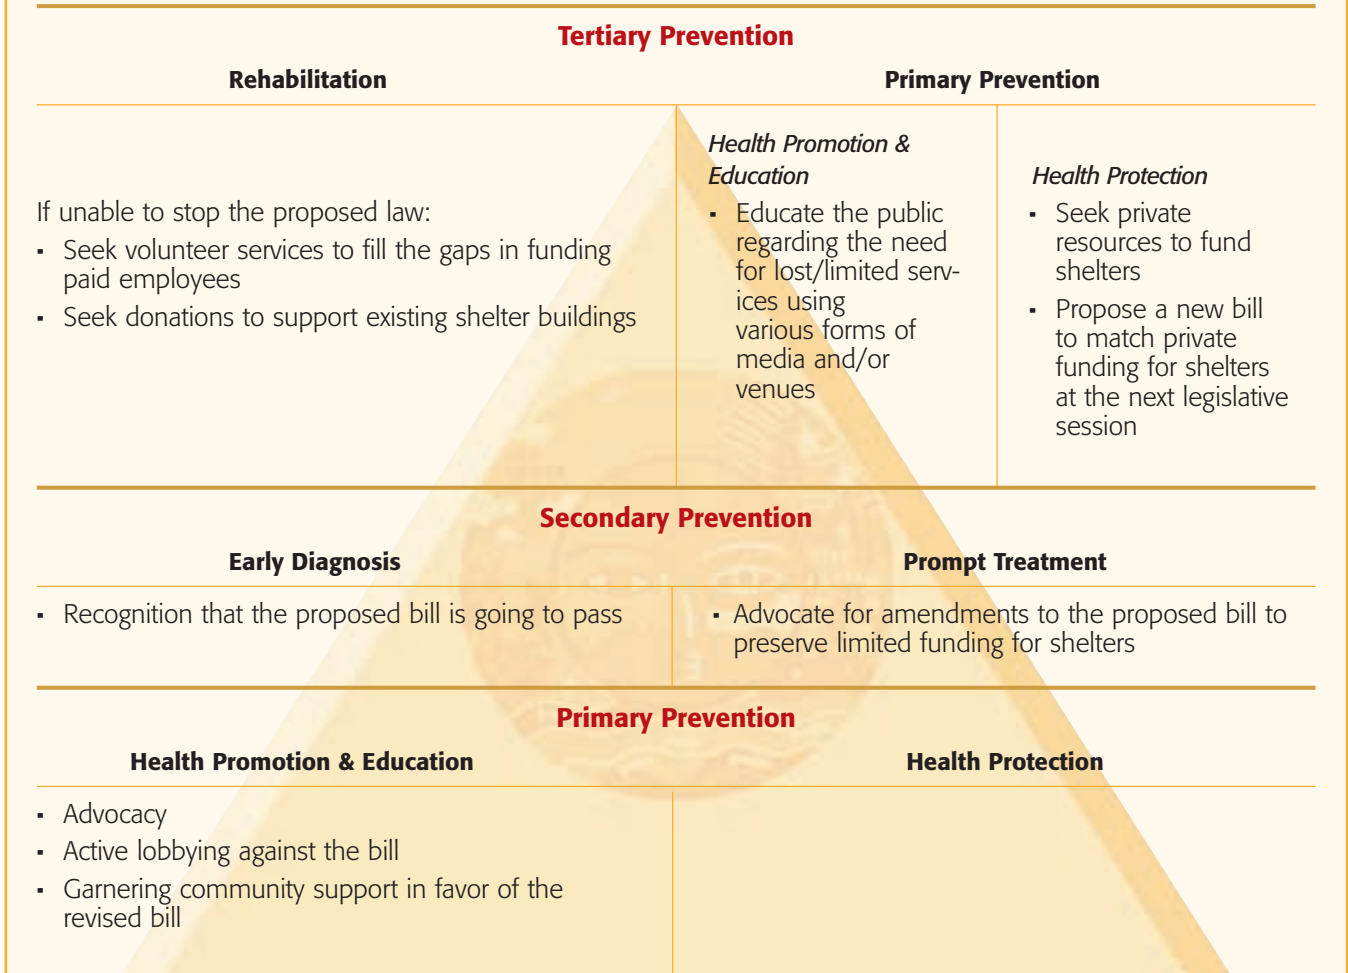

Contrasting value systems may be seen in many community health practice settings. Andrea Vargas, a community health nurse, experienced such a contrast on her first home visit to a family living in poverty. Referred by a school nurse for the children's recurring problems with head lice and staphylococcal infections, the family was living in the worst conditions that Andrea had ever seen. Papers, moldy food, soiled clothing, and empty beer cans covered the floor. Andrea recoiled in dismay. The children, home from school, were clustered around the television. Their mother, a divorced, single parent—unkempt and obese—sat smoking a cigarette and drinking a soda. Although she worked part-time as a waitress, she had been unable to earn enough money to support her family, so they were now temporarily receiving state aid. The mother's main pleasure in life was watching soap operas on television. The nurse interpreted the situation through the framework of her own value system, in which health and cleanliness were priorities. Yet the mother, who might have shared those values in the past, appeared to prize pleasurable diversion, perhaps as a way to cope with her situation. In this instance, it is possible that environmental influences reordered the family's value system priorities. Rather than imposing her own values, Andrea chose to determine the priorities of the family, assess their needs, and begin where they were. Will she have a greater chance at success by doing this?

## LEVELS OF PREVENTION PYRAMID

**SITUATION:** Provide distributive justice for battered women and children by changing a proposed state law that would eliminate funding for shelters for battered women and children to a law that preserves resources for this population.

**GOAL:** Using the three levels of prevention, negative health conditions are avoided, or promptly diagnosed and treated, and the fullest possible potential is restored.

by the nurse for choice are only the alternatives that will promote well-being. With shared decision-making, the nurse not only seeks to understand clients’ needs and develop reasonable alternatives to meet those needs, but also to present the alternatives in a way that enables clients to choose those they prefer. Well-being and self-determination are two values that are intricately related when providing community health nursing services.

### Equity

The third value that is important to decision-making in health care contexts is the value of **equity** or justice, which means being treated equally or fairly. The principle of equity implies that it is unjust (or inequitable) to treat people the

same if they are, in significant respects, unlike. In other words, different people have different needs in health care, but all must be served equally and adequately. Equity generally means that all individuals should have the same access to health care according to benefit or needs (see Levels of Prevention Pyramid).

The major problem with this definition of equity is, of course, that it assumes that an adequate level of health care can be economically available to all citizens. In times of limited technical, human, and financial resources, however, it may be impossible to fully respect the value of equity (Smith, Oveku, Homer, & Zuckerman, 2006; Franco, 2005). Choices must be made and resources allotted, while the value obligations of professional practice create conflicts of values that seem impossible to resolve.

Many of these conflicts are reflected in current health care reform efforts that focus on access to services, quality of services, and ways to control rising costs. However, the following list represents some of the most pressing aggregate health problems related to inequities in the distribution of and access to health and illness care facing our nation:

- ◆ *Too many women go without preventive care.* The overall rate of infant mortality (all infant deaths before 1 year of age) is 7 per 1,000 in the United States; it remains among the highest in the industrialized world (Centers for Disease Control [CDC], 2006). The rates for some people of color—African Americans (13.9), Native Hawaiian and other Pacific Islanders (9.6), and Native Americans (8.6) specifically—are higher than those for White, non-Hispanic (5.8) or Mexican Americans (5.4) (CDC, 2006). Forty-nine percent of pregnancies in the United States during 2001 were unintended—among White and Hispanic females 40% and 54%, respectively, were reported as unintended. But, among African American females, 69% report unintended pregnancies. Poverty is strongly related to difficulty in accessing family planning services (Finer & Henshaw, 2006).
- ◆ *Immunization rates for some diseases are at dangerously low levels.* For example, in 2004, about 82% of all children between 19 and 35 months of age had received full doses of childhood vaccines—below the 90% Healthy People 2010 objective. By ethnicity, though, only 76% of

Black children, 81% of Hispanic children, and 74% of American Indian/Alaska Native children received those immunizations. When poverty level was factored in, the total dropped to 78% for those living below the poverty level, with only 73% of Black children immunized (CDC, 2006). Vast disparities in immunization rates also exist for adults along racial and ethnic lines, as well as poverty level (Office of Minority Health, 2006).

- ◆ *The uninsured are likely to go without physician care.* Differences in access to expensive, discretionary procedures emerge according to health insurance status, race, and ethnicity, as well as other sociodemographic factors. In 2003, 17% of Americans below the age of 65 reported having no health insurance, with Black and Hispanic Americans being more likely than White non-Hispanic Americans to lack health insurance coverage. Interestingly, only 30% of those without health insurance live below the poverty level (National Center for Health Statistics, 2005).
- ◆ *Environmental hazards threaten global health.* Global trade, travel, and changing social and cultural patterns make the population vulnerable to diseases that are endemic to other parts of the world, as well as to previously unknown diseases. Pollution of air, water, and soil to support industry contributes to pathogen mutations and threatens public health.

#### DISPLAY 4.2

### SOCIETY AND INDIVIDUAL RESPONSIBILITY IN HEALTH CARE

To promote the achievement of equity, self-determination, and clients' well-being, certain conclusions drawn from the literature can enhance community health nursing practice (Des Jardin, 2001):

1. *Society has an ethical obligation to ensure equitable access to health care for all.* This obligation is centered on the special importance of health care and is derived from its role in relieving suffering, preventing premature death, restoring functioning, increasing opportunity, providing information about an individual's condition, and giving evidence of mutual empathy and compassion.
2. *The societal obligation is balanced by individual obligations.* Individuals ought to pay a fair share of the cost of their own health care and take reasonable steps to provide for such care when they can do so without excessive burdens.
3. *Equitable access to health care requires that all citizens can secure an adequate level of care without excessive burdens.* Equitable access also means that the burdens borne by individuals in obtaining adequate care ought not to be excessive or to fall disproportionately on particular individuals. Communities need to be empowered to address distribution problems.
4. *When equity occurs through the operation of private forces, there is no need for government involvement.* However, the ultimate responsibility for ensuring that society's obligation is met—through a combination of public and private sector arrangements—rests with the federal government.
5. *The cost of achieving equitable access to health care ought to be shared fairly.* The cost of securing health care for those who are unable to pay ought to be spread equitably at the national level and should not fall more heavily on the shoulders of particular practitioners, institutions, or residents of different localities.
6. *Efforts to contain rising health care costs are important but should not focus on limiting the attainment of equitable access for the least-served portion of the public.* Measures designed to contain health care costs that exacerbate existing inequities or impede the achievement of equity are unacceptable from a moral standpoint. Aggregates in the community should be involved in planning and problem-solving to increase the distribution of resources where those resources are most needed.

## Ethical Decision-making in Community Health Nursing

The key values of self-determination, well-being, and equity influence nursing practice in many ways. The value of self-determination has implications for how community health nurses regard:

- ◆ the choices of clients,
- ◆ privacy,
- ◆ informed consent, and
- ◆ diminished capacity for self-determination.

The value of well-being has implications for how community health nurses seek to:

- ◆ prevent harm and provide benefits to client populations,
- ◆ determine effectiveness of nursing services, and
- ◆ weigh costs of services against real client benefits.

The value of equity has implications for community health nursing in terms of its priorities for:

- ◆ distributing health goods (macroallocation issues), and
- ◆ deciding which populations will obtain available health goods and services (microallocation issues).

Decisions based on one value mean that this value often will conflict with other values. For example, deciding primarily on the basis of client well-being may conflict with deciding on the basis of self-determination or equity. How community health nurses balance these values may even conflict with their own personal values or the professional values of nursing as a whole. In these situations, values clarification techniques used with an ethical decision-making process may assist in producing decisions that promote the greatest well-being for clients without substantially reducing their self-determination or ignoring equity.

## Ethical Principles

Seven fundamental ethical principles provide guidance in making decisions regarding clients' care: respect, autonomy, beneficence, nonmaleficence, justice, veracity, and fidelity (Guido, 2006; Thompson, Melia, & Boyd, 2000).

### Respect

The principle of **respect** refers to treating people as unique, equal, and responsible moral agents. This principle emphasizes one's importance as a member of the community and of the health services team. To apply this principle in decision-making is to acknowledge community clients as valued participants in shaping their own and the community's health outcomes. It includes treating them as equals on the health team and holding them, as well as their views, in high regard.

### Autonomy

The principle of **autonomy** means freedom of choice and the exercise of people's rights. Individualism and self-determination are dominant values underlying this principle. As nurses apply this principle in community health, they promote individuals' and groups' rights to and involvement in decision-making. This is true, however, only so long as those decisions enhance these individuals' and groups' well-being and do not harm the well-being of others (Franco, 2005). When applying this principle, nurses should make certain that clients are fully informed and that the decisions are made deliberately, with careful consideration of the consequences (see From the Case Files III).

### Beneficence

The ethical principle of **beneficence** means doing good or benefiting others. It is the promotion of good or taking action to ensure positive outcomes on behalf of clients. In community health, the nurse applies the principle of benef-

## From the Case Files III

### Tom Hardy, PHN—An Elderly Client Gives Up

Tom Hardy, PHN, has been assigned to monitor Mr. Jack, an elderly man who was diagnosed with tuberculosis (TB) (positive skin test, positive sputum and x-ray). Mr. Jack's wife unexpectedly died recently, and he is depressed and wants to "join her." He is not eating or sleeping much. He refuses to take his TB medications, nor his eight other medications for heart disease, thyroid insufficiency, type 2 diabetes, glaucoma, high cholesterol and triglycerides, and hypertension. He has consistently refused any of Tom's suggestions or assistance. He does not want to see a mental health counselor, and Tom wonders if he should continue to make home visits. He has a busy caseload and needs to focus on the most pressing cases. Mr. Jack's children feel that his depression and refusal of medications is a "temporary condition" in response to his wife's death, and ask for Tom's assistance in keeping him healthy. Why is this an ethical dilemma? What are the ethical principles involved? What does Mr. Jack value? What are his children's values? Prioritize your values. What are the possible actions you could take?

licence by making decisions that actively promote community clients' best interests and well-being. Examples might encompass the development of a seniors' health program that ensures equal access to all in the community who are in need, and the support of programs to encourage preschool immunizations.

### Nonmaleficence

The principle of **nonmaleficence** means avoiding or preventing harm to others as a consequence of a person's own choices and actions. This involves taking steps to avoid negative consequences. Community health nurses can apply this ethical principle in decision-making by actions such as encouraging physicians to prescribe drugs with the fewest side effects, promoting legislation to protect the environment from pollutants emitted from gasoline even if it raises prices, and lobbying for lower speed limits or gun controls to save lives.

### Justice

The principle of **justice** refers to treating people fairly. It means the fair distribution of both benefits and costs among society's members. Examples might include: equal access to health care, equitable distribution of services to rural as well as urban populations, not limiting the amount or quality of services because of income level, and fair distribution of resources—all of these draw on the principle of justice.

Within this principle are three different views on allocation, or what constitutes the meaning of "fair" distribution. One, **distributive justice**, says that benefits should be given first to the disadvantaged or those who need them most (see Levels of Prevention Pyramid). Decisions based on this view particularly help the needy, although it may mean withholding goods from others who also are also deserving but less in need (e.g., food stamps). The second view, **egalitarian justice**, promotes decisions based on equal distribution of benefits to everyone, regardless of need (e.g., Medicare). The third, **restorative justice**, determines that benefits should go primarily to those who have been wronged by prior injustice, such as victims of crime or racial discrimination. Programs are in place to compensate victims for their injury or families for their loss—a beginning step to "restore justice." Another example includes the funds that were set up by several agencies, corporations, and groups to assist the families of the victims of the September 11, 2001 terrorist attacks. The principle of justice seeks to promote equity, a value that was discussed in the previous section.

### Veracity

The principle of **veracity** refers to telling the truth. Community clients deserve to be given accurate information in a timely manner. To withhold information or not tell the truth can be self-serving to the nurse or other health care providers and hurtful, as well as disrespectful, to clients. Truth-telling involves treating clients as equals, and it expands the opportunity for greater client involvement, as

well as provides needed information for decision-making (Arries, 2006).

### Fidelity

The final ethical principle, **fidelity**, means keeping promises. People deserve to count on commitments being met. This principle involves the issues of trust and trustworthiness. Nurses who follow through on what they have said earn their clients' respect and trust. In turn, this influences the quality of the nurse's relationship with clients, who then are more likely to share information, which leads to improved decisions and better health. Conversely, when a promise (e.g., a commitment to institute child care during health classes) is not kept, community members may lose faith and interest in participation.

## Ethical Standards and Guidelines

As the number and complexity of ethical decisions in community health increase, so too does the need for ethical standards and guidelines to help nurses make the best choices possible. The ANA's *Code for Nurses with Interpretive Statements* (2001) provides a helpful guide. Some health care organizations and community agencies, using the ANA code or a similar document, have developed their own specific standards and guidelines.

More health care organizations are using ethics committees or ethics rounds to deal with ethical aspects of client services (Guido, 2006). These committees are common in the acute care setting and in senior and long-term care settings, and they may focus on such issues as caregiving dilemmas that may involve practitioner negligence or poor client outcomes and the related health care decisions. However, these committees also function in a variety of community health care settings. In long-term care and home care settings, such a committee may consider conflicts in client care issues that involve family members. In public health agencies, cases of clients with complicated communicable disease diagnoses and health care provider concerns are discussed as they relate to policy, protocols, and the health and safety of the broader population.

## Summary

Involvement in community health nursing research can be an exciting opportunity to contribute to the body of nursing knowledge and influence changes in nursing practice and in community health programs and policies. Research findings also enable community health nurses to promote health and prevent illness among at-risk populations and to design and evaluate community-based interventions. Evidence-based practice is essential to ensuring cost-efficient and effective interventions for our clients. Systematic reviews can provide direction for those who have developed a "burning clinical question." Finding accurate, complete information and critically appraising it is vital (see Evidence-Based Practice: Handwashing).

*Research* is defined as the systematic collection and analysis of data related to a particular problem or phenomenon. *Quantitative research* concerns data that can be measured objectively. It is helpful in identifying a problem or a

## EVIDENCE-BASED PRACTICE

### Handwashing

As nurses, we are taught the importance of handwashing. In nursing school, we are educated to wash our hands before and after patient care—it is often drilled into us. But, when you work in the community, you do not always have ready access to soap and water. Many PHNs choose to carry small bottles of hand sanitizer as a practical alternative to handwashing. But, is this effective? A small study of health care workers in France found that handrubbing with an alcohol-based mixture was better than handwashing with antiseptic soap when it came to reducing hand bacterial contamination for workers in

intensive care settings (Girou, Loyeau, Legrand, et al., 2002). A larger French study found that handrubbing with an alcohol solution was as effective as handscrubbing with antiseptic soap in preventing infections of surgical sites. They noted no statistical differences in development of nosocomial infections of patients' surgical sites between the two groups (Parianti, Thibon, Heller, et al., 2002). Where would you go to find a systematic or integrative review of this subject? How would you go about presenting this information at a staff meeting to stimulate changes in policies and procedures?

relationship between two or more variables; however, because it requires the researcher to focus on a part instead of the whole, if used exclusively it can limit nursing knowledge. *Qualitative research* emphasizes subjectivity and the meaning of experiences to individuals.

The research process includes nine steps:

1. Identify an area of interest.
2. Formulate a research question or statement.
3. Review the literature.
4. Select a conceptual model.
5. Choose a research design.
6. Obtain Institutional Review Board or Human Subjects Committee approval.
7. Collect and analyze data.
8. Interpret results.
9. Communicate findings.

Although the process is the same regardless of nursing specialty, community health nurses have a unique opportunity to expand nursing knowledge in relation to community health issues and the health needs of aggregates and families.

Research has a significant impact on community health and nursing practice in three ways. It provides new knowledge that helps to shape health policy, improve service delivery, and promote the public's health. It contributes to nursing knowledge and the improvement of nursing practice. And it offers the potential to enhance nursing's status and influence through documentation of the effectiveness of nursing interventions and broader recognition of nursing's contributions to health services.

Nurses must become responsible users of research, keeping abreast of new knowledge and applying it in practice. Nurses must learn to evaluate nursing research articles critically, assessing their validity and applicability to their own practice. Nurses should subscribe to and read nursing research journals and discuss research studies with colleagues and supervisors. More community health nurses must also conduct research studies of their own or in collaboration with other

community health professionals. A commitment to the use and conduct of research will move the nursing profession forward and enhance its influence on the health of at-risk populations.

Values and ethical principles strongly influence community health nursing practice and ethical decision-making. Values are lasting beliefs that are important to individuals, groups, and cultures. A value system organizes these beliefs into a hierarchy of relative importance that motivates and guides human behavior. Values function as standards for behavior, as criteria for attitudes, and as standards for moral judgments, and they give expression to human needs. The nature of values can be understood by examining their qualities of endurance, their hierarchical arrangement, and their function as prescriptive–proscriptive beliefs, and by examining them in terms of reference and preference.

The nurse often is faced with decisions that affect client's values and involve conflicting moral values and ethical dilemmas. Understanding what personal values are and how they affect behavior assists the nurse in making ethical evaluations and addressing ethical conflicts in practice. Various strategies can guide the nurse in making these decisions; one example is values clarification, which clarifies what values are important. Several frameworks for ethical decision-making that include the identification and clarification of values impinging on the making of ethical decisions were discussed in this chapter.

Three key human values influence client health and nurse decision-making: the right to make decisions regarding a person's health (self-determination), the right to health and well-being, and the right to equal access and quality of health care. At times, these values are affected by the value of self-interest on the part of another person or a system. Seven fundamental principles guide community health nurses in making ethical decisions: respect, autonomy, beneficence, nonmaleficence, justice, veracity, and fidelity. ■

**ACTIVITIES TO PROMOTE CRITICAL THINKING**

1. As a community health nurse working in a large city, you notice a group of small children playing in a vacant, unfenced lot bordered by a busy street. List three research questions you might consider using to study the situation.
2. You want to determine whether a group of sexually active teenagers who are at risk for acquired immunodeficiency syndrome (AIDS) would be receptive to an educational program on HIV/AIDS. Formulate a research question, describe a conceptual framework you might use in your study, and defend your choice.
3. Select a community health nursing research article from the references listed in this chapter (or choose one of your own) and analyze its potential impact on health policy and on community health nursing practice.
4. You have just completed a study on the effectiveness of a series of birth control classes in three high schools, and the results show a reduction in the number of pregnancies over the last year. Describe three ways in which you could disseminate this information to your nursing colleagues and other community health professionals.
5. You are alarmed to note that the new area to which you have been assigned has high rates of tuberculosis. Using the Internet and your college library databases to research this topic, determine the most effective forms of treatment and discuss the feasibility of implementing some new approaches with your specific target population.
6. Describe where you stand on the following issues. For each statement, decide whether you strongly

- agree, agree, disagree, strongly disagree, or are undecided.
- a. Clients have the right to participate in all decisions related to their health care.
  - b. Nurses need a system designed to credit self-study.
  - c. Continuing education should not be mandatory to maintain licensure.
  - d. Clients always should be told the truth.
  - e. Standards of nursing practice should be enforced by state examining boards.
  - f. Nurses should be required to take relicensure examinations every 5 years.
  - g. Clients should be allowed to read their health record on request.
  - h. Abortion on demand should be an option available to every woman.
  - i. Critically ill newborns should be allowed to die.
  - j. Laws should guarantee desired health care for each person in this country.
  - k. Organ donorship should be automatic unless a waiver to refuse has been signed.
7. In a grid similar to the one shown, write a statement of belief in the space provided and examine it in relation to the seven steps of the process of valuing. Areas of confusion and conflict in nursing practice that should be examined are peer review, accountability, confidentiality, euthanasia, licensure, clients' rights, organ donation, abortion, informed consent, and terminating treatment. To the right of your statements, check the appropriate boxes to indicate when your beliefs reflect one or more of the seven steps in the valuing process. Is your belief a value according to the valuing process?

Statement	Freely chosen	Alternatives	Consequences	Cherished	Affirmed	Incorporated	Employed
	1	2	3	4	5	6	7

8. Rank in order the following 12 potential nursing actions, using "1" to indicate the most important choice in a client–community health nurse relationship and "12" to indicate the least important choice.
- \_\_\_\_\_ Touching clients
  - \_\_\_\_\_ Empathetically listening to clients
  - \_\_\_\_\_ Disclosing yourself to clients
  - \_\_\_\_\_ Becoming emotionally involved with clients
  - \_\_\_\_\_ Teaching clients

- \_\_\_\_\_ Being honest in answering clients' questions
- \_\_\_\_\_ Seeing that clients conform to professionals' advice
- \_\_\_\_\_ Helping to decrease clients' anxiety
- \_\_\_\_\_ Making sure that clients are involved in decision-making
- \_\_\_\_\_ Following legal mandates regarding health practices
- \_\_\_\_\_ Remaining "professional" with clients
- \_\_\_\_\_ (Add an alternative of your own)

(continued on next page)

Examine your ordering of these options. What values can be identified based on your responses in this exercise? How do these values emerge in your behavior?

9. Request to attend two or three sessions of an ethics committee meeting of a community health agency.

Observe and make notes on (a) what values are evident in the discussion, (b) what ethical principles are used, (c) what decision-making framework is used, and (d) what you would have liked to contribute if you had been a member of the committee.

## Transcultural Nursing in the Community

### LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Define and explain the concept of culture.
- ◆ Discuss the meaning of cultural diversity and its significance for community health nursing.
- ◆ Describe the meaning and effects of ethnocentrism on community health nursing practice.
- ◆ Identify five characteristics shared by all cultures.
- ◆ Contrast the health-related values, beliefs, and practices of selected culturally diverse populations with those of the dominant U.S. culture.
- ◆ Conduct a cultural assessment.
- ◆ Apply transcultural nursing principles in community health nursing practice.

*“People everywhere share common biological and psychological needs, and the function of all cultures is to fulfill such needs; the nature of the culture is determined by its function.”*

—Bronislaw Malinowski (1884–1942), Cultural Anthropologist

### KEY TERMS

Complementary therapies  
Cultural assessment  
Cultural diversity  
Cultural relativism  
Cultural self-awareness  
Cultural sensitivity  
Culture  
Culture shock  
Dominant values  
Enculturation

Transcultural nursing  
Value

 **American** society values individuality, and we are a country of immigrants. Many different cultural groups and races built this nation. For example, pilgrims came here hundreds of years ago, to seek freedom to practice their religious beliefs. It took powerful independence to pioneer the West in the 1800s. Partly because of this pioneer spirit, people from all nations have sought to live in America. Some came of their own free will for adventure and opportunity. Others saw this land as a refuge from political, religious, or economic strife. Still others were brought here against their will. Consequently, we have not become the ideal *melting pot* once described, but rather, an amalgamation of people who have different values, ideals, and behaviors.

Americans have many differences, but we also have much in common. In the Western culture, there is joy in seeing children grow and develop in unique ways. An individual's creative achievements are applauded. There is also respect for one another's personal preferences about food, dress, or personal beliefs. The right to be oneself—and thereby to be different from others—is even protected by state and federal laws.

Although individuality is a cherished American value, there are limits to the range of differences most Americans find acceptable. People whose behavior falls outside the acceptable range may be labeled as misfits. For example, the U.S. culture approves moderate social drinking, but not alcoholism. The beliefs and sanctions of the dominant or majority culture are called **dominant values**. In the United States, the majority culture is made up largely of European Americans whose dominant values include the work ethic, thrift, success, independence, initiative, privacy, cleanliness, youthfulness, attractive appearance, and a focus on the future. However, in some regions and states, European Americans are not the majority. For example, in California, 53% of the population are “people of color,” and the dominant culture is no longer European American (California Pan-Ethnic Health Network, 2007, ¶ 3); the proportion of the population identified as White is projected to continue to fall below other ethnicities (Legislative Analyst's Office, 2000).

Dominant values are important to consider in the practice of community health nursing because they can shape people's thoughts and behaviors. Why are some client behaviors acceptable to health professionals and others not? Why do nurses have such difficulty persuading certain clients to accept new ways of thinking and acting? Explanations can be found by examining the concept of culture, especially its influence on health and on community health nursing practice. For example, an emphasis on the need for milk in the diet may reflect cultural blindness, considering the number of people in diverse ethnic groups who are lactose intolerant (Swagerty, Walling, & Klein, 2002). Regardless of their own cultural backgrounds, nurses are socialized throughout the educational process; the biomedical model is frequently the framework, and dominant social values are often involuntarily reinforced.

## THE MEANING OF CULTURE

**Culture** refers to the beliefs, values, and behavior that are shared by members of a society and provide a design or “roadmap” for living. Culture tells people what is acceptable

or unacceptable in a given situation. Culture dictates what to do, say, or believe. Culture is learned. As children grow up, they learn from their parents and others around them how to interpret the world. In turn, these assimilated beliefs and values prescribe desired behavior.

Anthropologists describe culture as the acquired knowledge that people use to generate behavior and interpret experience (Spradley & McCurdy, 2005). This knowledge is more than simply custom or ritual; it is a way of organizing and thinking about life. It gives people a sense of security about their behavior; without having to consciously think about it, they know how to act. Culture also provides the underlying values and beliefs on which people's behavior is based. For example, culture determines the value placed on achievement, independence, work, and leisure. It forms the basis for the definitions of male and female roles. It influences a person's response to authority figures, dictates religious beliefs and practices, and shapes childrearing. According to Giger and Davidhizar (2002, p. 80), “culture is a patterned behavioral response that develops over time as a result of imprinting the mind through social and religious structures and intellectual and artistic manifestations.”

Every community and social or ethnic group has its own culture. Furthermore, all of the individual members believe and act based on what they have learned within that specific culture. As anthropologist Edward Hall (1959) said a half-century ago, culture controls our lives. Even the smallest elements of everyday living are influenced by culture. For instance, culture determines the proper distance to stand from another person while talking. A comfortable talking distance for Americans is at least 2.5 feet, whereas Latin Americans prefer a shorter distance, often only 18 inches, for dialogue. Culture also influences one's perception of time. In European American culture, when someone makes an appointment, it is expected that the other person will be on time or not more than a few minutes late; to keep a person waiting (or to be kept waiting) for 45 minutes or more is considered insulting. Yet other cultural groups, including Native Americans and Hispanics, have a much more flexible response to time; their members feel that time is much more elastic, and if someone is kept waiting, it is not considered a thoughtless act. So, as you can see, culture is the knowledge people use to design their own actions and, in turn, to interpret others' behavior (Spradley & McCurdy, 2005).

## Cultural Diversity

**Race** refers to biologically designated groups of people whose distinguishing features, such as skin color, are inherited; examples include Asian, Black, and White. An **ethnic group** is a collection of people who have common origins and a shared culture and identity; they may share a common geographic origin, race, language, religion, traditions, values, and food preferences (Spector, 2004). A person's **ethnicity** is that group of qualities that mark her association with a particular ethnic group, or “who share cultural and/or physical characteristics including one or more of the following: history, political system, religion, language, geographical origin, traditions, myths, behaviours, foods, genetic similarities, and physical features” (Ethnicity Online, 2007, ¶ 1). When a variety of racial or ethnic groups join a common, larger group, cultural diversity becomes apparent. **Cultural diver-**

sity, also called *cultural plurality*, means that a variety of cultural patterns coexist within a designated geographic area. Cultural diversity occurs not only between countries or continents, but also within many countries, including the United States (Spector, 2009). However, the term *culture*, used alone, has no single definition. We have defined it for use in this book at the beginning of this section. Others have described culture as meaning the total, socially inherited characteristics of a group, comprising everything that one generation can tell, convey, or hand down to the next. Culture has also been described as “the luggage that each of us carries around for a lifetime” (Spector, 2004, p. 9).

Immigration patterns over the years have contributed to significant cultural diversity in the United States. Early settlers came primarily from European countries through the 1800s, peaking in numbers just after the turn of the 20th century, with almost 9 million immigrants admitted in the first decade. During much of that time, especially during the late 1600s through the early 1800s, African slaves were brought to the United States against their will, mostly to southern states, where they were sold to plantation owners as laborers. This “forced immigration” has had profound effects for many generations (Berlin, 2005). Immigration stayed high during the early 1900s, and then dropped sharply from 1930 to 1950. Immigration from non-European regions such as Asia and South America then steadily increased. The total number of immigrants from all countries in the 1990s almost equaled the number who arrived during the 1910s, when immigration was at a peak (Table 5.1).

As shown in Table 5.2, immigrants come from all regions of the world, in greater numbers from some areas than others. According to the U.S. Committee for Refugees and Immigrants (USCRI, 2006), in 2005, the United States hosted 176,700 refugees and asylum seekers, down by over half from 2001. The largest numbers of refugees are listed as coming from Haiti, Cuba, and China.

**TABLE 5.1 Immigrants Admitted to the United States in the 20th Century**

Decade	Number of Immigrants
1901–1910	8,795,386
1911–1920	5,735,611
1921–1930	4,107,209
1931–1940	528,431
1941–1950	1,035,039
1951–1960	2,515,479
1961–1970	3,322,677
1971–1980	4,493,314
1981–1990	7,338,062
1991–2000	9,095,417

From U. S. Department of Commerce. (2001). *Statistical abstract of the United States, 2001* (121st ed.). Washington, DC: Government Printing Office.

**TABLE 5.2 Immigrants and Region of Birth (2006)**

Origin	No. of Immigrants
All Countries	41,150
Africa	18,185
Asia	9,245
Europe	10,456
North America	3,145
Oceania	—
South America	119

From U. S. Department of Homeland Security, Yearbook of Immigration Statistics: 2006.

Although the numbers of legal immigrants have dropped, illegal immigration continues to be a *hot button topic* in this country, especially after 9/11. Proposals to end the flow of illegal immigrants from Mexico include building a 700-mile fence along the border, and legislation that would penalize employers of undocumented workers more stiffly. In 1994, Operation Gatekeeper sought to close the most commonly traversed border crossings with more guards and fences. That year, deaths along the border numbered 30. The numbers of migrants losing their lives while crossing illegally into this country continue to rise, from 147 in 1998 to 387 in 2001; in 2005, the number climbed to 451 (Hing, 2006). What is often not considered in the debate over this issue is the economic desperation that drives people to put themselves in such jeopardy.

The population of this country continues to increase. Five years after the 2000 census, the population grew by over 14 million; and Whites and Hispanic/Latinos showed the greatest increases (Table 5.3). Such numbers can be

**TABLE 5.3 U.S. Population by Race and Hispanic/Latino Origin, Census 2000 and July 1, 2005**

Origin	Census 2000 (%)	July 1, 2005 (%)
White	75.1	80.2
Black	12.3	12.8
American Indian/ Alaska Native	.9	1
Asian	3.6	4.3
Two or More Races	2.4	1.5
Some Other Race	5.5	n/a*
Hispanic or Latino	12.5	14.4

\*Those answering “Other” have been allocated to one of the recognized race categories.

From Population of the United States by Race and Hispanic/Latino Origin, Census 2000 and July 1, 2005. Retrieved January 5, 2007 from <http://www.infoplease.com/ipa/A0762156.html>; © 2000–2006 Pearson Education, publishing as Infoplease.

deceiving, however, because the 2000 census was the first one in which individuals were able to indicate two or more races or ethnic groups. Over 6 million people indicated multiple races or ethnic groups, with the number dropping to over 4 million in 2005. Approximately 50% of these people indicated Hispanic along with a second or third race or ethnic group (U.S. Department of Commerce, 2001).

People representing more than 100 different ethnic groups—more than half of them significant in size—live in the United States. Significant minorities include Hispanic Americans, numbering more than 35 million in 2000 and over 42 million in 2005 and currently representing over 14% of the population; African Americans, numbering over 37 million, or approximately 12.8% of the population; Asian Americans, numbering more than 12 million, or approximately 4.3% of the population; and American Indians and Alaska Natives, numbering 2.8 million, or 1% of the population. In 2000, Hispanics surpassed the African American population as the largest race/ethnic group in the United States (U.S. Department of Commerce, 2001; Infoplease, 2007). By 2050, the total number of Hispanic Americans is projected to double, making up 24.5% of the population; Asian-Pacific Islanders are expected to more than double their numbers, to 8.2% of the U.S. population; and the number of African Americans will increase to 15.4% of the population. The American Indian and Alaska Native population will probably stay at or near 1%. These changes, primarily resulting from immigration, are projected to result in 49.8% of the U.S. population in 2050 belonging to “minority” groups, and European Americans/Whites may no longer be the majority. In some states, especially those bordering Mexico and some industrialized states in the eastern part of the country, the most current information reveals that this change already has occurred or will occur much sooner than 2050 (U.S. Bureau of the Census, 1992) (see Display 5.1).

Immigration patterns are strongly influenced by immigration laws established since the 1800s. The Immigration Reform and Control Act of 1986 (Public Law 99–603) and the Immigration Act of 1990 (Public Law 101–649) set new limits on the number of immigrants admitted. These laws set annual numerical ceilings on certain immigrant groups while authorizing increases for highly skilled workers or family members of aliens who have recently achieved legal status. After the terrorist attacks on September 11, 2001, President Bush suspended all immigration for 2 months. Suspicion about people from Middle Eastern countries permeated the nation—worsening the social climate for immigrants.

This social climate is characterized by ambivalence about whether immigrants should be accepted and ambiguity about their status. The newcomers find an environment that is both welcoming and hostile. On one hand, they may find tolerance of diversity in the United States—demonstrated by interest in ethnic food, cultural celebrations, and sensitivity to employees from different backgrounds. On the other hand, a backlash is demonstrated by a rise in hate crimes, national and local policies that limit services to undocumented immigrants, restriction in English as a Second Language (ESL) and bilingual education, and limits to potential class action suits challenging practices of the Immigration and Nationalization Service.

Although broad cultural values are shared by most large national societies, those societies contain smaller cultural groups—called subcultures. **Subcultures** are relatively large aggregates of people within a society who share sepa-

## DISPLAY 5.1

## HISPANIC POPULATION TREND IN THE UNITED STATES

A report conducted by the Pew Hispanic Center and the Brookings Institution Center on Urban and Metropolitan Policy and released in July 2002 indicated that the Hispanic population has spread out across the nation faster and farther than any previous wave of immigrants. Hispanics are moving from immigrant gateways into the heartland and suburbs at a rate possibly exceeding that of European immigrants in the early 20th century and of African Americans moving away from the Deep South in the years before World War II.

Although large metropolitan areas such as New York, Los Angeles, and Miami accounted for the largest increases in number of Hispanics between 1980 and 2000, smaller communities charted a faster rate of growth in their Hispanic populations.

More than half of Hispanics now live in suburbs, and many migrants are skipping metropolitan areas and heading straight to jobs and housing in outlying areas. Researchers indicate that this is not one trend replacing another, but several trends expanding at once.

Hispanic population spreads out. (2002, August 1). *The Fresno Bee*, p. A4.

rate distinguishing characteristics, such as ethnicity (e.g., African American, Hispanic American), occupation (e.g., farmers, physicians), religion (e.g., Catholics, Muslims), geographic area (e.g., New Englanders, Southerners), age (e.g., the elderly, school-age children), gender (e.g., women), or sexual preference (e.g., gay, lesbian).

Within these subcultures are even smaller groups that anthropologists call **microcultures**. “Microcultures are systems of cultural knowledge characteristic of subgroups within larger societies. Members of a microculture usually share much of what they know with everyone in the greater society but possess a special cultural knowledge that is unique to the subgroup” (Spradley & McCurdy, 2005, p. 15). Examples of microcultures can range from a group of Hmong immigrants from Southeast Asia adopting selected aspects of the United States culture to a third-generation Norwegian American community whose members share unique foods, dress, and values.

The members of each subculture and microculture retain some of the characteristics of the society from which they came or in which their ancestors lived (Mead, 1960). Some of their beliefs and practices—such as the food they eat, the language they speak at home, the way they celebrate holidays, or their ideas about sickness and healing—remain an important part of their everyday life. American Indian groups have retained some aspects of their traditional cultures. Mexican Americans, Irish Americans, Swedish Americans, Italian Americans, African Americans, Puerto Rican Americans, Chinese Americans, Japanese Americans, Vietnamese Americans, and many other ethnic groups have their own microcultures.

Furthermore, certain customs, values, and ideas are unique to the poor, the rich, the middle class, women, men,

youth, or the elderly. Many deviant groups, such as narcotics abusers, transient alcoholics, gangs, criminals, and terrorist groups, have developed their own microcultures. Regional microcultures, such as that of the White Appalachian people living in the hills and hollows of Kentucky or West Virginia, also have distinctive ways of defining the world and coping with life. Other microcultures, such as those of rural migrant farm workers or urban homeless families, acquire their own sets of beliefs and patterns for dealing with their environments. Many religious groups have their own microcultures. Even occupational and professional groups, such as nurses or attorneys, develop their own special languages, beliefs, and perspectives.

### Ethnocentrism

There is a difference between a healthy cultural or ethnic identification and ethnocentrism. Anthropologists note “**ethnocentrism** is the belief and feeling that one’s own culture is best. It reflects our tendency to judge other people’s beliefs and behavior using values of our own native culture” (Spradley & McCurdy, 2005, p. 16). It causes people to believe that their way of doing things is right and to judge others’ methods as inferior, ignorant, or irrational. Ethnocentrism blocks effective communication by creating biases and misconceptions about human behavior. In turn, this can cause serious damage to interpersonal relationships and interfere with the effectiveness of nursing interventions (Leininger, 2006).

People can experience a developmental progression along a continuum from ethnocentrism, feeling one’s own culture is best, to **ethnorelativism**—seeing all behavior in a cultural context (Narayanasamy & White, 2005). Some people may stop progressing and remain stagnated at one step, and others may move backward on the continuum. The left side of the continuum represents the most extreme reaction to intercultural differences: refusal or denial. On the right side is the characterization of people who show the most sensitivity to intercultural differences: incorporation (Fig. 5.1).

## CHARACTERISTICS OF CULTURE

In their study of culture, anthropologists and sociologists have made significant contributions to the field of community health. Their findings shed light on why and how culture influences behavior. Five characteristics shared by all cultures are especially pertinent to nursing’s efforts to improve community health: culture is learned, it is integrated, it is shared, it is tacit, and it is dynamic.

### Culture Is Learned

Patterns of cultural behavior are acquired, not inherited. Rather than being genetically determined, the way people dress, what they eat, and how they talk are all learned.

Spradley and McCurdy (2005, p. 14) offered the following explanation:

At the moment of birth, we lack a culture. We don’t yet have a system of beliefs, knowledge, and patterns of customary behavior. But from that moment until we die, each of us participates in a kind of universal schooling that teaches us our native culture. Laughing and smiling are genetic responses, but as infants we soon learn when to smile, when to laugh, and even how to laugh. We also inherit the potential to cry, but we must learn our cultural rules for when crying is appropriate.

Each person learns about culture through socialization with the family or significant group, a process called **enculturation**. As a child grows up in a given society, he or she acquires certain attitudes, beliefs, and values and learns how to behave in ways appropriate to that group’s definition of the female or male role; by doing so, children are learning about their culture (Spradley & McCurdy, 2005; Spector, 2009).

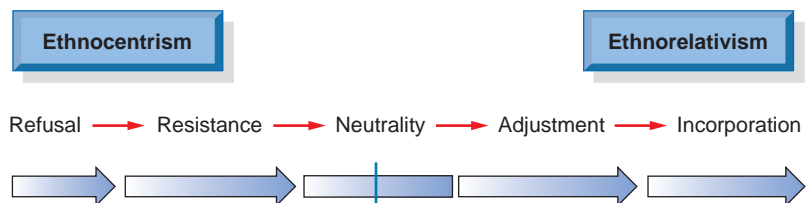

Although culture is learned, the process and results of that learning are different for each person. Each individual has a unique personality and experiences life in a singular way; these factors influence the acquisition of culture. Families, social classes, and other groups within a society differ from one another, and this sociocultural variation has important implications (Wang, 2004). Because culture is learned, parts of it can be relearned. People might change certain cultural elements or adopt new behaviors or values. Some individuals and groups are more willing and able than others to try new ways and thereby influence change.

### Culture Is Integrated

Rather than being merely an assortment of various customs and traits, a culture is a functional, integrated whole. As in any system, all parts of a culture are interrelated and interdependent. The various components of a culture, such as its social mores or religious beliefs, perform separate functions but come into relative harmony with each other to form an operating and cohesive whole. In other words, to understand culture, single traits should not be described independently. Each part must be viewed in terms of its relationship to other parts and to the whole.

A person’s culture is an integrated web of ideas and practices. For example, a nurse may promote the need for consuming three balanced meals a day, a practice tied to the beliefs that good nutrition leads to good health and that prevention is better than cure. These cultural beliefs, in turn, are related to the nurse’s values about health. Health, the nurse believes, is essential for maximum energy output and productivity at work. Productivity is important because it enables people to reach goals. These values are linked to

**FIGURE 5.1** Cross-cultural sensitivity continuum. Being extremely ethnocentric (left of midpoint) and totally ethnorelative (far right) are reflected in the diagram. The steps toward ethnorelativism begin at the most ethnocentric view, with refusal and resistance. Neutrality is midpoint, and adjustment and incorporation bring the person to an ethnorelative perspective.

social or religious beliefs about hard work and taboos against laziness. Through such connections, these ideas and beliefs about nutrition, health, economics, religion, and family are all interrelated and work to motivate behavior.

For example, parents who are Jehovah's Witnesses may refuse a blood transfusion for their child. Their actions might seem irrational or ignorant to those who do not understand the parents' religious beliefs. However, the couple's choice represents behavior consistent with their cultural values and standards. The single behavior of refusing blood transfusions, when viewed in context, is seen to be part of a larger religious belief system and a basic component of the parents' culture. Even mothers' expectations for their children's development can vary between cultures, as evidenced by various research studies (Bornstein & Cote, 2004; Bradley & Corwyn, 2005; Pachter & Dworkin, 1997)—something to keep in mind when we use developmental screening tools.

In some cultural groups (e.g., Muslims), modesty for women may make it uncomfortable and perhaps traumatic to be examined by a person of the opposite sex. Asking certain Native American groups to comply with rigid appointment scheduling requires them to reframe their concept of time. It also violates their values of patience and pride (Spector, 2009). Before nurses attempt to change a person's or group's behavior, they need to ask how that change will affect the people involved through its influence on other parts of their culture. Extra time and patience or different strategies may be needed if change still is indicated. Nurses often may find, however, that their own practice system can be modified to preserve clients' cultural values.

## Culture Is Shared

Culture is the product of aggregate behavior, not individual habit. Certainly, individuals practice a culture, but customs are phenomena shared by all members of the group. Over thirty years ago, anthropologist G. Murdock explained (1972, p. 258):

Culture does not depend on individuals. An ordinary habit dies with its possessor, but a group habit lives on in the survivors and is transmitted from generation to generation. Moreover, the individual is not a free agent with respect to culture. He is born and reared in a certain cultural environment, which impinges on him at every moment of his life. From earliest childhood his behavior is conditioned by the habits of those around him. He has no choice but to conform to the folkways current in his group.

A culture's values are among its most important elements (see Chapter 4). A **value** is a notion or idea designating relative worth or desirability. For example, some cultures place value on honesty, loyalty, and faithfulness more than other traits. Also, there may be strong values against lying, stealing, and cheating—behaviors to avoid. Each culture classifies phenomena into good and bad, desirable and undesirable, right and wrong. When people respond in favor of or against some practice, they are reflecting their culture's values about that practice. One person may eagerly anticipate eating a steak for dinner. Another, who believes that eating meat is sacrilegious or unhealthful, experiences revulsion at the idea of steak for a meal. Some American

subcultures think that loud, vocal expressions are a necessary way to deal with pain; others value silence and stoicism. Some have high regard for speed and efficiency, whereas others prefer patience and thoughtfulness. Either way, values serve a purpose. Shared values give people in a specific culture stability and security and provide a standard for behavior. From these values, members know what to believe and how to act (Lockwood, Marshall, & Sadler, 2005). The normative criteria by which people justify their decisions are based on values that are more deeply rooted than behaviors and, consequently, more difficult to change.

Knowing that culture is shared helps us to better understand human behavior. For example, a community health nurse tried unsuccessfully to persuade a mother to limit the amount of catnip tea she fed her infant. The infant was pacified with the tea and was not consuming a sufficient amount of infant formula, thus putting him at risk for nutritional deficiencies and developmental problems. The nurse discovered that the mother was acting in the tradition of her rural subculture, which held that catnip promoted good health (it acts as an antispasmodic, perhaps causing relaxation and resulting in a more contented infant with fewer symptoms of colic [Spector, 2009]). The fact that all of the other mothers in her small rural community also used catnip with their babies proved a powerful deterrent to the change suggested by the nurse. Other members of the same culture frequently influence health behaviors. It is difficult for one person to eliminate a cultural practice, especially when that practice is reinforced by so many other members of the group. Group acceptance and a sense of membership usually depend on conforming to shared cultural practices (Spradley & McCurdy, 2005).

Community health nurses may need to focus on an entire group's health behavior to affect individual practices. In the example described, the pattern of consuming large amounts of catnip tea was modified after the nurse worked with the entire rural community. She began with a well-recognized cultural strategy: working through formal or informal leaders. She contacted the oldest woman in the community and discussed the cultural practice. The elder shared the group's beliefs that catnip tea is vital to the well-being of infants for the first 6 months. When the nurse explained her concerns about low formula intake and low weight gain, the community leader clarified that only 1 or 2 ounces of the tea a day was needed. The nurse and the community leader shared this information among the women, and as a result, the mothers gradually reduced the amount of tea they gave their infants. Consequently, the clients' infants drank more formula and gained weight appropriately. A cultural tradition was retained while the health of the infants was improved. The community health nurse could then use this new information and other supportive information from the community leader to improve the health of more infants.

## Culture Is Mostly Tacit

Culture provides a guide for human interaction that is **tacit**—that is, mostly unexpressed and at the unconscious level. Members of a cultural group, without the need for discussion, know how to act and what to expect from one another. Culture provides an implicit set of cues for behavior, not a written set of rules. Spradley and McCurdy

explained that culture often is “so regular and routine that it lies below a conscious level” (2005, p. 16). It is like a memory bank in which knowledge is stored for recall when the situation requires it, but this recall process is mostly unconscious. Culture teaches the proper tone of voice to use for each occasion. It prescribes how close to stand when talking with someone and how one should appropriately respond to elders. Individuals learn to make responses that are appropriate to their sex, role, and status. They know what is right and wrong. As an example, a recent study showed that cultural factors influence the desired affective state of children through their exposure to different types of storybooks (Tsai, Louie, Chen, & Uchida, 2007). All of these attitudes and behaviors become so ingrained—so tacit—that they are seldom, if ever, discussed.

Because culture is mostly tacit, realizing which of one’s own behaviors may be offensive to people from other groups is difficult. It also is difficult to know the meaning and significance of other cultural practices. In some groups, such as American Indians or Islamic women, silence is valued and expected, but may make others uncomfortable. Offering food to a guest in many cultures is not merely a social gesture but an important symbol of hospitality and acceptance; to refuse it, for any reason, may be an insult and a rejection. Touching or calling someone by their first name may be viewed as a demonstration of caring by some groups, but is seen as disrespectful and offensive by others. Even how one trusts others in a group context is affected by cultural influences (Yuki, Maddux, Brewer, & Takemura, 2005). Consequently, community health nurses have a twofold task in developing cultural sensitivity: not only must we try to learn clients’ cultures, but we also must try to make our own culture less tacit and more explicit. We must be more aware of our own biases and preconceived values and beliefs. Nurses bring both their professional and personal cultural history to the workplace, often developing unique values not shared with others who are not in the profession (Blais, Hayes, & Kozier, 2005). Cross-cultural tension can be resolved through conscious efforts to develop awareness, patience, and acceptance of cultural differences (Display 5.2).

### Culture Is Dynamic

Every culture undergoes change; none is entirely static. Within every cultural group, some individuals generate innovations. More important, some members see advantages in doing things differently and are willing to adopt new practices. Each culture is an amalgamation of ideas, values, and practices from a variety of sources. This process depends on the extent of exposure to other groups. Nonetheless, every culture is in a dynamic state of adding or deleting components. Functional aspects are retained; less functional ones are eliminated.

When this adaptation does not occur, the cultural group may face serious difficulty. For example, Hmong teenagers from Southeast Asian refugee families in the United States are among the first generation to be raised in America. Their parents had high hopes for them to restore honor and pride to a displaced people, but the teens struggle to balance their American lifestyle with Hmong traditions. The stresses they feel as a result of the generational and cultural gaps between

#### DISPLAY 5.2

#### CULTURE SHOCK

An increasing number of immigrants and refugees from many different countries have been assimilated into American culture in recent years. Although they quickly adapt in many respects, such as learning the language and seeking housing and employment, they continue to operate within the framework of their own cultural beliefs and behaviors. The conflict between their culture and American culture often causes **culture shock**, “a state of anxiety that results from crosscultural misunderstanding . . . and an inability to interact appropriately in the new context” (Spradley & McCurdy, 2000, p. 16). Immigrants and refugees find themselves in a strange setting with people who act in unfamiliar ways. Speaking their own language in their homes and retaining values and familiar practices all help to promote some sense of security in the new environment.

The same is true for nurses and others working in unfamiliar countries. No longer are the small but important cues available that orient a stranger to appropriate behavior. Instead, a person in a different culture may feel isolated and anxious and even become dysfunctional or ill. Immersion in the culture over time and learning the new culture are the major remedies. As adjustment occurs, old beliefs and practices that are still functional in the new setting can be retained, but others that are not functional must be replaced.

themselves and their parents are often overwhelming. Many have not been successful in balancing these stresses and have chosen gang membership or suicide as a way to relieve their frustration and depression (Ellis, 2002). Hmong community leaders, community health workers, school districts, law enforcement, and Hmong families have joined together to develop interventions to address these issues (see Perspectives).

Another example of problematic cultural adaptation is the case of the “one child rule” in China. In an effort to contain population growth, in 1979, China began limiting married couples to having only one child. The government strictly enforces this policy, with few exceptions. Because male offspring are more highly valued than female in the Chinese culture, there is now a significant increase in the ratio of male to female births. Couples who have a female infant may choose to place the baby in an orphanage and make her available for adoption, but, although they are considered illegal, it is thought that a large number of sex-selective abortions occur. The goal of the government’s policy was to change the Chinese culture from large- to small-family preference, and recent surveys indicate that this appears to be taking place; however, there are other untoward consequences of this cultural shift (Hesketh, Lu, & Xing, 2005). “Only-children” are now caring for their elderly parents, along with their “one child,” as a widespread pension system does not yet exist in China. This strain, along with the shortage of women that leads to “kidnapping and trafficking of women for marriage, and increased numbers of commercial sex workers” are issues that must still be resolved (p. 1173).

Community health nurses must remember the dynamic nature of culture for several reasons. First, cultures and subcultures do change over time. Patience and persistence are key attributes to cultivate when working toward improving health behaviors. Second, cultures change as their members see greater advantages in adopting “new ways.” Discussions of these advantages need to be conducted in a language understood by members and in the context of their own cultural value system. This is an important reason for nurses to develop an understanding of their clients’ culture and to deliver culturally competent care (Callister, 2001; Giger & Davidhizar, 2002; Leininger, 2006). Third, it is important to remember that, within a culture, change is usually brought about by certain key individuals who are receptive to new ideas and are able to influence their peers. These key persons can adapt the change process, so that “new” practices are culturally consistent and fit with group values. Tapping into this resource becomes imperative for successful change. Finally, the health care culture is dynamic, too. Westerners are just beginning to appreciate the validity of many non-Western health care practices such as acupuncture, meditation, and the use of various therapeutic herbs and spices (e.g., turmeric, fenugreek). We can learn much from our clients and their cultures (Spector, 2009) (see Perspectives: Voices from the Community).

## ETHNOCULTURAL HEALTH CARE PRACTICES

Throughout history, people have relied on natural elements to treat various maladies that family, clan, tribe, or community members experience. Knowledge of culturally recognized

practices or substances, such as berries, plants, barks, or rituals and incantations usually becomes the responsibility of one person in the community. This revered community leader is known as a medicine man/woman, healer, or shaman (Spector, 2009). As time passes, this person teaches the skills of recognizing and treating ailments or performing rituals to an apprentice, thereby continuing the healing knowledge and traditions.

In the following sections, we discuss how various geographic or ethnocultural groups view health care, including the biomedical, magicoreligious, and holistic views. You may encounter many distinctive ways that your clients manage their health and illness, so we will discuss selected folk medicines and home remedies, such as herbs, over-the-counter (OTC) drugs, and patent medications. In addition to these forms of treatments, there are complementary or alternative therapies (e.g., folk remedies) and various self-care practices. This section concludes with the community health nurse’s role and responsibilities to provide culturally competent care in relation to caring for, respecting, teaching, and treating clients from different cultures.

## The World Community

Beliefs about the causes and effects of illness, health practices, and health-seeking behaviors are all influenced by a person’s, a group’s, or a community’s perception of what causes illness and injury and what actions can best treat or cure the health problem. The three major views in the world community are biomedical, magicoreligious, and holistic health beliefs (Spector, 2009).

### Biomedical View

Western societies in general have a biomedical view of health and illness. The biomedical view relies on scientific principles and sees diseases and injuries as life events controlled by physical and biochemical processes that can be manipulated through medication, surgery, and other treatments. Examples of this view include the following beliefs:

- ◆ Elements, such as bacteria, fungi, or viruses, are causes of illness.
- ◆ Lack of certain elements, such as an adequate diet, calcium, or iron, causes other health problems, such as malnutrition, osteoporosis, or anemia.
- ◆ An accepted treatment for many physical ailments is to remove diseased organs, or to treat injuries from falls or accidents.

People living in countries where Western medicine is practiced believe that theirs is the best and, perhaps the only way, to deal with illness or injury. The dominant values presume that science is value-free and not constructed by the social norms of the cultural group. The same is true, however, where Western medicine is not practiced and the social norms of the cultural group support the healing practices of that group (Leininger, 2006; Spector, 2009). Many people, including community health nurses, are not open to other ways of looking at a person’s wellness capabilities. As a result, clients may not receive culturally competent care from their caregivers. To be effective with clients, community health nurses must be knowledgeable and accepting of others’ cultural practices.

### PERSPECTIVES VOICES FROM THE COMMUNITY

“You are talking about parents who are medieval, coming to a country that is hundreds of years ahead of theirs. They’re trying to catch up, but it’s hard.”—Mymee (college instructor)

“There is much research that shows people who stand in the middle of two cultures are really at risk of depression and anxiety.”—Valerie (psychologist)

“The kids are constantly living between two cultures. At some point, they may give up.”—Leng (psychologist. Southeast Asian adult services center)

“I think it’s a topic that nobody wants to talk about. It’s hard for me to say if the Hmong community is ready to deal with it.”—Xong (social worker, Hmong suicide task force)

“We parents think we know only one way to raise our kids. We ignore that these children are living in America and are espousing everything that is American, good and bad.”—Andy (Hmong parent)

*Ellis, A.D. (2002, August 11). Hmong Teens: Lost in America [Special report]. The Fresno Bee, pp. 1–12.*

### Magicoreligious View

Magicoreligious themes of health and illness, which focus on the control of health and illness by supernatural forces, are prominent in some cultural groups. Diseases occur as a result of “committing sins” or “going against God’s will.” Good health is a gift from God, and illness is a form of punishment that affords an opportunity to be forgiven and to realign oneself with God. Prayer to God or other religious figures is used to cope with illness, seek intervention for healing, and ask for forgiveness and entrance into heaven, if death be God’s will.

Some cultures mix traditional folk beliefs with organized religious practices and participate in forms of magic or voodoo. In cultures that have such beliefs, a hex or spell can be placed on another person through the use of incantations, elixirs, or an object resembling the person. For some, illness results from a look or a touch from another person considered to have special powers or intent to harm (Leininger, 2006; Spector, 2009). Later in this chapter, we discuss some specific health beliefs and practices common to cultural groups in North America.

Religious beliefs, an individual’s spirituality, and how these factors interface with feelings of wellness and specific healing practices are personal and important to clients and cannot be separated from their culture. This makes it imperative for community health nurses to be familiar with folk beliefs commonly seen in their practice. Only then can culturally competent nursing care be provided.

### Holistic View

Holistic health believers come from many different cultural groups and generally view the world as being in harmonious balance. If the principles guiding natural laws to maintain order are disturbed, an imbalance in the forces of nature is created, resulting in chaos and disease. For an individual to be healthy, all facets of the individual’s nature—physical, mental, emotional, and spiritual—must be in balance.

Some cultural groups believe that all things in creation or the universe have a spirit and therefore are considered equal in value, purpose, and contribution (Lowe, 2002). Individuals have universal connectedness and are viewed as holistic beings. Persons are extensions of and integrated with family, community, tribe, and the universe. For example, “mother and fetus are viewed as interrelated and as affecting each other: They are one, but also they are two. In the circle of life, each individual is believed to be on a journey experiencing a process of being and becoming” (Lowe & Struthers, 2001, p. 6).

### Folk Medicine and Home Remedies

Many of us remember our mothers giving us hot herbal tea with lemon, or slathering on ointments and piling on blankets to lessen the effects of a mild illness. Many folk medicines and home remedies came about as a means of providing health care to family members when no medical care was available or deemed affordable.

**Folk medicine** is a body of preserved treatment practices that has been handed down verbally from generation to generation. It exists today as the first line of treatment for many individuals. Some clients may never plan to seek Western medical treatment but may share with you, the community health

nurse, a practice they are using to treat a family member. Your response and actions may mean the difference between health and illness or injury. Some maternal–child health practices from the U.S. rural Midwest or South that may be encountered in community health nursing practice include the following (Giger & Davidhizar, 2004; Spector, 2009):

- ◆ Not reaching above your head if you are pregnant, because doing so will cause the umbilical cord to strangle the baby
- ◆ Pregnant women eating handfuls of clay, dirt, or cornstarch
- ◆ Taping coins over a newborn’s umbilical area to prevent hernias
- ◆ Giving catnip tea to infants because it saves their lives
- ◆ Holding a baby upside down by her heel to “wake up her liver”
- ◆ Not letting a cat in a room with a sleeping baby, because the cat will “suck the life” out of the baby

**Home remedies** are individualized caregiving practices that are passed down within families. Even individuals who routinely seek the guidance of a health care practitioner for diagnosis and treatment may try home remedies before seeking professional advice. Each of us has a set of home remedies our parents used on us that we are likely to use on our own children before or instead of calling the pediatrician. Examples include using baking soda paste on a bee sting, ice on a “cold sore,” or cranberry juice to prevent a urinary tract infection.

### Herbalism

Textbooks have been written on the many uses of medicinal herbs (Gruenwald, 2004). The use of some herbs has waxed and waned in favor. Some continue to be much touted, whereas others have been designated as dangerous and to be avoided (Medline Plus, 2007). Increasingly, the public is using herbal preparations in the form of self-selected over-the-counter (OTC) products for therapeutic or preventive purposes.

In an increasingly multicultural society, the source, form, and identity of many herbs, roots, barks, and liquid preparations become impossible for most community health nurses to distinguish. The most astute among us may be familiar with herbs used by one cultural group, whereas herbs used by another escape us. A book with pictures and descriptions, botanical form, purported indications and uses, and implications for nursing management is an important tool to keep handy when interacting with clients. *Nursing Herbal Medicine Handbook* (Lippincott, Williams, & Wilkins, 2005) is also available in software version for PDAs (Handango, 2007)—an even more efficient method of retrieving information quickly. Basic safety questions that community health nurses should answer about an herb when teaching or interacting with families include the following:

- ◆ Is the herb contraindicated with prescription medications the client is taking?
- ◆ Is the herb harmful? Does it have negative side effects?
- ◆ Is the client relying on the herb, without positive health changes, while neglecting to get effective treatment from a health care practitioner?

Herbs are not regulated as drugs and are not risk free. Dosages are not standardized and are left to the individual. Quality of the product may be suspect. For these reasons, herbs must be used only in moderation and with caution, preferably with guidance by a health care practitioner.

### **Prescription and Over-the-Counter (OTC) Drugs**

The cautions mentioned about herbs can also apply to prescription and OTC medications. First, they are not risk free. In this country, prescription drugs are reviewed and tested by the U.S. Food and Drug Administration (FDA)'s Center for Drug Evaluation and Research (CDER), and OTC drugs go through a somewhat less-rigorous process through the CDER's Division of OTC Drug Products. Over-the-counter drugs comprise six out of every 10 medications bought in the United States (U.S. FDA, 2007). However, many OTC drugs were once available only by prescription, and remain powerful medicines. All drugs can have major side effects, may be contraindicated in people with certain conditions, and may not be safe to use in combination with certain other drugs. Medication instruction and review is an important part of the community health nurse's role on home visits, especially with elderly clients (see Chapter 24).

Second, some new prescription medications are so expensive that clients cannot afford to take them as prescribed. Often, older, less expensive, and more frequently used drugs work as well as the newer, more expensive ones, which are heavily marketed by drug companies to health care practitioners and consumers. If you encounter clients who are unable to pay for drugs, you may need to advocate for them with health care providers to prescribe a less expensive medication or change to the generic form of the same drug, usually sold at a fraction of the cost. Some health care practitioners have samples of drugs available and may be able to use them for medically indigent clients. Many pharmaceutical companies now have low-cost prescription assistance programs for those in need (NeedyMeds.com, 2007).

Third, the efficacy of medications must be assessed. At times, the use of a new drug or an additional drug does not have the intended effect. As someone who sees the client managing at home over time, the community health nurse may be able to give the best information to the health care provider about the effectiveness of new medications for a particular client.

### **Complementary Therapies and Self-care Practices**

**Complementary therapies** (also called alternative medicine or alternative therapies) are practices used to complement contemporary Western medical and nursing care and are designed to promote comfort, health, and well-being (Snyder, 2001). The range of complementary therapies is broad and includes:

- ◆ Therapies (cancer diets, juice diets, fasting)
- ◆ Treatments (coffee enemas, high colonic enemas)
- ◆ Exercise activities (t'ai-chi, yoga)
- ◆ Exposure (aromatherapy, music therapy, light therapy)
- ◆ Manipulation (acupuncture, acupressure, reflexology)

Most cultural groups engage in some form of complementary therapy, either alone or in conjunction with Western medicine. **Integrated health care** is defined as the combination of complementary therapies with biomedical or Western health care (Snyder, 2001). Complementary therapies have become so commonplace today that many states are developing policies and guidelines for their use.

Consumers need to be well informed regarding the efficacy and safety of complementary therapies and how they can be true complements to other treatment modalities. The community health nurse should be aware of the variety of therapies available and how to get information for clients while remaining objective and supportive of the client's choices. At times, if a therapy contradicts the recommendations of the client's health care practitioner, the nurse may be in a position to provide the pros and cons of continuing the complementary therapy. On the other hand, the nurse may be able to suggest therapy forms that would complement Western medicine for the client, such as music therapy to promote relaxation and reduce stress or biofeedback for chronic pain management.

Self-care activities include complementary therapies, medications, and spiritual and cultural practices. They are uniquely individual for each person, as well as among different cultural groups. Chapter 19 includes a Self-Care Assessment Guide that may be helpful in assessing the self-care practices of families.

### **Role of the Community Health Nurse**

When working with different cultural groups in the area of health care practices, the community health nurse can be an effective advocate for the client. First, however, the nurse must be prepared to speak knowledgeably about health care practices and choices. The nurse also must be able to assess the client or family adequately, so as to know what belief system motivates their choices. Finally, the nurse must be prepared to teach clients about the limits and benefits of cultural health care practices. The community health nurse should always individualize assessment and caregiving for the client within her culture and should not generalize about the client based on cultural group norms.

### **Preparation of the Community Health Nurse**

To be effective when working with clients in the area of cultural health care and spirituality, the nurse must be prepared. Many ways exist for you to increase your cultural awareness and promote sensitivity to the differences among people from ethnocultural groups different from your own. You can acquire information from peers who are from the same cultural group as your clients; attend workshops or conferences on chosen cultural topics; read books on ethnocultural health care practices, herbalism, or complementary therapies; talk with clients about their views and practices and learn from them; keep an open mind and be curious about various practices; or attend community cultural events such as Native American powwows, ethnic food events held in some cities, or Cinco de Mayo celebrations. There are textbooks, novels, and articles about cultures in the community in which one practices. For example, the book *The Spirit Catches You and You Fall Down* (Fadiman, 1997) describes a Hmong child, her American doctors, and the collision of two cultures.

## From the Case Files I

### Learning About Other Cultures

I was always interested in learning about other countries and cultures, but I didn't realize that an overseas assignment would teach me so much about myself, in addition to other cultures and ways of living. The lessons were sometimes difficult, but always rewarding. I knew that my expectations would not always be met, yet it did surprise me how different the experience was from what I had imagined. My job assignment, location, and team members changed frequently. Flexibility, comfort with ambiguity, a sense of humor, a deeper reliance upon my faith, patience when results were not forthcoming, trust in others, and the ability to cross multiple cultures with some degree of ease were all skills that I developed over time. Most important to being successful at my job was to maintain the attitude of a "learner," not a "solver of problems" or the person "with all the answers." I made friends with people from all over the world who graciously accepted me into their lives, thus enriching mine. I learned that we all are different, but that every behavior has a reasonable explanation when you take the time to listen with your heart as well as with your ears. I found that I actually preferred other ways of doing and being while still maintaining those parts of my identity that were valuable to me. When I returned home, I found that my newly developed skills were still necessary—I had changed and had to adjust to re-entry back into my home culture!

*Karin Urso, PHN*

Universities offer courses in transcultural nursing, ethnic studies courses or programs, and cultural events that can be valuable. The experience of Karin Urso, who worked with people from many different countries and cultures, illustrates the benefits of being open-minded (see From the Case Files I).

### Assessment

When beginning to work with a group or family, it is important for you to become as familiar with them as possible. In addition to a family assessment or an individual health assessment, you can enhance your aggregate care by doing an ethnocultural or self-care assessment. Such an assessment reveals information about day-to-day living, cultural/spiritual influences, traditional/cultural health care choices and practices, and cultural taboos. Often this type of information is most useful as you work with clients on a regular basis. Useful tools include the two cultural assessment reviews at the end of this chapter (see Tables 5.7 and 5.8) and the self-care assessment tool in Chapter 19.

### Teaching

As you are aware from your studies and preparation, teaching is a most important role in nursing, both in acute care settings and in the home. When working with families as a community health nurse, teaching takes a good deal of your time, because health care education is vitally important to communities, groups, and families. However, teaching that is undertaken in ways that are incomplete, culturally inappropriate, or inadequate may be frustrating and even harmful to your clients. Becoming ethnoculturally focused and prepared to teach from the client's view of the world will start you in the right direction. The suggestions in Display 5.3 offer ideas for providing culturally competent care. Chapter 11 on Health Promotion and Education will help prepare you as well.

## SELECTED CULTURAL COMMUNITIES

An examination of the meaning and nature of culture clearly underscores the need to recognize cultural differences and to understand clients in the context of their cultural backgrounds. Practically speaking, how can knowledge of cultural diversity be integrated into everyday community health nursing practice? What are the diverse cultural communities served by community health nurses? What are their differences? Do they share some features?

To provide insights and answers to these questions, this section describes five cultural communities, out of the more than 100 different ethnic groups living in the United States. Three are dominant in the United States; the other two represent populations native to North America and people from a Middle Eastern culture, an expanding group in the United States. These brief descriptions should not be considered as a stand-alone guide to cultural competence; each culture is complex and unique, deserving of a more comprehensive study than is possible within the scope of this chapter. Many good references are available for nurses on cultural diversity (see References and Selected Readings).

Four of the groups highlighted represent those identified in *Healthy People 2010* (U.S. Department of Health and Human Services [USDHHS], 2000). The fifth group, Saudi Arabians, is presented because of the significant media attention people of the Middle East have received in recent years.

*Healthy People 2010* (USDHHS, 2000) described significant disparities among members of some of the five groups highlighted here. Several of the disparities are displayed in Table 5.4.

### Native American Indians, Aleut, and Eskimo Communities

Native American Indians and Alaska Natives (Eskimo communities residing in Alaska), the first known settlers of this continent, form a large cluster of tribal groups whose members are descendants of the original Native Americans who

**DISPLAY 5.3** **DEVELOPING CULTURAL COMPETENCE**

**First:** Know that culture is dynamic.  
 It is a continuous and cumulative process.  
 It is learned and shared by people.  
 Cultural behaviors and values are exhibited by people.  
 Culture is creative and meaningful to our lives.  
 It is symbolically represented through language and interaction.  
 Culture guides us in our thinking, feeling, and acting.

**Second:** Become aware of culture in yourself.  
 Thought processes that occur within you also occur within others but may take on a different shape or meaning.  
 Cultural values and biases are interpreted internally.  
 Cultural values are not always obvious since they are shared socially with those you meet on a daily basis and are perceived through your senses.

**Third:** Become aware of culture in others, especially among client groups you serve.  
 This is best represented by the belief that there are many cultural ways that are correct, each in its own location and context.  
 It is essential to build respect for cultural differences and appreciation for cultural similarities.  
 Develop the ability to work within others' cultural context, free from ethnocentric judgments.

inhabited this country before White Europeans settled here. The earliest European explorers were the Vikings (circa 1010 AD); they were followed by various other Europeans in the 16th century (Spector, 2009). Native Americans, Aleuts, and Eskimos have adopted many European American values and practices, yet they preserve many aspects of their own culture.

**Population Characteristics and Culture**

Native Americans and Alaska Natives are a diverse group made up of different tribes and 561 federally recognized nations that speak approximately 250 languages. Eskimos, Aleuts, and Native Americans living in Alaska are known as Alaska Natives; those living in other states are known as Native Americans or

**TABLE 5.4** *Healthy People 2010 and Disparities*

Goal of Healthy People 2010	Baseline Values				
	White	Native American	Hispanic	Black	Asian
Health insurance: 79% of population	89%	79%	70%	84%	83%
Cancer deaths/100,000: 158.7	202.2	131.8	125.5	262.1	127.2
End-stage renal disease/1 million: 217	218	586	N/A	873	344
Diabetes deaths/100,000: 45	68	107	86	130	62
CHD deaths/100,000: 166	214	134	151	257	125
Stroke deaths/100,000: 48	60	39	40	82	55
HIV/AIDS deaths/100,000: 0.8	2.8	2.5	8.9	26.6	0.9
Deaths from firearms/100,000: 4.9	10.4	11.4	10.7	22.9	5.0
Motor vehicle deaths/100,000: 9.0	15.8	31.5	15.2	17.0	10.6
Unintentional injury deaths/100,000: 20.8	34.3	62.7	30.1	40.9	20.9
Residential fire deaths/100,000: 0.6	1.1	2.2	0.8	3.4	0.8
Homicides/100,000: 3.2	4.3	10.4	9.9	25.2	4.1
Low-birth-weight babies: 7.6% of births	6.5	6.8	6.4	13.0	7.2
Suicides/100,000: 6.0	12.8	12.4	6.4	6.3	7.0
Drug induced deaths/100,000:1.0	5.7	6.6	6.0	9.0	1.6
Smokers: 12% of population	25%	34%	20%	26%	16%

CHD, (coronary heart disease); HIV/AIDS, (human immunodeficiency virus/acquired immunodeficiency syndrome); N/A, (not available).

American Indians. In this chapter, the term *Native American* is used to encompass all facets of this diverse group of people. These people make up just 1% of the U.S. population, or about 2.8 million people (Infoplease, 2007). In the 2000 Census, 4.1 million people said they were at least “part” Native American, and 2.5 million identified themselves only as Native American. These people proudly identify themselves as being Native American, unlike in the past, when to claim Native American blood carried a social stigma. In addition to societal changes in the acceptance of Native Americans, financial incentives exist for many Americans who are recognized tribal members. More than 300 of the Indian Nations receive revenue from gambling casinos—roughly half of all tribes have casinos (Walton, 2005). In 1988, when Congress passed the Indian Gaming Regulatory Act, casinos owned by Native Americans made \$212 million; by 2000, they grossed \$10 billion (U.S. Department of Commerce, 2001). By 2002, the 290 Native American casinos generated \$12.7 billion, but only a small number of casinos (about 13%) generated the majority of the revenues (66%), and the amounts given to tribe members varied widely (e.g., less than \$400 to over \$200,000) (Barlett & Steele, 2002). To put this in perspective, 11 states have commercial (non-Indian) casinos that generated almost \$29 billion in gross revenues in 2004 (Walton, 2005). Taylor and Kalt (2005) reported that real per capita income for gaming tribes increased by 36% between 1990 and 2000, while the total U.S. increase was 11%. However, even though the poverty rate fell for Native Americans overall, it is still three times the U.S. average. Although gaming and other ventures have improved access to health, education, and employment for most Native Americans, they still fall behind many other U.S. citizens.

The population of Native Americans and Alaska Natives is primarily concentrated in 26 states in the United States, including Alaska and the Aleutian Islands (Spector, 2009). Many live on reservations and in rural areas; however, more than half live in urban counties and have greater difficulty accessing the health care available to them through Indian Health Service (a federal program providing comprehensive health care to Native Americans) (Brenneman, Rhoades, & Chilton, 2006). The largest numbers live in Oklahoma, Arizona, California, New Mexico, North Carolina, and Alaska, as a result of forced westward migration (Spector, 2009). By 2050, the U.S. Census Bureau estimates about 4.5 million Native Americans will live in the United States, nearly double the number in 2000 (U.S. Department of Commerce, 2001). Some of this increase can be attributed to official recognition of persons who can provide information linking them to a tribe or nation; if they are accepted, they can then declare themselves as Native Americans.

Each tribe or nation has its own distinct language, beliefs, customs, and rituals. The community health nurse cannot assume that knowledge of one group can be generalized to others. Knowledge of certain similarities among the various Native American cultures (Display 5.4) can assist nurses working with members of a specific tribe. For many Native American groups, large, extended family networks reinforce cultural standards and expectations and provide emotional support and practical assistance.

### Health Problems

Health problems among Native Americans tend to be both chronic and socially related. One third of Native Americans

#### DISPLAY 5.4

### SIMILARITIES AMONG NATIVE AMERICAN CULTURES

All of creation/universe has Spirit and is considered equal in value.  
 Everything is considered alive with energy and importance.  
 People have universal connectedness.  
 Harmony is a way of life based on cooperation and sharing.  
 Dignity of the individual, family, and community is valued.  
 Respect for advancing age is valued; elders are leaders.  
 There is present-time orientation, grounded in what is happening at the moment.  
 Symbolic arts and crafts are valued.  
 Life is lived in the present, with little concern for the distant future.  
 Generosity, harmony, and sharing are valued.  
 Religion is integrated into everyday life.  
 Herbal medicines and traditional healing practices are used.  
 Rituals and ceremonies are valued.  
 Silence is used as a way to practice presence and strength.  
 Thoughtful speech is valued.  
 Patience is valued.

Adapted from Lowe, 2002; Lowe and Struthers, 2001; and Spector, 2009.

live in abject poverty and experience the afflictions associated with poor living conditions, including malnutrition, tuberculosis (TB), and high maternal and infant death rates (Spector, 2009). The highest-ranking health problems in children include a postneonatal mortality rate double that of White infants (due largely to sudden infant death syndrome [SIDS], injuries, and congenital anomalies); overweight, obesity, and type 2 diabetes; and morbidity and mortality as a result of unintentional and intentional injuries (often motor vehicle injuries) (Brenneman, Rhoades, & Chilton, 2006). For adults, diabetes, TB, and obesity all rank higher among Native Americans than in the general population. Deaths from TB (seven times higher), alcoholism (six times higher), motor vehicle crashes (three times higher), diabetes (almost three times higher), unintentional injuries, and suicide and homicide (both 1.6 times higher) are higher for Native Americans than other Americans (Indian Health Service, 2006). Poor sanitation, crowded housing, and low immunization levels contribute to the prevalence of a variety of communicable diseases. On the other hand, the prevalence of heart disease is slightly lower in this population than among the population as a whole (236.2 versus 247.8 per 100,000) (Indian Health Services, 2006).

Alcoholism is the major health problem of Native Americans. Both traditional/cultural and medical explanations exist for the disproportionate number of alcohol-related health problems in Native Americans. Tribal medicine men have attributed the problems of alcoholism to losing “the opportunity to make choices,” stating that until “people return to a sense of identification within themselves they will not rid themselves of this problem of alcoholism”

(Spector, 2004, p. 199). Medically, it appears that Native Americans have a much lower tolerance for alcohol and therefore demonstrate the effects of alcohol with lower amounts consumed. When individuals are under the influence of alcohol, other health and safety problems occur. Instances of domestic violence, child abuse and neglect, traffic injuries and deaths, and homicides are more frequent because of the abuse of alcohol. Along with these high rates of injuries and deaths, alcohol's destructive effects on the unborn lead to a high incidence of fetal alcohol syndrome (FAS) and fetal alcohol effects (FAE). Substance abuse is also prevalent among those living on reservations, and increasingly among youth using alcohol, tobacco, and other drugs (Substance Abuse & Mental Health Services Administration [SAMHSA], 2004).

### Health Beliefs and Practices

Native Americans as a group prefer traditional healing practices and folk medicine to Western medicine. Most Native Americans today still seek out a medicine man or rely on traditional remedies before going to a health clinic. Many of their beliefs about health and illness have common traditional roots, regardless of tribe or location. Health and dietary practices are closely tied to cultural and religious beliefs. Beliefs about health reflect living in total harmony with nature. The Earth is considered a living organism that should be treated with respect, as should the body (Spector, 2009). Native Americans practice purification rituals such as immersion in water and the use of sweat lodges to maintain their harmony with nature and to cleanse the body and spirit. The basis of therapy lies in nature, with herbal teas, charms, and fetishes used as preventive and curative measures (Kavasch & Baar, 1999).

Because of decades of racism and government paternalism, many Native Americans feel oppressed and dehumanized and carry considerable resentment and lack of trust toward Whites. As a result, many maintain a degree of separateness from overall American culture. Nurses must overcome these barriers through patience, acceptance, and respect for their clients' culture, as illustrated in the case study of the community health nurse, Sandra Josten, and her new client from a Native American community (see From the Case Files II).

### Blacks or African Americans

Some of the ancestors of Black Americans, or African Americans, originally came to this continent as free settlers as early as 1619, but most of the approximately 4 million who followed came as slaves in the 17th and 18th centuries, mostly from the west coast of Africa (Byrd & Clayton, 2002). Most African Americans living today were born in the United States; some, however, have recently emigrated from African countries. Other Black Americans come from the West Indies, the Dominican Republic, Haiti, and Jamaica, often to escape poverty or political persecution. These people do not self-identify as African Americans but as Hispanics, a fact that may cause some difficulty for others trying to identify and accommodate to their culture. (Similarly, some people from the Philippines have Hispanic surnames and skin tones similar to those of Mexicans or other Latinos; when Filipinos—a culturally distinct group—settle in areas with large Hispanic populations, they can be similarly misidentified and misunderstood [Spector, 2009].)

### Population Characteristics and Culture

In 2004, African Americans numbered 38.6 million and constituted approximately 13% of the U.S. population; projections show an increase to 15.4% by the year 2050 (National Center for Health Statistics, 2007a; U.S. Census Bureau, 1992; U.S. Department of Commerce Bureau 2001). One-third of the African American population is younger than 18 years of age. Slightly more than 8% of African Americans are older than 65 years, and most of them are women; in comparison, 13% of the total population is older than 65 years of age. Fifty-eight percent of Black children live with their mothers only, compared with 21% of White children.

Despite improvements in the legal and social climate for African Americans, great disparities exist between them and White Americans (Byrd & Clayton, 2002). Average family income for African Americans is 62% of the income earned by White families. More than 26% of African Americans live in poverty, compared with 8.9% of Whites. Although African Americans make up only 13% of the population, more than 50% of prison inmates are Black. A greater percentage of Blacks use illicit drugs (7.7%), compared with Whites (6.6%) or Hispanics (6.8%) (Antai-Otong, 2002). Approximately 36% of African American families in households headed by women live below the poverty level. Unemployment among African Americans is 8.9%, compared with 3.9% for Whites (U.S. Department of Commerce, 2001).

Educational disparities also exist. Among people age 25 years and older, 76% of Blacks and 83.7% of Whites have a high school education. More than half of those African Americans with less than a high school education are not in the workforce, compared with 36% of Whites with a similar education. However, 89% of both Blacks and Whites with a college degree are employed; 14.7% of Blacks and 25% of Whites are college graduates (Williams & Collins, 2001). African American women acquire more educational training than their Black male counterparts do, but their earnings are lower than those of the men, as is also the case with White and Hispanic women compared with men in those groups.

Like Native Americans and Asian Americans, African Americans do not comprise a single culture; rather, this group forms a heterogeneous community. As with other large ethnic and racial groups, many factors influence their culture, resulting in much diversity within the African American population. Among the variables determining specific microcultures within the African American community are economic level, religious background, education, occupation, social class identity, geographic origin, and residence in an integrated or segregated neighborhood. For community health nurses, this means that specific groups of African Americans have their own unique values, character, lifestyle, and health needs.

The primary language of most African Americans is English. Recent Black immigrants from Caribbean or other countries may retain the language of their country of origin, but usually learn to use English as well. Many African Americans speak nonstandard dialects of English, also called Black English, Ebonics, or African American Vernacular English. These dialects evolved from pidgin English spoken during the era of slavery, and they have become a dynamic and meaningful language of their own. For some African Americans, Ebonics symbolizes racial pride and identity—it can also be used to differentiate them from the mainstream culture (Novak, 2000; Spector, 2009).

## From the Case Files II

### Sandra's New Clients

As she drove up the dirt road and parked her car next to the community hall, Sandra Josten felt apprehensive. She had been alerted by the previous community health nurse about the difficulty of working with these Native American people: "This tribe is lazy and unappreciative. You can't get anywhere with them." Only through the urging of Mrs. Brown, an Indian community aide, had a group of the women reluctantly agreed to meet with the new nurse. They would see what she had to say.

Sandra's steps echoed hollowly as she walked across the wooden floor of the large room to the far corner where a group of women sat silently in a circle. Only their eyes turned; their faces remained impassive. Mrs. Brown rose slowly, greeted the nurse, and introduced her to the group. Swallowing her fear, Sandra smiled. She told them of her background and explained that she had not worked with Indian people before. There was a long silence. No one spoke. Sandra continued, "I'd like to help you if I can, maybe with problems about care of your children when they are sick or questions about how to keep them healthy, but I don't know what you need or want." Silence fell again. She would like to learn from them, she repeated. Would they help her? Again Sandra felt an uncomfortable silence.

Then one woman began to speak. Quietly, but with deep feeling, she described several bad experiences with the previous nurse and the county social worker. Then others spoke up: "They tell us what we should do. They don't listen. They say our way is not good." Seeing Sandra's interest and concern, the women continued. One of their main concerns was their children's health. Another was the high incidence of accidents and injuries on the reservation. They wanted to learn how to give first aid. Other concerns were expressed. The group agreed that Sandra could help them by teaching a first-aid class.

In the weeks that followed, Sandra taught several classes on first aid and emergency care. She then began a series of sessions on child health. Each time, she asked the women to choose a topic or problem for discussion and then elicited from them their accustomed ways of dealing with each problem; for example, how they handled toilet training or taught their children to eat solid foods. Her goal was to learn as much as she could about their culture and incorporate that information into her teaching, which preserved as many of their practices as possible. Sandra also visited informally with the women in their homes and at community gatherings.

She learned about their way of life, their history, and their values. For example, patience was highly valued. It was important to be able to wait patiently, even if a scheduled meeting was delayed as much as 2 hours. It also was important for others to speak, which explained the Indian women's comfort with silences during a conversation. Other values influenced their way of life. Courage, pride, generosity, and honesty all were important determinants of behavior. These also were values by which they judged Sandra and other professionals. Sandra's honesty in keeping her promises enabled the women to trust her. Her generosity in giving her time, helping them occasionally with some household task and arranging for child care during classes won their respect.

The women came to accept her, and Sandra was invited to eat with them and share in tribal get-togethers. The women criticized and advised her on acceptable ways to speak and act. Her openness and patience to learn and her respect for them as a people had paved the way to improving their health. At first, Sandra felt that her progress was slow, but this slowness was an advantage. She had built a solid foundation of cross-cultural trust, and in the months that followed she saw many changes in her clients' health practices.

### Health Problems

African Americans have much higher mortality rates than White Americans, with a life expectancy of 71.1 years (U.S. Department of Commerce, 2001). This number is the same as the life expectancy of Whites in 1966, revealing a 35-year lag for the Black population compared with the White population. This demonstrates the inequality in mortality and life expectancy, an outcome of health care, economic, and educational disparity (Levine et al., 2001). Life expectancy for Whites in 2000 was 76.8 years (U.S. Department of Commerce, 2001). The gap for Blacks is 6.3 years for males and 4.5 years for females (Harper, Lynch, Burris & Smith, 2007). The major health problems for Blacks include cardiovascular disease and stroke, cancer, diabetes mellitus, cirrhosis, a high infant mortality rate

(twice that of whites), homicide, accidents, and malnutrition (Display 5.5).

Stress and discrimination, poverty, lack of education, high rates of teen pregnancy, inadequate housing, and inadequate insurance for health care are among the risk factors influencing the health of this population. In the last three decades, a dramatic increase in Black households headed by women, single-parent births (most frequently among teenagers), and a limited presence of male role models has further exacerbated family vulnerability (Lewis, Gutierrez, & Sakamoto, 2001).

Leading causes of death for African Americans are heart disease, cancer, and stroke. As noted, infant death rates are higher in Blacks than in other groups (13.6 per 1,000 live births), leading many health departments to provide Black Infant Health programs (National Center for Health Statistics, 2007a). Mortality rates for communicable diseases,

including the acquired immunodeficiency syndrome (AIDS), also are higher for Blacks than for Whites. The incidence of TB in this population is rising, with many cases being diagnosed in conjunction with AIDS (see Chapters 8 and 26). Other infectious and parasitic diseases are three to six times more prevalent among African Americans than among Whites (U.S. Department of Health and Human Services, 2000). Hypertension is a real concern in this population (37% of men and 41% of women over the age of 20 report having hypertension). In the same age group, 66% of men and 79% of women are reported as overweight (National Center for Health Statistics, 2007a). In two health-related areas, Blacks demonstrate a lower incidence than Whites: suicide is 50% less prevalent among Blacks, and the rate of chronic obstructive pulmonary disease (COPD) is 20% to 30% less. All other leading causes of death are higher for Black populations, much of which can be attributed to lifestyle and poverty (Hong et al., 2006). However, some genetic studies have shown significant differences between African Americans and Whites in those genes associated with hypertension and cardiovascular disease (Lange et al., 2006; Wang et al., 2006).

Blacks may have specific skin problems (e.g., keloids, melasma). In addition, sickle cell anemia occurs in Blacks, an inherited genetic trait thought to have originated in Africa as a defense against malaria (Spector, 2009).

### Health Beliefs and Practices

Although African Americans have assimilated into the more dominant European American culture in the United States,

some retain aspects of their ancestors' traditional values and practices. Some, for example, hold traditional African beliefs about health being a sign of harmony with nature and illness being evidence of disharmony. Evil spirits, the punishment of God, or a hex placed on the person might account for this disharmony. Healers treat body, mind, and spirit. Prayer, laying on of hands, magic or other rituals, special diets, wearing of preventive charms or copper bracelets, ointments, and other folk remedies sometimes are practiced (Spector, 2009). A recent study by Aaron, Levine, and Burstin (2003) found that, for African Americans, church attendance is significantly associated with positive health care practices (e.g., blood pressure measurements, Pap smears, mammograms, dental visits). This was even stronger for the chronically ill and uninsured subgroups. This is an important consideration when public health nurses plan programs targeting this population. Each African American community has its own set of health beliefs and practices that must be determined by the community health nurse before any interventions are planned.

### Asian Americans

A third cultural cluster is composed of immigrants and refugees from various Pacific Rim countries, such as China, Korea, Japan, Thailand, Laos, the Philippines, Vietnam, and Cambodia (Display 5.6). Some Asian Americans have been transplanted fairly recently from their native countries and cultures to an entirely different culture, whereas others may have lived here many years or were born in America.

## DISPLAY 5.6

## ASIAN-PACIFIC POPULATIONS

Asian refers to:	Pacific Islander refers to:
Chinese	Polynesian
Filipino	Hawaiian
Japanese	Samoan
Asian Indian	Tongan
Korean	Micronesian
Vietnamese	Guamanian
Laotian	Melanesian
Thai	Fijian
Cambodian	Tahitian
Pakistan	Marshallese
Indonesian	Trilese
Hmong	
Mien	

### Population Characteristics and Culture

In 2004, more than 14 million Asians and Pacific Islanders were living in the United States, representing 4.3% of the total population (National Center for Health Statistics, 2006; Infoplease, 2007; U.S. Department of Commerce, 2001).

The largest groups were Chinese and Filipinos, with more than 1.5 million persons from each country; Vietnamese numbered a close second. Other fairly large groups came from Korea, India, Laos, and Cambodia. Each group represents a distinct culture with its own unique challenges for community health nurses, as illustrated in the case study of the Kim family (see From the Case Files III).

Whereas each Asian culture is distinct in language, values, and customs, many Asians share some general traits. Traditional Asian families tend to be patriarchal (the father is the head of the household) and patrilineal (the genealogy is carried through the male line). Male members are valued over female members. Elders are respected. The male role generally is that of provider, whereas the female role is that of homemaker. Traditional Asians value achievement because it brings honor to the family name. Saving face or preserving dignity and family pride is important. Cooperation is valued over competition (Leininger, 2006; Spector, 2009).

### Health Problems

Leading causes of death among Asians include cancer, heart disease, and stroke (National Center for Health Statistics, 2006). Smoking is lower in this group (18% of males and 6% of females over age 18 smoke). Health problems for Asian Americans include malnutrition, TB, mental illness, cancer, respiratory infections, arthritis, parasitic infestations, and chronic

## From the Case Files III

### The Kim Family

Armed with enthusiasm and pamphlets on pregnancy and prenatal diet, Paula Morrow, the community health nurse, began home visits to the Kim family. Paula's initial plan was to discuss pregnancy and fetal development, teach diet, and prepare the mother for delivery. Mr. Kim, a graduate student, was present to interpret, because Mrs. Kim spoke little English. Their two boys, ages 1½ and 3 years, played happily on the kitchen floor. The family offered tea to the nurse and listened politely as she explained her reasons for coming and asked, "How can I be most helpful to you? What would you like from my visits?"

The Kims were grateful for this approach. Hesitant at first, they hinted at Mrs. Kim's fears of American doctors and hospitals; her first two children had been born in Korea. None of the family had any experience with Western medicine. They shared some concerns about adjustment to living in the United States. It was difficult to shop in American food stores with their overwhelming variety of foods, many of which the Kims found unfamiliar. Mrs. Kim, who had come from a family whose servants prepared the food, was an inexperienced cook. Servants also had cared for the children, and her role had been that of an aristocrat in hand-tailored silk gowns.

Listening carefully, Paula began to realize the striking differences between her own culture and that of her clients. Her care plans changed. In subsequent visits, she was determined to learn about Korean culture and base her nursing intervention on that knowledge. She learned about their traditional ways of raising children, the traditional male and female roles, and practices related to pregnancy and lactation. She respected their value of "saving face" and attempted never to offend their pride or dignity. As time went on, her interest and respect for their way of life won their trust. She inquired about their cultural practices before attempting any intervention. As a result, the Kims were receptive to her suggestions. Whenever possible, Paula adapted her teaching and suggestions to comply with the Kim's culture. For example, appropriate changes were made in Mrs. Kim's diet that were compatible with her food preferences and cultural eating patterns. Because she was not accustomed to drinking milk, she increased her calcium intake by learning to prepare custards (which disguised the milk flavor) and by eating more green, leafy vegetables. After 5 months, a strong, positive relationship had been established between this family and the nurse. Mrs. Kim delivered a healthy baby girl and looked forward to continued supportive visits from the community health nurse.

diseases associated with aging. Suicide rates and stress-related illness are particularly high among Asian refugee groups who have had to flee their countries under stressful conditions and among teens born in the United States to Asian immigrants; many of these children have difficulty living between two cultures (Mui & Kang, 2006). However, Asians can view mental illness as shameful, and the stigma attached to it prompts them to express the mental illness as a disturbed bodily function or to hide it as long as possible (Mui & Kang, 2006; Spector, 2009).

### Health Beliefs and Practices

Asian health beliefs vary among subcultures. Many Asians believe in the Chinese concepts of *yin* (cold) and *yang* (hot), which do not refer to temperature but to the opposing forces of the universe regulating normal flow of energy. A balance of yin and yang results in *qi* (pronounced *chee*), which is the desired state of harmony. Illness results when an imbalance occurs in these forces. If the imbalance is an excess of yin, then “cold” foods, such as vegetables and fruits, are avoided, and “hot” foods, such as rice, chicken, eggs, and pork, are offered. Some Asians view Western medicines as “hot” and Eastern folk medicines and herbal treatments as “cold,” which explains why some groups practice both for balance. The Vietnamese have a similar hot-and-cold belief, but call it *am* and *dong*. Other Asian groups, such as the Filipinos, view illness as an act of God and pray for healing, reflecting their strong religious beliefs as Catholics or Muslims. The Khmer of Cambodia believe that illness reflects a deviation from moral standards, and the Hmong consider illness to be a visitation by spirits (Her & Culhane-Pera, 2004; Spector, 2009).

Many Asian groups have traditional healers, who, depending on the culture, may include acupuncturists, herbalists, herb pharmacists, spirit and magic experts, or a shaman. Most Asian cultures also exercise traditional self-care practices, including herbal medicines and poultices, types of acupuncture, and massage (Davis, 2001; Kim et al., 2002; Plotnikoff et al., 2002; Ryan, 2003; Spector, 2009). Southeast Asians also practice dermabrasive techniques of coining, cupping, pinching, rubbing, and burning. These methods are used to relieve symptoms such as headache, sore throat, cough, fever, and diarrhea by bringing toxins to the skin surface or compensating for heat lost. Cupping was a common medical practice in colonial America (Cash, Christianson, & Estes, 1981). Because these techniques leave a bruise-like lesion on the skin, they can be mistaken for physical abuse. Each client requires a careful **cultural assessment** (a detailed data-gathering about the client’s cultural practices) before nursing action is implemented (Leonard, 2001).

### Hispanic Americans

A fourth cultural cluster comprises groups who are of Hispanic or Latino origin and have immigrated to the United States, some many generations ago. More than half come from Mexico, followed by Puerto Rico, Cuba, Central and South America, and Spain (Spector, 2009). Those with Mexican and Central American backgrounds generally are referred to as Latinos. Depending on the region of the country, socioeconomic status, immigration or citizenship status, or age, members of this large minority group refer to themselves as Mexican American, Spanish American, Chicano, Latin American, Latin, Latino, or

Mexican (Eggenberger, Grassley, & Restrepo, 2006; Spector, 2009). In this chapter, for convenience, the term *Hispanic* is used to encompass this entire diverse population.

The subgroups of Hispanics vary by their patterns of geographic distribution in the United States. Those from Mexico tend to live predominantly in the west (56.7%) and south (32.6%), Puerto Ricans are most likely to live in the northeast (63.9%), and Cubans are highly concentrated in the South (80.1%). Central and South Americans are concentrated in the northeast (32.3%), the south (34.6%), and the west (28.2%) (U.S. Census Bureau, 2001).

### Population Characteristics and Culture

Hispanics are the fastest growing and largest ethnic group in the United States, and people of Hispanic origin are predicted to number more than 58 million, or 17.5% of the population, by 2025 (U.S. Department of Commerce, 2001). In 2004, this group comprised more than 42.6 million people and accounted for over 14% of the U.S. population (Info-please, 2007; National Center for Health Statistics, 2007b).

The Hispanic population uses Spanish as its common and primary language; nonetheless, its diverse cultural and linguistic backgrounds account for diversity in dialects. Hispanic people value extended, cohesive families. Families have been patriarchal, with male members perceived as superior and female members seen as a family-bonding life force. These traditional family structures are changing because of migration, urbanization, women in the work force, and social movements. Spousal roles are becoming more egalitarian (Giger & Davidhizar, 2004; Eggenberger, Grassley, & Restrepo, 2006; Spector, 2009). However, vestiges of the *macho* man and the self-sacrificing woman still are evident in the Hispanic culture and continue to shape behavior (see From the Case Files IV).

### Health Problems

Leading causes of death for the Hispanic population include heart disease, cancer, and accidents (unintentional injuries). A large number of this population is uninsured (34%) and do not have a usual source of health care (31% for adults, almost 10% for children) (National Center for Health Statistics, 2007b). Health problems among the Hispanic population are complicated by experiences in their countries of origin, as well as by socioeconomic and lifestyle factors in this country. Tuberculosis is high in this group, especially among those younger than 35 years of age. Hypertension, diabetes, and obesity are major concerns. Other problems include infectious diseases, particularly AIDS and pneumonia, parasitic infections, malnutrition, gastroenteritis, alcohol and drug abuse, accidents, and violence. Frequently, the most important health issues for Hispanics are related to the fact that the population is young and has a high birth rate (97.7 per 1,000 births) (National Center for Health Statistics, 2007b). Posttraumatic stress disorder is a major problem among refugees from Central and South America who have experienced war and physical and emotional torture.

### Health Beliefs and Practices

Religion plays an important part in Hispanic culture. For most Hispanics, Catholicism is the dominant religion (95%

## From the Case Files IV

### Maria Juarez

Maria Juarez, a 53-year-old Mexican American widow, was referred to a community health nursing agency by a clinic. Her married daughter reported that Mrs. Juarez was having severe and prolonged vaginal bleeding and needed medical attention. The daughter had made several appointments for her mother at the clinic, but Mrs. Juarez had refused at the last minute to keep any of them.

After two broken home visit appointments, the community health nurse made a drop-in call and found Mrs. Juarez at home. The nurse was greeted courteously and invited to have a seat. After introductions, the nurse explained that she and the others were only trying to help. Mrs. Juarez had caused a lot of unnecessary concern to everyone by not cooperating, she scolded in a friendly tone. Mrs. Juarez quickly apologized and explained that she had felt fine on the days of her broken appointments and saw no need “to bother” anyone. Questioned about her vaginal bleeding, Mrs. Juarez was evasive. “It’s nothing,” she said. “It comes and goes like always, only maybe a little more.” She listened politely, nodding in agreement as the nurse explained the need for her to see a physician. Her promise to come to the clinic the next day, however, was not kept. The staff labeled Mrs. Juarez as unreliable and uncooperative.

Mrs. Juarez had been brought up in traditional Mexican American culture that taught her to be submissive and interested primarily in the welfare of her husband and children. She had learned long ago to ignore her own needs and found it difficult to identify any personal wants. Her major concern was to avoid causing trouble for others. To have a medical problem, then, was a difficult adjustment. The pain and bleeding had caused her great apprehension. Many Mexican Americans have a particular dread of sickness and especially hospitalization. Furthermore, Mrs. Juarez’s culture had taught her the value of modesty. “Female problems” were not discussed openly. This cultural orientation meant that the sickness threatened her modesty and created intense embarrassment. Conforming to Mexican American cultural values, she had first turned to her family for support. Often, only under dire circumstances do members of this cultural group seek help from others; to do so means sacrificing pride and dignity. Mrs. Juarez agreed to go to the clinic because refusal would have been disrespectful, but her fear of physicians and her reluctance to discuss such a sensitive problem kept her from going. Mrs. Juarez was being asked to take action that violated several deeply felt cultural values. Her behavior was far from unreliable and uncooperative. With no opportunity to discuss and resolve the conflicts, she had no other choice. Knowing this, how would you approach Mrs. Juarez?

of Mexican Americans, for example, are Catholic), but religious beliefs often consist of a blend of Catholicism and pre-Columbian Indian beliefs and ideology, along with magi-coreligious practices. Hispanics believe in submission to the will of God and that illness may be a form of *castigo*, or punishment for sins. They cope with illness through prayers and faith that God will heal them. Their religion also determines the rituals used in healing. For example, *solito*, a condition of depression in women similar to a midlife crisis in American culture, is treated by having the patient lie on the floor while her body is stroked by the *curandero* (native healer) until the depression passes. Latino culture includes beliefs that witchcraft (*brujeria*) and the evil eye (*mal de ojo*) are supernatural causes of illness that cannot be treated by “Anglo” or Western medicine. *Empacho*, a stomachache in children that occurs after a traumatic event, is treated by the *curandero* with herbal mixtures made into teas. After tender loving care and a bowel movement, the child is considered healed (Table 5.5). As with Asians, Hispanics use “hot” and “cold” categories of foods to influence their diet during illness. Many Hispanics tend to be present-oriented, and consequently are not as concerned as the mainstream culture about keeping to time schedules or preparing for the future (Giger & Davidhizar, 2004; Leininger, 2006; Eggenberger, Grassley, & Restrep, 2006; Spector, 2009).

### Arab Populations and Muslims

The final cultural community selected for this discussion is made up of groups of people who come from Arabic countries, especially those who espouse the Muslim religion. By comparison with the groups previously mentioned, the number of people from Arabic countries in the United States is small, but because of the terrorist attacks of September 11, 2001 and the wars in the Middle East, increasing racial and religious animosity has been directed toward people from this part of the world and against those who bear physical resemblance to members of these groups. This unwarranted ostracism has led to mental anguish and distress in Arab and Muslim communities (Giger & Davidhizar, 2002; Goodman, 2002). Hopefully, factual information about these groups of people will dispel myths and alleviate fear.

About 4 million people of Arab descent live in the United States. For purposes of the U.S. Census, Arabs are characterized as White (Electronic Resource Center, 2007a). Los Angeles County (California), Wayne County (Michigan), and Cook County (Illinois) have the largest populations of Arab Americans, with Detroit, Los Angeles, and New York metropolitan areas reporting the largest numbers (Samhan, 2006). Arab Americans have generally done very well economically: 41% are college graduates, over 50% own their

**TABLE 5.5 Hispanic Health Beliefs and Folk Diseases**

Belief Name	Explanation/Treatment
Ataque	Severe expression of shock, anxiety, or sadness characterized by screaming, falling to the ground, thrashing about, hyperventilation, violence, mutism, and uncommunicative behavior. Is a culturally appropriate reaction to shocking or unexpected news, which ends spontaneously.
Bilis	Vomiting, diarrhea, headaches, dizziness, nightmares, loss of appetite, and the inability to urinate brought on by livid rage and revenge fantasies. Believed to come from bile pouring into the bloodstream in response to strong emotions and the person “boiling over.”
Bilong (hex)	Any illness may be caused by this; proper diagnosis and treatment requires consulting with a santero or santera (priest or priestess).
Caide de mollera	A condition thought to cause a fallen or sunken anterior fontanel, crying, failure to nurse, sunken eyes, and vomiting in infants. Popular home remedies include holding the child upside down over a pan of water, applying a poultice to the depressed area of the head, or inserting a finger in the child's mouth and pushing up on the palate. (Note: According to Western medicine, these symptoms are indicative of dehydration and can be life-threatening. The community health nurse's role is imperative—to promoting hydration and definitive health care.)
Empacho	Lack of appetite, stomach ache, diarrhea, and vomiting caused by poorly digested food. Food forms into a ball and clings to the stomach, causing pain and cramping. Treated by strongly massaging the stomach, gently pinching and rubbing the spine, drinking a purgative tea ( <i>estafiate</i> ), or by administering <i>azarcon</i> or <i>greta</i> , medicines that have been implicated, in some cases, in lead poisoning. (Note: The community health nurse must assess family for the use of these “medicines” and initiate appropriate follow-up).
Fatigue	Asthma-like symptoms treated with Western health care practices, including oxygen and medications.
Mal de ojo	A sudden and unexplained illness including vomiting, fever, crying, and restlessness in a usually well child (most vulnerable) or adult. Brought on by an admiring or covetous look from a person with an “evil eye.” It can be prevented if the person with the “evil eye” touches the child when admiring him or her if the child wears a special charm. Treated by a spiritualistic sweeping of the body with eggs, lemons, and bay leaves accompanied by prayer.
Pasmo	Paralysis-like symptoms in the face and limbs treated by massage.
Susto	Anorexia, insomnia, weakness, hallucinations, and various painful sensations brought on by traumatic situations such as witnessing a death. Treatment includes relaxation, herb tea, and prayer.

Adapted from Spector, R. E. (2004). *Cultural diversity in health and illness* (6th ed.). Upper Saddle River, NJ: Pearson Education, Inc.

own home, 42% work as professionals or managers, and the median income for Arab American families is 4.6% higher than other Americans (Naim, 2005). Many Arab immigrants have only arrived since the 1990s, fleeing war-torn countries or repressive regimes (Goodman, 2002; Naim, 2005).

A common language (Arabic) and background unite them, yet only 18% of Muslims (followers of Islam) reside in Middle Eastern countries. Arabs are largely Christian or Muslim, although some Arabs may be Jews or Druze (Electronic Resource Center, 2007b). Christian Arabs first began emigrating to the U.S. in the late 19th and early 20th centuries (mostly from Syria and Lebanon), but during the middle of the 20th century, Muslim Arabs began to emigrate in greater numbers (commonly from Palestine, Egypt, Iraq, and Yemen). Islam is the fastest-growing global religion, with more than 1 billion followers worldwide. Most Muslims live in Indonesia, the southern Philippines, and the United States (Electronic Resource Center, 2007c). The Council on American-Islamic Relations (2008) reports that, in the U.S., 25% of Muslims are of Southeast Asian ancestry, while only 23% are of Arab descent. Approximately 8 million Americans are Muslim. In Britain, it is estimated that Muslim worshippers will outnumber Anglicans within a few years, and the Christian Research Organization in England projected that, if current

trends continue, by 2039 Muslims will surpass all British Christians in worship attendance (Baqi-Aziz, 2001). The tenets of Islam are interpreted more liberally in some nations and more strictly in others, but all practicing Muslims adhere to the five tenets of Islam in some fashion (Table 5.6).

### Population Characteristics and Culture

An Arab is defined as “an individual who was born in an Arab country, speaks the Arabic language, and shares the values and beliefs of an Arab culture” (Kridli, 2002, p. 178). Arab Americans can trace their ancestry to the North African countries of Morocco, Tunisia, Algeria, Libya, Sudan, and Egypt, as well as the western Asian countries of Lebanon, Palestine, Syria, Jordan, Bahrain, Qatar, Oman, Saudi Arabia, Kuwait, United Arab Emirates, and Yemen. Iran is sometimes listed in this group, although Iraqis generally consider themselves to be Persian, not Arab (Arab American Institute Foundation, 2002). Assyrian/Chaldean/Syriac and Sub-Saharan (Somalian and Sudanese) groups are also noted as Arab. In general, the beliefs and practices of people from such disparate and distant countries cannot be encompassed into one culture. Despite the fact that some of these countries are highly Westernized, enjoy natural resources such as crude

**TABLE 5.6 The Five Pillars (Tenets) of Islam**

1. Faith	Declaration of faith ( <i>shahada</i> ) that there is no God but Allah and that Mohammad is the messenger of Allah.
2. Prayer	Obligatory prayers five times a day at dawn, noon, mid-afternoon, sunset, and when night falls (called <i>salat</i> ) link the worshipper to God. Prayers are led by a learned man who knows the Quran, as there is no hierarchical authority in Islam (such as a minister or priest).
3. Almsgiving	This is like tithing and is a very important principle, as all wealth is thought to belong to God. It is called <i>zakat</i> , and each Muslim is expected to pay 2.5% of his or her wealth annually for the benefit of others in need.
4. Fast	To abstain from food, drink, and sexual intercourse during daytime (from dawn to sunset) throughout the ninth lunar month (Ramadan). It is a means of self-purification and spirituality. The sick, elderly, or pregnant/nursing women may be permitted to break the fast.
5. Pilgrimage	The pilgrimage to Makkah (the Hajj) once in a lifetime for those who are physically and financially able to do so. About 2 million people go to Makkah every year (located in Saudi Arabia).

Adapted from *The Five Pillars of Islam*. Retrieved from: <http://www.islamicity.com/mosque/pillars.shtml>.

oil and the riches that may follow, and are more liberal in following traditional cultural practices, others do not. It must also be noted that the Middle East has one of the slowest growing levels of personal income in the world and the highest unemployment rates among developing nations (Naim, 2005).

Arabs are mostly divided into two distinct religious groups: Muslims and Christians. Arabs value Western medicine, trust American health care workers, and do not generally postpone seeking medical care (Electronic Resource Center, 2007d). Several practices, however, are unfamiliar to most Americans. Many Arabic women stay at home and are not in the workforce. Families impose stricter rules for girls than for boys. After menarche, teenage girls may not socialize with boys. The adolescent female also begins to cover her head and perhaps wears a *hajib*, which takes the form of a modest dress and veil designed to diminish attractiveness and appeal to the opposite sex. Some Arab groups take this mode of dress to extremes, not even allowing a woman's eyes to show out of the *hajib*. Modesty is one of the core values for Arabs; it is expressed by both genders, although more evidently by females (Al-Shahri, 2002; Goodman, 2002).

Within the Arabic population, strict sexual taboos and social practices exist. All sexual contacts outside the marital bond are considered illegal. Those known to have been involved in such activities can be socially rejected, or in some countries even put to death. The stigma of lost honor can continue with their families for generations to come. Another social practice, at times mistakenly related to the Islamic religion, is the practice of female genital mutilation. This is practiced in a few of the Arabic countries on the African continent and has spread to southern Egypt, but it is rare or nonexistent in other Arabic countries. This horrific practice may include the removal of a young woman's labia, clitoris, or both, and it sometimes includes closing the vaginal opening by suturing (Kridli, 2002).

### Health Problems

Health problems among Middle Easterners are most frequently lifestyle related. These include poor nutritional practices, resulting in obesity, especially among women; smoking among men; and lack of physical exercise (Al-Shahri, 2002). In some rural areas, especially in Saudi Arabia, men and

women chew tobacco, and an increase of oral cancers is seen. Major public health concerns for most Arabs are related to motor vehicle accidents, maternal-child health, TB, malaria, trachoma, typhus, hepatitis, typhoid fever, dysentery, and parasitic infections (Giger & Davidhizar, 2002).

Most social restrictions are directed toward women and can affect their health. Pregnancy can be complicated by genital mutilation, which results in infections and difficult deliveries. Childbearing continues up until menopause, and 30% of marriages in some Arabic countries are between first cousins; both factors can contribute to the prevalence of genetically determined diseases (Giger & Davidhizar, 2002). The desire to have more sons than daughters often results in very large families and closely spaced pregnancies—often without the benefit of family planning. It is often debated whether birth control methods are sanctioned by Islam or not, but Akbar (2007) states that Muslims can reason for themselves, and notes that family planning is not forbidden by the beliefs of Islam. Abortion and infanticide are not accepted, however.

### Health Beliefs and Practices

Traditional medicine is practiced in spite of the growth of Western medical services in some of the richer Arab nations. Traditional health care practices are much more common in the poorer Middle Eastern countries and in rural areas of all Arabic countries.

Muslims believe in predestination—that life is determined beforehand—and they attribute the occurrence of disease to the will of Allah. However, this does not prevent people from seeking medical treatment. Islamic law prohibits the use of illicit drugs, which include alcohol. Users of such substances are liable to trial, and those convicted of smuggling substances into an Arab country can be sentenced to death in some cases. *Sharaf*, or honor, is an important concept in Arab American beliefs, and drug addiction, mental illness, or unwed pregnancy of a family member brings shame to the entire family (Electronic Resource Center, 2007e). Conversely, when a member does something good or is recognized for an achievement, that honor is reflected on the family as a whole.

Cleanliness is paramount and ritualistic, especially before prayers and after sexual intercourse. The bodies of

both genders are kept free of axillary and pubic hair. The left hand is used for cleaning the genitals and the right one is reserved for eating, hand shaking, and other hygienic activities. Muslims fast during Ramadan from sunrise to sunset, and this can include abstinence from all things (including medications or intravenous fluids). Illness can be an exception to this rule, but public health nurses should consult with a family elder or Muslim leader to encourage the client to continue with any necessary treatments. Also, Muslims pray several times daily, facing toward Mecca. Home visits should be planned so that prayers are not interrupted (Electronic Resource Center, 2007e).

When caring for Arabs in clinics or at home, a nurse of the same sex as the client should be assigned. Many topics (e.g., menstruation, family planning, pregnancy, and childbirth) must be discussed only with and by women; men are not included in these discussions.

Additional guidelines for nurses working with all immigrant groups include the following:

- ◆ Do not make assumptions about a client's understanding of health care issues.
- ◆ Permit more time for interviewing; allow time to evaluate beliefs and provide appropriate interventions.
- ◆ Provide educational programs to correct any misconceptions about health issues; this can occur in clinics, mosques, schools, or homes.
- ◆ Provide an appropriate interpreter to improve communication with immigrants who do not speak English well.

## TRANSCULTURAL COMMUNITY HEALTH NURSING PRINCIPLES

Culture profoundly influences thinking and behavior and has an enormous impact on the effectiveness of health care. Just as physical and psychological factors determine clients' needs and attitudes toward health and illness, so too can culture. Kark emphasized over 30 years ago "culture is perhaps the most relevant social determinant of community health" (1974, p. 149). Culture determines how people rear their children, react to pain, cope with stress, deal with death, respond to health practitioners, and value the past, present, and future. Culture also influences diet and eating practices. Partly because of culturally derived preferences, dietary practices can be very difficult to change (Leininger, 2006; Spector, 2009).

Despite its importance, the client's culture often is misunderstood or ignored in the delivery of health care (Leininger, 2006). With the growth in non-White populations, "health care providers must be prepared for interactions with increasingly diverse health care team members and clients" (Giger & Davidhizar, 2002, p. 80). Especially in public health, the nurse must avoid ethnocentric attitudes and must attempt to understand and bridge cultural differences when working with others. It is important to develop knowledge and skill in serving multicultural clients and an ability to place clients' responses to experiences within the context of their lives, or else risk ineffectiveness in the face of a limited understanding and interpretation of client experience.

Overcoming ethnocentrism requires a concerted effort on the nurse's part to see the world through the eyes of

clients. It means being willing to examine one's own culture carefully and to become aware that alternative viewpoints are possible. It means attempting to understand the meaning other people derive from their culture and appreciating their culture as important and useful to them (Campinha-Bacote, 2003). Ignoring consideration of clients' different cultural origins often has negative results, as illustrated in From the Case Files IV discussion about Maria Juarez.

Culture is a universal experience. Each person is part of some group, and that group helps to shape the values, beliefs, and behaviors that make up their culture. In addition, every cultural group is different from all others. Even within fairly homogeneous cultural groups, subcultures and microcultures have their own distinctive characteristics. Further differences, based on such factors as socioeconomic status, social class, age, or degree of acculturation, can be found within microcultures. These latter differences, called *intraethnic variations*, only underscore the range of culturally diverse clients served by community health nurses.

Given such diversity, community health nurses face a considerable challenge in providing service to cross-cultural groups. This kind of practice, known as **transcultural nursing**, means providing culturally sensitive nursing service to people of an ethnic or racial background different from the nurse's (Leonard, 2001; Leininger, 2006). Community health nurses in transcultural practice with client groups can be guided by several principles: develop cultural self-awareness, cultivate cultural sensitivity, assess the client group's culture, show respect and patience while learning about other cultures, and examine culturally derived health practices.

## Develop Cultural Self-Awareness

The first principle of transcultural nursing focuses on the nurse's own culture. Self-awareness is crucial for the nurse working with people from other cultures (Leininger, 2006). Nurses must remember that their culture often is sharply different from the culture of their clients. **Cultural self-awareness** means recognizing the values, beliefs, and practices that make up one's own culture. It also means becoming sensitive to the impact of one's culturally based responses. The community health nurse who assisted Mrs. Juarez in the fourth Case File discussion probably thought that she was being friendly, efficient, and helpful. In terms of her own culture, this nurse's behavior was intended to reassure clients and meet their needs. Unaware of the negative consequences of her behavior, the nurse caused damage rather than meeting needs.

To gain skill in understanding their own culturally based behavior, nurses can complete a cultural self-assessment by analyzing their own:

- ◆ Racial background influences
- ◆ Verbal and nonverbal communication patterns
- ◆ Values and **norms**, or expected cultural practices or behaviors
- ◆ Beliefs and practices

Start with a detailed list of values, beliefs, and practices relative to each point. Next, enlist one or more close friends to call attention to selected behaviors, to bring them to a more conscious level. Videotaping practice interviews with colleagues and actual interviews with selected clients creates

further awareness of the nurse's unconscious, culturally based responses. Finally, ask selected clients to critique nursing actions in light of the clients' own culture. Feedback from clients' perspectives can reveal many of the nurse's own cultural responses.

Because culture is mostly tacit, as discussed earlier, it takes conscious effort and hard work to bring the nurse's own cultural biases or influence to the surface. Doing so, however, rewards the nurse with a more effective understanding of self and enhanced ability to provide culturally relevant service to clients (Leonard, 2001; Narayanasamy, 2003).

### Cultivate Cultural Sensitivity

The second transcultural nursing principle seeks to expand the nurse's awareness of the significance of culture on behavior. Nurses' beliefs and ways of doing things frequently conflict with those of their clients. A first step toward bridging cultural barriers is to recognize those differences and develop cultural sensitivity. **Cultural sensitivity** requires recognizing that culturally based values, beliefs, and practices influence people's health and lifestyles and need to be considered in plans for service (Campinha-Bacote, 2003; Leininger, 2006). Mrs. Juarez's values and health practices sharply contrasted with those of the clinic's staff. Failure to recognize these differences led to a breakdown in communication and ineffective care. Once differences in culture are recognized, it is important to accept and appreciate them. A nurse's ways are valid for the nurse; clients' ways work for them. The nurse visiting the Kim family in the third case file discussion avoided the dangerous ethnocentric trap of assuming that her way was best, and she consequently developed a fruitful relationship with her clients.

As a part of developing cultural sensitivity, nurses need to try to understand clients' points of view. They need to stand in their clients' shoes and try to see the world through their eyes. By listening, observing, and gradually learning other cultures, the nurse must add a further step of choosing to avoid ethnocentrism. Otherwise, the nurse's view of a different culture will remain distorted and perhaps prejudiced (Leonard, 2001; Leininger, 2006). The ability to show interest, concern, and compassion enabled one nurse to win the trust and respect of the Native American women in the second case file example and told the Kims that their nurse cared about them. These nurses attempted to understand the feelings and ideas of their clients; in this way, they established a trusting relationship and opened the door to the possibility of their clients' adopting healthier behaviors.

### Assess the Client Group's Culture

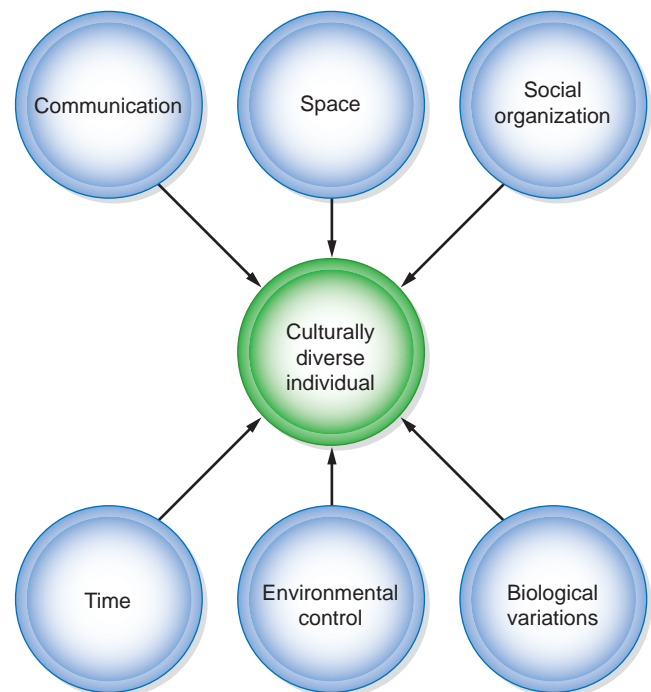

A third transcultural nursing principle emphasizes the need to learn clients' cultures. All clients' actions, like one's own, are based on underlying culturally learned beliefs, values, and ideas (Ludwick & Silva, 2000; Spector, 2009). Mrs. Kim did not like milk because her culture had taught her that it was distasteful and many Asians are lactose intolerant. The Native American women's response to waiting or keeping someone else waiting was influenced by their valuing patience. There usually is some culturally based reason that causes clients to engage in (or avoid) certain actions. Instead of making assumptions or judging clients' behavior, the

nurse first must learn about the culture that guides that behavior (Giger & Davidhizar, 2002). During a cultural assessment, the nurse obtains health-related information about the values, beliefs, and practices of a designated cultural group. Learning the culture of the client first is critical to effective nursing practice. The Giger and Davidhizar Transcultural Assessment Model (2002) denotes six interrelated factors for assessing differences between people in cultural groups (Figure 5.2). Understanding these phenomena is a first step toward appreciating the diversity that exists among people from different cultural backgrounds. Interviewing members of a subcultural group can provide valuable data to enhance understanding (Eggenberger, Grassley, & Restrepo, 2006).

To fully understand a group's culture, it should be studied in depth, as Bernal maintains (1993, p. 231):

Although a general knowledge base and skills are applicable transculturally, immersion in a given culture is necessary to understand fully the patterns that shape the behavior of individuals within that group. Experience with one group can be helpful in understanding the concept of diversity, but each group must be understood within its own ecologic niche and for its own historical and cultural reality.

Practically speaking, however, it is not possible to study in depth all of the cultural groups that the nurse encounters. Instead, the nurse can conduct a cultural assessment by questioning key informants, observing the cultural group,

**FIGURE 5.2** Components of the Giger and Davidhizar Transcultural Assessment Model, showing the culturally diverse individual through communication, space, social organization, time, environmental control, and biologic variations. Adapted from Giger, J.N., & Davidhizar, R. (2002). Culturally competent care: Emphasis on understanding the people of Afghanistan, Afghan Americans, and Islamic culture and religion. *International Nursing Review*, 49(2), 79–86, with permission.

and reading additional information in the literature. The data can be grouped into six categories:

1. *Ethnic or racial background*: Where did the client group originate, and how does that influence their status and identity?
2. *Language and communication patterns*: What is the preferred language spoken, and what are the group’s culturally based communication patterns?
3. *Cultural values and norms*: What are the client group’s values, beliefs, and standards regarding such things as family roles and functions, education, child rearing, work and leisure, aging, death and dying, and rites of passage?
4. *Biocultural factors*: Are there physical or genetic traits unique to this cultural group that predispose them to certain conditions or illnesses?
5. *Religious beliefs and practices*: What are the group’s religious beliefs, and how do they influence life events, roles, health, and illness?
6. *Health beliefs and practices*: What are the group’s beliefs and practices regarding prevention, causes, and treatment of illnesses?

The cultural assessment guide presented in Table 5.7 gives suggestions for more detailed data collection.

Many cultural assessment guides can be found throughout the nursing literature. Nonetheless, a thorough cultural assessment may be too time-consuming and costly.

Category	Sample Data
Ethnic/racial background	Countries of origin Mostly native-born or U.S. born? Reasons for emigrating if applicable Racial/ethnic identity Experience with racism or racial discrimination?
Language and communication patterns	Languages of origin Languages spoken in the home Preferred language for communication How verbal communication patterns affected by age, sex, other? Preferences for use of interpreters Nonverbal communication patterns (e.g., eye contact, touching)
Cultural values and norms	Group beliefs and standards for male and female roles and functions Standards for modesty and sexuality Family/extended family structures and functions Values re: work, leisure, success, time Values re: education and occupation Norms for child-rearing and socialization Norms for social networks and supports Values re: aging and treatment of elders Values re: authority Norms for dress and appearance
Biocultural factors	Group genetic predisposition to health conditions (e.g., hypertension, anemia) Socioculturally associated illnesses (e.g., AIDS, alcoholism) Group attitudes toward body parts and functions Group vulnerability or resistance to health threats? Folk illnesses common to group? Group physical/genetic differences (e.g., bone mass, height, weight, longevity)
Religious beliefs and practices	Religious beliefs affecting roles, childbearing and child-rearing, health and illness? Recognized religious healers? Religious beliefs and practices for promoting health, preventing illness, or treatment of illness Beliefs and rituals re: conception and birth Beliefs and rituals re: death, dying, grief
Health beliefs and practices	Beliefs re: causes of illness Beliefs re: treatment of illness Beliefs re: use of healers (traditional and Western) Health promotion and illness prevention practices Folk medicine practices Beliefs re: mental health and illness Dietary, herbal, and other folk cures Food beliefs, preparation, consumption Experience with Western medicine

**TABLE 5.8 Two-Phased Cultural Assessment Process****Phase I—Data Collection**

Stage 1	Assess values, beliefs, and customs (e.g., ethnic affiliations, religion, decision-making patterns).
Stage 2	Collect problem-specific cultural data (e.g., cultural beliefs and practices related to diet and nutrition). Make nursing diagnoses.
Stage 3	Determine cultural factors influencing nursing intervention (e.g., child-rearing beliefs and practices that might affect nurse teaching toilet training or child discipline).

**Phase II—Data Organization**

Step 1	Compare cultural data with Standards of client's own culture (e.g., client's diet compared with cultural norms) Standards of the nurse's culture Standards of the health facility providing service.
Step 2	Determine incongruities in above standards.
Step 3	Seek to modify one or more systems (client's, nurse's, or the facility's) to achieve maximum congruity.

Instead, the two-phase assessment process is proposed, as outlined in Table 5.8. Categories to explore in the assessment include values, beliefs, customs, and social structure components. Two methods that have proved highly effective for in-depth study of cultural groups are ethnographic interviewing and participant observation. Classic models of these methods have been published by Spradley (1979, 1980).

### Show Respect and Patience While Learning About Other Cultures

The fourth transcultural nursing principle emphasizes key behaviors for the nurse to practice during the cultural learning process. Respect is the first behavior, and it is shown in many ways. When Sandra Josten involved the Native American women in decisions and gave them choices, she was showing respect. When the nurse gave positive recognition to the importance of the Kims' culture, she was showing respect. Attentive listening is a way to show respect and to learn about a client's culture. Within the United States, people of minority groups particularly need respect (Cowan & Norman, 2006). At times, for groups with limited English skills and a community health nurse who is not bilingual, an interpreter who can assist with communication becomes a necessity (Display 5.7).

A **minority group** is part of a population that differs from the majority and often receives different and unequal treatment. Their ways contrast with those of the dominant culture. It is difficult for them to retain pride in their lifestyles, or in themselves, when the majority culture suggests that they are inferior (Leininger, 2006; Spector, 2009). This message may be only implied or even unintentional, as was the case for Mrs. Juarez in From the Case Files IV. The clinic's routine and the manner of the staff were not intended to show disrespect. They did, nevertheless, and Mrs. Juarez was intimidated and was unable to receive the help that she needed. Everyone needs respect to enhance pride, dignity, and self-esteem; it is an important contributor to good mental health. Showing respect also is an important means for breaking down barriers in cross-cultural communication. For community health nurses, culturally relevant care means practicing cultural relativism. **Cultural relativism** is recognizing and respecting alternative viewpoints and understanding values, beliefs, and practices within their cultural context.

In addition to respect, patience is essential. It takes time to build trust and effect cultural change. It can be difficult to

establish the nurse–client relationship when it involves two different cultures. Trust must be won, and winning it may take weeks, months, or years. Time must be allowed for both nurse and clients to learn how to communicate with one another, to test one another's trustworthiness, and to learn about one another. Change in behavior (learned aspects of the culture) occurs gradually. Some aspects of both the nurse's and the clients' cultures can, and probably will, change. The Kims' nurse, Paula Morrow, for example, modified

**DISPLAY 5.7****INTERPRETER GUIDELINES**

1. Unless the community health nurse is thoroughly effective and fluent in the client's language, an interpreter should be used.
2. Speak at a normal to slow pace and make eye contact with the client.
3. Confidentiality must be maintained by the interpreter, who divulges nothing without the full approval of the client and community health nurse.
4. Evaluate the interpreter's style, approach to clients, and ability to develop a relationship of trust and respect. Try to match the interpreter to the client.
5. Be patient. Careful interpretation often requires that the interpreter use long, explanatory phrases.
6. Interpreters must interpret everything that is said by all of the people in the interaction but should inform the community health nurse if the content might be perceived as offensive, insensitive, or harmful to the dignity and well-being of the client.
7. When appropriate, encourage interpreters to explain cultural differences to the client and to yourself.
8. Interpretation conveys the content and spirit of what is said, with nothing omitted or added.
9. Volunteer interpreters receive no fee. Employed interpreters receive their fee or salary from the hiring agency. They should not accept money or favors from clients or the community health nurse. A sincere "thank you" is most appropriate (Kaufert & Putsch, 1997; Putsch, 1985. University of Washington Medical Center, 2008).

## From the Case Files V

### The Importance of Cultural Sensitivity

In Australia, well-intentioned government officials, including representatives of the health ministry, identified problems related to substandard housing among a particular aggregate of aboriginal people. To assist this community, the officials spent a great deal of time, energy, and finances planning and building homes for the Aborigines. The homes were small but modern and offered many of the conveniences that officials believed would improve the quality of life for the community.

The Aborigines were appreciative of the group's efforts and moved into their new homes. Before long, however, officials realized that one by one the community members were moving back to their "substandard" housing. When asked about their lack of appreciation for the improved lifestyle, the group informed the officials that their watering hole was their life-line and that the houses were not only uncomfortable to them but were too far from their watering hole. Soon, all of the aboriginal families had returned to living on the land, and the homes were part of a veritable ghost town in the middle of nowhere.

### QUESTIONS

- Was the aboriginal community truly "poor," as the officials seemed to think?
- Discuss your perception of the following issues:
  - Cultural imposition
  - Cultural poverty
  - Dignity and spirit
- If you were part of an international health team assigned to return to the community to try again to improve their quality of life, what steps would you take to ensure that previous mistakes are not repeated?

some of her usual practices and adapted them to the Kims' culture and needs. They, in turn, began to assume some American practices and values. However, the process took several months. Time, respect, and patience help to break down cultural barriers (Campinha-Bacote, 2003).

### Examine Culturally Derived Health Practices

The final transcultural nursing principle involves scrutiny of the client group's cultural practices, as they affect the group's health status. Once the community health nurse has assessed the culture of the client group, cultural practices affecting the health of the client group need to be examined. Are these behaviors preserving and enhancing the group's health, or are they harmful to their health? Some traditional practices, such as customary diet, birth rituals, and certain folk remedies, may promote both physical and psychological health. These can be considered healthful. Other practices may be neither harmful nor particularly health-promoting but are useful in preserving the culture, security, and sense of identity of a particular ethnic group. And some traditional practices may be directly harmful to health. Examples include using herbal poultices to treat an infected wound or "burning" the abdomen to compensate for heat loss associated with diarrhea (Leininger, 2006).

Cultural assessment and aggregate health assessment must go hand in hand. If the group is experiencing a high incidence of low-birth-weight babies, pregnancy complications, skin infections, mental illness, or other evidence of health problems, these can be clues to prompt an examination of cultural health practices. Those that are clearly damaging to health can be discussed with group leaders and healers. In this situation, knowing the group's cultural norms for authority and decision-making can be helpful. Often, a cultural practice can be continued or modified while combined with Western medicine,

so that respect for the culture is maintained while full treatment efficacy is accomplished (see From the Case Files V).

### Summary

Community health clients belong to a variety of cultural groups. A culture is a design for living; it provides a set of norms and values that offer stability and security for members of a society and plays a major role in motivating behaviors. The increase in and great variety of cultural groups reinforce the need for community health nurses to understand and appreciate cultural diversity. Ethnocentrism is the bias that a person's own culture is best and others are wrong or inferior. It can create serious barriers to effective nursing care. Understanding cultural diversity and being sensitive to the values and behaviors of cultural groups often is the key to effective community health intervention.

Culture has five characteristics: it is learned from others; it is an integrated system of customs and traits; it is shared; it is tacit; and it is dynamic. Every culture preserves its integrity by deleting nonfunctional practices and acquiring new components that better serve the group. To gain acceptance, nurses must strive to introduce improved health practices that are presented in a manner consistent with clients' cultural values.

Five transcultural nursing principles, drawn from an understanding of the concept of culture, can guide community health nursing practice:

1. Develop cultural self-awareness.
2. Cultivate cultural sensitivity.
3. Assess the client group's culture.
4. Show respect and patience while learning other cultures.
5. Examine culturally derived health practices. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

- Based on your own cultural background, how would you feel and what behaviors would you exhibit if you were:
  - A client sitting in a clinic waiting room in a foreign country whose language you did not know?
  - Part of a nutrition class being told to eat foods you had never heard of before?
  - Visited in your home by a nurse who told you to discipline your child in a way that contradicted everything you had been raised to believe about parenting?
- Describe three tacit cultural rules that govern your own behavior. How might these affect your interactions with clients from another culture?
- What does the term *ethnocentrism* mean to you? Have you ever experienced someone else's being ethnocentric in their attitude toward you? If so, describe that experience. Using the Cross-Cultural Sensitivity Continuum (see Fig. 5.1), explore where your own attitudes are on the continuum toward several of the cultural groups with which you regularly come in contact or from which you know people well.
- Imagine that you are assigned to work with a Mexican American migrant population. What steps would you take to gather the appropriate information to provide culturally relevant nursing service? What sources might provide that information?
- A Hmong father who severely beat his 12-year-old son with a belt, leaving cuts and bruises, is charged with child abuse. "If I can't discipline my son, how can he be a good child?" said the father. What nursing responses would show respect for this cultural group's norms and values, yet be constructive in resolving the cultural conflict?
- Find websites that elaborate on transcultural nursing and cross-cultural health care concerns. Print materials of interest and develop a resource file for your professional use.
- Interprofessional communication techniques among diverse health care disciplines are imperative to effective caregiving. How comfortable are you with knowing the linguistic style, practice, and research backgrounds of social workers, pharmacists, physical therapists, educators, psychologists, and others? Seek out a colleague from a different interprofessional discipline and discuss developing a "shared language."

# 6

## Structure and Economics of Community Health Services

### LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Trace historic events and philosophical developments leading to today's health services delivery systems.
- ◆ Outline the current organizational structure of the public health care system.
- ◆ Examine the three core functions of public health as they apply to health services delivery.
- ◆ Differentiate between the functions of public versus private sector health care agencies.
- ◆ Examine the public health services provided by selected international health organizations.
- ◆ Explain the influence of selected legislative acts in the United States on shaping current health services policy and practice.
- ◆ Explore how the structure and functions of community health services affect community health nursing practice.
- ◆ Define the concept of health care economics.
- ◆ Describe three sources of health care financing.
- ◆ Compare and contrast retrospective and prospective health care payment systems.
- ◆ Analyze the trends and issues influencing health care economics and community health services delivery.
- ◆ Explain the causes and effects of health care rationing.
- ◆ List the pros and cons of managed competition as opposed to a single-payer system.
- ◆ Explain the philosophical implications of health care financing patterns on community health nursing's mission and values.

*“There are  $10^{11}$  stars in the galaxy. That used to be a huge number. But it's only a hundred billion. It's less than the national deficit! We used to call them astronomical numbers. Now we should call them economical numbers.”*

—Richard Feynman (1918–1988)

Single-payer system  
Supply  
Third-party payments  
Universal coverage  
Voluntary health agencies

 **Nurses** preparing for population-based practice need to be familiar with how the health care delivery system is organized and operates, because it is through this system that we are able to offer community health services (see Chapter 3). This system forms an organizing framework for the design and implementation of programs aimed at improving the health of communities and vulnerable groups. It is within this system or framework that community health nurses labor, realize the opportunity to shape future health services, and develop innovative and more effective means of improving community health.

Nurses concerned with the delivery of needed community health services also must understand how those services are financed. In an era when health care costs are rising while resources are limited and providers are competing for scarce dollars, nurses must be well-informed about the issues related to health care financing and about ways to obtain funding to address identified health needs in the community. The structure and economics of community health care are intertwined. **Health care economics** is a specialized field of economics that describes and analyzes the production, distribution, and consumption of goods and services, as well as a variety of related problems such as finance, labor, and taxation (Aday, 2005). The goal of health care economics, much like public health, is to overcome scarcity by making good choices and providing essential services.

Service delivery systems directed at restoring or promoting the public's health have evolved over centuries. The structure, function, and financing of health care systems have changed dramatically during that time in response to evolving societal needs and demands, scientific advancements, more effective methods of service delivery, new technologies, and varying approaches to resource acquisition and allocation (Barton, 2003). Although progress has been made toward a healthier global society, many problems remain, particularly those of controlling health care costs, assuring equitable distribution and effectiveness of health services, and assuring the quality of and access to those services (Pan American Health Organization, 2001; U.S. Department of Health and Human Services [USDHHS], 2000).

This chapter examines the current structure and functions of community health services in the United States and reviews historical and legislative events that influenced the planning for and the delivery of those services. It also provides an overview of health care economics and the ever-changing landscape of financial incentives and disincentives for enhancing the public's health.

## HISTORICAL INFLUENCES ON HEALTH CARE

Despite centuries of change, some personal and community hygiene and health care practices have gone on from the beginning of time. Many primitive tribes engaged in sanitary practices such as burial of excreta, removal of the dead, and isolation of members with certain illnesses. Treatment of the sick has always included using a variety of therapeutic agents administered by a "healer."

Whether health care practices were based on superstition, derived from survival needs, or primarily tied to religious beliefs is unknown. Nonetheless, records show that in Egypt and the Middle East, as early as 3000 BC, people were

building drainage systems, using toilets and systems for water flushing, and practicing personal cleanliness (Scutchfield & Keck, 2003). The Hebrew hygienic code, described in the Bible in Leviticus circa 1500 BCE, probably was the first written code in the world and was the prototype for personal and community sanitation. It emphasized bodily cleanliness, protection against the spread of contagious diseases, isolation of lepers, disinfection of dwellings after illness, sanitation of campsites, disposal of excreta and refuse, protection of water and food supplies, and maternal hygiene (Scutchfield & Keck, 2003). Even more advanced were the Athenians, circa 1000 to 400 BCE, who emphasized personal hygiene, diet, and exercise in addition to a sanitary environment, albeit for the benefit of the wealthy. Their successors, the Romans, added more community health measures, such as laws regulating environmental sanitation and nuisances and construction of paved streets, aqueducts, and a subsurface drainage system.

The Middle Ages (from about 500 to 1500 AD) were distinguished by a distinct change in health beliefs and practices in Europe, based on the philosophy that to pamper the body was evil. During this regressive period in history, health care was scarce, private, and reserved for the wealthy few, whereas public health problems were rampant, and only minimally and ineffectively addressed.

Neglected personal hygiene (e.g., infrequent bathing), improper diets, and accumulation of refuse and body wastes led to widespread epidemics and pandemics of disease, including cholera, plague, and leprosy (Hecker, 1839). Increased trade between Europe and Asia, military conquests, and Christian crusades to the Middle East furthered the spread of disease. Bubonic plague, known as the Black Death, was the most devastating of pandemics, reportedly killing more than 60 million people in the mid-1300s (Hecker, 1839). Fear of Black Death caused Venice to ban entry of infected ships and travelers—a form of quarantine.

**Quarantine** is a period of enforced isolation of persons exposed to a communicable disease during the incubation period of the disease, to prevent its spread should infection occur. The first known official quarantine measure was instituted in 1377, at the port of Ragusa (now Dubrovnik in Croatia, formerly Yugoslavia), where travelers from plague areas were required to wait 2 months and to be free of disease before entry.

By the 1700s, more enlightened Europeans began to challenge the prevailing beliefs and conditions (e.g., disease as a punishment for sin). Even in the 1800s, many people in the United States thought that disease and poverty were visited upon the ignorant and the dirty. We now know the cause of disease; however, stigma regarding such conditions as leprosy and tuberculosis (TB) still exists today, and some regard sexually transmitted diseases and acquired immune deficiency syndrome (AIDS) as punishment for immoral conduct. During the late 18th century, new efforts at reform were influenced by a growing emphasis on human dignity, human rights, and the search for scientific truth. These efforts continued through the 19th and 20th centuries (Scutchfield & Keck, 2003).

Despite improvement during the 17th and 18th centuries, serious problems persisted and new ones developed. Industrialization, masses of people moving to cities, and low regard for human life all contributed to deplorable living

and working conditions. Hundreds of poor children died in England's abusive but socially approved workhouses and apprentice slavery system. Most European communities were characterized by unspeakable misery and filth. Householders dumped their refuse from windows or doors into the streets. Rivers and water supplies were seriously contaminated. Diseases, including cholera, typhus, typhoid, smallpox, and TB, took a tremendous toll on human life (Greene, 2001).

In the 16th and 17th century, London was one of the largest cities in the world, with the population tripling by the end of the 17th century (Cockayne, 2007, p. 9). By the mid 18th century, noise from carriages and carts, animals, and vendors created a "hideous din" (Cockayne, p. 107). Air pollution from burning coal and wood for fuel caused Londoners to cough and spit. People "rarely washed their bodies and lived in the constant sight and smell of human feces and human urine" (Cockayne, p. 60).

Around the turn of the 19th century, England's leaders became increasingly concerned about social and sanitary reform. The term **sanitation** refers to the promotion of hygiene and prevention of disease by maintenance of health-enhancing (sanitary) conditions. The first sanitary legislation, passed in 1837, established vaccination stations in London. One of the most notable reformers, Edwin Chadwick, the father of modern public health, published his *Report on an Inquiry into the Sanitary Conditions of the Laboring Population of Great Britain* in 1842 (Richardson, 1887). His efforts resulted in passage of the English Public Health Act and establishment of a General Board of Health for England in 1848, as reported by Lewis more than a century later (1952).

An epidemiologist and anesthetist, John Snow (1813–1858) worked on the cholera outbreak in London in 1854. His investigations of cholera outbreaks and conclusions led to changes in the practice of sewage dumping into the Thames River, thus improving London's morbidity and mortality from cholera (see Chapter 7). His 1855 work, *On the Mode of Communication of Cholera* (2nd ed.), was a landmark public health contribution. Conditions improved, and scientific study advanced in England and, concurrently, in France, Germany, Scandinavia, and other European countries. England, however, set the pace for application of research, particularly with reference to public health measures, through steadily improved legislation. British laws subsequently became the pattern for American sanitary ordinances (Greene, 2001).

## PUBLIC HEALTH CARE SYSTEM DEVELOPMENT IN THE UNITED STATES

The current U.S. public health care system was long in developing. Most health-related services in the United States were initially reactive, responding to the pressure of immediate needs and uncoordinated from one locality to another. Over time, events and insights contributed to a gradually improving system of programs and services, along with recognition that the health of individuals was affected by the health of the wider community (Table 6.1 highlights some of these changes). Our current public health system is not really a "single entity, but rather a loosely affiliated network of approximately 3,000 federal, state, and local

governmental health agencies often working closely with private sector voluntary and professional health associations" (Trust for America's Health, 2005, p. 8).

## Precursors to a Health Care System

Early health care in the American colonies consisted of private practice, with occasional (but infrequent) governmental action for the public good. Action usually was in the form of isolated local responses to specific dangers or nuisances, such as the 1647 regulation to prevent pollution of Boston Harbor or the 1701 Massachusetts law requiring ship quarantine and isolation of smallpox patients. New York City, in the late 1700s, formed a public health committee to monitor water quality, sewer construction, marsh drainage, and burial of the dead. Physicians in the early 19th century had few tools at their disposal and could do little to change the course of illness. They made house calls, as most quality care was given in the home, not in hospitals (Cutler, 2004). The U.S. Constitution, adopted in 1789, made no direct reference to public health, nor did the federal government take an active stance on health matters. It was the responsibility of each sovereign state to manage its own health affairs. The first federal intervention for health problems was the Marine Hospital Service Act of 1798. It subsidized medical and hospital care for sick and injured merchant seamen, with the first marine hospital being located in Boston.

During the early years, a scourge of epidemics, especially smallpox, cholera, typhoid, and typhus, caused deaths throughout the colonies and decimated the Native American population (Woodward, 1932). Slave trade further threatened the lives of colonists by introducing diseases, such as yaws (an infectious nonvenereal disease caused by a spirochete), yellow fever, and malaria (Marr, 1982). Local control of quarantine efforts proved ineffective. In 1837, Congress finally instituted the national port quarantine system, which was regulated and enforced by the Marine Hospital Service. Epidemics were quickly checked, causing society to recognize the benefits of uniform central government policy. However, improvements in public health and sanitation on a state and local level competed with other needs, such as police and fire protection (Greene, 2001) (see Table 6.2).

## Calls for Sanitary Reforms

The **Shattuck Report**, a landmark document, made a tremendous impact on sanitary progress. Lemuel Shattuck, a physician and legislator, chaired a legislative committee that studied health and sanitary problems in the Commonwealth of Massachusetts. In 1850, he produced the *Report of the Sanitary Commission of Massachusetts* (Shattuck et al., 1850) describing the public health concepts and methods that form the basis for current public health practice. Shattuck advocated the establishment of state and local boards of health, environmental sanitation, collection and use of vital statistics, systematic study of diseases, control of food and drugs, urban planning, establishment of nurses' training schools (there were none before this time), and preventive medicine.

A similar report by John Griscom on conditions of the working poor in New York City, published in 1845, concluded that illness, premature death, and poverty were directly related and were not the result of immoral or intemperate

**TABLE 6.1 Changes in Health Status and Health Care Services**

Turn of the 20th Century		Turn of the 21st Century	
<b>MORBIDITY AND MORTALITY</b>			
<b>Then</b>		<b>Now</b>	
High communicable disease and mortality Little prevention Infrequent cure Life span of 47 yr High infant mortality High maternal mortality Alcohol abuse Many undiagnosed and untreated conditions		High chronic disease morbidity and mortality Old and new sexually transmitted diseases Resurgence of tuberculosis Life span of 76 yr Significant infant mortality High teenage pregnancy Multiple substance abuse New strains of multidrug-resistant diseases, long-term chronicity, and disability	
<b>ACCESS TO HEALTH CARE</b>			
<b>Then</b>		<b>Now</b>	
Access primarily for those who could pay a fee No health insurance Public health clinics for poor and underserved Limited treatments available		Access for those with health insurance Insurance with copayments shifting to managed care Free health clinics for medically indigent (especially children) Multitude of treatments with regular new advances	
<b>HEALTH CARE DELIVERY SYSTEM</b>			
<b>Then</b>		<b>Now</b>	
Extended hospital stays Discharge on recovery Extended maternal and newborn hospitalization Many home deliveries with lay assistance Home care through not-for-profit agencies PHN begun in health departments Health departments provide personal care services for poor and underserved		Short-term, acute-care hospitalizations Recovery occurs at home or in a transitional setting Short-stay maternal and newborn care Few home deliveries with skilled assistance Home care through not-for-profit and proprietary agencies Shifting PHN role in health departments Health department's personal care services a part of managed care systems

behaviors, as many public health officials advocated. He recommended sanitary reform as did others, such as Barton, Jarvis, and Martin Snow (Duffy, 1990). Almost 25 years passed before these recommendations were fully appreciated and implemented.

### Recent Calls to Action

In 1988, the Institute of Medicine published *The Future of Public Health*, highlighting the state of disarray in our current public health system and calling for improvements in the public health infrastructure—largely focusing on governmental responsibilities. In 2002, the Institute issued a new publication, *The Future of the Public's Health in the 21st Century*. This report called for expanding the responsibilities of the public health system beyond governmental agencies to include private and nongovernmental entities. The report outlined how partnerships could be formed with communities, businesses, the media, universities, and other components of the health care delivery system to expand the reach of public health and achieve the Healthy People 2010 goals (Institute of Medicine, 2002). Other needed changes included a spotlight on multiple determinants of health along with a population

focus, transdisciplinary utilization of evidence-based practice, and better communication and systems of accountability.

### Official Health Agencies

The beginnings of an organized health care system in the United States came in the form of **official health agencies**, later called public health agencies. These were publicly funded and operated by state or local governments with a goal of providing population-based health services. Development occurred initially at the local level. Many cities established local boards of health in the late 1700s and early to middle 1800s. Among the earliest were those in Baltimore, Maryland (1798); Charleston, South Carolina (1815); and Philadelphia, Pennsylvania (1818). As their efforts expanded from handling public “nuisances” to dealing with epidemics and complex public health problems, local health boards recognized that full-time staffs were needed, and thus health departments were formed. Louisiana was first in 1855; Massachusetts followed in 1869.

Again at the national level, the Marine Hospital Service, now with a broader function, became the Public Health and Marine Hospital Service in 1902. Congress gave it a more clearly defined organizational structure and specific functions

TABLE 6.2 Societal Events and Situations Affecting Health Care Needs	
Turn of the 20th Century	Turn of the 21st Century
<b>SOCIETAL AND POPULATION SHIFTS</b>	
<b>Then</b>	<b>Now</b>
Industrial society focusing on production Rural to urban Limited violence Wide gaps between rich and poor Growing philanthropy Intense immigration from eastern Europe	Postindustrial, service and information oriented Urban to suburban Rampant violence and terrorism Widening gaps between rich and poor Declining support for charitable health care Moderate immigration—Africa, Europe, Asia
<b>ENVIRONMENT</b>	
<b>Then</b>	<b>Now</b>
Overcrowded, unsanitary housing Unsafe workplaces, lack of worker safeguards Rampant child labor Poor public sanitation Multiple health risks	Deteriorating inner-city neighborhoods Environmental hazards in some workplaces Homelessness Good public sanitation Increasing environmental and behavioral risks
<b>SKILL CHANGES AND EMPLOYMENT</b>	
<b>Then</b>	<b>Now</b>
Farm to factory Low wages Dramatic disparity in wages between men and women Not enough jobs	Factory to service and information Improving wages, limited benefits Slowly resolving disparity in male/female wage differences Downsizing, layoffs, corporate streamlining, failing companies
<b>PEOPLE LIVING IN POVERTY</b>	
<b>Then</b>	<b>Now</b>
Women and children Immigrants—European Migration—south to north	Women, children, the aged Immigrants—Hispanic, Caribbean, Middle Eastern, and Asian Seasonal migration of farm workers

for its director, the Surgeon General. In 1912, it was renamed the United States Public Health Service (PHS) (Melosi, 2000; Turnock, 2004; USDHHS, 2007; Ward & Warren, 2007).

Rapidly expanding through World War I and the Great Depression, the PHS strengthened its research activity through the National Institutes of Health (NIH, founded in 1912), added demonstration projects, and initiated greater cooperation with the states. Responding to increasingly complex needs, the NIH added programs significant to public health, such as the Children's Bureau (1912); the National Leprosarium at Carville, Louisiana (1917); examination of arriving aliens (1917); the Division of Venereal Diseases (1918); the Food and Drug Administration [FDA] (1927); and the Narcotics Division (1929), which later became the Division of Mental Hygiene. Title VI of the 1935 Social Security Act promoted stronger federal support of state and local public health services, including health workforce training (USDHHS, 2007; Ward & Warren, 2007).

As health, welfare, and educational services proliferated, the need for consolidation prompted the creation of the Federal Security Agency in 1939. In 1953, the agency was enlarged and renamed the Department of Health, Education,

and Welfare (DHEW), under President Eisenhower. In 1979, education was made a separate cabinet-level department, and the DHEW was renamed the Department of Health and Human Services (DHHS). Other significant events include the establishment during World War II of the Communicable Disease Center in Atlanta, currently known as the Centers for Disease Control and Prevention (CDC), and the development after World War II of the National Office of Vital Statistics, now called the National Center for Health Statistics (NCHS) (Centers for Disease Control & Prevention, 2006).

## Voluntary Health Agencies

The private sector responded first to America's health problems and continues to complement and supplement the government's role in providing health services. By the late 1800s, **voluntary health agencies** (sometimes called private agencies or **nongovernmental organizations [NGOs]**) began to emerge. They were privately funded and operated to address specific health needs. The first of these was the Anti-Tuberculosis Society of Philadelphia, which was formed in 1892 to educate the public and the government about TB, then causing 10% of all

deaths. Other agencies followed: the National Society to Prevent Blindness was formed in 1908, the Mental Health Association in 1909, the American Cancer Society in 1913, the National Easter Seal Society for Crippled Children and Adults in 1921, and the Planned Parenthood Federation of America, also in 1921. In the late 1800s, organized charities such as the Red Cross, previously denounced for promoting dependent poverty, began to be recognized for their contributions to health and welfare. Philanthropy, too, became prominent with the establishment of the Rockefeller Foundation in 1913, followed by the Carnegie-Mellon, Kellogg, and Robert Wood Johnson Foundations (Public Health Encyclopedia, 2007).

## Health-related Professional Associations

Many health-related professional associations have influenced the quality and type of community health services delivery. Among these, the National Organization for Public Health Nursing, from 1912 to 1952, significantly influenced early preparation for and the quality of public health nursing services (Abrams, 2004). The American Public Health Association (APHA), founded in 1872, maintains a prominent role in the dissemination of public health information, influence on health policy, and advocacy for the nation's health. Other nursing and community health organizations that have promoted quality efforts in community health include the Association of State and Territorial Directors of Nursing (ASTDN), the Association of State and Territorial Health Officers (ASTHO), the National League for Nursing (NLN), the American Nurses Association (ANA), and the Association for Community Health Nursing Educators (ACHNE).

## HEALTH ORGANIZATIONS IN THE UNITED STATES

Over the years, responsibility for meeting community health needs has shifted between private groups and governing institutions, each offering different viewpoints and benefits. Only within the last century have they gradually begun to work together to create a loosely structured system of health care.

Barton spoke of the growing interdependence of the public and private sectors (2003), and this partnership was encouraged by the Institute of Medicine (2002). How does that system work today? What are its strengths and weaknesses? To answer these questions, its structure must first be examined. Structure is important because it becomes the operational base for assessment, diagnosis, planning, implementation, and evaluation of services—and it provides a framework for intersystem and intrasystem communication and coordination.

Health services occur at four levels: local, state, national, and international. Like ever-widening concentric circles, these levels encompass broader populations. The organization of health services at each level can generally be classified as one of two types: public or private sector.

## Public Sector Health Services

Government health agencies, the tax-supported arm of the public health effort, perform a vital function in community health practice. With their jurisdiction and types of service dictated by law, they coordinate and administer activities

that often can be carried out only by group or community-wide action (e.g., proper sewage disposal, provision of sanitary water systems, or regulation of toxic wastes). Many community health activities require an authoritative legal backing to ensure enforcement—another useful function of public health agencies—in areas such as environmental pollution, highway safety practices, communicable disease control, and proper, safe handling of food. Official or public health agencies provide important record-keeping services, including the collection and monitoring of vital statistics. They also conduct research, provide consultation, and sometimes financially support other community health efforts.

## Core Public Health Functions

Public health services encompass a wide variety of activities, but all can be grouped under one of three **core public health functions** (Institute of Medicine, 1988). They are assessment, policy development, and assurance (Figure 3.1). As discussed in Chapter 3, public health nurses practice as partners with other public health professionals within these core functions.

**Assessment** refers to measuring and monitoring the health status and needs of a designated community or population. As a core function, it is a continuous process of collecting data and disseminating information about health, diseases, injuries, air and water quality, food safety, and available resources. This function helps to identify trends in morbidity, mortality, and causative factors. It identifies available health resources, unmet needs, and community perceptions about health issues.

**Policy development** is the formation of a guide for action that determines present and future decisions affecting the public's health. As a core public health function, good public policy development builds on data from the assessment function and incorporates community values and citizen input. It provides leadership and administration for the development of sound health policy and planning.

**Assurance** is the process of translating established policies into services. This function ensures that population-based services are provided, whether by public health agencies or private sources. It also monitors the quality of and access to those services. The specific functions of assessment, policy development, and assurance are described in Table 6.3.

The roles of public health agencies vary by level, with each level carrying out the core functions in different ways to form a partnership in protecting the public's health (Turnock, 2004; Williams & Torrens, 2002). International health agencies focus on issues of global concern, setting policy, developing standards, and monitoring health conditions and programs. At the national level, government health agencies engage in similar functions aimed at regional or nationwide concerns.

The federal level provides funds (e.g., through the Medicaid program, block grants, categorical grants) and develops policy (e.g., air pollution policy, occupational safety) but depends on the states to implement them. Agencies at the federal level also develop facilities and programs for special groups, such as Native Americans, migrant workers, inmates of federal prisons, and military personnel and veterans, whose health care is not the direct responsibility of any one state or locality (CDC, 2002).

**TABLE 6.3 Core Public Health Functions Applied to Populations and People at Risk**

Population-Wide Services

Personal Services and Home Visits for People at Risk
<ul style="list-style-type: none"> <li>• Primary care for unserved and underserved people</li> <li>• Treatment services for targeted conditions</li> <li>• Clinical preventive services</li> <li>• Payments for personal services delivered by others</li> </ul>

State government health agencies function fairly autonomously while working within federal guidelines. They assess, develop, and monitor statewide health needs and services. Historically, they have been responsible for communicable disease control, vital statistics, laboratory services, environmental sanitation and hygiene, health education and maternal–child health, with the addition of categorical programs (e.g., heart disease, migrant health) in the 1950s (Scutchfield & Keck, 2003). In the 1980s, block grants were instituted to give more flexibility to states in how funds are targeted.

At the local level, one may find a city government health agency, a county agency, or a combination of both to assess, plan, and serve the health needs of that locality. Most local health departments are under county jurisdiction, with only a small percentage of cities (usually large cities) having local health departments. Some are city–county agencies or special districts, and most local health departments report to either local government councils or boards of health (Scutchfield & Keck, 2003). In some states, local health departments also report to state public health agencies. In about 30% of the states, local health departments are operated by the state health agency, which provides services locally, without city or county oversight (Turnock, 2004).

Unlike private organizations that tend to have a specific focus, government health agencies exist to accomplish a broad goal of protecting and promoting the health of the total population under their jurisdiction. Such a task requires a wide range of services and the combined talents of many types of professional disciplines. Among them are nurses, physicians, health educators, sanitarians, epidemiologists, statisticians, engineers, administrators, accountants, computer programmers, planners, sociologists, nutritionists, laboratory technicians, chemists, physicists, veterinarians, dentists, pharmacists, demographers,

and meteorologists. Furthermore, public health agencies must function not only on an interdisciplinary basis but also on an interorganizational basis. Other government services (e.g., education) can meet their goals fairly autonomously, but public health cannot accomplish its important objectives without the collaboration of many agencies and organizations, both public and private (Barton, 2003; Williams & Torrens, 2002). To manage the AIDS epidemic, for example, public health agencies, educational institutions, welfare agencies, mental health programs, home care services, Medicaid, and private groups, among others, may be called upon to collaborate.

Many different government agencies contribute to the health of a community. Most obvious are the local and state health departments, which provide a variety of direct and indirect health services, including community health nursing. Other tax-supported agencies that sponsor health care or health-related services include welfare departments, departments of public works, public schools and hospitals, police departments, county agricultural services, and local housing authorities.

### Local Public Health Agencies

At the grassroots level, government health agencies vary considerably in structure and function from one locality to the next. This partly results from variations in local needs and the size and resources of the community. For example, a rural community served by a county or state health department may have needs and services that differ widely from those of a densely populated urban community (see Chapter 29). Differing health care standards and regulations, as well as the type and stipulations of funding sources, also contribute to variations in the structure and function of health agencies. Nonetheless, each local governmental health agency shares some commonly held responsibilities, functions, and structural features.

The primary responsibilities of the local health department are to assess the population's health status and needs, determine how well those needs are being met, and take action toward satisfying unmet needs (Scutchfield & Keck, 2003). Specifically, local government health agencies should fulfill these core functions as follows:

- ◆ Monitor local health needs and the resources for addressing them.
- ◆ Develop policy and provide leadership in advocating equitable distribution of resources and services, both public and private.
- ◆ Evaluate availability, accessibility, and quality of health services for all members of the community.
- ◆ Keep the community informed about how to access public health services.

The local health agency represents a critical level of health services' provision because of its closeness to the ultimate recipients—health care consumers. The most recent survey of local health departments revealed the top three expenditure categories as enforcing laws and regulations; informing, educating, and empowering people; and ensuring the provision of care (Barry et al., 1998).

The structure of the local health department varies in complexity with the setting. Rural and small urban agencies need only a simple organization, whereas large metropolitan agencies require more complex organizational structures to support the greater diversity and quantity of work.

Where a board of health exists, it holds the legal responsibility for the health of its citizens. About 80% of local public health departments work with a board of health, and they are more commonly found with smaller populations (Turnock, 2004). Health board members may be appointed by the mayor if the board of health serves a city, by a board of supervisors if the board of health serves a county, or by voters if they are publicly elected. In turn, the board of health usually appoints a health officer (about 80%)—often a physician (about 50%) with public health training (about 15%)—who directs the remaining staff of the health department, including public health nurses, environmental health workers, health educators, and office personnel (Turnock, 2004). Others, such as nutritionists, statisticians, epidemiologists, social workers, physical therapists, veterinarians, or public health dentists, may be added as needs and as resources dictate. The number of staff at local health departments can range from five to over 100, depending upon the size of the agency and population served (Scutchfield & Keck, 2003).

Revenues to support local health departments come from various sources. Local and county general appropriations

make up the largest share of the local health department’s budget—around 44%. State revenues account for about 30% of the total local budget—with additional funds provided through special levies and programs such as school health, Head Start, air pollution, toxic substance control, primary care, immunizations, fees, and private foundation grants. Federal funds provide another source of revenue (about 3%) targeted at specific efforts, such as AIDS research and services, family planning, child health, environmental protection, and hypertension and nutrition programs. According to Turnock (2004), fees, reimbursements, and additional miscellaneous sources, such as state laboratory revenues and food supply supplements, make up the remaining portion of the budget (about 23%). A good number of health departments bill Medicaid for personal health services rendered (e.g., prenatal care, TB treatment, well-baby care), but an increasing number of states are offering Medicaid managed care, and moving personal health care out of local health departments (Scutchfield & Keck, 2003). Figure 6.1 depicts the organization of one local health department serving a population of approximately 300,000.

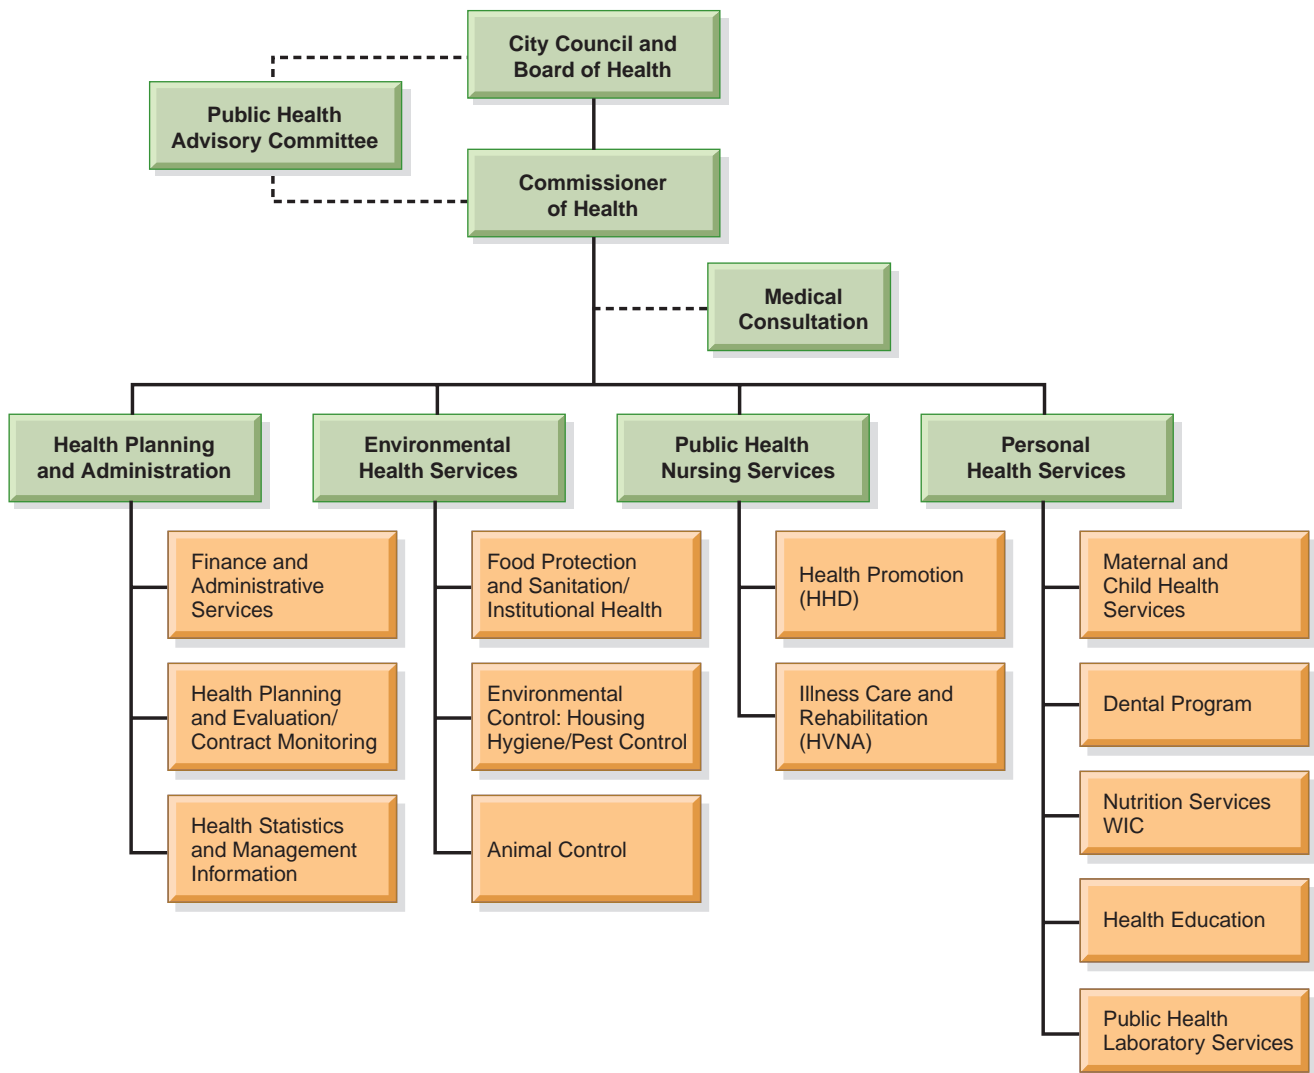

FIGURE 6.1 Organizational chart of a city public health department.

## State Public Health Agencies

State-level government health agencies also vary in structure and in how they carry out the core functions. Each state, as a sovereign government, establishes its own health department, which in turn determines its goals, actions, and administrative structure. The state health department is responsible for providing leadership in and monitoring of comprehensive public health needs and services in the state. It establishes statewide health policy standards, assists local communities, allocates funds, promotes state-level health planning, conducts and evaluates state-level health programs, promotes cooperation with voluntary (private) health agencies or NGOs, and collaborates with the federal government for health planning and policy development (Scutchfield & Keck, 2003). Of the various levels of government health agencies, the states recently have played the most pivotal role in health policy formation.

General functions of state health departments include (Scutchfield & Keck, 2003):

- ◆ Statewide health planning
- ◆ Intergovernmental and other agency relations
- ◆ Intrastate agency relations
- ◆ Certain statewide policy determinations
- ◆ Standards setting
- ◆ Health regulatory functions

Specifically, the Institute of Medicine (1988) described the role of state government related to health. Summarized, it includes:

- ◆ A statewide method of collecting and analyzing data to assess health needs
- ◆ Adequate statutory base for state health activities
- ◆ Statewide health objectives (holding localities accountable where power for implementation has been delegated)
- ◆ Statewide development and maintenance of essential personal, educational, and environmental health services
- ◆ Identification of problems that threaten the health of the state
- ◆ Support for local health services (when needed to achieve adequate service levels) through subsidies, technical and administrative assistance, or direct action

State public health agencies face a challenge in addressing the health-related issues confronting them. Health insurance, long-term care, organ transplants and donations, AIDS, care of the **medically indigent** (those who are unable to pay for and totally lack medical services), malpractice, and certificates of need for new health services are among the problems faced by most states. Clearly, state health departments must collaborate closely with other agencies, such as social services, education, public works, the legislature, and the housing bureau, to effectively solve such problems. Thus, the solution of state health problems and delivery of health services requires the functioning of an interdependent network of organizations, many of which are not health agencies per se.

Budgetary sources for a state health department include state-generated funds, federal grants and contracts, and fees and reimbursements. A large source of federal

monies to the states comes through the Department of Agriculture, which supports the Women, Infants, and Children (WIC) Program, a supplemental nutrition program. State health agencies often provide grant opportunities for local health departments (often through federal grant monies awarded to states). Fragmentation of public health roles and functions among different state agencies poses problems for coordinating the core public health functions at this level (Turnock, 2004). Funding for state public health agencies comes largely from state coffers, with less than 40% coming from federal contracts and grants, and a smaller percentage generated from fees and third-party reimbursements, local taxes and funds, as well as other sources (Scutchfield & Keck, 2003). The Department of Agriculture, the Centers for Disease Control and Prevention, and Health Resources and Services Administration (HRSA) all provide substantial funding at the state level. Less than 6% of all state health care expenditures go toward population health (e.g., health promotion, chronic disease control), even with the addition of new federal bioterrorism monies (Milbank Memorial Fund et al., 2003). In many states, these new funds have been accompanied by state and local funding cuts that actually leave agencies in worse financial shape (Elliott, 2002).

State-level population health expenditures in 2001 accounted for 6.3% of all health care expenditures. Most expenditures were for promotion of chronic disease control and healthy behaviors, along with environmental hazards control programs (Milbank Memorial Fund et al., 2003). Prevention of epidemics and communicable disease control, injury prevention, disaster preparation and response, and health infrastructure were also included under this spending category.

Each of the 50 state health departments in the United States has developed its own unique structure. Some are strongly centralized organizations, whereas others are decentralized. In most states, the appointed director or executive of the agency reports to a state board of health or directly to the governor. Some states have advisory boards that make health policy recommendations and review departmental activities. Significant variation occurs in the types of programs managed by state health agencies—in 2002, about 90% reported administrative responsibility for the WIC program, public health laboratories, vital statistics, and tobacco programs, but only 25% served as the state's environmental regulatory agency (Turnock, 2004). Over 70% regulate health care facilities and deal with food safety and environmental health issues, while over 30% regulate licensing of health professionals. Organizational structures vary from state to state, but there are usually several divisions or bureaus under the director. Those most commonly found in state health department organizational structures are disease prevention and control, community health services, maternal and child health, health systems and technical services, laboratory services, environmental health, and a state center for health statistics. Figure 6.2 shows the organizational chart of a state health department.

## National Public Health Agencies

The national level of public health organization consists of many government agencies. They can be clustered into four groups. First and most directly focused on health is the

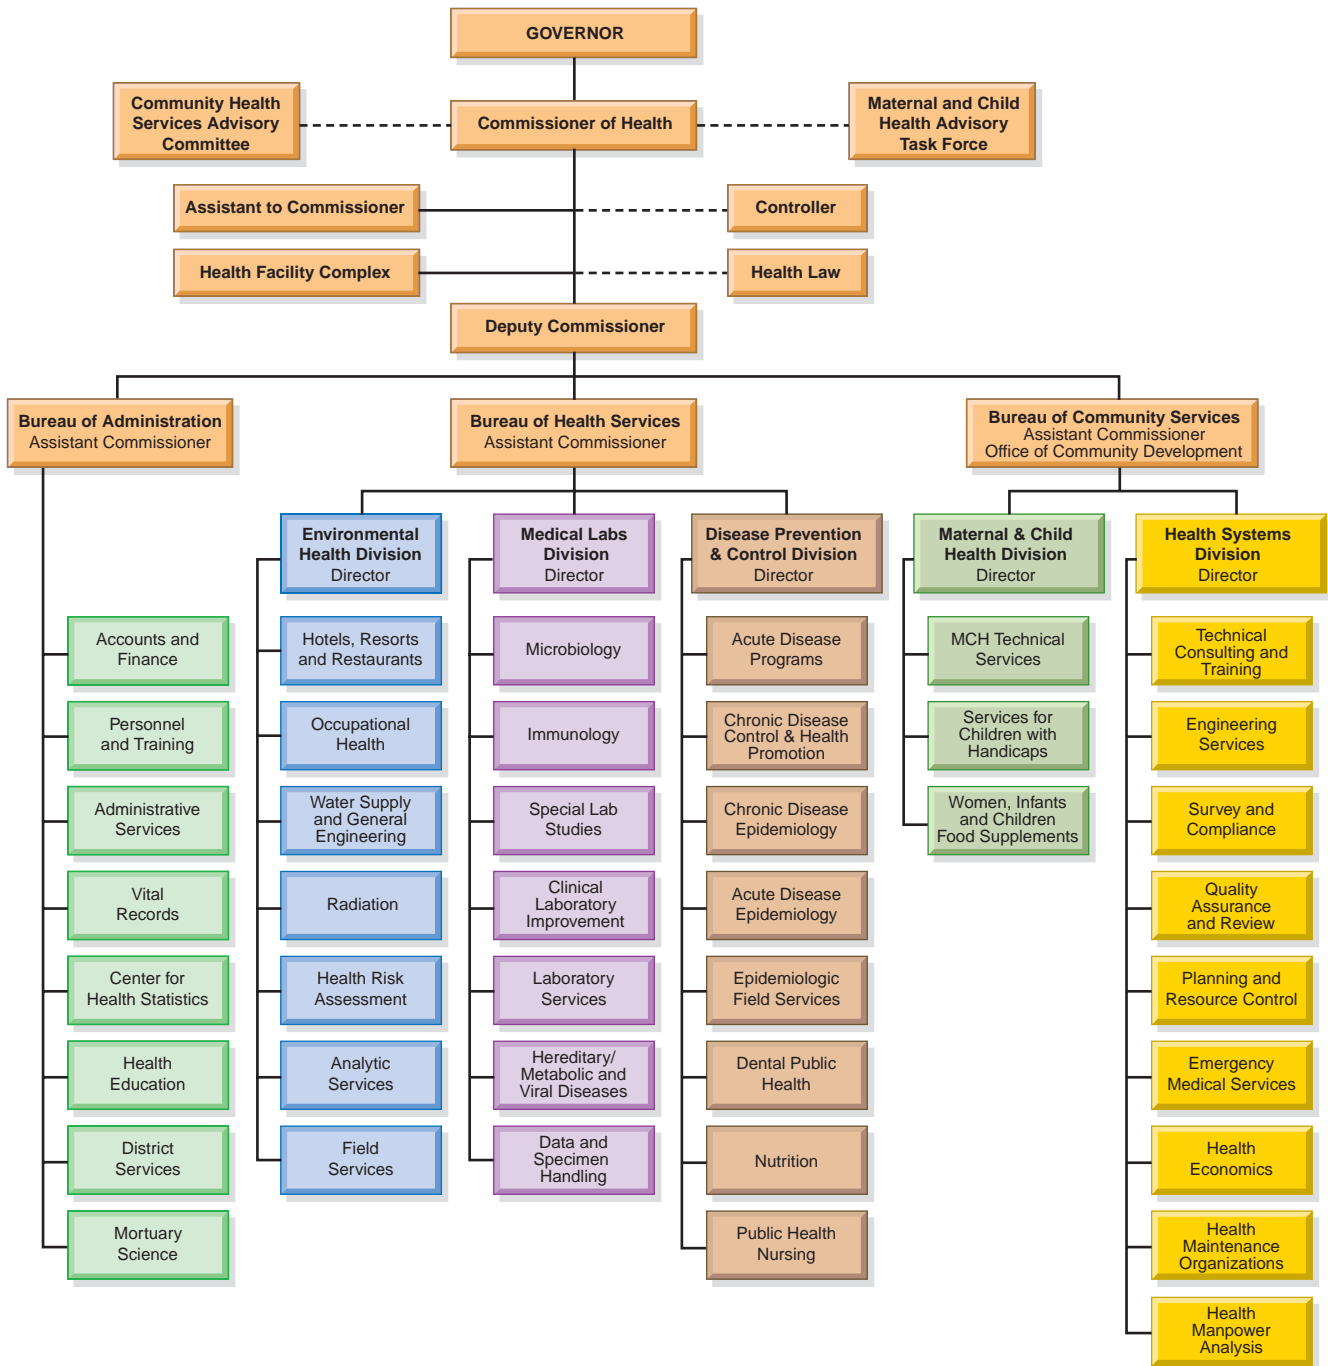

FIGURE 6.2 Organizational chart of a state public health department.

**Public Health Service (PHS).** It is concerned with the broad health interests of the country and is a functional (not organizational) unit of DHHS (see Chapter 30 for more on the PHS Commissioned Corps).

The Secretary of Health and Human Services (a cabinet-level position) has ultimate responsibility for the PHS. The PHS consists of the Office of Public Health and Science (headed by the Assistant Secretary for Health), and comprises the Commissioned Core (over 6,000 uniformed health professionals), the Office of the Surgeon General, and 12 public health offices (e.g., Office of Women’s Health, National Vaccine Program Office, Office of HIV/AIDS Policy, Office of

Minority Health). The PHS is made up of eight functional branches: the CDC, the FDA, the NIH, the Substance Abuse and Mental Health Services Administration (SAMHSA), the HRSA, the Agency for Healthcare Research & Quality (AHRQ), the Indian Health Service, and the Agency for Toxic Substances and Disease Registry (ATSDR). One of its major functions through these eight branches is the administration of grants and contracts with other government agencies, private organizations, and individuals. In some instances, the PHS provides hospital, clinical, and other types of health services, for example, for Native Americans and Eskimos through the Indian Health Service. Through the CDC and the

NIH, it provides epidemiologic surveillance and numerous research programs. The FDA of the PHS monitors the safety and usefulness of various food and drug products, as well as cosmetics, toys, and flammable fabrics (Office of the Public Health Service Historian, 2004; USDHHS, 2006, 2007).

Through its staff offices, the PHS offers other services. It has responsibility for the formation, planning, and evaluation of health policy; health promotion; health services management; health research and statistics; intergovernmental affairs; legislation; population affairs; and international health. It provides financial assistance to the states through grants-in-aid—monies raised by Congress through taxes for specific purposes. It also offers consultation through national advisory health councils and special advisory committees made up of lay experts. The PHS maintains 10 regional offices to make its services more readily available to the states. These offices are located in New York City, Boston, Philadelphia, Atlanta, Chicago, Kansas City, Dallas, Denver, Seattle, and San Francisco.

At the federal level, the primary agencies concerned with health are organized under the DHHS. Assistant secretaries manage offices for Health, Administration and Management, Resources and Technology, Planning and Evaluation, Public Health Emergency Preparedness, Legislation, and Public Affairs. Within the DHHS, clusters of federal agencies deal with the needs of special population groups, such as the elderly (Administration on Aging), children (Administration for Children and Families), and Native Americans (Bureau of Indian Affairs), and government health insurance programs (Centers for Medicare and Medicaid Services) (USDHHS, 2006). Figure 6.3 is the organizational chart for USDHHS.

Another cluster of service departments addresses special programs or problems. Examples are the Department of Labor, the Department of Education, the Department of the Interior, the Department of Agriculture, and the Department of Transportation. A final cluster of federal agencies focuses on international health concerns of interest to the nation. Two important ones are the U.S. Agency for International Development (USAID), an independent agency, and the Office of International Health Affairs, under the Department of State (Turnock, 2004).

### **Budgets and Funding for Public Health**

Annually, only 8% of health spending goes toward health promotion and improvement, while 92% is spent for medical care (Trust for America's Health, 2005). Actual government spending for public health is estimated at only 3% of total U.S. health spending (Sensenig, 2007). In 2000, the state and local levels contributed about 70% of spending for public health service. Federal funds for public health are more often directed toward research, health status monitoring, program evaluation, and workforce training (Turnock, 2004). In 2004, the CDC spent just under \$15 per capita, with individual state spending ranging between just above \$9 to almost \$46 per person (Trust for America's Health, 2005). The sum is paltry considering that total current per capita annual health expenditure well exceeds \$6,100 (Colliver, 2007). This disproportionate funding for health continues despite estimations that more “robust” public health funding would provide the following benefits:

- ◆ Prevent 43,000 amputations, 165,000 kidney failures, and over 10,000 cases of eye disease among diabetics every year
- ◆ Reduce annual traffic deaths by 9,000
- ◆ Reduce, by 50%, new cases of HIV (40,000 annually)
- ◆ Reduce the number of alcohol-exposed fetuses by two-thirds
- ◆ Eliminate childhood lead poisoning by the year 2010 (Trust for America's Health, 2005, p. 7)

Most of the Healthy People 2010 goals remain unmet, and strategies for wide scale change and capturing of sufficient funding have not materialized. The Public Health Foundation (n.d., ¶1) estimates that “2 million deaths may occur this decade . . . as a result of not meeting only nine of the Healthy People 2010” objectives. But, in addition to health promotion, public health services must be ready for disasters, bioterrorism, and pandemics, and evidence is mounting that the system is structurally weak and suffers from poor access and inconsistent preparation (CDC, 2002, 2008; Institute of Medicine, 2002). To meet the necessary standards and immediate needs, an estimated \$10 billion plus in new funding is required (Public Health Foundation, 2007).

### **Private Sector Health Services**

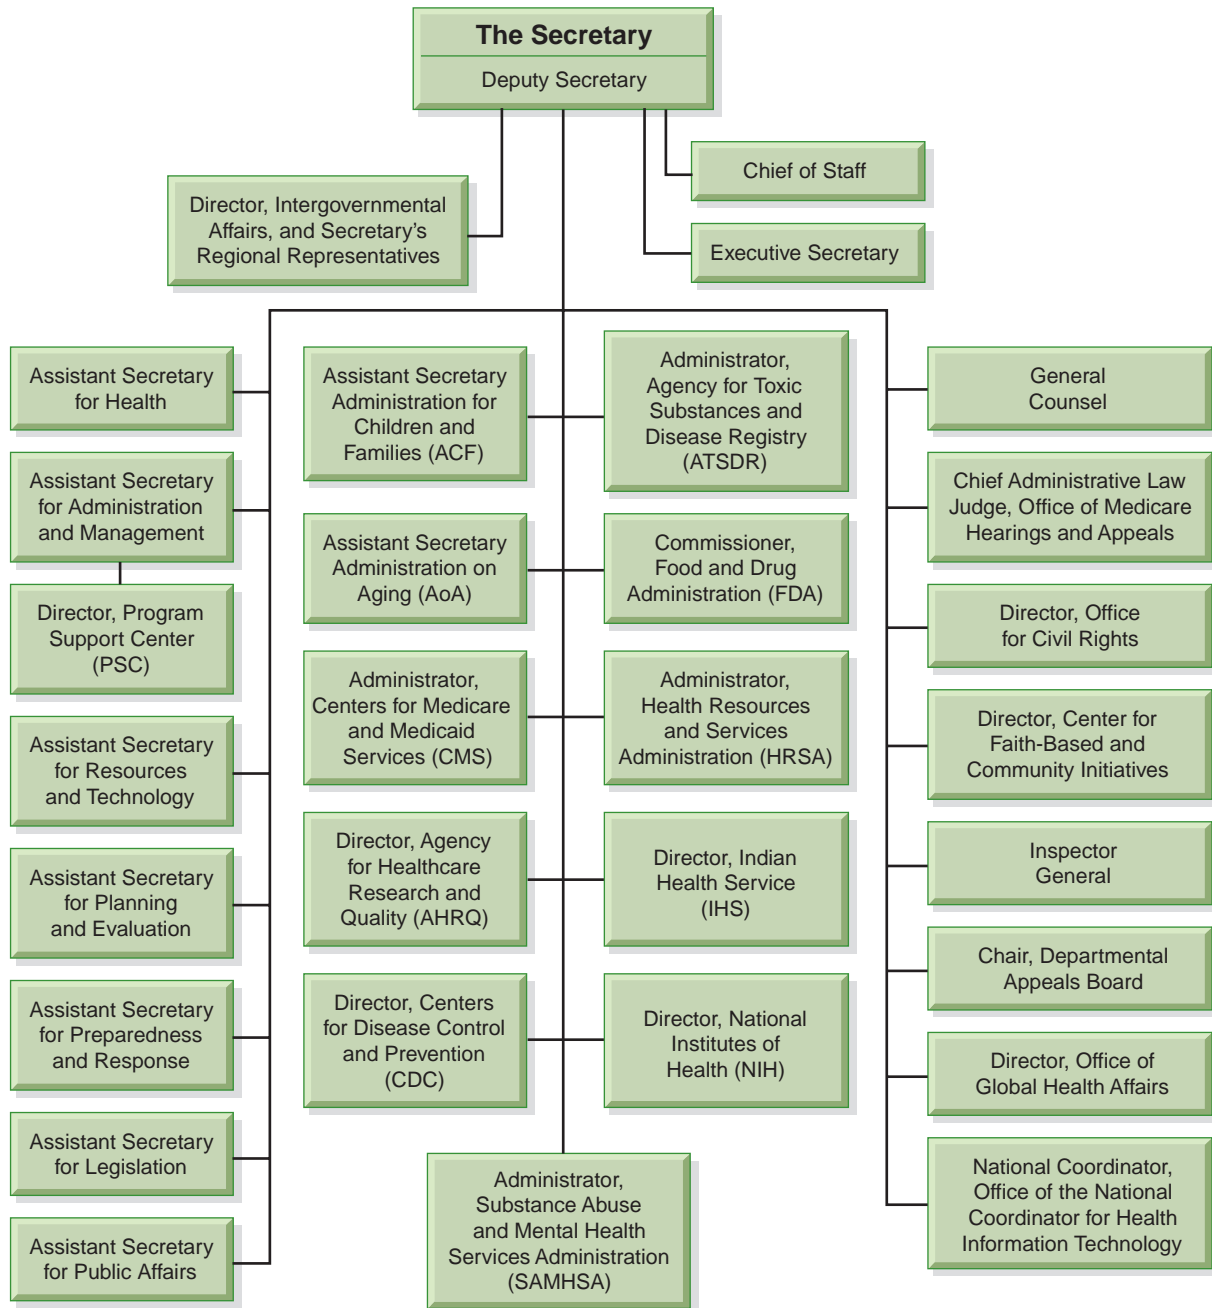

The nongovernmental and voluntary arm of the health care delivery system includes many types of services. Privately owned, nonprofit health agencies (most hospitals and welfare agencies) make up one large group. Privately owned (proprietary), for-profit agencies are another. Private professional health care practice, composed largely of physicians in solo or group practice, forms a third group. These make up the non-tax-supported, nongovernmental dimension of community health care.

Private health services are complementary and supplementary to government health agencies. They often meet the needs of special groups, such as those with cancer or heart disease; they offer an avenue for private enterprise or philanthropy; they are less constrained than government agencies in developing innovations in health care; and they have been spurred to development, in part, by impatience or dissatisfaction with government programs. Their financial support comes from voluntary contributions, bequests, or fees (Scutchfield & Keck, 2003).

### **For-Profit and Not-for-Profit Health Agencies**

**Proprietary health services** are privately owned and managed. They may be nonprofit or for-profit. Many hospitals and nursing homes offer nonprofit services, but must generate sufficient revenues to keep ahead of operating costs. Often, one or more special services offered by a hospital generate enough income to cover the drain from more expensive programs or uncompensated care. As more hospitals have merged or been integrated into larger health conglomerates, the practice in many cases has been to establish a separate, for-profit corporation that generates revenues so that the basic organization can retain its nonprofit, tax-exempt status.

**FIGURE 6.3** Department of health and human services organizational chart, September 27, 2006.

Examples of for-profit health services include a wide range of private practices by physicians, nurses, social workers, psychologists, and laboratory and radiology technologists. With the greater demand for home care services since the 1980s, the number of new, for-profit services (e.g., home care agencies, nursing personnel pools, and durable medical equipment supply companies) increased dramatically. Medicare's annual costs for home care services per enrollee went from \$4 in 1969 to more than \$300 by the late 1990s (Tyson, 2001). Partially in response to these escalating home care costs to Medicare, the Balanced Budget Act of 1997 was passed, and payments for home health care services to the elderly dropped by 12.5% annually through

the year 2000 (Meara, White, & Cutler, 2004). Even with these budget adjustments, average total Medicare expenditures grew from \$5,080 per person in 1991 to \$7,310 in 2001 (Congressional Budget Office, 2005).

Not-for-profit private health agencies are organizations that are established and administered by private citizens for a specific health-related purpose. Often, this purpose is seen as a special need either not addressed or served inadequately by government. An example is visiting nurse associations, which were formed to provide care for the sick in their homes. The contribution of the private, not-for-profit health agency then becomes complementary to public health services.

Three types of private, not-for-profit health agencies have specialized interests. Some, such as the American Cancer Society and the American Diabetes Association, focus on specific diseases. Others, such as the National Society for Autistic Children, Planned Parenthood Federation of America, and the National Council on Aging, focus on the needs of special populations. A third group, including agencies such as the American Heart Association and the National Kidney Foundation, are concerned with diseases of specific organs. All of these agencies are funded through private contributions.

Another group of private, not-for-profit agencies affecting health and health care includes the many foundations that support health programs, research, and professional education. Examples include the W.K. Kellogg Foundation, the Pew Charitable Trusts, the Robert Wood Johnson Foundation, and the Bill and Melinda Gates Foundation. Some agencies, such as the United Way, exist to fund other voluntary efforts.

Another group includes professional associations that work to improve the public's health through the promotion of standards, research, information, and programs. Examples are the APHA, the National League for Nursing (NLN), the ANA, and the American Medical Association (AMA). These organizations are funded primarily through membership dues, bequests, and contributions.

### Functions of Private-sector Health Agencies

The general functions of private-sector health agencies are as follows:

- ◆ Detecting unmet needs or exploring better methods for meeting needs already identified
- ◆ Piloting or subsidizing demonstration projects
- ◆ Promoting public knowledge
- ◆ Assisting official agencies with innovative programs not otherwise possible
- ◆ Evaluating official programs and assuming a public advocacy role
- ◆ Promoting health legislation
- ◆ Planning and coordinating to promote collaboration among voluntary services and between voluntary and official agencies
- ◆ Developing well-balanced community health programs that seek to make services relevant and comprehensive

Both public and private agencies are needed to maintain a viable public health system (Porche, 2004). Future functions of both private and public sectors most likely will remain much the same. However, the structure of the organizations within both sectors is changing dramatically and will continue to do so as managed care organizations blur the lines between private and public sectors. The blurring of the private and public health care sectors has opened the doors to emerging creative health care services.

## INTERNATIONAL HEALTH ORGANIZATIONS

The health of countries around the world cannot be ignored. Besides important humanitarian and moral concerns, there are pragmatic reasons for addressing health issues at the

international level. Today, health—along with politics and economics—has become a global issue. Health care among most of the world's population continues to be based on traditional medicine. At the same time, technology is revolutionizing health practices via distance education, training, and telemedicine. The nations of the world depend on one another for goods and services, and, as in any set of interdependent systems, a problem in one nation has repercussions on others (Jamison et al., 2006).

As stated in the 2002 executive summary of the Pan American Health Organization (PAHO), *Health in the Americas*, “new information technologies have played an invaluable role in improving access to and the quality of health care, as well as in the organization, administration, and operation of new health services models being introduced in the Region [the Americas, the United States, Central and South America]” (p. 14).

It may not seem possible that the health of a resident of a country 9,000 miles away can affect that of a student from the United States or vice versa; however, when boarding an international flight for a school holiday, the student will likely be seated among people from many nations. Despite close scrutiny of airline passengers for passports, visas, customs regulations, weapons, and drugs, how can anyone know whether any passenger sitting near the student has an airborne communicable disease that is resistant to known antibiotics? (See From the Case Files I.)

International cooperation in health dates back to early concerns for epidemics. In 1851, representatives from 12 countries met in Paris for the First International Sanitary Conference. They later established a more permanent organization, the Office Internationale d'Hygiene Publique, in 1907. Epidemics in the Western Hemisphere also prompted representatives from 21 American republics to meet for the First International Sanitary Conference in Mexico City in 1902. In that same year, the International Sanitary Bureau was formed and, later, renamed the Pan American Health Organization (PAHO) (Geneva Foundation for Medical Education & Research, 2007). (See Chapter 16 for more on global health.)

## World Health Organization

The World Health Organization (WHO), an agency of the United Nations, was developed to direct and coordinate the promotion of health worldwide. It was formed after World War II, in 1948, and assumed the functions of the League of Nations's health organization. The PAHO remained separate but became the WHO regional office for the Americas. The WHO began with 61 member nations, one of which was the United States. By 1998, membership had expanded to 193 nations and two associate members (WHO, 2007a). The mission of the WHO is to serve as the one directing and coordinating authority on international health. From its inception, the WHO has influenced international thinking with its classic definition of health as “a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity” (Grad, 2002, p. 984). The primary function of the WHO is to help countries improve their health status and services by assisting them to help themselves and each other. To accomplish this, it provides member countries with technical services, information from epidemiology and statistics reports, advisory and consulting services, and demonstration teams.

## From the Case Files I

### Medication-Resistant Tuberculosis

In 2007, the Centers for Disease Control and Prevention (CDC) ordered federal isolation (or quarantine)—something it hadn't done since 1963—for a 31-year-old Atlanta lawyer diagnosed with tuberculosis (TB). In his initial examination, Andrew Speaker says he was told he had TB but was “not contagious or a danger to anyone” and was not forbidden to fly to Greece and Europe for his wedding and honeymoon, but rather told by county health officials that they preferred that he didn't fly (*Toronto Star*, 2007, p. 5). While he and his new wife were honeymooning, lab test results revealed that he had an extensively drug resistant (XDR) strain of tuberculosis, and the CDC warned him not to take another long flight home. However, he and his wife disregarded this admonition, flying back to Canada on Czech Air and then “sneaking” across the border to the United States. He was quarantined a day later and sent to National Jewish Medical and Research Center in Denver, Colorado—a hospital with a long history of TB research and treatment. Several months later, new tests showed that his sputum samples were positive for multi-drug resistant (MDR) TB, with no signs of the XDR TB first noted on bronchoscopy samples. MDR TB is less resistant to antituberculosis medications and requires less intensive treatment than XDR TB (although it sometimes requires surgical removal of diseased sections of the lung). The CDC recommended that fellow travelers on Mr. Speaker's transatlantic flights have TB tests to determine if they contracted the disease. Although a number of lawsuits have been filed, no TB cases have been reported (Hitti, 2007). This incident brought TB to the forefront and reinforced the concept of the world as a global community.

For 20 years, the WHO had a realistic expectation that by the year 2000, no individual citizen in any country would have a level of health below an acceptable minimum, and that the global community would later adopt a new strategy to take people further toward the goal of health for all in the future (WHO, 1998). The target date of the year 2000 was intended as a challenge to the member nations. Although the goal has not been met entirely, WHO continues to focus on environmental health, control of infectious and diarrheal diseases, maternal and child health care, poverty and hunger, and education (WHO, 2007b). These emphases point to a change in focus from primarily reactive programs (e.g., stopping epidemics, instituting quarantines) to the more proactive promotion of health for the world community.

Headquartered in Geneva, Switzerland, WHO has six regional offices. The Regional Office for the Americas is located in Washington, D.C. (WHO, 2007c). The other regional offices are in Copenhagen, Denmark (Europe), Alexandria, Egypt (Eastern Mediterranean), Brazzaville, Congo (Africa), New Delhi, India (Southeast Asia), and Manila, Philippines (Western Pacific). Funding comes from member countries and from the United Nations. The WHO holds an annual World Health Assembly to discuss international health policies and programs. The organization publishes several periodicals of interest to the global community, which are available by subscription for a fee and in partial text through WHO's various websites [www.who.int/publications/en/](http://www.who.int/publications/en/).

*Bulletin of the World Health Organization*—monthly  
*WHO Drug Information*—quarterly  
*Weekly Epidemiological Record*—weekly  
*Pan American Journal of Public Health*—monthly.

### Pan American Health Organization

The PAHO, the central coordinating organization for public health in the Western Hemisphere, is the oldest continuously

functioning international health organization in the world. Its budget comes from assessments contributed by member states, augmented by funds from WHO, the United Nations, and other sources, including private donations (PAHO, 2007a).

As WHO's regional office for the Americas, PAHO disseminates epidemiologic information, provides technical assistance, finances fellowships, and promotes cooperative research and professional education. Conferences convened by PAHO provide an opportunity for delegates from member nations to discuss issues of concern and plan strategies for addressing health needs. The most widely read journal published by PAHO is the *Pan American Journal of Public Health*, published monthly (PAHO, 2007b).

### United Nations International Children's Emergency Fund

Organized in 1946, the United Nations Children's Fund, now called the United Nations International Children's Emergency Fund (UNICEF), was established initially as a temporary emergency program to assist the children of war-torn countries. That focus has broadened, and UNICEF is now a permanent agency for promoting child and maternal health and welfare globally, through a variety of programs and activities, including provision of food and supplies to underdeveloped countries, immunization programs in cooperation with the WHO, disease control, prevention demonstrations, and, in particular, promotion of family planning in developing countries (UNICEF, 2007).

### United States Agency for International Development

Existing for more than 30 years, the U.S. Agency for International Development (USAID) lists goals of improving the health, education, and well-being of the populations of

developing countries. It is “an independent agency that provides economic, development and humanitarian assistance around the world in support of the foreign policy goals of the United States” (USAID, 2006, ¶1).

### Other International Health Organizations

Many other organizations deal with health concerns at the international level. The United Nations Educational, Scientific, and Cultural Organization (UNESCO) promotes “cooperation . . . in the fields of education, science, culture and communication” (UNESCO, 2007, ¶2). The World Bank addresses health problems through funding and technical assistance. The Food and Agriculture Organization (FAO) works to “defeat hunger” by providing information and technical assistance (FAO, 2007, ¶1). In addition to these international organizations, most developed countries have agencies that provide assistance, some in major proportions, to underdeveloped countries.

### SIGNIFICANT LEGISLATION

During the past century in the United States, an ever-widening sense of responsibility for health in the public sector led to passage of an increasing amount of health-related legislation. Some acts are of particular significance to the financing and delivery of community health services (see Display 6.1). Only after World War I and the Great Depression did the U.S. government enact significant legislation that affected the health and well-being of a wider range of citizens. Before that, legislation dealt with specific sectors of society (e.g., merchant seamen, mothers and infants).

In 1935, the Social Security Act ensured greater public health services and programs and provided retirement income to participating workers age 65 years and older. The act also included aid to dependent children and unemployment insurance (Social Security Administration, 2003). Later legislation provided federal support for expansion of hospitals; care for the mentally retarded; and research and support for heart disease, cancer, and stroke, as well as the training of health care personnel.

The landmark Medicare and Medicaid legislation moved the federal government deeper into the role of providing health care, especially for many elderly and poor people who, prior to this time, either could not get services or had to rely on charity care. More recent legislation, especially during President Reagan’s term, sought to contain health care spending, assure the quality of health care, promote national health objectives, and facilitate data collection and research (see Display 6.2). More recent laws have protected the confidentiality of health records and made it easier for workers to continue insurance coverage after being laid off.

President Clinton made an attempt at universal health care during his first term in office and supported legislation to reform the welfare system. In 1997, the State Children’s Health Insurance Program (SCHIP) was created to expand coverage to uninsured children at no or low cost (USDHHS, 2007). President George W. Bush added prescription drug benefits to Medicare and promoted Health Savings Accounts (HSAs).

### Development of the Current Health Care System

In 1900, a total of 20% of infants died before they reached the age of 10, and life expectancy was about 47 years. Infectious diseases and poor sanitation and nutrition contributed to the poor outcomes. Physicians were not well trained, and the AMA had only 8,000 members (PBS, 2007). Hospital infection rates were high, and most care was given in the home—and then only to those who could afford to pay for it or those who received charity care. (See From the Case Files II.)

As the public health system acted to improve water supplies, sanitation, and personal hygiene, the incidence of infectious disease began to diminish. Antibiotics, first widely available during World War II, and better-trained physicians began to change the health care system in the 1950s—although medical and surgical care was not at all sophisticated by today’s standards. (See From the Case Files III.)

Since 1950, Americans have come to expect longer lives made possible by medications and treatments that can cure or control a wide variety of diseases and by expanding technology and services that provide a dizzying array of choices to health care consumers. These advances have come at a price, however. Health spending in 2006 represented 16% of the U.S. **gross domestic product (GDP)**—the total amount of goods and services produced within a year; whereas health spending in 1950 represented 4.5%. Viewed as a separate economy, U.S. health care today would be the fourth largest economy in the world and, by 2016, U.S. health spending is projected to exceed \$4 trillion (Gardner, 2007; Rice & Rhodes, 2002). Clearly, to gain a deeper understanding of this phenomenon, some basic concepts must be examined. For instance, what are the economic principles behind this rapid growth in health care costs?

### THE ECONOMICS OF HEALTH CARE

**Economics** is defined as the science of making decisions regarding scarce resources. Economics permeates our social structure—it affects and is affected by policies. Consequently, health is closely tied to economic growth and development, in that a healthy population is necessary for adequate national productivity. Ample evidence exists for a “health–income gradient,” as personal income (specifically poverty) is linked to health status (Aday, 2005, p. 191).

Health economics can be better understood by examining the two basic theories underlying the science of economics: microeconomics and macroeconomics. In addition, concepts of health care payment must be understood.

#### Microeconomics

**Microeconomic theory** is concerned with supply and demand. **Supply** is the quantity of goods or services that providers are willing to sell at a particular price. **Demand** denotes the consumer’s willingness to purchase goods or services at a specified price (Chang, Price, & Pfoutz, 2001). In our free market–driven economy, supply-and-demand is a key concept. Economists using microeconomic theory study the supply of goods and services as these relate to how we, as consumers, allocate and distribute our resources—as well as how markets compete. They further study how allocation and

## DISPLAY 6.1

## LANDMARK HEALTH CARE LEGISLATION

**The Shepard-Towner Act of 1921**

The Shepard-Towner Act of 1921 provided federal grant-in-aid funds to the states for administration of programs to promote the health and welfare of mothers and infants. The act expired in 1929, but it set a pattern for maternal and child health programs that later was revived and strengthened through the successful and far-reaching efforts of the Children's Bureau (now known as the Maternal and Child Health Bureau), housed in the Department of Labor. Through the leadership of this bureau, many programs were instituted that enhanced children's health. Among them were services targeting prematurity, perinatal mortality, nutrition, mental retardation, audiology, rheumatic fever, cerebral palsy, epilepsy, dentistry, juvenile delinquency, and the problems of migrant workers' children (Scutchfield & Keck, 2003). The Children's Bureau maintained its impact through several administrative changes (it was moved to the Federal Security Agency in 1946 and to the Department of Health, Education, and Welfare in 1953), but was phased out in 1972, when it became the Office of Maternal and Child Health. Now under the Department of Health and Human Services, it is known as the Maternal and Child Health Bureau (Ruhl, 2007).

**The Social Security Act of 1935**

The Social Security Act of 1935 had tremendous consequences for public health. In addition to its revolutionary welfare insurance and assistance programs, which particularly benefited high-risk mothers and children, Title VI of the act financially assisted states and localities in providing public health services. These funds were and still are allocated on the basis of population public health problems, economic need, and need for training of public health personnel. Many of the grants had to be matched by the states or localities. This served to increase their knowledge of and commitment to health programs. The act strengthened local health departments and health programs in most states (Scutchfield & Keck, 2003; Social Security Online, 2007). Most commonly, this act is known for retirement benefits for those over age 65, but it also provides aid for dependent children and unemployment insurance (Social Security Administration, 2003). In 2007, over 50 million Americans will receive more than \$602 billion in benefits; the vast majority of recipients are retired workers (Social Security Administration, 2007a; 2007b).

**The Hill-Burton Act (Hospital Survey and Construction Act) of 1946**

The Hill-Burton Act of 1946 was an important breakthrough in nationwide health facilities planning. It marked the first real effort to link health planning with population needs on a comprehensive basis. The act provided federal funds to states for hospital construction (about one-third of the total cost). It helped to provide access, especially in rural areas, to acute care services, but did not address public health or preventive care. It also required participating hospitals to provide services to residents, such as "community services," regardless of "race, color, national origin, or creed" (USDHHS, 2006, ¶2).

Emergency services were to be provided "without regard to the person's ability to pay" (¶1). A 1961 medical facilities bill expanded grant money to states for public health services, nursing homes, and planning for hospitals, as well as for outpatient services for elderly and chronically ill. Expenditures for this act ended in 1975, but it has provided close to 500,000 hospital beds, and has had a lasting effect on the U.S. health care system. Few people remember that this bill was sponsored by the American Hospital Association in response to a proposal by President Harry Truman to add a comprehensive medical insurance program to Social Security—an effort to provide universal health coverage (Brookings Institution, 2007; Perlstadt, 1995).

**The Maternal and Child Health and Mental Retardation Planning Amendments of 1963**

Although the Social Security Act of 1935 provided for some services for "crippled children," the Maternal and Child Health and Mental Retardation Planning Amendments of 1963 opened the door for improved services to selected mothers and children. Recognizing the nation's high infant mortality rate and the accompanying problems of premature births, handicapping conditions, and mental retardation, Congress—through this law—authorized grants to fund projects offering comprehensive care to high-risk, low-income mothers and children. It also provided grants to states to design comprehensive programs addressing mental retardation (National Center for Education in Maternal & Child Health, 2007).

**The Heart Disease, Cancer, and Stroke Amendments of 1965 (PL 89-239)**

The Heart Disease, Cancer, and Stroke Amendments of 1965 are noteworthy for their establishment of regional medical programs, one of the first real efforts at comprehensive health planning. Fifty-six regions in the United States were designated, and each was charged with the responsibility to evaluate the overall health needs of its region and cooperate with other regions for program development. Although the amendments initially were categorical (limited to heart disease, cancer, and stroke), amendments in 1970 expanded the legislation's focus. The act was important for two additional reasons: it encouraged local participation in health planning, which was previously done at federal and state levels, and it funded program operations and planning (National Library of Medicine, 2003).

**The Social Security Act Amendments of 1965 (PL 89-97)**

The Social Security Act Amendments of 1965 addressed a concern for some version of national health insurance. Title XVIII, Medicare, provided federally funded health insurance for the elderly (65 years and older) and for disabled persons. Title XIX, Medicaid, is a joint federal-state welfare assistance program that serves the blind, certain families with dependent children, the disabled, and eligible elderly. These two pieces of legislation have enabled many of the poor, disabled, and elderly to receive quality

*(text continues on page 140)*

health care that otherwise would not be available to them (Scutchfield & Keck, 2003; Williams & Torrens, 2002).

### **The Comprehensive Health Planning and Public Health Service Amendments Act (Partnership for Health Act) of 1966 (PL 89–749)**

The Partnership for Health Act of 1966 promoted further advances in comprehensive health planning. It established comprehensive health planning agencies and coordinated the many categorical health and research efforts into an integrated system. It emphasized comprehensive health planning and cost containment at local, state, and regional levels. Its goals were improved efficiency and effectiveness of health care, and it also provided for some public health services and training (Brookings Institution, 2007).

### **The Health Manpower Act of 1968 (PL 90–490)**

The Health Manpower Act of 1968 increased the supply of health personnel by providing federal money to educational institutions for construction, training, special projects, student loans, and scholarships. This act replaced several previous acts that had similar goals but resulted in only fragmentary efforts to address the problem. Among them were the Health Amendment Acts of 1956, the Nurse Training Act (1966), and the Allied Health Professions Personnel Training Act (1966). In 1976, Congress passed the Health Professions Education Assistance Act (Pub. L. No. 94–484) to effect a better balance between the country's health needs and the supply of available health professionals. One of its major emphases was to address the problem of physician maldistribution between underserved (rural) and overserved (urban) areas through educational incentive programs (National Institutes of Health, 2007). The Health Professions Education Extension Amendments (1992) also provided educational assistance to many in the health professions (Duffy, Chen, & Sampson, 1998).

### **The Occupational Safety and Health Act of 1970 (PL 91–956)**

The Occupational Safety and Health Act of 1970 provided protection to workers against personal injury or illness resulting from hazardous working conditions. It established the National Institute for Occupational Safety and Health (NIOSH) and OSHA—the Occupational Safety and Health Administration (U.S. Environmental Protection Agency, 2007).

### **The Professional Standards Review Organization Amendment to the Social Security Act of 1972 (PL 92–603)**

The Professional Standards Review Organization (PSRO) Amendment to the Social Security Act of 1972 had two goals: cost containment and improved quality of care. The PSRO legislation created autonomous organizations, external to hospitals and ambulatory health care agencies, to monitor and review objectively the quality of care delivered to Medicare and Medicaid patients. The PSRO review boards, composed mostly of physicians, examined such things as need for care, length of stay, and quality of care against predetermined standards developed locally. Failure to meet standards could mean

denial of federal funding. In 1983, Professional Review Organizations replaced PSROs. These private organizations, employed by government agencies to review medical records and avoid excessive and inappropriate costs to taxpayers, strive to identify “best practices” (Dranove, 2000).

### **The Health Maintenance Organization Act of 1973 (PL 93–222)**

In a cost-controlling move, the Health Maintenance Organization Act of 1973 added federal support to the concept of prepayment for medical care. President Nixon, a proponent of wage controls, was concerned about the rising costs of health care for employers and citizens. Congress authorized funding for feasibility studies, planning, grants, and loans to stimulate growth among qualifying health maintenance organizations (HMOs). In addition, this act required a business employing 25 people or more to offer an HMO health insurance option, if available locally. A subsequent law, the Employee Retirement Income Security Act (ERISA), passed in 1974, served to protect HMOs from many malpractice lawsuits, even though the intent of the law was to standardize employee benefit laws among the states (Wood, 2001).

### **The National Health Planning and Resource Development Act of 1974 (PL 93–641)**

The National Health Planning and Resource Development Act of 1974 was a major breakthrough in comprehensive health planning. Replacing the Partnership for Health Act, it combined Hill-Burton, comprehensive health planning agencies, and regional medical programs into a single, new program. It fostered not only comprehensive health planning, but also regulation and evaluation, and it promoted collaborative efforts among regional, state, and federal governments. An important contribution of this act was its emphasis on consumer involvement in health planning. The act was divided into two titles. Title XV, National Health Planning and Development, established national health priorities and assisted the development of area-wide and state planning through Health Systems Agencies (HSAs) and state health planning and development agencies. Title XVI, Health Resources Development, coordinated health facilities planning with health planning, replacing the Hill-Burton Act. The HSAs set targets and limited services, reviewing certificates of need (CON) for all health care facilities seeking to expand. If a facility expanded without HSA approval, its Medicaid and Medicare reimbursements could be denied. Because many providers were members of the HSA and supported each other's projects, and others learned to “work the system,” these cost-control systems failed to produce the desired results and were ended during the Reagan era (Dranove, 2000).

### **The National Center for Health Statistics of 1974 (PL 93–353)**

The National Center for Health Statistics (NCHS), established in 1974, arose from the earlier National Office of Vital Statistics and became part of the Centers for Disease Control (CDC) under the Public Health Service in 1987. The NCHS operates data collection systems that provide

vital information for public health planning and service delivery (National Committee on Vital and Health Statistics, 2000).

### **The Omnibus Budget Reconciliation**

#### **Act of 1981 (PL 97–35)**

The Omnibus Budget Reconciliation Act (OBRA) of 1981 had a profound effect on public health. In this act, Congress halted the progress made in most of the public health laws of the previous 45 years, substantially reducing their funding authorization. To shift more power to the states and reduce the budget, the Reagan administration consolidated categorical grants into four block grants (Centers for Medicare and Medicaid Services, 1981). The first block grant targeted general preventive health services; the second addressed alcohol, drug abuse, and mental health; the third focused on maternal and child health; and the fourth addressed primary care, which covered federal support for community health centers. Although block grants provide some advantages, these came with limiting restrictions on the amount and use of the funds. The result was a significant reduction in funding for state and local health programs, but states worked to better coordinate health promotion and disease prevention (Scutchfield & Keck, 2003).

#### **The Social Security Amendments of 1983 (PL 98–21)**

The Social Security Amendments of 1983 became law in response to accelerating health care costs. The act represented a major reform in health care financing from retrospective to prospective payment. It introduced a billing classification system consisting of 467 diagnosis-related groups (DRGs), with Medicare payments provided to hospitals based on a fixed rate set in advance (Social Security Online, 2007). The fixed payment could not be increased if hospital costs for care exceeded that amount. Conversely, if costs were less than the paid amount, the hospital could keep the difference. Thus, a positive incentive was introduced to reduce hospital costs and promote timely patient discharge (Institute of Medicine, 2001).

### **The Consolidated Omnibus Budget**

#### **Reconciliation Act of 1985 (PL 99–272)**

The Consolidated Omnibus Budget Reconciliation Act (COBRA) of 1985 extended the Medicare prospective payment system. The act also expanded Medicaid services and permitted states to offer hospice services to terminally ill recipients (CMMS, 1985). It also authorized demonstration projects to determine the effectiveness of health promotion and disease prevention services for Medicare recipients. The 1990 extension of this act mandated longer-term evaluation of the demonstration projects. Results of the experimental design showed a 12% improvement in self-reported health status and better results in the areas of exercise, seat belt use, recent mammograms, and alcohol consumption (Gale Group, 2004).

### **Omnibus Budget Reconciliation**

#### **Act Expansion of 1986 (PL 99–509)**

The OBRA Expansion of 1986 extended the prospective payment system for hospital outpatient services, and

required certain employers to provide extended (eventually up to 36 months) group-rate insurance coverage for laid-off workers and their dependents. This expense is paid by the former employee, but cannot exceed 102% of the cost for other employees (U.S. Department of Labor, 2007). In 1989, a further OBRA expansion regulated fee schedules for physicians and mandated other measures to attempt to slow the growth in both Medicare and Medicaid (Kaiser Family Foundation, 2007b). Also under OBRA 1989, nursing home reforms were instituted, and the Agency for Health Care Policy and Research was established to study the effectiveness of health care services.

### **The Medicare Catastrophic Coverage**

#### **Act of 1988 (PL 100–360)**

The Medicare Catastrophic Coverage Act (MCCA) of 1988 expanded Medicare benefits significantly. Coverage was extended to include a portion of outpatient prescription drug costs and greater post-hospital extended care facility and home health benefits. Also, the MCCA set limits on beneficiary liability and provided increased inpatient hospital benefits, as well as set up a commission to examine the possibility of providing long-term care benefits through Medicare (Kaiser Family Foundation, 2007b). In 1989, a second MCCA rescinded the drug benefit and the limits on out-of-pocket spending, among other things.

### **The Family Support Act of 1988 (PL 100–485)**

The Family Support Act of 1988 reformed the federal welfare system to emphasize work and child support. It established child support programs, work opportunities, and basic skill and training programs. It included a requirement that recipients seek employment and that states establish an education, training, and work program, along with the child care support. It established the Commission on Interstate Child Support to aid in locating absent parents and assure payment of child support. It also provided for paternity testing and withholding of wages in cases in which child support was in arrears (Office of Inspector General, 1989).

### **The Health Objectives Planning Act of 1990**

#### **(PL 101–582)**

The Health Objectives Planning Act of 1990 was significant for its support of the report by the Institute of Medicine, *Healthy People 2000*, with funding to improve the health status of the nation. Funding for health promotion and disease prevention was added in the 1991 legislative session (Centers for Disease Control & Prevention [CDC], 1991). Ten years later, *Healthy People 2010* followed.

### **Preventive Health Amendments of 1992 (PL 102–531)**

The Preventive Health Amendments of 1992 placed a focus by the federal government on preventive health and primary prevention initiatives. It added *prevention* to the CDC (now the Centers for Disease Control and Prevention). It enhanced services to Migrant Health Centers, especially in maternal and child health and community education, as well as lead poisoning prevention. It promoted international exchange programs for public health

officials from around the world who have an interest in working in another country (Woolley & Peters, 2007).

#### **Personal Responsibility and Work Opportunity Reconciliation Act of 1996 (PL 104–193)**

The Personal Responsibility and Work Opportunity Reconciliation Act of 1996 is commonly known as the “Welfare Reform Bill.” It amended the Social Security Act to reform the federal welfare system, imposing a 5-year lifetime limit on welfare benefits. It ended Aid to Families with Dependent Children (AFDC) and enacted Temporary Assistance to Needy Families (TANF). It provided child care to working parents or those receiving training or education, and required unmarried minor parents to live with their parents or another responsible adult and attend school or training programs in order to receive government assistance. Finally, it restricted benefits to legal immigrants (Administration for Children & Families, 2008). As aid to children and families is usually tied to Medicaid benefits, this legislation affected health by moving people off welfare rolls and onto payrolls—but often at minimum-wage jobs without insurance benefits.

#### **Health Insurance Portability & Accountability Act (HIPAA) of 1996 (PL 104–191)**

This landmark piece of legislation has two major components: one that provides protection for workers in group health insurance plans and another that protects the privacy of health records. It first became effective in 2001, with compliance dates set for 2003 and 2004 (for smaller health plans). It set national standards for protecting individually identifiable health information (including electronic health data), and limited exclusions for workers with preexisting conditions as well as prohibited discrimination based upon health status (Office of Civil Rights, 2003; U.S. Department of Labor, 2004). This legislation made it easier for people to obtain or keep health insurance.

#### **Nurse Reinvestment Act of 2002 (PL 107–205)**

The Nurse Reinvestment Act of 2002 addresses the nation’s critical shortage of nurses. Developed with support and

input from female legislators, the bill is well designed to address several issues contributing to the nursing shortage. It emphasizes a media campaign to promote the nursing profession, offers scholarships for nursing students who agree to work upon graduation in an agency facing a critical shortage of nurses, cancels student loans, provides grants to hospitals and other medical facilities that are willing to offer career incentives to nurses to advance in their field and to take on larger responsibilities for organizing and directing patient care, and includes strategies to attack the burn-out and frustration that are driving many people out of nursing. It also promotes career ladders, recruitment of minority students into nursing, increased interprofessional collaboration, encouragement of nurses to focus on community-based practices and to address the needs of vulnerable populations. It provides forgivable loans for new nursing faculty as well (Donley et al., 2002).

#### **Medicare Prescription Drug, Improvement, and Modernization Act of 2003 (PL 108–173)**

Commonly known as Medicare Part D, this voluntary program was added to Medicare Part A and Part B in 2003, and extended and improved coverage for beneficiaries beginning in January 2006 (Medicare Advocacy, 2007). Participants can enroll in one of over 100 private plans to be covered, unlike the original Medicare program that is administered through the federal government. The plans must offer the standard benefit package, or a comparable one. The 2007 deductible was \$265. Beneficiaries pay 25% of the cost of covered medications up to \$2,400, at which point they reach the *coverage gap* (or “donut hole”) and must pay for all covered medications above the set limit. After spending \$3,850 out-of-pocket in one calendar year, they reach *catastrophic coverage* and then pay only \$2.15 for covered generic medications (Medicare Advocacy, 2007). The annual enrollment period for Medicare Part D is from November 15 to December 31. Senior citizens can change plans or begin coverage during that time period.

distribution affect consumer demand for these goods and services. The concepts of supply and demand are influenced by each other and, in turn, affect prices. In a simplified example, an increase in, or oversupply of, certain products usually leads to less overall consumption (decreased demand) and, usually, lowered prices. The opposite also is true. Limited availability of desired products means that supply does not meet demand, and prices usually increase. An example is the price of a gallon of gasoline. When demand for oil is high and supply begins to dwindle, the prices go up. When demand drops and supplies become more plentiful, prices go down to attract more purchasers. This occurs as long as there are no monopolies to artificially control prices, or only a few choices for goods and services that inhibit competition.

In health care, demand-side policies are enacted to reduce demand for health care (e.g., raising insurance deductibles and co-payments), and supply-side policies restrict the supply of resources (e.g., preadmission screening to reduce the likelihood of insuring someone with a serious

health condition, denial of coverage for specific services, utilization of preferred providers who practice within boundaries set by insurance companies) (Nyman, 2003).

Microeconomic theory is useful for understanding price determination, resource allocation, consumer income, and spending distribution at the level of individuals and organizations (Aday, 2005). Microeconomic theory comes into play when health care competition increases, because the success of the supply-and-demand concept depends upon a competitive market. Issues such as cost containment, competition between providers, accessibility of services, quality, and need for accountability continue as targets of major concern in the 21st century.

### **Macroeconomics**

**Macroeconomic theory** is concerned with the broad variables that affect the status of the economy as a whole. Economists using macroeconomics study factors influencing

## DATA COLLECTION SYSTEMS

### The National Center for Health Statistics Data Collection Systems

Some collection systems of the National Center for Health Statistics (NCHS) are ongoing annual systems, and others are conducted periodically. There are two major types of data systems: those based on populations (these data are collected by personal interview and examination) and those based on records, with data collected from vital and medical records.

#### National Health Interview Survey

The National Health Interview Survey (NHIS) is a continuous nationwide survey of illness and disability. It is the main source of data on the health of the U.S. population (nonmilitary, noninstitutionalized). This survey, which monitors the health of the nation, has been conducted since 1957.

#### National Health and Nutrition Examination Survey

The National Health and Nutrition Examination Survey (NHANES) provides physical, physiologic, and biochemical data related to nutrition of national population samples. Conducted for over 40 years, NHANES provided data that led to the development of pediatric growth charts, vitamin fortification of grains and cereals, and phasing out of lead-based gasoline. It also provided information about the link between cholesterol and heart disease and information on smoking, bone density, obesity, and changes in diet over time.

#### National Health Care Survey

The National Health Care Survey (NHCS) is a series of surveys of providers that yields clear information about health care services, patients, organizations, and providers.

##### *Ambulatory Health Care Data (NAMCS/NHAMCS):*

Gathers data from physicians on ambulatory services by specialty and target population

##### *Hospital Discharge and Ambulatory Survey Data:*

Provides annual data on such things as length of stay, diagnosis, procedures performed, and patient use patterns

*National Home and Hospice Care Survey:* Administrators and staff are personally interviewed to retrieve information about patients and discharges

*National Nursing Home Survey:* Collects data about nursing home services, staff, and residents regarding need, level of care, costs, and use patterns

##### *National Employer Health Insurance Survey:*

Provides estimates on employer-sponsored health insurance, the types of plans provided, and detailed information about the plans

#### National Vital Statistics System

The National Vital Statistics System is the oldest survey and best example of public health intergovernmental data sharing. Vital statistics registries around the country provide uniform data to the national system on the following categories: births, marriages, divorces, deaths, and fetal deaths. Specific data are available through the following systems:

- Birth data
- Mortality data
- Fetal death data
- Linked birth/infant deaths
- National Mortality Followback Survey
- National Maternal and Infant Health Survey

#### National Survey of Family Growth

The National Survey of Family Growth (NSFG) assembles information on marriage and divorce, pregnancy, use of contraception, family life, infertility, and women's and men's health. The data is used to plan health programs and services.

#### National Immunization Survey

The National Immunization Survey is a list-assisted random-digit-dialing survey employed to gather information on vaccination coverage rates for children between the ages of 19 and 35 months. A mailed survey follows the telephone call, and this produces timely estimates of the rates of recommended vaccine doses.

#### The Longitudinal Studies of Aging

The Longitudinal Studies of Aging (LSOAs) are done as a collaboration between the National Center for Health Statistics (NCHS) and the National Institute on Aging (NIA). These studies measure changes in functional status, living arrangements, health, and the utilization of health services for persons age 70 and above. They involve two cohorts of Americans moving into old age and on to the oldest ages.

#### State and Local Area Integrated Telephone Survey

The State and Local Area Integrated Telephone Survey (SLAITS) collects in-depth data needed at state and local levels to meet the needs of program planners, policy makers, and government agencies. Some of the topics researched include access to care, utilization of services, health insurance coverage, perceived health status, and measurement of child well-being. The same random-digit-dialing method employed by NIS is utilized on a regional basis.

“aggregate consumption, production, investment and international trade, as well as inflation and unemployment” (Aday, 2005, p. 186). The focus is on the larger view of economic stability and growth. Macroeconomic theory is useful for providing a global or aggregate perspective of the variables affecting the total economic picture (Aday, 2005).

Macroeconomic theory has been useful in providing a large-scale perspective on health care financing, ultimately resulting in various proposals for national health plans, health care rationing, competition, and managed care. For instance, when the United States compares overall health spending with countries across the world, it becomes clear

## From the Case Files II

### 20th and 21st Century Hospital Care

At the turn of the 20th century, riots occurred in Milwaukee when a child suspected of having smallpox was to be taken to a local hospital by ambulance. One of the child's siblings had already died of smallpox in the same hospital, and his family did not want the second child to risk death at the same institution. A crowd of 3,000 or more people, carrying clubs, kept the ambulance attendants at bay. Why was there such concern about hospitalizing a sick child? In the 1890s, when this occurred, hospitals were rife with infection, and doctors could do little to halt its spread (Cutler, 2004).

In the early 21st century, are hospitals any safer? The Centers for Disease Control and Prevention (CDC) reports that over 1.7 million health care-related infections occur annually, resulting in almost 100,000 deaths (2007). Can you be assured of good care when you or your loved one enters a hospital emergency room (ER)? In the case of a busy trauma center located in South Los Angeles, you might have reason for concern. Martin Luther King/Drew Medical Center was created after the 1965 Watts Riot, and has a history of providing stellar neonatal care—95% of babies under 2 pounds survive—and excellent training for trauma surgeons—one-fourth of U.S. military surgeons have trained there (The Associated Press, 2004). But, numerous incidents of patients in the ER going untreated and unnoticed have been reported. In 2004, a 20-year-old art student entered the ER writhing in pain and vomiting. He was left alone in the crowded ER for 18 hours, while his heart rate climbed and his blood pressure fell. He was later found dead, having dropped to the floor covered in his own vomit—he died of gangrene of the bowel (The Associated Press, 2004). Another patient died in the ER after waiting 22 hours to be treated. The patient had a gangrenous leg, a pneumothorax, and was in kidney failure. In 2003, two patients died while on cardiac monitors, and the hospital blamed the lapse in care on the nursing shortage. Inpatient care was often no better, though, as a 46-year-old man admitted for meningitis was given chemotherapy medication for 4 days. Even after the pharmacy error was noted, nurses continued to give medications in error (at least 40 incidents). The patient subsequently lost vision in one eye. In 2007, a 43-year-old woman was admitted to the now-named Martin Luther King/Harbor Medical Center three times in 3 days complaining of intense stomach pain. Her diagnosis was listed as gallstones and she was prescribed pain medication and released each time. After the third discharge, she remained on the hospital grounds and was eventually taken to the ER by police, who were notified of a woman screaming for help. According to the police officers, the ER triage nurse refused to help the woman, and she lay on the floor in severe pain for almost an hour. She “spit up a dark-colored substance, which her boyfriend said was blood” and security cameras showed a janitor mopping around her as she lay in agony on the floor (Ornstein, 2007, p. 11). By fall 2007, after the federal government withdrew \$200 million in annual funding, the hospital closed its doors (Ornstein, Weber, & Leonard, 2007).

What is different about these two scenarios is the reaction of the public. In the last century, it was an angry mob trying to keep a child out of harm's way by not allowing ambulance personnel to take him to the hospital. In this century, it was the federal and local government who moved to close what was deemed an unsafe facility. Some in the community are happy to see the closure, especially those who lost loved ones to what they feel was substandard care. Others are sad to see a much-needed neighborhood medical center close—its ER saw almost 50,000 patients in 2006—and wonder where they can go now for care (Ornstein, Weber, & Leonard, 2007).

that we spend a large percentage of our GDP on health care—more than any other country, and we often have worse indicators of health (e.g., life expectancy, infant mortality) (University of Maine, 2001). See Figure 6.4 for a comparison of health care expenditure per capita among 10 industrialized countries.

The economics of health care encompasses both microeconomics and macroeconomics, and an intricate and complex set of interacting variables. Health care economics is concerned with supply and demand: Are available resources sufficient to meet the demand for use by consumers? Are the resources expended achieving the desired outcomes? When health care resources are scarce or insufficient to address all needs (for example for programs and services for at-risk populations), how should they be applied?

### Supply and Demand in Health Care Economics

When you purchase textbooks, for instance, you as the purchaser are able to determine the best value for your money (generally based on price, availability, and condition of the book). As a health care consumer, however, can you truly be an efficient and effective purchaser of health care goods and services? How does a patient determine what services are needed, where to buy them, and how to evaluate the quality of the goods and services—much less how to coordinate all necessary services? Does health care truly represent a competitive free market, then? For instance, when purchasing a new LCD flat-screen television, consumers often rely on word-of-mouth from friends and relatives, advice from experts, past experiences with brands, and

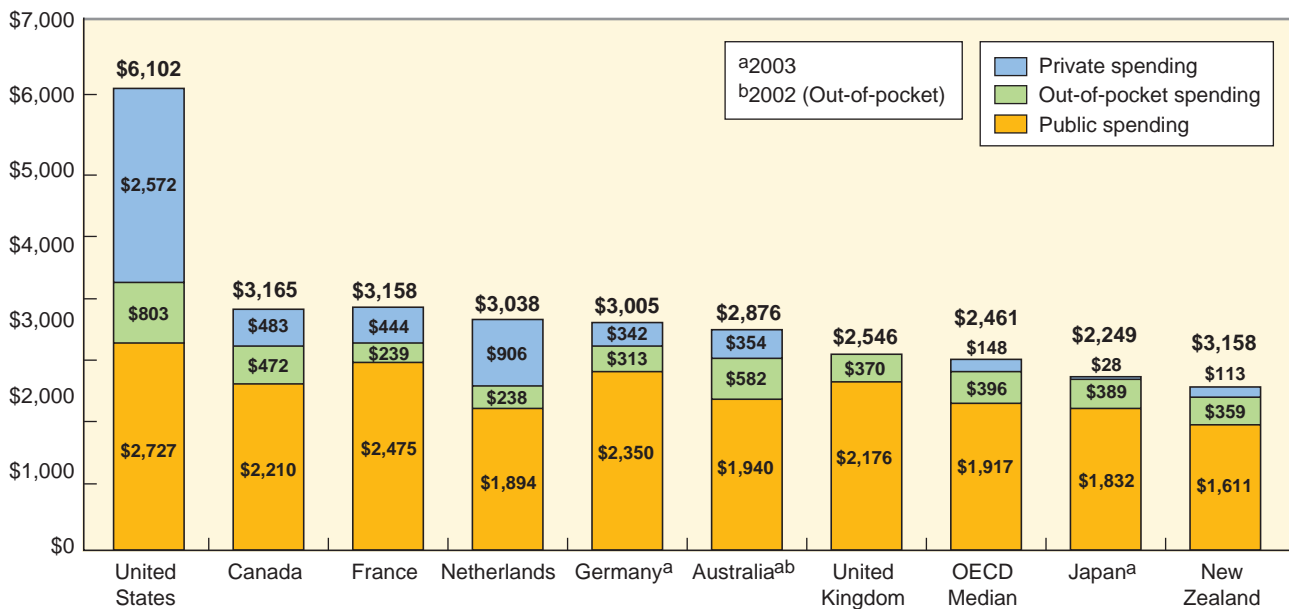

## From the Case Files III

### Care for Cardiovascular Patients

In 1950, the role that hypertension and high cholesterol levels played in heart disease was unclear. Only when someone presented with chest pain were they then monitored for blood pressure and cholesterol control. Doctors frequently recommended that their patients cut down on salt consumption and lose weight. They were also counseled to “slow down” and “rest around midday,” as there were essentially no effective medications to treat these two problems (Cutler, 2004, p. 50). It was not until the 1960s that the Framingham Heart Study confirmed that hypertension leads to cardiovascular disease, and oral antidiuretic medications were used to control it. In the 1950s and 1960s, epidemiologist Ancel Keys’ research revealed that high cholesterol intake was associated with cardiovascular disease. In the 1950s, cardiac patients were treated with absolute bed rest for a minimum of 6 weeks, morphine for pain, and oxygen. That was the state-of-the-art regimen prescribed for President Eisenhower after his heart attack in 1955 (Cutler, 2004).

Today, bed rest is known to promote blood clots, and is ineffective in treating myocardial infarctions (MIs)—or heart attacks. Quick, intensive therapy is the standard. Aspirin, heparin, beta ( $\beta$ )-blockers, and thrombolytic medications help to prevent and reduce blood clots, reduce the workload on the heart, and dissolve tiny clots in cardiac vessels (Cutler, 2004). Cardiac catheterization permits physicians to visualize arterial blockages. Percutaneous angioplasty to open the blocked arteries or coronary artery bypass graft (CABG) surgery is now routine. Well-trained emergency medical service personnel and specialized cardiac intensive care units with highly expert nurses are found in most communities. CPR is promoted and automated external defibrillators (AEDs), which are now placed in schools, shopping malls, government buildings, and other common spaces, have saved the lives of many victims of heart disease (AED.com, 2006; Cutler, 2004). Because of all of these advances in the last 50 years, post-MI death rates have dropped by 75%. Antihypertensive and cholesterol-lowering medications, along with healthier lifestyles that include no smoking, regular exercise, and diets low in sodium and saturated fats, have also reduced the rates of hypertension and hyperlipidemia. About 25% fewer people develop serious cardiovascular disease today than in 1950 (Cutler, 2004).

With all of these advances over the past half-century, it is reasonable to expect increased health care costs. In return, more lives have been saved and extended. But, how much can we afford to pay in the future? How many more new advances lie ahead? And, what will we receive in return for our investment?

**FIGURE 6.4** Health care expenditure per capita by source of funding in 2004: adjusted for differences in cost of living. (From Shea, Holmgren, Osborn & Schoen. [2007, May]. *Health system performance in selected nations: a chartpack*. As cited originally in Cylus & Anderson. [2007, April]. *Multinational Comparisons of Health Systems Data, 2006*. New York: The Commonwealth Fund, used with permission.)

rating services like *Consumer Reports*. Also, we most often plan for large purchases, like newer and bigger televisions, in advance.

With health care, this is seldom the case; health care is typically unpredictable and difficult to research. Even with the growth of health information (and sometimes misinformation) available on the Internet, physicians are still the system's main gatekeepers, and patients must trust that these care providers have the competence to appropriately diagnose and treat them, and coordinate necessary resources to provide quality health care. Further, they trust that physicians will put the patients' interests before their own (e.g., give them accurate information about risks and benefits and not induce them to have expensive procedures to enrich the provider) (Dranove, 2000; Newhouse, 2002). Now, enter health insurance companies and managed care into the mix, and you can see why health care purchases are not straightforward and easily understood. In a free-market system, competition is an important factor, but is competition truly possible with employer-based health insurance that limits the choice of plans and providers?

In 1963, economist Kenneth Arrow wrote an influential article about health care economics detailing the lack of information in the medical marketplace (cited in Newhouse, 2002). The main points of the article noted that consumers:

- ◆ Do not know when or if they will become ill—but they know they will need and want medical treatment, thus the demand for health insurance
- ◆ Do not know what services will be needed and what works best for their condition—thus the need for physicians
- ◆ Do not know about the quality of health care good and services—thus the need for government regulation (e.g., licensing, certification) and malpractice lawsuits
- ◆ Have an asymmetric level of information, compared to the insurer, about the likely demand for health care services, resulting in **adverse selection** (e.g., high-risk patients are denied insurance or care) and market failure (e.g., inefficiencies and lack of appropriate competition)—although this is less severe in large group insurance plans that spread out the risk

A fundamental problem of the health care economy is that it is difficult for any person or organization (e.g., patient, physician, health plan, government) to be “an efficient and effective purchaser of health care goods and services” (Dranove, 2000, p. 9).

One area of health care, however, that seems to more closely follow the free-market supply-and-demand model is LASIK eye surgery. The average cost of this surgery in 1998 was \$2,200 per eye. This dropped to \$1,350 in 2004 as over 3 million surgeries were performed. Many believe this is due to the lack of third-party reimbursement and the evidence of *consumer driven purchases* in response to advertising and competition (Tabarrok, 2004).

### Health Insurance Concepts

Conventional theories posit that people pay small premiums monthly to offset the risk of large medical bills should they become seriously ill. This represents an *indemnity policy*,

much like car or homeowners' insurance, and this is the type of health insurance first offered in the United States. In the past, patients could choose any doctor or hospital and submit the providers' bills to the insurance company for payment. “Moral hazard” is the term used by economists to explain how health insurance changes the behavior of people, resulting in more risk-taking and wasteful behaviors. They liken it to fire insurance without a deductible, noting that a person may be less careful about clearing brush from a house if it costs the owner nothing to have the home replaced. If a person has health insurance, many economists posit, they are less likely to take good care of themselves, and if they don't pay for their health care (through premiums, co-payments, deductibles), they are more likely to misuse it or overuse it (Gladwell, 2005). In other words, insurance has a paradoxical effect and often leads to wasteful and risk-taking behaviors. In this scenario, patients will demand expensive health care, even if it provides only the smallest benefit (Dranove, 2000). The concept of moral hazard is the reason behind larger deductibles and co-payments—it is an effort to control wasteful and excessive use of health care resources.

A newer theory states that consumers purchase health insurance not to avoid risk, but to earn a “claim for additional income (i.e., insurance paying for medical care) if they become ill” and that co-payments and managed care actually work against the system by reducing the amount of income transferred to ill persons or limiting their access to needed services (Nyman, 2003). Some economists argue that moral hazard doesn't accurately apply to health insurance, as even those with unlimited insurance coverage don't just “check into the hospital because it's free” (Gladwell, 2005, ¶11). Most people do not seek infinite numbers of colonoscopies or surgeries, for instance.

### Employer-sponsored Health Insurance

Currently, 63% of those under age 65 receive employer-sponsored health care (only 5% have private nongroup insurance), and in bad economic times, company downsizing and lay-offs lead many people to “feel they are only a pink slip away from being uninsured” (Brink, 2002, p. 63; Goldman & McGlynn, 2005). Many small businesses do not offer employee health insurance because of the high costs. Even Wal-Mart, one of the United States' largest employers, offers high-premium/high-deductible plans (with 6-month waiting periods for full-time workers) that more than half of their employees cannot afford—thus shifting costs to taxpayers because 60% of workers must rely on government insurance or other remedies (United Food & Commercial Workers International Union, 2007). The average Wal-Mart worker pays one-fifth of his paycheck for company health insurance coverage, as many of them work for the minimum wage for fewer than 40 hours per week.

The average worker contributed about 27% of the total cost of group insurance in 2004 (around \$10,000 for a family of four). Few people (between 5% and 7%) purchase individual insurance, and these small numbers have fallen even more over the past 15 years. Cost keeps many people from purchasing insurance; one study found that premiums for individual insurance rose 25% in a 7-year period (Goldman & McGlynn, 2005; 2006). The Kaiser Family Foundation

(2006a), in its 2006 Employer Health Benefits Survey, reported an 87% increase in premiums since 2000, and noted an increase to \$11,480 for the average family group policy, with the cost to workers at just under \$3,000 annually. However, the Foundation also noted that the increase in premiums for 2006 (7.7%) was down from the past 2 years (9.2% and 13.9%, respectively). See Figure 6.5 for trends in health insurance premium costs as compared to wages and overall inflation.

The most chilling fact is that a minimum-wage worker in 2005 earned an average of \$10,712, but the cost of an annual premium for a family of four averaged \$10,880—helping to explain the large number of uninsured Americans (Colliver, 2005). Employers are either not offering health insurance or are passing along the higher costs to employees in the form of higher employee premiums, deductibles, co-payments, and stricter enrollment requirements. According to a study by the Agency for Healthcare Research and Quality (Stanton & Rutherford, 2004), even though offers of workplace health insurance increased from 1996 to 2002, eligibility and enrollment rates dropped—mostly because of rising employee costs (e.g., over 65% increases in employee premium contributions). In 2003, about 5 million fewer jobs provided health insurance, even though employers shopped around for the best value and about one-third either changed insurance carriers or changed the type of insurance plan offered to employees (Gabel et al., 2004). The number of small companies offering health plans continues to decline, and state efforts to reform small-group health insurance have been relatively unsuccessful in increasing the numbers of employers offering coverage (Gabel et al., 2004; RAND Health, 2005).

About 25% of Americans who are insured are underinsured, and 33% report problems accessing medical care, as well as paying for it. They often exhaust their savings, run up credit card debt, or else delay necessary medical care to avoid going into debt (RAND Health, 2006; Forbes, 2007).

## SOURCES OF HEALTH CARE FINANCING: PUBLIC AND PRIVATE

Financing of health care significantly affects community health and community health nursing practice. It influences the type and quality of services offered, as well as the ways in which those services are used. Sources of payment may be grouped into three categories: third-party payments, direct consumer payment, and private or philanthropic support.

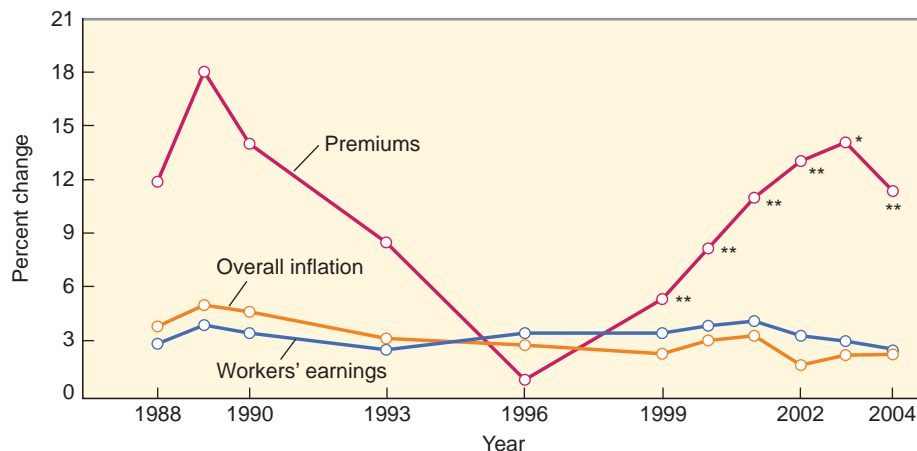

### Third-Party Payments

**Third-party payments** are monetary reimbursements made to providers of health care by someone other than the consumer who received the care. The organizations that administer these funds are called *third-party payers* because they are a third party, or external, to the consumer–provider relationship. Included in this category are four types of payment sources: private insurance companies, independent or self-insured health plans, government health programs, and claims payment agents (Harrington & Estes, 2004).

### Private Insurance Companies

Private insurance companies currently pay the majority of U.S. health care expenditures for those under age 65. They market and underwrite policies aimed at decreasing consumer risk of economic loss because of a need to use health services. Traditional indemnity health insurers have been experiencing decelerating growth for more than a decade as the result of a shift to lower-cost managed-care plans offered through employers. In 2006, only 3% of those under age 65 who were insured had this type of plan (Kaiser Family Foundation, 2006a).

There are three types of private insurers. First are commercial stock companies that sell health insurance, usually as a sideline. They are private, stockholder-owned corporations that sell insurance nationally; examples are Aetna,

**FIGURE 6.5** Increases in employer health insurance premiums compared with other indicators, selected years 1988–2004. Data on premium increases reflect the cost of health insurance premiums for a family of four. Statistical significance indicators denote that premium estimates are statistically from the previous year shown (\* $p < .10$ , \*\* $p < .05$ ). (From Gabel et al. [2004]. Health benefits in 2004: Four years of double-digit premium increases take their toll on coverage. *Health Affairs*, 23(5), 200–209, used with permission.)

Travelers, and Connecticut General (CIGNA). A second type of insurer operates in the national marketplace and is owned by policyholders—a *mutual company*. Examples are Mutual of Omaha, Prudential, and Metropolitan Life. The third type, *nonprofit insurance* plans, includes companies such as Blue Cross, Blue Shield, and Delta Dental. These operate under special state-enabling laws that give them an exclusive franchise to the whole state (or a part of it) and to a specific type of insurance. For example, traditionally, Blue Cross sold only hospital coverage; Blue Shield, only medical insurance; and Delta Dental, only dental insurance. Because they are nonprofit, they are tax exempt and, at the same time, subject to tighter state regulation than are the commercial health insurance companies. Combined, the nonprofit and commercial carriers have sold most of the private health insurance in the United States over the last decade (Lee, Estes, & Rodriguez, 2003).

A recent trend in private insurance is the move to consumer-directed or **consumer-driven health plans (CDHP)** and **health savings accounts (HSAs)**. Beginning in 2004, legislation provided for tax-exempt HSAs tied to high-deductible health insurance plans that can be rolled over yearly and move with the employee (Gabel, Pickreign & Whitmore, 2006). The high deductibles (e.g., over \$1,100 for an individual and over \$2,200 for a family) allow for lower premiums, but the attendant HSAs can only be used on medical expenses—nothing else—or tax-exempt status is lost and a penalty is also incurred (Mayo Clinic, 2007). Most plans require employees to pay a percentage of their total health costs (coinsurance, e.g., 20%)—not just a small co-payment per office visit or prescription as in many other plans. Some think that this improves **cost sharing**—whereby the insured assumes a greater share of health care costs, without a third-party payer intervening. Others think that this trend will not result in expanded coverage for the uninsured, and may lead to more employees forgoing health insurance offered by their employers (Glied & Remier, 2005).

Employers may or may not contribute to HSAs, and when they do, the cost savings in premiums are nullified and the accounts usually cannot be moved to a new employer. Only about 4% of workers are enrolled in these types of plans, and 39% of those who did enroll in 2006 had no other choice of health plan. When given a choice, few workers have chosen CDHPs, even though premiums are lower than for any other type of plan (Gabel, Pickreign, & Whitmore, 2006). See Table 6.4 for a comparison of premium costs for CDHP and other forms of health insurance.

A large-scale study of the effect of cost on compliance with antihyperlipidemic (cholesterol-lowering) therapy found that for every \$10 increase in prescription co-payment, patient compliance levels fell by 5%. Researchers concluded that lowered patient compliance with medication regimens was inversely related to utilization of expensive medical services (e.g., emergency room [ER] visits, hospitalizations); in other words, when people didn't properly take their medications (or stopped taking them), they were more likely to need hospitalization, thereby increasing health care costs. These researchers also provided projections showing that requiring no prescription drug co-payments for high-risk patients would result in fewer hospitalizations and ER visits, for savings of more than \$1 billion (Goldman, Joyce, & Karaca-Mandic, 2006).

**TABLE 6.4 Comparison of Consumer-Directed Health Plans with Other Health Plans When Enrollees Have a Choice of Plans, 2006**

	CDHP	HMO	PPO	POS
Monthly premium, single	\$299	\$339	\$364	\$363
Monthly employer contribution*	\$243	\$288	\$303	\$307
Monthly employee contribution	\$56	\$51	\$61	\$56
Average single deductible, in-network	\$1,459	\$30	\$261	\$94
% Employees with office visit co-payments	15%	95%	79%	98%

\*Average monthly employer contribution to CDHP savings account \$54 in addition to premium.

### Independent or Self-insured Health Plans

Independent or self-insured health plans underwrite the remaining private health insurance in the United States. These plans have been offered through a limited number of organizations, such as large businesses, unions, school districts, consumer cooperatives, and medical groups. Employers with self-insured plans take on all or a major part of the risk for health care costs of their employees. These plans may be self-administered or utilize third-party claims administrators. Minimum premium plans are another form of self-insurance for which employers pay medical costs up to an agreed-upon limit, and insurers assume responsibility for the excess claims (Bureau of Labor Statistics, 2002). Self-insurance plans are not subject to regulation by the states, and it is estimated that 54% of employees receiving work-related insurance benefits are part of self-insurance plans (Dow, Harris, & Liu, 2006; Lawlor & Hall, 2005).

### Government Health Programs

Government health programs make up the next largest source of third-party reimbursement in the United States. The government's four major health insurance programs are Medicare, Medicaid, the Federal Employees Health Benefits Plan, and the Civilian Health and Medical Program of the Uniformed Services (CHAMPUS). As a whole, the proportion of government funding of health care in the United States is less than that of many other countries. Of the government's health insurance programs, Medicare and Medicaid are the largest. Medicare pays the majority of health care costs (56%) for citizens age 65 and older, while private insurance pays for 54% of health care costs for those under age 65 (Goldman & McGlynn, 2005). In 2005, Medicare covered 42.5 million people at a cost of \$330 billion for health care

costs (Centers for Medicare & Medicaid Services [CMMS], 2006). Spending for Medicaid in 2006 was \$180.6 billion (Center on Budget & Policy Priorities, 2006). Less than half of the total health care expenditure per person is paid by public sources in the United States, compared with the United Kingdom (England) at close to 90% and Canada at 71% (Cylus & Anderson, 2006; Lemieux, 2006; Organization for Economic Cooperation & Development, 2007).

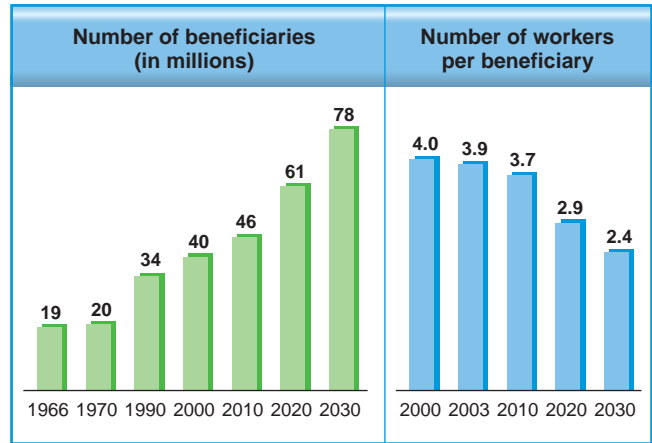

### Medicare and Social Security Disability Insurance

**Medicare**, known as Title XVIII of the Social Security Act Amendments of 1965, has provided mandatory federal health insurance since July 1, 1966, for adults age 65 years and older who have paid into the Social Security system. It also covers certain disabled persons. Medicare is the largest health insurer in the United States, covering about 16% of the population. Of the approximately 42 million beneficiaries, over 7 million qualify for Social Security Disability Insurance (SSDI); these recipients are younger than age 65 and permanently disabled or chronically ill (CMMS, 2007; Kaiser Family Foundation, 2006b). The Medicare population is projected to grow to 44.5 million by 2008, and to more than 63 million by 2027, and their share of GDP is expected to grow from just under 3% in 2005 to over 9% in 2050 (Van de Water & Lavery, 2006) (see Figs 6.6 and 6.7).

Medicare is administered by the Centers for Medicare and Medicaid Services (formerly the Health Care Financing Administration—HCFA) of the U.S. Department of Health and Human Services.

Part A of Medicare, the hospital insurance program, covers inpatient hospitals, limited-skilled nursing facilities, home health, and hospice services to participants eligible for Social Security. It is financed through trust funds derived from employment payroll taxes. A total tax of 2.8% of employee wages is split between the employer and employee. These payroll taxes, along with interest earned on trust fund investments, provide the income for this program (Van de Water & Lavery, 2006).

Part B, the supplementary and voluntary medical insurance program, primarily covers physician services, but also covers home health care for beneficiaries not covered under

**FIGURE 6.7** Historical and projected number of Medicare beneficiaries and number of workers per beneficiary. (From *Fact sheet: Medicare spending & financing*. [2005, April]. part A. It is funded through enrollee monthly premiums (\$88.50 in 2006) (Van de Water & Lavery, 2006).

Part D, the prescription benefit plan added through the Medicare Prescription Drug, Improvement and Modernization Act of 2003 cost just over \$27 monthly in 2007—although premiums can vary across regions, with plans from \$9.50 for a basic prescription drug plan (PDP) to \$135 for a PDP with enhanced benefits (Van de Water & Lavery, 2006; Kaiser Family Foundation, 2007a).

Medicare was managed in the same manner for more than 30 years until August 1997, when President Clinton signed the Balanced Budget Act (PL No. 105–33). This act, which took effect in 1998, provided Medicare beneficiaries with markedly different options. Among the most significant alterations brought about by the Balanced Budget Act are those to the fast-growing managed-care side of Medicare (Kaiser Family Foundation, 2001). To control

**FIGURE 6.6** Measures of Medicare spending, 2005–2014. (From *Fact sheet: Medicare spending & financing*. [2005, April]. Kaiser Family Foundation, Publication No. 7305. 	2005	2006	2010	2012	2014
Spending as % of Gross Domestic Product	2.7%	3.3%	3.5%	3.7%	4.0%
Spending as % of National Health Expenditures	17.2%	20.4%	20.2%	20.3%	20.8%
Years to HI Trust Fund Depletion (2005 projections)	15 years	14 years	10 years	8 years	6 years
General Revenue as a Share of Total Medicare Spending	36.8%	42.8%	44.5%	45.6%	47.9%

Medicare costs while expanding the range of available health care options, beneficiaries were offered a program called Medicare Plus Choice Plans. This program was an effort to accelerate the migration of patients away from Medicare's traditional and more expensive fee-for-service (FFS) program into various managed care options. Enrollees opting to remain in traditional Medicare continued to be covered by the traditional FFS program, which gives patients unlimited choice of doctors, hospitals, and other providers. Those moving to the Medicare Plus Choice plans have a limited choice of providers but, in return, are offered options such as joining coordinated care plans, including health maintenance organizations (HMOs), preferred provider organizations (PPOs), provider-sponsored organizations, private FFS plans, and on a limited basis, medical savings account plans. As benefit coverage for these managed care plans was cut and premiums increased, along with cost sharing for physician and hospital visits, a good number of seniors chose to return to the traditional Medicare coverage (Gold & Achman, 2002). For more information on Medicare trends and concerns about its solvency, see Chapter 24.

## Medicaid

**Medicaid**, known as Title XIX of the Social Security Act Amendments of 1965, provides medical assistance for children; for those who are aged, blind, or disabled; and for people who are eligible to receive federally assisted income maintenance payments (CMMS, 2005). In 2001, almost 44 million Americans received Medicaid-sponsored health and long-term care (Kaiser Family Foundation, 2001). It is jointly funded between federal and state governments to assist the states in providing adequate medical care to eligible needy persons. The states have some discretion in determining which groups their Medicaid programs will cover and the financial criteria for Medicaid eligibility, as well as the scope of services, rate of payment, and how the program will be administered (CMMS, 2005). To be eligible for federal funds, however, states are required to provide Medicaid coverage for most individuals who receive federally assisted income maintenance payments (welfare), as well as for related groups not receiving cash payments (especially the elderly). The states determine the type, amount, duration, and scope of services. According to the Centers for Medicare and Medicaid Services (2005), the following are examples of mandatory Medicaid eligibility groups:

- ◆ Citizens on federally assisted income maintenance, including Supplemental Security Income recipients
- ◆ Offspring of Medicaid-eligible pregnant women
- ◆ Children younger than 6 years and pregnant women who meet the state's assisted income maintenance requirements or whose family income is at or below 133% of the federal poverty level (FPL)
- ◆ Children on adoption assistance and foster care under Title IV of the Social Security Act
- ◆ Medicare beneficiaries (qualified disabled workers and certain poor Medicare recipients)
- ◆ Protected groups who lose cash assistance because of the cash programs' rules (e.g., earnings from

work or increases in Social Security benefits—may keep Medicaid for a period of time)

- ◆ Minors born after September 30, 1983, who are under age 19, from families at or below the FPL

Optional “categorically related” groups also exist, which states may or may not choose to cover (§ 7). These include infants and pregnant women with a family income at or below 185% of the FPL, people under age 21 who meet more liberal criteria than those listed above, individuals who are institutionalized or are receiving care under waivers for home and community-based services, some working disabled persons, some TB-infected persons, women with low incomes who need breast and cervical cancer screenings, and “medically needy” persons (often elderly who must spend down their resources in order to be covered for long-term care) (§ 9).

Coverage includes preventive, acute, and long-term care services. Potential Medicaid recipients must apply for coverage and prove their eligibility in terms of category and limited income. About 65% of Medicaid funds are spent on the elderly and disabled, with 25% going to children and adults with low incomes (Kaiser Family Foundation, 2001).

Medicaid has historically reimbursed providers at a lower rate than Medicare and other insurances, and this has caused problems with access to care. Even with lower reimbursement rates, costs continue to rise. As with Medicare, Medicaid programs moved to a managed care concept, following mandates within the Balanced Budget Act of 1997. In 2006, over 29 million Medicaid enrollees participated in a managed care plan (Kaiser Family Foundation, 2006c).

The move has not been without its problems for those receiving Medicaid. Medicaid beneficiaries are economically disadvantaged, frequently reside in medically underserved areas, and often have more complex health and social needs than do Americans with higher incomes. Early evidence on the implementation of Medicaid managed care showed “some improvement in access to a regular provider but more difficulties in obtaining care and dissatisfaction with care” compared with those in Medicaid FFS (Kaiser Family Foundation, 2001, ¶12). In recent years, many people who were never before eligible for Medicaid benefits have become eligible as a result of downward national economic trends, company downsizing, and corporate scandals. Subsequent to these economic issues, families have lost employer-subsidized health care benefits, and some now find themselves among those eligible for Medicaid managed care programs.

Medicaid's use of managed care has grown dramatically. The percentage of Medicaid recipients enrolled in a broad array of managed care arrangements increased from just below 10% in 1991 to almost 56% in 2000. However, during that same time, the number of commercial plans withdrawing from the Medicaid market increased, and new plans entering the market decreased (Kaiser Family Foundation, 2001). The future success of Medicaid managed care depends on the adequacy of the **capitation rates** (fixed amounts of money paid per person by the health plan to the provider for covered services) and the ability of state and federal governments to monitor access and quality. Quality performance standards are evolving. Ensuring access and quality of care in a managed care environment

will require fiscally solvent plans, established provider networks, education of providers and beneficiaries about managed care, and awareness of the unique needs of the Medicaid population.

### State Children's Health Insurance Plan

In 1997, as another part of the Balanced Budget Amendment, the State Children's Health Insurance Plan (SCHIP) provided health coverage to uninsured children under age 19 for families caught in the gap between Medicaid and affordable health insurance (Congresspedia, 2007; FirstGov, 2007). All 50 states participate, and for little or no cost, provide insurance for hospitalization, physician visits, prescription drugs, and in some cases dental and vision services (FirstGov, 2007). There are variations among the states, but SCHIP is geared to working families who may earn up to \$34,100 yearly for a family of four (FirstGov, 2007). In 2007, SCHIP coverage was expanded by imposing an excise tax on tobacco products (Congresspedia, 2007).

### Other Government Programs

In addition to third-party reimbursement, the government offers some direct health services to selected populations, including Native Americans, military personnel, veterans, merchant marines, and federal employees. Government support, largely through grants administered through the CDC, provides immunizations and well-child care, as well as prenatal care and other programs at the state and local level.

### Payment Concepts in Health Care

Reimbursement for health care services generally has been accomplished through one of two approaches: retrospective or prospective payment. Conceptually, these approaches are polar opposites. It is helpful to understand their differences and their meaning for the financing and delivery of health services, past and present.

#### Retrospective Payment

A traditional form of reimbursement for any kind of service, including health care, is **retrospective payment**, which is reimbursement for a service after it has been rendered. A fee may be established in advance. However, payment of that fee occurs after the fact, or retrospectively. This is known as the **fee-for-service** (FFS) approach (Cutler, 2004; Newhouse, 2002).

In health care, limited accountability in the use of retrospective payment has created several problems. With third-party payers (e.g., insurance companies, the government) serving as intermediaries, neither consumers nor providers of health services were accountable for containing costs. Patients and providers alike often insisted on expensive or unnecessary tests and treatments. Because reimbursement was made retrospectively by the insuring agency, there was no incentive to keep a lid on this spending. Third-party reimbursement increased, along with other factors, to create an inflationary spiral of escalating costs. Abuse of the FFS system made it more difficult to develop retrospective payment for other health care providers, including nurses (Chang, Price, & Pfoutz, 2001).

A further problem associated with the FFS concept was its tendency to encourage sickness care rather than wellness services. Physicians and other providers were rewarded financially for treating illness and for providing additional tests and services. There were few incentives for prevention or health promotion in an industry that reaped its revenues from keeping hospital beds full and caring for the sick and injured. Although retrospective payment worked well in other industries, from a cost-containment as well as a public health perspective, it was problematic in health care.

#### Prospective Payment

Prospective reimbursement, although not a new concept, was implemented for inpatient Medicare services in 1983, in response to the health care system's desperate need for cost containment (Newhouse, 2002). It has since influenced the Medicaid program, as well as private health insurers. The prospective payment form of reimbursement has virtually eliminated the retrospective payment system (Chang, Price, & Pfoutz, 2001; Newhouse, 2002). **Prospective payment** is a payment method based on rates derived from predictions of annual service costs that are set in advance of service delivery. Providers receive payment for services according to these fixed rates, set in advance. Payments may be in the form of premiums paid before receipt of service or in response to fixed-rate (not cost) charges. To correct unlimited reimbursement patterns and counteract disincentives to contain costs, prospective payment involves four classic steps (Dowling, 1979):

1. An external authority is empowered (by statute, market power, or voluntary compliance by providers) to set provider charges, third-party payment rates, or both.
2. Rates are set in advance of the prospective year during which they will apply and are considered fixed for the year (except for major, uncontrollable occurrences).
3. Patients, third-party payers, or both pay the prospective rates rather than the costs incurred by providers during the year (or charges adjusted to cover these costs).
4. Providers are at risk for losses or surpluses.

The concept of prepayment, or consumers paying in advance of health care, has existed for many years. As far back as 1933, prepaid medical groups were advocated to reduce costs and make services more accessible (Premera, 2007). Examples of early plans were the Health Insurance Program of Greater New York City and the Kaiser Plan (Chang, Price, & Pfoutz, 2001). The success of these two plans helped to influence the growth of the HMO, a type of managed care discussed later in this chapter.

Prospective payment imposes constraints on spending and provides incentives for cutting costs. The federal government, as mentioned earlier, enacted a prospective payment plan (Social Security Amendments Act 1983; see Landmark Health Care Legislation). The plan is a billing classification system known as **diagnosis-related groups (DRGs)**. The system is based on about 500 diagnosis and procedure groups. It provides fixed Medicare reimbursement to hospitals based on weighted formulas (Newhouse, 2002). Flat rates of payment are based on average national costs for a specific group,

adjusted annually, with some regional variations accounting for higher wages and other costs (Chang, Price, & Pfoutz, 2001). This system was enacted to curb Medicare spending in hospitals and to extend the program's solvency period. The regulatory approach of DRGs changed Medicare hospital reimbursement from a cost-based retrospective payment system, in which a hospital was paid its costs, to a fixed-price prospective payment system. It was designed to create incentives for hospitals to be more efficient in delivering services.

Indeed, the prospective payment system has reduced Medicare's rate of increase in inpatient hospital spending and increased hospital productivity (Institute of Medicine, 2001). Thought to reduce hospital stays and unnecessary admissions, the system led to "DRG creep" (e.g., classifying patients into more lucrative categories) and "patient dumping" (e.g., transferring patients whose reimbursement is expected to be lower than actual costs of services) in an effort to counteract the losses in revenue to hospitals that spend more on Medicare patients than they are reimbursed (Dranove, 2000, p. 52). It also led to fierce competition among providers and mounting concern about quality of care—in hospitals, ambulatory settings, and home care.

A more vigorous version of prospective payment is *capitation*. As noted before, capitation refers to a fixed fee per person that is paid to a managed care organization for a specified package of services. Fees remain in effect until renegotiated, regardless of the number of services provided. Because profit margins are very tight, utilization, quality, and costs are carefully monitored (Chang, Price, & Pfoutz, 2001).

The prospective payment concept has proved useful from a public health perspective. Prepaid services create incentives for providers to keep their enrollees healthy, thus reducing provider costs. A potential, indirect benefit from fixed rates and reduced costs is that more of the health care dollar is available to spend on prevention programs.

### Claims Payment Agents

Claims payment agents administer the process for government third-party payments. That is, the government contracts with private fiscal agents to handle the claims payment process and function as an intermediary between them and the health care provider. More than 80% of the government's third-party payments have been handled by these private contractors, who sometimes are known as fiscal intermediaries (when processing Medicare hospital claims), carriers (when dealing with insurance under Medicare), or fiscal agents (as applied to Medicaid programs). As an example, Blue Cross, in addition to being a private insurance company, also is a claims payment agent for Medicare (Virginia Commonwealth University, 2007).

### Direct Consumer Reimbursement or Out-of-Pocket Payment

Another source of health care financing comes from direct fees paid by consumers. This refers to individual out-of-pocket payments made for several different reasons, such as payments made by individuals who have no insurance coverage (fees must be paid directly for health and medical services) or payments for limited coverage, insurance caps, and exclusions (services for which the consumer must bear the entire expense).

For example, some individuals carry only major medical insurance and must pay directly for physician office visits, prescriptions, eyeglasses, and dental care. In other instances, the insurance contract may include a deductible amount that must be paid by the insured before reimbursement begins (e.g., \$500 for individuals, \$1,500 for a family). The contract may be established on a coinsurance basis, which determines a percentage to be paid by the insurer and the rest by the individual (e.g., 80/20 plans for which individuals pay 20% of costs after deductibles). Or, the individual may pay the remainder of a health service bill after the insurer has paid a previously agreed-on fixed amount, such as a fixed fee (known as a coverage cap) for labor and delivery, for example. About 21% of people under age 65 pay out-of-pocket for health care costs; about 16% of people age 65 and more pay health care costs directly (Goldman & McGlynn, 2005).

Another important factor for those paying directly for their health care expenses is **cost shifting**. This practice of charging different prices to different consumers most often affects those without health insurance who are paying out-of-pocket for care (Morrissey, 2003). As health insurance plans or large companies contract with hospitals and physicians for services, they purchase these services at a reduced cost. Those without this "buying power" pay full price. For example, a \$500 radiology procedure may be discounted to \$225 for an insurance plan, but an individual paying out-of-pocket will pay the full price.

### Private and Philanthropic Support

Private or philanthropic support, a third funding source, contributes both directly and indirectly to health care financing. Many private agencies fund programs, underwrite research, and provide benefits for people who otherwise would go without services. In addition, volunteerism, the efforts of numerous individuals and organizations that donate their time and services (e.g., hospital guild members), provides tremendous cost savings to health care institutions. It also enables many individuals to receive services, such as home-delivered meals or transportation to health care facilities, at no charge.

Philanthropic financing of health care has significantly decreased in the last two decades. One study tracking physicians noted that over 76% offered charity care in 1996–1997, but that number decreased to just over 68% in 2004–2005, and that the charity care hours per 100 people decreased by 18% in the same time period (Cunningham & May, 2006). Surgeons were most often noted to provide free care to patients without insurance, and hospitals are required to provide emergency care to everyone. Uncompensated care costs for hospitals, though, have remained steady, and their payments from private insurance have risen faster than their costs (Cunningham & May, 2006). Even though some providers offer charity care, continued private support is essential, particularly when federal and state monies for health and social programs have been severely restricted (Harrington & Estes, 2004).

Further understanding of health economics and its impact on community health and community health nursing can be obtained by examining methods of health care finance, trends and issues influencing health care economics, and the effects of finance patterns on community health practice.

## TRENDS AND ISSUES INFLUENCING HEALTH CARE ECONOMICS

### The High Cost of Health in America

America paid over \$6,100 per person for health care in 2004 (Davis et al., 2007) through a combination of public tax money, individual and corporate contributions to insurance plans, and other sources. Not only do we pay almost twice the per capita expenditure of Canada and Germany and almost three times that of New Zealand and the United Kingdom, but we have had “one of the highest growth rates in per capita health care spending since 1980 among higher income countries” (Davis et al., 2007; Kaiser Family Foundation, 2007c, ¶2).

Many Americans believe that we have the best health care system in the world. But what actually constitutes a good health care system? Are we truly getting our money’s worth? The WHO’s groundbreaking report of member countries outlined a *good health system* as one that provides good health for the whole population over the entire life cycle, responds to client’s expectations for respectful treatment and a client-oriented system of health care providers, and ensures that costs are distributed according to ability to pay and provides financial protection for all (2000). A “good and fair” health care system exhibits (p. 2):

- ◆ Overall good health (e.g., low infant mortality)
- ◆ Fair distribution of good health (e.g., long life expectancy distributed evenly across population groups)
- ◆ High level and fair distribution (across population groups) of overall responsiveness
- ◆ Fair distribution of health care financing (e.g., based on ability to pay, distributed fairly, so that everyone has equal protection from financial risks incurred by illness)

What researchers found was that the U.S. health care system was the “most expensive . . . in the world” largely because of high administrative costs (estimated then to range between 19.3% and 24.1%), the system of complex multiple payers, and the rising costs of prescription medications and advanced medical technology (p. 2). They also noted the shift from nonprofit to for-profit hospitals and the aging population as causative factors, along with the high proportion of uninsured people (and the attendant high cost of untreated illness). Access was a significant problem, as the United States was found to be “the only country in the developed world, except for South Africa, that does not provide health care for all of its citizens” (p. 3). In the United States, the patchwork quilt of private and public insurance—mostly tied to either employment or low-income status—makes it difficult for many people to get the care they need. The researchers noted that those without health insurance are “sicker and die younger than people with health insurance” (p. 4).

Americans believe that we have a quality health care system, and that this can make up for other deficits. The United States did rank first among all WHO countries on *responsiveness*—a construct relating to how respectfully clients are treated. However, as noted in Chapter 25, for many racial and ethnic minorities, this is not the case.

*Disability-adjusted life expectancy* (DALE, or the average number of healthy years expected in a population) was very low, and the United States was ranked 24th, with an unequal distribution, especially among males. The United States was ranked lowest among 14 industrialized nations and placed 54th among WHO countries on the measure of *fairness in financing* (Anderson & Hussey, 2001; WHO, 2000). This inequality disproportionately affects the poor, underinsured, and the uninsured, as many public health nurses (PHNs) can corroborate.

Compared to the other 190 countries studied by the WHO, the United States ranked 15th for attainment of the criteria listed above, and 37th for *performance* (a comparison of how well it *could* perform based on available resource levels). Also, only 40% of those in the United States reported that they were *satisfied* with the health care system. Many factors contribute to this, and shrinking patient choices, increased influence of managed care, and nursing shortages, along with quality of care, were noted as important (University of Maine, 2001; WHO, 2000).

The Commonwealth Fund created a *National Scorecard on U.S. Health System Performance*, and defined several dimensions of a “high performance health system” (Schoen, Davis, How, & Schoenbaum, 2006, p. 457) as:

- ◆ Long, healthy, and productive lives
- ◆ Quality
- ◆ Access
- ◆ Efficiency
- ◆ Equity

On a total possible score of 100, the United States scored 66 overall, and only 51 on the dimension of *efficiency*. The researchers also found that less than half of U.S. adults receive preventive care and all recommended screening tests (using national standards), and that 30-day hospital readmission rates varied greatly. They were over 50% greater in regions with the highest rates when compared with those with the lowest rates—highlighting a wide disparity in quality care across the country.

Increasing influenza and pneumonia vaccinations would cost between \$200 and \$400 million annually, but could save between 20,000 and 40,000 deaths. Other inefficiencies could be corrected by the widespread implementation of *health information technology* (HIT)—including computerized physician order entry and electronic medical records (Hillestad et al., 2005). Over \$77 billion per year could be saved if hospitals and outpatient clinics adopted widespread use of these technologies. Over 200,000 adverse drug events could be avoided annually, with a savings exceeding \$1 billion and many lives spared. Earlier research found a “fragmented system fraught with waste and inefficiency”—indicating what could be termed an “*un-system*” of health care. It was also noted that the United States spends more than two times the per capita average for health care among industrialized nations (Gauthier & Serber, 2005, ¶1).

Why does health care cost so much? Explanations include the following:

- ◆ Medical malpractice costs and the need to practice *defensive medicine* by ordering excessive tests and x-rays (Sage & Kersch, 2006; RAND Institute for Civil Justice, 2004)

- ◆ An aging population (Cutler, 2004)
- ◆ Advances in and the spread of medical technology; for instance, in the last decade 12 of 19 Nobel prizes in medicine have been awarded to U.S. scientists—and this comes at a price (Cowan, 2006; Morris, 2005)
- ◆ Rapidly rising prescription drug and hospital costs (Goldman & McGlynn, 2005; Rice & Rhodes, 2006)
- ◆ The failure of market forces, in that health care doesn't respond to supply and demand as in other areas of the economy (Nyman, 2003; Rice & Rhodes, 2006; Sharma, 2006)
- ◆ High costs of insurance administration—in some cases, three times that of the cost in other nations (Commonwealth Fund Commission on a High Performance Health System, 2006; Nyman, 2003)
- ◆ Ineffective, inappropriate, and inadequate health care leading to increased morbidity and mortality and costs (Institute of Medicine, 2001)
- ◆ High proportion of uninsured—it has been estimated that the U.S. economy would benefit by \$130 billion a year if all citizens were provided health insurance (Commonwealth Fund Commission on a High Performance Health System, 2006)
- ◆ Americans' demand for high-tech health care and preference for freedom of choice among providers and services (Jones, 2005)
- ◆ The higher U.S. cost of living and level of income—things just cost more in the USA. Some argue that the high proportion of GDP spent on health care actually benefits the U.S. economy (Gaynor & Gudipati, 2006)

A study by Anderson, Hussey, Frogner, and Waters (2005) examined two commonly held views regarding U.S. health care and rejected these arguments:

- ◆ Restriction of the supply of health care in many countries leads to decreased spending but also long waiting lists.
- ◆ U.S. malpractice litigation results in higher malpractice insurance costs and defensive medicine practices to protect physicians from lawsuits.

They noted that, despite high per capita expenditures, the United States was in the bottom 25% of countries in the Organization for Economic and Co-operative Development (OECD) for per capita hospital beds, and the average malpractice payment was 36% below the United Kingdom and 14% below Canada. While generally more malpractice claims are filed in the United States than in other countries, payments for claims were lower on average and the total costs of malpractice only encompassed less than .5% of the total expenditures for health care.

A striking example of cost differences found in different countries involves prescription drugs. For example, the cancer drug Campath (alemtuzumab) costs \$2,400 in the United States, but only \$760 in France, \$660 in Sweden, \$570 in the United Kingdom, and only \$500 in Italy (McKenzie, 2007). Canada has enacted price controls that limit costs of new classes of medications to the median price paid by other

countries, making the price for Campath in Canada \$600. The United States is the only industrialized country without some form of price control on patented drugs. Drug companies say that limiting prices on new medications will reduce innovation and research for new drugs; however, for instance, in Canada only a handful of U.S. medications are not readily available (McKenzie, 2007).

## Controlling Costs

As noted earlier, cost-control measures utilizing both supply-side and demand-side strategies have been attempted. Utilization review techniques have further enhanced utilization and cost control (Sultz & Young, 2006). Yet, despite various public and private cost-control strategies, health care costs continue to rise (Cutler, 2004). Although expenditures in the 1990s decelerated slightly from the escalation experienced during the 1970s and 1980s, in the early 2000s costs rose and continue to rise. Many factors influenced this increase. Between 1965 and 2001, the price per day of hospitalization rose tenfold from under \$200 to over \$1,300 (Kaiser Family Foundation, 2007c). As medical care became more complex, insurance costs rose dramatically, as did costs of public health care financing through Medicare and Medicaid (Cutler, 2004). More than half of the health care dollar goes to hospital and physician costs (31% and 22%, respectively) (Goldman & McGlynn, 2005). The explosion of medical technology has been characterized as a “medical arms race” by some (Dranove, 2000, p. 46), and a youth-oriented culture and unwillingness to accept illness and death has helped fuel this and the growth of elective procedures, such as plastic surgery.

A focus on primary prevention demands a paradigm shift in thinking about the practice and delivery of health care (see Chapter 1). It is one that fits more closely with the mission of public health. It expects that citizens are involved in their health care, are knowledgeable about their health status, can manage self-care practices, and can modify lifestyle behaviors to promote wellness. This creates a rich environment for community health nurses to collaborate with primary care practitioners and other health care professionals to control health care costs while providing quality care focusing on primary prevention.

## Access to Health Services: The Uninsured and Underinsured

A growing segment of the U.S. populace (estimated at between 16% and 33%) is uninsured, resulting in limited or no access to health care (Aday, 2005; Forbes, 2007). More than 45 million Americans are currently without any form of health insurance coverage (Collins et al., 2006). There is wide variation between states—from 11% in Minnesota to over 30% in Texas—contributing to great inconsistencies in health care quality and access (Collins, 2007). By 2015, the number of uninsured is expected to reach 54 million (Broder, 2005).

As noted earlier, about 25% of Americans who have health insurance are underinsured (Forbes, 2007), and they often must choose between paying insurance and health-related expenses or foregoing needed care. The underinsured are more likely to “go without care because of costs”

at a rate similar to those without health insurance, and 46% of underinsured were contacted by debt collectors, while 35% reported changing their usual way of life to pay medical expenses (Himmelstein, Warren, Thorne, & Woolhandler, 2005, p. 6). As an example of this, one large-scale study found that those with private health insurance paid close to \$13,500 in out-of-pocket expenses for medical costs in 2001—while those who were uninsured paid close to \$11,000 (Himmelstein et al., 2005). In addition, many underinsured have no dental or vision coverage, and have higher deductibles.

A particularly ominous study indicates that adults in the 50- to 64-year age range—baby boomers—have unstable health insurance coverage (Collins et al., 2006). More than half of these working older adults with annual incomes below \$25,000 report that they have times without insurance coverage, and one-third of those with incomes between \$25,000 and \$39,999 also experience insurance instability. People in this age group have higher rates of chronic illness (62% had at least one chronic condition, such as diabetes or hypertension) and higher medical expenses. One-third of those in the study reported that they had problems paying medical bills or that they were paying off medical debt. Two-thirds were concerned that they would be unable to afford medical care in the future.

## Medical Bankruptcies

Bankruptcy filings have been rising over the last decade—as much as 360%. In a 2001 study conducted by Harvard and Ohio University researchers, almost half of participants cited illness—sometimes with loss of work—and medical expenses as the chief cause for their bankruptcy (Himmelstein, Warren, Thorne & Woolhandler, 2005). The average study participant who filed for bankruptcy was a “42-year-old woman with children and at least some college education” (¶ 22). Most owned a home, and more than 75% of them had insurance coverage at the start of the illness that led to their bankruptcy. The reasons that those without insurance lacked coverage included unaffordable premiums, pre-existing conditions, lack of employer insurance coverage, gaps in coverage, and loss of employment. Of those filing medical bankruptcies, over 20% had gone without food, over 40% had their phone service disconnected, and around 30% lost electricity or water in the 2 years before filing. About 60% reported going without a needed doctor or dentist visit during that same time (Himmelstein, Warren, Thorne, & Woolhandler, 2005).

The consequences of not getting needed medical care are not trivial and can result in unnecessary hospitalization and serious health problems—along with increased costs. Death rates for the uninsured are 25% higher each year than for those with health insurance (Gladwell, 2005). It is estimated that not having health insurance leads to 18,000 deaths annually, making it the sixth leading cause of death for adults between age 25 and 64 (Davis, 2003). One of the largest groups among the uninsured are young adults between ages 19 and 29 (Collins et al., 2007), as well as workers and their families with low incomes. Most of these families have one member working full time; some have two or more full-time workers.

Access to health care is a prime concern for the uninsured. Many have no **medical home**—defined as seeing the

same health care provider for regular care. Because there is a lack of care coordination, duplicative and wasteful services are often the case (Collins, 2007). And without a reliable care provider, the uninsured tend to use ERs for non-emergency care. Recent research noted that 33% of ER visits could have been handled in a primary physician's office (Davis, 2003). Other consumers utilize public clinics and other charity care services. Cost estimates for uncompensated care in 2001 reached \$34.5 billion.

Government costs to reimburse “safety net” hospitals and other entities involved in care of the uninsured exceed \$30 billion yearly—exemplifying just some of the costs to taxpayers. Because of the instability of the system, about half of the uninsured lose their health insurance coverage in a year—racking up higher administrative costs as they move between private and public insurers and change their usual sources of medical care. Interruptions in care, duplication in medical records, and verification of eligibility all lead to higher costs for everyone (Davis, 2003).

In the private sector, numerous firms do not offer health insurance to their employees; almost 80% of the uninsured are employees of these firms or are their dependents (Hellander, 2002). Self-employed individuals also find it difficult to pay the higher costs of insurance premiums without the benefit of group rates. Consequently, many of the self-employed can access health services only by purchasing expensive individual insurance policies with high-deductibles and coinsurance or by making expensive out-of-pocket payments.

## Managed Care

The term **managed care** became popular in the late 1980s. It refers to systems that coordinate medical care for specific groups to promote provider efficiency and control costs. Although the term *managed care* is relatively new, the concept has been practiced for many years through various models of alternative health care delivery. Managed care is a cost-control strategy used in both public and private sectors of health care. Care is *managed* by regulating the use of services and levels of provider payment. This approach includes using HMOs and PPOs. In contrast to FFS models, managed care plans operate on a prospective payment basis and control costs by managing utilization and provider payments. The managed care model encourages the provision of services within fixed budgets, thus avoiding cost escalation. Because costs are tight, preventive services are generally encouraged, so that more expensive tertiary care costs can be avoided, if possible.

## Health Maintenance Organizations

The HMOs and various companies' self-insured plans also are included in this category. Usually, they sell only health insurance; in some cases, they also may provide actual health services. They focus on a localized population. As a group, they generate a large amount of premium revenues; HMOs represent 20% of employer-sponsored group insurance (Kaiser Family Foundation, 2006a). Consumers have often resisted the strenuous cost-containment policies of many HMOs, and prefer to have their physicians make decisions about their care—not insurance company employees. However, employers are often drawn to alternatives as a cost-saving method. HMO premiums are usually lower than other types of insurance

premiums, and out-of-pocket costs to consumers are generally lower (Gabel, Pickreign, & Whitmore, 2006).

A **health maintenance organization (HMO)** is a system in which participants prepay a fixed monthly premium to receive comprehensive health services delivered by a defined network of providers. The HMOs are the oldest model of coordinated or managed care. Several HMOs have existed for decades, but many have developed more recently. HMO enrollees benefit from a lower premium, reduced cost sharing, and fewer administrative costs.

From 1930 to 1965, the HMO movement, supported initially by the private sector, gradually gained federal backing. Group plans were included as a part of Medicare and Medicaid legislation. The HMO Act of 1973 demonstrated stronger federal support and assistance for growth of this industry (Chang, Price, & Pfoutz, 2001). Amendments to this act in 1976 lifted restrictions and further encouraged HMO growth. The skyrocketing employer health insurance costs of the 1980s and 1990s encouraged many companies to move from traditional insurance and FFS to HMOs. Currently, there are numerous HMOs with a variety of configurations. The unique set of properties of HMOs include:

- ◆ A contract between the HMO and the beneficiaries (or their representative), the enrolled population
- ◆ Absorption of prospective risk by the HMO
- ◆ A regular (usually monthly) premium to cover specified (typically comprehensive) benefits paid by each enrollee of the HMO; few additional charges are levied, because the payment mechanism is not FFS
- ◆ An integrated delivery system with provider incentives for efficiency; the HMO contracts with professional providers to deliver the services due the enrollees, and the basis for reimbursing those providers varies among HMOs (Harrington & Estes, 2004)

Official encouragement, government subsidies, and the pressures for cost control spurred the growth of HMOs. Some HMOs follow the traditional model, employing health professionals (e.g., physicians, nurses), building their own hospital and clinic facilities, and serving only their own enrollees. Other HMOs provide some services while contracting for the rest. Variations of the HMO model include solo practice physicians (some also continuing FFS medicine) who affiliate with hospitals (Chang, Price, & Pfoutz, 2001; Cutler, 2004). Enrollment in HMOs through employer-based programs numbered more than 77.7 million in 2006 (Managed Care Online [MCOL], 2007).

HMOs have been viewed as a positive alternative delivery system because of their potential for conserving costs, which results from their emphasis on prevention, health promotion, and ambulatory care, with a concomitant reduction in hospital and medical care utilization. However, there are questions as to whether the cost savings result partly from favorable selection of enrollees. Quality concerns also have been raised about the dangers of underserving enrollees in order to stay within payment limits (Baker et al., 2004; Sultz & Young, 2006). Scanlon, Swaminathan, Chernen, and Lee (2006) examined longitudinal data, and found that HMO competition was related to consumer satisfaction surveys, but not necessarily to better quality of care for chronic

conditions. Greater penetration of HMOs in some regions of the United States was associated with better outcomes for six common medical conditions (e.g., hip fracture, heart attack), but in other areas, the outcomes were worse—indicating no solid evidence of either higher or lower quality of care (Escarce, Jain, & Rogowski, 2006).

These concerns about HMOs and managed care in general have not gone unattended. The Health Insurance Portability and Accountability Act (HIPAA) and the Newborns' and Mothers' Health Protection Act are both significant pieces of legislation, addressing health care concerns among the nation's citizens and official organizations, such as the APHA. HIPAA reassured people that they would not lose health care coverage if they changed jobs. In addition, for a while in the United States, insurance for labor and delivery hospitalization covered only 24 or fewer hours after birth. Infants and mothers were being sent home in unstable post-delivery conditions. Newborns would go home when younger than 1 day of age, in some cases so soon after birth that body temperature was not stabilized and the ability to suck and take breast milk or formula was not established. The Newborns' and Mothers' Health Protection Act eliminated these "drive through deliveries," ensuring that mothers and newborns would have the right to remain in the acute care setting for at least 48 hours, covered by their insurance plan (see Landmark Health Care Legislation).

In response to concerns from managed care clients, recommendations from the Advisory Commission on Consumer Protection and Quality (1998) stipulated that health plans should subscribe to *The Patient's Bill of Rights*:

- ◆ *Information disclosure*: This is the right to accurate and easily understood information about the health plan, health care professionals, and facilities. This includes information in the patient's primary language.
- ◆ *Choice of providers and plans*: This is the right to a sufficient choice of providers to ensure access to appropriate, quality health care.
- ◆ *Access to emergency services*: This is the right to receive timely screening and stabilization emergency services whenever and wherever needed, without prior authorization or financial penalty, under certain circumstances (e.g., severe pain, injury).
- ◆ *Participation in treatment decisions*: Patient's have the right to know treatment options and to participate in care decisions.
- ◆ *Respect and nondiscrimination*: This is the right to considerate, respectful, and nondiscriminatory care from providers and others associated with the health care plan.
- ◆ *Confidentiality of health information*: Patient's have a right to talk confidentially with their health care provider and to have health information protected. This also includes the right to review and copy the patient's own medical records and the ability to request changes when indicated.
- ◆ *Complaints and appeals*: This is the right to a fast, fair, and objective review of any complaints against the health plan, providers, or other personnel, including waiting times, hours of operation,

conduct of personnel, and adequacy of health care system facilities.

These principles have been adopted by many health plans, on a voluntary basis. Legislation requiring these and more stringent rules (e.g., liability for medical malpractice, external appeals processes, discontinuation of provider financial incentives to reduce service utilization) have failed to be enacted by Congress (House of Representatives, 1998).

### Preferred Provider Organizations

A **preferred provider organization (PPO)** is another model of managed or coordinated care that developed earlier than the HMO. A PPO is a network of physicians, hospitals, and other health-related services that contracts with a third-party payer organization to provide comprehensive health services to subscribers on a fixed FFS basis. Because of contractual fixed costs, employing organizations that subscribe can offer medical services to their employees at discounted rates. In PPOs, consumer choice exists. Enrollees have a choice among providers within the plan and contracted providers out of the plan. The PPOs practice utilization review and use formal standards for selecting providers (Chang, Price, & Pfoutz, 2001).

PPOs did not exist in their present form until after 1980. Enrollment in PPOs grew from about 10 plans in 1981 to more than 700 plans in the 1990s. The number of people enrolled in PPOs also increased, from an estimated 10.4% of individuals with private insurance in 1988 to 40% by the late 1990s, with the numbers leveling off as the decade came to a close (Dranove, 2000; Sultz & Young, 2006). As consumers became more frustrated with limits imposed by HMOs, they began to move toward PPOs that provide more choices. In 2006, 81.3 million

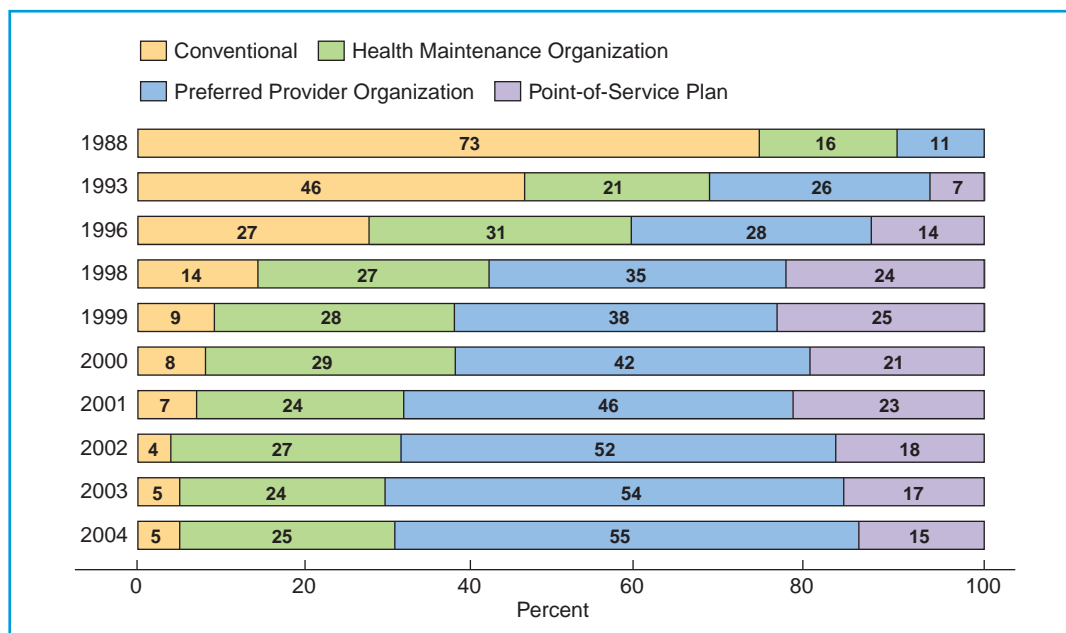

Americans were enrolled in a PPO, more than the number in HMOs (MCO, 2007). Early use of PPOs appeared to promote cost savings, but the long-range cost effectiveness of this model has yet to be proved (Hurley, Strunk, & White, 2004). PPOs have been criticized for their lack of vigorous case management—more often found in HMOs—and some have begun to move toward this model, especially in the case of chronic diseases (e.g., hypertension, diabetes) (Porter & Teisberg, 2006).

### Point of Service Plans

A variation on the just-mentioned plans is the **point-of-service (POS) plan**, which permits more freedom of choice than a standard HMO or PPO. At an extra cost, enrollees can go outside the HMO or PPO network of contracted providers unless their primary physician has made a specific referral (California Healthcare Foundation, 2007). This type of plan covers a small percentage of the market, estimated at around 10 million people (Dranove, 2000). For a look at the trend in types of health plan coverage among those employees who are covered by their employers, see Figure 6.8.

### Health Care Rationing

The concept of **rationing** in health care refers to limiting the provision of health care services to save costs. Sometimes, this may jeopardize the well-being of groups of individuals. Rationing implies that resources are fixed or limited and therefore must be used sparingly. Rationing may occur by restricting people's choices, denying access to services, or by limiting the supply of services or personnel. It may be overt, as in the oft-cited case of Britain, or more covert, as

**FIGURE 6.8** Health plan enrollment among covered workers, by type of plan, selected years 1988–2004. For 1998, 1999, 2000, 2001, and 2003, the distribution is significantly different from the previous year shown, at the 0.05 level. (From Gabel et al. [2004]. Health benefits in 2004: Four years of double-digit premium increases take their toll on coverage. *Health Affairs*, 23(5), 200–209, used with permission.)

practiced by many managed care organizations or health plans. Often, insurers and providers of health care services make rationing decisions to contain costs. With rationing, there is a danger of compromising quality and effectiveness (Aaron, 2005).

Rationing in health care has been practiced for many years. With limited resources for health services delivery, government programs have had to establish strict eligibility levels and monitor the use of these resources to ensure the most equitable distribution. To maintain viability and some kind of profit margin, private insurers have engaged in rationing by excluding enrollees who are at greatest risk for health problems—and, thus, higher expenditures (Dranove, 2000; Porter & Teisberg, 2006; Sultz & Young, 2006).

Advances in knowledge and technical capabilities through research and technology compound rationing decisions. When several individuals need an organ transplant and only one organ is available, what criteria should be used to select the recipient? Now that it is known that certain lifestyle behaviors, such as smoking and alcohol consumption, or driving without restraints, create health risks, should people who engage in these activities pay a higher price for health care or be excluded from certain services? Should a younger person needing specialized surgery take priority over an elderly person needing similar care? There are no easy answers. Providers and insurers have struggled with these difficult policy issues for years.

With today's health care costs, the problems are even more complex. As health care spending rises, calls for rationing may intensify. The spending for Medicare and Medicaid in 2040 could be as great as our current combined income and payroll taxes (Aaron, 2005). Technological advances have added years to life and improved national welfare, but as spending continues to consume more and more of the GDP, many will ask if the costs outweigh the benefits and may seek to limit high-cost, low-benefit health procedures, such as expensive MRIs for rare conditions or conditions with no effective treatments or cures.

Oregon began a system of rationing in 1994. The state approached the problem pragmatically and openly. In an effort to reach universal coverage, Medicaid was expanded to cover all state residents with incomes below the federal poverty level, and then health care services were planned to be rationed to pay for the increase public coverage. A list of 709 medical services was decided upon. The state envisioned a plan for legislative determination of a cutoff point, depending on yearly budget allocations (Dranove, 2003; Loewy & Loewy, 2001). In 1999, Oregon's Medicaid program covered 574 of 743 conditions; however, the current Medicaid benefit package is still considered more generous than the state's previous plan (there is better coverage for dental care and mental health) and better than many private insurance plans (Oberlander, Marmor, & Jacobs, 2001). Although Oregon has not seen substantial savings with this plan and has not been able to achieve true universal coverage, it did reduce the number of uninsured residents to 11% (below the national average of around 16%). Some feel that the failure to reach universal coverage was partly due to the breakdown of legislation requiring business to provide insurance for all employees. Oregon made very public decisions about rationing health care, but more subtle means of rationing—budgetary caps, limits to the spread of technology—may

actually be more effective in achieving lower costs (Oberlander et al., 2001).

### Competition and Regulation

Often, competition and regulation in health economics have been viewed as antagonistic and incompatible concepts. **Competition** means a contest between rival health care organizations for resources and clients. **Regulation** refers to mandated procedures and practices affecting health services delivery that are enforced by law. In a society in which long-held values of freedom of choice and individualism reign supreme, competition provides opportunities for entrepreneurial endeavor, free enterprise, and scientific advancement. Yet, to promote the public good, oversee equitable distribution of health services, and foster community-wide participation, regulation also serves an important role.

Health care incorporates four major kinds of regulation (Sultz & Young, 2006):

- ◆ Laws
- ◆ Regulations
- ◆ Programs
- ◆ Policies

Laws that regulate health care include any legislation that governs financing or delivery of health services, such as legislation regulating Medicare reimbursement to hospitals. Regulations guide and clarify implementation; they are issued under the authority of law and are part of most federal health care programs. Examples include regulations governing project grants such as HMO development; formula grants, such as those provided under the Hill-Burton Act; and entitlements, such as Medicare and Medicaid. Regulatory programs are created from legislative enactments and are designed to accomplish specific goals, such as accreditation and licensing rules for hospitals, public health agencies, and other health service providers. Regulatory policies have a broader focus and involve decisions that shape the health care system by channeling the flow of resources into it and setting limits on key players' actions. Examples of regulatory policies are found by reviewing state or federal budget proposals for funding programs, such as health manpower training, research, and technology development (Porter & Teisberg, 2006).

From the 1950s through the 1970s, the federal government assumed a strong role in regulating health services. First, federal subsidy of health care costs increased, and there was greater federal control of state programs. Health services became regionalized and more comprehensive. Federal appropriations supported operational as well as capital and planning costs. Health research and the training of health professionals gained greater federal support. Group medical practice multiplied as a cost-saving measure. More than 60% of the population was covered by some form of prepaid health insurance, largely because of the effects of Medicare and Medicaid. Interagency health planning cooperation increased, and health program evaluation improved. Neighborhood health centers, community mental health centers, and other programs were developed to improve health care access for everyone. Although costs rose, the period was one of relative economic stability that emphasized quality of care, with the federal government assuming a major role in

regulating the planning, use, and reimbursement of health care services (Dranove, 2000; Sultz & Young, 2006).

In the early 1980s, government cost control measures were greatly diminished as the Reagan era ushered in deregulation in many areas. The passage of the Omnibus Budget Reconciliation Act caused dramatic changes affecting health care. The federal government, having failed to contain rising health care costs, shifted responsibility for the public's health and welfare back to state and local governments. Large amounts of federal funding for health research, health manpower training, and public health programs were withdrawn. Continued escalation of health care costs prompted a concentrated effort among public and private providers alike to find cost-containment measures. From all this grew the competition-versus-regulation debate (Dranove, 2000; Sultz & Young, 2006).

The 1990s were marked by “merger mania” and the move from nonprofit to for-profit hospitals (Dranove, 2000, p. 115). The Clinton health plan failed to gain support, and many hospitals downsized, laying off nurses. Managed care became more popular as a means of reducing employer premiums in the early 1990s, but by the late 1990s, as they restricted benefits, fears were raised about managed care organizations withholding necessary care and a consumer “backlash” resulted (Marquis, Rogowski, & Escarce, 2004/2005, p. 1). Many states and the federal government enacted benefit laws between 1990 and 2002, in response to these concerns (Laugesen et al., 2006, p. 1,081). During this time, many smaller managed care plans merged to gain a larger market share and provide more “efficiencies, avoid duplication, and improve services” (p. 121). We are still feeling the results of these changes, and one of the most obvious consequences deals with competition in health care.

Competition, its proponents say, offers wider consumer choice and positive incentives for cost containment and enhanced efficiency (Porter & Teisberg, 2006; Sultz & Young, 2001); that is, consumers are free to select among various health plans on the basis of cost, quality, and range of services. Competing providers must develop efficient production and distribution methods to stay in business, and consumers are more likely to use only necessary services, because of the required cost sharing that is part of the competition model.

Examples of competition are increasingly evident as more health plans, including HMOs and PPOs, vie with traditional insurance companies for subscribers. Many hospitals, too, compete aggressively for patients. Some hospitals now advertise maternity care depicting a new mother and father having a candlelight dinner in the hospital with their newborn infant in the bassinet beside them. Some surgical centers advance the “hotel guest” concept, with beautifully appointed rooms, including meals and lodging for a guest.

Although it appears that competition offers the best service for the least cost, regulation advocates have for almost 20 years argued that there are at least four problems associated with the competition model: (1) consumers often do not make proper health care choices because of limited knowledge of health services; (2) competition may discriminate against enrolling certain consumers, especially high-risk, high-cost patients, thus excluding those who may need services the most; (3) the competition model may not encourage enough teaching and research—expensive

elements of our present system; and (4) quality may be sacrificed to keep costs down.

Regulation advocates conclude that standardization and controls are needed to guarantee quality and equal access. Leaders in the field have concluded that both competition and regulation are needed (Kongstvedt, 2004; Sultz & Young, 2006). With foresight, McNerney wrote in 1980, “It is rapidly becoming apparent that what we need is a proper balance between competition and regulation with more effective links [and] regulation [should be] used as a force to keep the market honest” (p. 1,091).

## HEALTH CARE REFORM POSSIBILITIES

HMOs and PPOs have become accepted methods of delivering health care in the United States in the past 30 years. During recent decades, other methods have been considered, yet not passed by legislation and adopted as law. Two plans worth further review are managed competition and universal coverage, with and without a single-payer system. The benefits and drawbacks of each are important to discuss here.

### Managed Competition

The idea of managed competition, as a health care delivery method, was born from the controversy regarding competition versus regulation and was driven by the need for health care reform. **Managed competition**, it was hoped, would combine with market competition to achieve cost savings with government regulation to achieve expanded coverage. This idea, whose origin is credited to economist Alain C. Enthoven of Stanford University, has played a major part in debates on health care reform. It sought to address the two fundamental issues driving reform: cost containment and universal access to health care (Enthoven & Talbott, 2004).

Managed competition has been viewed as a market-based solution that places accountability for resolving the health care crisis with the insurance industry and with consumers. Insurers would be required to accept all applicants, without excluding those at poorer risk. At the same time, the insurers must control costs. Consumers would choose among competing health insurance plans, paying above fixed amounts paid by their employers to receive the best value. But for true competition, employers must offer real choices and a wide variety of plans. To do this, employers may form “regional exchanges” that select health plans, manage risk selection, and establish equity rules (those plans with sicker participants would be subsidized by plans with younger, healthier participants) (Sipkoff, 2003, ¶6).

Another concept of managed competition is consumer choice, and consumers must be able to access information, so that they can make responsible choices and feel that they have purchased something of value for their money. Other common features of managed competition proposals include regulations that prevent screening-out of high-risk enrollees, penalties for companies that try to achieve better risk pools, community ratings to prevent companies from setting rates by risk pool, and guaranteed coverage for all who apply. Another critical component involves management; some standardization must be established among benefit packages and an effort

must be made to dismantle health care monopolies that endeavor to gain uneven market power—in other words, a more level playing field (Enthoven, 2004).

Proponents of managed competition cite many advantages. Managed competition would encourage insurance companies to compete on price and quality of services to attract enrollees. It would also offer consumers tax incentives to purchase the lowest-cost plans that meet minimum benefit requirements. Managed competition, although market driven, would be highly regulated to ensure quality and access. Cost-effectiveness and quality/outcomes information must be made available to consumers, although currently this information is not always easy to find or to decipher. Providers have not widely accepted systems of ranking on measures of quality. According to its proponents, managed competition, as a reform concept, would have the potential for reducing expenditures and improving access to health care coverage (Enthoven, 2004).

Managed competition may not be beneficial for physicians, however. A study commissioned by the AMA found that, in many regions of the United States, only a few health insurance companies dominate the market, and they exert significant market power. Because physicians are often unable to exert bargaining power against these large insurers—in 64% of areas studied, one health plan had a 50% or greater market share—they have called for antitrust action by the federal government to stem the further consolidation of health plans (AMA, 2007).

This example highlights some of the problems with the managed competition concept. Can market forces really work in the health care market? It remains fully untested anywhere in the world, and many believe that it would fail to achieve the needed cuts in the growth of health care spending. Similar models, such as HMOs and the Federal Employee Health Benefits Program, have failed to slow increasing health care costs (Sultz & Young, 2006).

Some argue that managed care networks, which enhance managed competition and enable health insurance plans to control cost and quality, also would limit consumers' choices in selecting their own providers and hospitals. Consumers would have to pay out of pocket if they chose services from outside the network. Cost-saving incentives built into managed competition networks still have the potential for reducing quality of services and denying care to enrollees. Other countries, such as New Zealand, have initiated health care reforms based on principles of managed competition, and these plans have not been well received by voters (Laugesen, 2005). Recent research found that health plan competition did not measurably improve quality (Encinosa & Hagan, 2006).

Another major criticism of managed competition is its potential failure to provide equitable and universal coverage. This was one of the key provisions of the Clinton Health Security Act (Budetti, 2004). It is possible that large employers would benefit financially under managed competition, but small businesses would find the cost burden heavy, and many individuals, such as the self-employed, would remain uninsured. A basic benefits package, critics argue, must address the special concerns affecting groups such as women and elderly adults, including coverage for long-term care, home care, mental health, dental care, and prescribed drugs. Competition among providers would be inefficient in rural areas, where there are fewer provider

choices, such as county nursing agencies and isolated small-town hospitals scattered over great distances.

Although the private insurance industry and many physicians have endorsed the managed competition concept, a number of respectable groups in the United States strongly oppose it. Among the organizations that oppose managed competition and support some kind of single-payer plan are the ANA, the National League for Nursing, the APHA, Physicians for a National Health Program, and the American Association for Retired Persons (AARP). Dissatisfaction with managed competition as a reform solution has spurred a host of different proposals, all addressing cost savings and access issues.

## Universal Coverage and a Single-payer System

A different approach to health care reform emphasizes universal health insurance coverage, often through a stronger role played by government. Some proponents of this system of health care promote a **single-payer system** that would replace the health insurance companies in the United States with a single, public-sector insurer that would entitle all citizens to **universal coverage** (everyone would have health insurance of some type, assuring better access to care). Efforts to accomplish this approach have been evident for many years.

Since the time of Teddy Roosevelt in 1912, national health insurance (NHI) has been debated while its proponents have sought comprehensive health care protection, in particular, for the aged, children, and the needy. Presidents Roosevelt (both Theodore and Franklin), Truman, Nixon, Carter, and Clinton have all lobbied for some form of NHI or universal health coverage (Cutler, 2004). Growing concern over the cost and accessibility of health services in the 1960s and again in the mid 1970s led to a renewed focus on NHI as a solution by which health insurance coverage could be provided for all citizens through a single-payer system or a mix of public and private insurers. Numerous attempts to pass some form of NHI resulted in piecemeal legislation that added various benefits for Social Security recipients. The Kerr-Mills bill (1960) set a precedent of public financing for elderly persons who were medically needy but not receiving public assistance. Medicare (1965) was the first compulsory NHI program in the United States. By 2001, it reached some 40 million people—only 16% of the total U.S. population (CMMS, 2007).

Most other developed countries offer some type of NHI or attempt to provide universal health coverage to their citizens. Other countries believe that health care is a fundamental right, and provide it as a social service, unlike the United States, which tends to view it as a commodity that is only available based on one's ability to pay (Woolhandler et al., 2003). The APHA has long been an advocate of universal health care, initially endorsing a single-payer system. The APHA is now endorsing more incremental extensions of current forms of health coverage along with health care delivery system reforms (Akhter, 2003).

Although many agree that insuring all Americans will improve overall national health and performance, the concept of a government-sponsored, single-payer system is controversial (Himmelstein & Woolhandler, 2003). Even though polls reveal that Americans are dissatisfied with the current health care system, they usually report being satisfied with

their own arrangements for health care—and they are uncomfortable with the idea of a government-controlled health plan (Blendon et al., 2006). Single-payer plans could provide cost savings from reduced overhead and administrative costs. Compelling evidence suggests that between \$320 billion to \$1.1 trillion could be saved through universal health care coverage over the first decade, and the quality of the health care system would substantially improve (Broder, 2005). Once everyone has access to health care, attention can focus more on primary interventions and less on expensive tertiary care because people will either remain healthier or be treated earlier at lower costs (Broder, 2005).

What is the best way to provide universal coverage? Should health insurance still be linked to employment? How can the expense be funded? Should citizens become more responsible for their health outcomes? How can quality be ensured and costs managed? These are important questions, and many policy makers and health care economists are working on potential solutions (Heskett, 2007).

In testimony to Congress, experts from the Commonwealth Fund encouraged the design of a universal health care system that meets four criteria: improves access to care, has the potential to slow cost increases and improve efficiency, improves equity in the system, and has the potential to improve health care quality (Collins, 2007).

Some politicians propose expanding Medicare, Medicaid, and the SCHIP programs, or focusing more on prevention and individual responsibility. Other groups support a system of tax credits, employer and individual taxes, and more “transparent information about costs and quality” (International Foundation for Education, Benefits & Compensation [IFEBC], 2007, ¶10). Some states have begun to initiate legislation to extend coverage to uninsured residents. Illinois extended coverage to all children through a program called *All Kids*, and ways to extend coverage to uninsured adults are being examined. Washington extended insurance coverage for unmarried dependents to age 25 and organized a “state purchasing pool” to help small businesses find health insurance for employees (¶ 27). Maryland attempted to tax large, for-profit employers (the “Wal-Mart bill”) in an effort to provide health coverage for the large uninsured population, but the attempt was overturned in the courts. Massachusetts initiated universal health coverage in 2006, and created a state agency to provide information on health insurance plans to consumers and employers. At the same time, Massachusetts requires all residents above a set income level to get insurance coverage from their employer or purchase it individually (IFEBC, 2007). Some people think that universal coverage will not be attained because of the partiality toward private insurers and the plan’s lack of cost control measures and lack of adequate provisions for low-income families (Himmelstein & Woolhandler, 2007). Setting potential inadequacies aside, some states have at least begun to incrementally approach the problem of universal coverage.

Proposals to build upon the current mix of public and private insurance may be most acceptable (Tooker, 2003). This could be accomplished by expanding Medicare, Medicaid, and SCHIP coverage, along with a new group insurance program with a variety of options similar to the Federal Employees Health Benefits Program (FEHBP) and requirements for insurance coverage for all with income-related subsidies, as needed (Broder, 2005; Collins, 2007; Tooker,

2003). Currently, the federal government provides health insurance through FEHBP to over 9 million employees (e.g., members of congress, park rangers, postal workers) by contracting with a variety of insurers who must agree to provide coverage to everyone at the same premium rate (Cutler, 2004). Most agree that a combination of higher taxes and employer/employee fees could subsidize a public–private plan that could cover all Americans (Cutler, 2004; Kahn & Pollack, 2001).

How much will universal coverage cost? It depends upon which type of plan is chosen, but most agree it will not come cheaply. One economist projected costs of coverage for the current uninsured population to run about \$75 billion annually. However, by the end of 10 years, net savings would be between \$125 billion and \$182 billion annually (Broder, 2005). Others have projected \$200 billion cost savings annually by providing universal health coverage and “eliminating the high overhead and profits of the private, investor-owned insurance industry and reducing spending for marketing and other satellite services” (Woolhandler, et al., 2003, p. 798).

Even if everyone receives health insurance, how can quality be assured? Some believe that the overall performance of the health care system will improve as everyone gains access to care. However, others propose “quality-based bonus payments” as an incentive (Cutler, 2004, p. 115). Still others think that a system providing incentives to *both* providers and patients to use services efficiently and effectively will produce the best results (Collins, 2007). Providing information to consumers is another component of quality assurance, and this is sorely lacking. But, information is becoming more readily available. For instance, the Leapfrog Group (2007) promotes *transparency* through surveys of standard measurements and practices to enable comparisons, and reimbursement incentives to encourage quality and efficiency. Scores for local hospitals can be reviewed at the Leapfrog website (see Internet Resources at the end of this chapter). The quality of insurance plans, measured by the Health Plan Employer Data and Information Set (HEDIS), includes information on patient satisfaction, data on risk factor control, and procedures such as prescribing beta ( $\beta$ )-blockers after heart attacks, and is monitored by the National Committee for Quality Assurance (NCQA). Other systems of quality measurement, like health outcomes, the process of care, and adherence to standardized guidelines, among other things, are still needed (Cutler, 2004).

## Health Care Reform: Making the Change

The cry for health care reform is not new. Perkins examined the work of the 1927 to 1932 Committee on the Costs of Medical Care. More than 75 years ago, the committee defined *costs* as the major problem and *business models of organization* as the major solution (Perkins, 1998). Today, consumers and professionals agree that health care reform is needed in the United States. The disagreement lies in the form that it should take and the speed at which it should be completed. At issue is a fundamental conflict in values between advocates of the managed competition model and advocates of the universal coverage or single-payer plan. On the one hand are those who strongly value the competition model, which ensures a free market, individualism, and the right to choose the type of health care desired. On the other

hand are those who propose a more regulated, statutory model.

Proponents of universal coverage argue that more comprehensive benefits are needed to include the unemployed and those who are physically or economically disadvantaged and cannot afford individual health care coverage. Furthermore, they argue that universal coverage emphasizes prevention and primary health care as key factors in reducing long-range health care costs and, more importantly, in ensuring improved levels of health for the public (Collins, 2007). *Nursing's Agenda for Health Care Reform* (American Nurses Association [ANA], 2002) supports this emphasis by promoting nurses as primary providers of health care. The ANA's nursing's agenda proposes a *core of care* that involves restructuring of the health care system, a federally defined standard package of essential health care services, planned change to anticipate the needs of a population with changing demographics, steps to decrease costs, insurance reform, case management, assured access to health care for all, and establishment of public/private sector review. This plan is enthusiastically endorsed by more than 60 nursing organizations and four non-nursing organizations.

Designers of health reform have faced a difficult challenge in reconciling these conflicting views. As a result, elements of both models have been used to shape an improved system. Reform proposals include an incremental plan that allows for a flexible transition and opportunities for states to experiment with both approaches. Sultz and Young (2006) and Collins (2007) point out the importance of separating the task of financing (how insurance funds are collected) from that of disbursement (how providers receive payment) and implementation (how to put a plan in place). Financing might be tried through an income-based premium that would go into a publicly administered health insurance fund. The methods of collection and administration can then be decided. Japan and Germany have used a payroll-collection method for years to successfully finance their health care systems. Supplemental financing (to adjust for low-income or no-income households) might come from an extra tax on those with moderate to high incomes or from a tax on products that are known to contribute directly to health care costs, such as alcohol and tobacco. Some have even proposed a tax on fat in foods as a means of raising revenues while impacting the problem of obesity (Chouinard, Davis, LaFrance, & Perloff, 2007).

Disbursement of health insurance funds could occur in at least two ways. First, a strictly federal program could enroll all Americans who are not privately insured and disburse funds through a program similar to Medicare or the Federal Employees Health Benefits Plan, as noted earlier. A second option could be to disburse capitation funds from the federal government to the states for payment to providers. In some cases, state funds could supplement federal disbursement. Forms of either the single-payer or the managed competition models could be tried to accomplish disbursement, allowing states to adjust for local preferences and existing delivery systems (Cutler, 2004; Sultz & Young, 2006).

Another aspect of health care reform that has been considered is a global budget. In this system, a single, nationwide health budget would help to control certain aspects of national health spending. Much like the Oregon Health Plan (mentioned earlier), funding might come from

income-based premiums plus supplemental sources (Loewy & Loewy, 2001). The amount of money in this budget would help to determine the size of disbursements to federal programs (e.g., Medicare) and to the states. States could choose to spend more on health care out of their own resources, or to limit the provision of services.

A standard set of benefits, set by law and enjoyed by the entire population, regardless of age, health, income, and employment status, is an important health care reform element. Many countries have successfully implemented such a package under a plan called a *statutory model*. Various versions of this model have worked well in Austria, France, Belgium, Japan, Germany, Israel, Poland, the Netherlands, and Switzerland. In this model, health insurance falls under the rubric of social security, and is funded through government-mandated payroll premiums or taxes. Payment is made to private-sector health insurers, from a fund called a *sickness fund* in some countries (Loewy & Loewy, 2001). Individuals select among nationwide plans and choose their doctor and hospital, and can switch plans when desired. This element of consumer choice is thought to encourage the sickness funds to respond to consumer preferences and improve efficiency in the health care system (van de Ven et al., 2007). Reimbursement for services is made directly by insurers to providers. In Germany, a disease management program was added to the statutory health insurance plan in the 1990s; its purpose is to both promote competition and increase the quality of care (Stock, Redaelli, & Lauterbach, 2007). This statutory model eliminates the need for separate programs such as Medicaid and Medicare. It also provides uniform and comprehensive benefits (Harrington & Estes, 2004; Loewy & Loewy, 2001). See Display 6.3 for a comparison of health systems in four developed countries.

Other issues to be addressed in health reform include making the system more accountable, eliminating adverse risk-selection, and providing informed choices to consumers. Although reform is under way, the need continues for strong advocates of universal access and cost containment. Furthermore, health reform proposals must be encouraged to focus on the central question: Do they fund the promotion of health and prevention of illness or simply pay for the diagnosis and treatment of those who are already ill? World Bank evaluations show that public health interventions have been found to be consistently more cost-effective than medical services, yet health reform proposals have often paid minimal attention to this critical issue. In addition, "the current emphasis on managing medical care for cost containment disregards the social and environmental genesis of many health problems" (McIntosh, 2002, p. 85). Community health nurses can play an influential role in emphasizing health promotion services as being central to future health reform efforts through political involvement and policy development.

## EFFECTS OF HEALTH ECONOMICS ON COMMUNITY HEALTH PRACTICE

Health economics has significantly affected community health and community health practice by advancing disincentives for efficient use of resources, incentives for illness care, and conflicts with public health values.

## DISPLAY 6.3

## HOW FOUR OTHER COUNTRIES APPROACH UNIVERSAL HEALTH CARE

**Canada**

- Publicly financed, provincially run insurance plans that cover *all* residents (70% from national and provincial funds)
- Covers all “medically necessary” physician and hospital care
- Nonprofit administration of health plans
- Comprehensive coverage, portability between provinces, not dependent on employment, addresses universality and accessibility
- Has intermittent problems and some complaints of long wait times, but access, quality, and satisfaction is generally high

**France** (ranked first by the WHO in 2000 when the French reached 100% coverage)

- Public and private mix (funding from general revenues for social insurance and patient cost sharing)
- Covers ambulatory and hospital care, medications, dental and vision, nursing home, thermal spa cures, and some other alternative therapies
- Compulsory universal coverage
- Higher health status indicators, consumer satisfaction, more health care resources

**Germany**

- German Statutory Health Insurance since 1883 (93% covered by national health insurance, remainder by private insurance; between 7% and 10% have both)
- Mandatory contributions by employers and employees (work-based social insurance and patient cost sharing)
- Choice of physician, hospital, long-term care facility; medication and dental
- Portability of coverage, legally set caps or fixed budgets, modest co-payments and no deductibles

**Great Britain (United Kingdom)**

- National Health Service since World War II (funded from general revenues)
- Well-designed system, but chronically underfunded

- Tax-based, free at point of service (covers ambulatory care, hospital, medications, long-term care, vision)
- Choice of physician, generally short wait times for appointments, but longer waiting lists for elective referrals to specialists (average of 46 days)
- Private care is available (11.5% have this), and patients with this are seen more quickly and have more luxurious accommodations; new additions include registered nurse call-in service, web-based information, and integrated services (social/community-based)

**All Four Nations**

- Spend substantially lower percentage than the United States for health expenditures
- Pay physicians less and have fewer specialized and high-tech services
- Try to cap health spending (budget caps, spending targets, linking health cost increases to wage increases, utilize waiting lists, offer less widely diffused technology)
- Are working to improve integration of care (networks of care, comprehensive integrated community-based care, better managed care)
- Have interest in analytic tools (evidence-based medicine, report cards, cost-effectiveness analysis)
- Report high levels of satisfaction with their systems (but they are not without some criticism)
- Have strong central government leadership (states, provinces, and regional bodies consult on policy making and administrative decisions)

Adapted from Brown, L.D. (2003). Comparing health systems in four countries: Lessons for the United States. *American Journal of Public Health, 93*(1), 52–56.

## Disincentives for Efficient Use of Resources

All of the system structures that directly or indirectly promote cost escalation and prevent cost containment contribute to disincentives for efficient use of resources. For example, retrospective financial reimbursement, with its lack of setting limits, encourages spending on nonessential tests and treatments and drives up costs. Tax-deductible employer contributions for health care coverage and nontaxable employee health benefits encourage unnecessary use of services and result in cost increases. Lack of cost sharing by consumers and of financial risk for decisions made by providers may create further disincentives to keep costs down (Cutler, 2004; Dranove, 2000).

Community health has been affected in several ways. Abuse of resources in some parts of the system leads to depletion in other areas. The trend of diminished federal and

state allocations has had profound effects on community and public health programs, and severe budget cuts have affected even basic community health services. Competition from the private sector in home care and other community services, such as health education programs, has forced traditional public health agencies to reexamine their traditional programs and seek new avenues for the provision of services, along with new revenue sources (Institute of Medicine, 2002). Costs indirectly affect even appropriate use of nursing personnel in community health. Failing to recognize the differences in skill levels of community health nurses and their less-prepared counterparts, public health departments and agencies often have hired persons who are underqualified to give the high-caliber and comprehensive care required. Finally, the advent of prospective payment and limits on lengths of stay have encouraged early hospital discharge, resulting in more acutely ill people needing home

care services. The immediate effect was an increase in the demand for highly skilled and more expensive home care services, which required changes in provision patterns of community health care. As acute care nursing shortages have intensified and salaries have increased, the number of open, unfilled PHN positions has mounted (Chiha & Link, 2003). The long-range effects of this phenomenon on family stress and caregiver health, on community health care reimbursement, and on the nature and structure of community health services, including the role of the community health nurse, have yet to be determined.

### Incentives for Illness Care

The traditional American health care system tends to promote illness, because health care providers have primarily been rewarded for treating problems, not for preventing them. Hospitals derive more income when their beds are full of sick or injured people. Health insurance plans compete, not by lowering costs or increasing quality, but by “avoiding the sick”—leaving many without access to necessary health care (Woolhandler et al., 2003, p. 798).

The bulk of most reimbursable health services centers on treating illness or disability in hospitals, nursing homes, and ambulatory care facilities, using physicians or skilled nursing care in the home (home health services)—situations in which the individual must play the role of patient. Our disease-focused system of health care is thought by many to be the basic problem (Adams, 2006). It rewards disease by paying doctors who diagnose, treat, and refer ill patients. It does not pay them for keeping their patients healthy. Most preventive care is woefully inadequate and largely overlooked by both practitioners and patients alike: Remember, fewer than half of all U.S. adults receive recommended health screening tests annually (Schoen et al., 2006). Health promotion nursing activities, such as comprehensive prenatal, maternal, and infant care; health education; childhood immunizations; and home services to enable the elderly to live independently have not always been consistently covered by most insurers.

A system that financially supports illness care affects community health practice in several ways. The number and severity of health problems in a community increase when individuals postpone care because they cannot afford visits to the doctor or clinic. It has been more difficult to encourage community clients to assume responsibility for their own health and to engage in self-care, prevention, and active health promotion. Furthermore, such illness-oriented incentives create a basic societal valuing of illness care that, conversely, devalues wellness care. Health promotion and disease prevention efforts become second-ranked priorities in the competition for scarce resources. In communities where a greater proportion of community health practice is spent in the treatment of disorders and rehabilitation, resources are more limited for prevention and health promotion.

Prepayment methods and the growth of managed care have been positive moves in the direction of a more wellness-oriented financial incentive structure. An HMO has the incentive to offer preventive and health-promoting services, such as early detection and treatment of symptoms, regular physical examinations, and health teaching, because the HMO loses money when it must pay out for expensive tertiary

care. Health care reform proposals show promise of greater recognition of the cost-saving value of prevention efforts. In the Michael Moore documentary, *Sicko*, British physicians reveal that they are awarded “bonuses” for encouraging healthy behaviors (e.g., getting patients to stop smoking) and for successful management of diseases (e.g., hypertensive patients who remain on medications to control blood pressure and cholesterol levels). Some in the United States have proposed a paradigm shift to “health consultants” or “healers” who “only get paid when you stay healthy, not when you are sick,” and a change from managed care to *life maintenance organizations* (LMOs) that provide life insurance and advise on needed health care—thus, having a true incentive to keep you in good health because they will be paying your life insurance claim if your life is shortened by an avoidable illness (Adams, 2006, ¶4; Hanson, 1994). The focus of the system would be on proper nutrition, exercise, health education, and prescription drugs to keep people healthy, not just treating disease.

Managed care has evolved but remains a “system of business strategies employed to make health care services efficient and cost-effective,” with the highest priority to maximize market principles (Drevdahl, 2002, p. 163). This makes individual rights significant, whereas societal obligations are pushed to the background. “Freedom of choice and action take precedence over issues of equality and equity” (p. 163). The managed care organizations (MCOs) have business-focused goals that are given more consideration than is the issue of equal access to health care.

### Managed Care and Public Health Values

Initially, MCOs focused on event-driven cost avoidance. Strategies included decreasing inpatient days, decreasing specialty physician use, using physician extenders, and implementing provider discounting. This evolved into a second stage, in which the principal objective was to control resource intensity and improve the delivery process. Strategies used to meet this objective included capitation of specialist costs, controls on units of service, patient-focused redesign, clinical pathways, and total quality management.

The emphasis, however, is now shifting to a focus on community-based health status improvement that goes beyond just measuring utilization of care or mortality outcomes. This focus calls for new strategies, such as community health assessments, identification of high-risk individuals, targeted interventions, case management, and management of illness episodes across the continuum. (Weiss, 1997, p. 28)

Some believe that community health assessments could become standard quality tools for MCOs (Porche, 2004; Weiss, 1997). Community assessments establish the baseline health status of a community and measure changes in the health of the community over time. Community health assessments must include source information that is both primary (health status assessment surveys, focus groups, and satisfaction surveys) and secondary (data collected by public health agencies and state agencies, such as birth rates, mortality rates, and incidence of communicable diseases in the community) (see Chapter 15).

Improving the health status of a community mandates that the MCO—the organization providing health care services through managed care agencies, such as an HMO or PPO—be actively involved in accurately assessing the community's health status and the major issues facing the community. This involves “informing health care consumers of how to care for themselves, and empowering them to do so, and developing a community action plan that fosters collaboration among organizations and focuses on preventive service strategies” (Weiss, 1997, p. 29). Are these not the proposals that public health advocates have been making for more than a century?

In 2002, Drevdahl expressed concerns regarding the paradoxical missions of public health and managed care. One relies on partnerships for fostering health care equity and creating healthy communities and populations as it embraces a social justice mission, whereas the other “falls more along the line of market justice” (p. 163). Perhaps the incentive to keep costs down will be the motivation needed to work with clients at the primary prevention level of care. Although public health proponents have advocated preventive care as the best care for the individual, family, and community as long as the goal of community health is reached, the motivating factor becomes insignificant. If the community health approach is embraced by MCOs, the conflict with public health can be minimized and perhaps eliminated.

Competition in health care is a reality with which community health practice must cope. Although competition offers several benefits, it poses some dilemmas for community health that may be difficult to resolve. Values underlying the competition model can be in direct conflict with several basic public health values (Drevdahl, 2002; Scutchfield & Keck, 2003). Competition for the healthier and younger enrollee, for example, encourages MCOs to develop market strategies that entice the client to choose one plan over another. This is a win–lose situation for the MCO: one MCO wins while another loses. Public health, however, operates on the basis of collaboration and cooperation.

Competition among MCOs serves a selected market partly determined by those who are able to purchase products or services. Public health is committed to serving all persons in need, regardless of ability to pay. Traditionally, the competition model has focused on individuals and has been oriented to the present. Public health is concerned with aggregates and is future oriented, emphasizing prevention. Competition establishes relatively fixed limits for service, whereas public health must remain flexible if it is to respond to the health needs of the entire population. These dramatic differences between MCOs and public health are beginning to blur and, out of necessity, will continue to be less adversarial and more collegial. By shifting their focus to community health as a systems outcome, MCOs can create several positive changes, including a safe environment, wholesome nutrition, healthy lifestyle, adequate education, sufficient income, meaningful spirituality, challenging work, recreation, and functional families (Meador & Linnan, 2006; Weiss, 1997).

If enrollees in health insurance programs like Medicare, Medicaid, or other MCOs become empowered to assume responsibility for their own self-care and well-being, a cooperative and collaborative relationship can be achieved between MCOs and public health. A nurse-directed diabetes management program at a county public health clinic in Los

Angeles County reflects the potential benefits of public health services for clients of MCOs and other private health care plans. PHNs were able to significantly reduce the numbers of urgent care and ER visits, along with hospitalizations, for diabetic patients from a minority population (Davidson, Ansari, & Karlan, 2007). Working together, better health can be achieved for large numbers of patients.

Along with philosophical differences, other constraints exist, such as civil service restrictions and political influences, under which most public health agencies must operate and that make it difficult for them to compete. Likewise, MCOs have stockholders, boards of directors, employees, and state and federal regulations that they must satisfy. Public health agencies must remain committed to providing the health promotion and disease prevention services that are their public trust. This may become the commitment of MCOs as they see the cost savings and health benefits of disease prevention. Yet, some aspects of competition seem necessary if both forms of health care delivery are to stay in business. Exclusion from health care competition, freedom from unreasonable constraints, and dependable financial support are needed to maintain the organizational viability of many public health agencies. Public health systems can incorporate marketing principles common to MCOs as a means of improving utilization and visibility (Lega, 2006). Competition also may stimulate new and innovative community health services and the introduction of new roles and revenue sources for traditional public health agencies. The evolution of the reform of health care implementation may see developing public and private health care partnerships, with MCOs contracting with public health agencies for certain services and MCOs more effectively expanding the reach of public health agencies into the suburbs or rural areas. Reform will need to continue to address issues affecting the delivery of public health services.

## IMPLICATIONS FOR COMMUNITY HEALTH NURSING

The structure and functions of the health care delivery system, as well as particular legislative acts, have had a significant impact on community health nursing. Community health nurses have had to adapt to a constantly changing system. They have developed innovative modes of service delivery, such as community-based nursing centers for health education, counseling, and screening of low-income populations. They have learned to practice in a variety of settings extending beyond homes, worksites, schools, churches, clinics, and voluntary agencies. They have acquired skills in teamwork, leadership, and political activism. They have recognized the importance of outcomes research to document the value of nursing interventions with at-risk populations.

At the national, state, and local level, community health nursing has important ties to both private and public health agencies. Either type of organization may employ community and public health nurses. When serving in the public sector, they often provide consultation, serve on boards, volunteer their services, or collaborate with private-sector health organizations to ensure quality and access of care to the broader community. Examples include joint efforts to promote certain types of health legislation and collaboration to produce and disseminate health education materials targeting specific

populations (Porche, 2004). Sometimes, community health nursing services operate within a single organization that combines public- and private-sector organization and funding. An example is the Metropolitan Visiting Nurse Association of Minneapolis, Minnesota, which is a combined public–private agency supported by taxes and voluntary funds.

Community health nurses also have many opportunities to serve in international health. Some work with the WHO, PAHO, or other agencies to assist in direct care projects such as famine relief, immunization efforts, or nutritional screening and education programs (see Chapter 16). Other nurses serve as health planners, assist with policy development, conduct collaborative needs assessment projects and research efforts, or engage in program development.

## Summary

Many factors and events have influenced the current structure, function, and financing of community health services. Understanding this background gives the community health nurse a stronger base for planning for the health of the population under her care.

Historically, health care has progressed unevenly, marked by numerous influences. Primitive practices of early centuries were replaced with more advanced sanitary measures by the Greeks and Romans. The Middle Ages saw a serious health decline in Europe, with raging epidemics leading to extensive 19th-century reform efforts in England and, later, in the United States.

Organized health care in the United States developed slowly. Public health problems, such as the need for isolation of persons with communicable diseases and control of environmental pollution, prompted the gradual development of official interventions. For example, quarantines to control the spread of communicable disease were imposed in the late 1700s. Sanitary reform was pursued more vigorously during the 1800s. Local and then state health departments were formed starting in the late 1700s. By the early 1900s, the federal government had assumed a more active role in public health, with a proliferation of health, education, and welfare services.

For years, efforts to address community health needs have been made by public agencies and private individuals. These two arms of service were not well coordinated in the past. Only gradually and recently have they begun to work together to form an emerging health care system.

The public arm of health services includes all government, tax-supported health agencies and occurs at four levels: local, state, national, and international. Each level deals with the health needs of the population encompassed within its boundaries. Each level has a different structure and set of functions. Public health services include three core public health functions: assessment, policy development, and assurance.

Private health services are the unofficial arm of the community health system. They include voluntary nonprofit agencies as well as privately owned (proprietary) and for-profit agencies. Their financial support comes from voluntary contributions, bequests, or fees. Private health organizations often supplement and complement the work of official agencies.

The delivery and financing of community health services has been significantly affected by various legislative acts. These acts have prompted such innovations as health insur-

ance and assistance for the poor, the elderly, and the disabled; money to train health personnel and conduct health research; standards for health planning and delivery; health protection for workers on the job; and the financing of health services.

Health care economics studies the production, distribution, and consumption of health care goods and services to maximize the use of scarce resources to benefit the most people. This science underlies the financing of the health care system. It is influenced by microeconomics as well as macroeconomics.

Health care is funded through public and private sources, which fall into three categories: third-party payers, direct consumer payment, and private support. Health care services have been reimbursed either retrospectively, typical of FFS plans, or prospectively, typical of most HMOs.

Several trends and issues have influenced community health care financing and delivery and are important in understanding health care economics and helping to improve community health. They include cost control, financial access, managed care, health care rationing, competition and regulation, managed competition, universal coverage, a single-payer system, and health care reform.

The changing nature of health care financing has adversely affected community health and its practice in three important ways: (1) retrospective payment without limiting costs, tax-deductible employer contributions for health care coverage and nontaxable employee health benefits, together with a lack of consumer involvement in cost sharing, have created disincentives for efficient use of resources; (2) because the health care system traditionally has reimbursed only for treatment of the ill or disabled, with no reward for health promotion and prevention efforts, it has promoted incentives to focus only on illness care; and (3) the competition model, which has long driven up health care costs and eliminated many from being able to afford health care services, has generated a conflict with the basic public health values of health promotion and disease prevention for all persons. Health care reforms have been proposed, but the United States remains the only industrialized nation without some type of universal health coverage. We also rank significantly lower than most other developed countries on health indicators, such as infant mortality and life expectancy.

Public health nurses can lead the effort in making health care more accessible to all citizens and encourage policies and practices that promote health, rather than reward illness. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Interview someone at your local health department. How do the services offered compare with those listed in this chapter? How do PHNs in this agency incorporate the core public health functions?
2. Make an onsite visit to your state health department or visit its website. Compare its functions with the core public health functions described in this chapter. Identify areas where improvement may be needed.
3. Conduct an interview onsite with someone at a private health agency, voluntary agency, or community-based

non-governmental organization (or NGO). Compare the agency's functions with those listed in this chapter for private health agencies. Describe how this agency works collaboratively with public health agencies and other community organizations. What is the role of the nurse in this agency? How does the role compare to PHNs in the local public health agency?

4. Look up various international health agencies online. Explore websites that discuss current international health care issues. What topics are of current concern? For example, are new epidemics or emerging strains of a virus being highlighted? What could (or should) a community health nurse in your local community do with this information?
5. With your classmates, debate the pros and cons of a strong federal role in health care provision, as opposed to decentralized (state and local) control.
6. Interview two consumers about their perception of the problems and strengths of our health care system. Select people who represent distinctly different age groups and life situations, such as a single 25-year-old mother of three children making minimum wage and a 75-year-old widower.
7. Form two teams and debate the advantages and disadvantages of managed competition as opposed to mandatory universal coverage. What are the advantages and disadvantages of a single-payer system? Is some form of national health insurance feasible in the United States? What would be the most efficient way of assuring universal coverage?
8. Locate recent articles and legislation on health care reform, strengths and weakness of the public health system, and the uninsured population. What are the most common themes on each issue? What most surprised you about your results?
9. Talk with your classmates and other students at your college or university about their access to health care and if they have some type of health insurance. Does your campus have a student health center? What services are offered there? What are the average costs to students?

## Epidemiology in Community Health Care

### LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Explore the historical roots of epidemiology.
- ◆ Explain the host, agent, and environment model.
- ◆ Describe theories of causality in health and illness.
- ◆ Explain a *web of causation* matrix that assists you with recognizing multi-causal factors in disease or injury occurrences.
- ◆ Define immunity and compare passive immunity, active immunity, cross-immunity, and herd immunity.
- ◆ Explain how epidemiologists determine populations at risk.
- ◆ Identify the four stages of a disease or health condition.
- ◆ List the major sources of epidemiologic information.
- ◆ Distinguish between incidence and prevalence in health and illness states.
- ◆ Use epidemiologic methods to describe an aggregate's health.
- ◆ Discuss the types of epidemiologic studies that are useful for researching aggregate health.
- ◆ Use the seven-step research process when conducting an epidemiologic study.

*“Investigation may be likened to the long months of pregnancy, and solving a problem to the day of birth. To investigate a problem is, indeed, to solve it.”*

—Mao Tse-Tung

### KEY TERMS

Agent  
Analytic epidemiology  
Case-control study  
Causality  
Cohort  
Cross-sectional study  
Descriptive epidemiology  
Endemic  
Environment  
Epidemic  
Epidemiology  
Experimental epidemiology  
Experimental study  
Global health patterns  
Host  
Immunity  
Incidence  
Morbidity rate  
Mortality rate  
Natural history  
Pandemic  
Prevalence  
Prevalence study  
Prospective study  
Rates  
Retrospective study  
Risk

 **Epidemiology** is “concerned with the distribution and determinants of health and diseases, morbidity, injuries, disability, and mortality in populations” (Friis & Sellers, 2004, p. 5). It is a specialized form of scientific research that can provide health care workers, including community health nurses, with a body of knowledge on which to base their practice and methods for studying new and existing problems. The term is derived from the Greek words *epi* (upon), *demos* (the people), and *logos* (knowledge): the knowledge or study of what happens to people. Epidemiologists ask such questions as the following:

- ◆ What is the occurrence of health and disease in a population?
- ◆ Has there been an increase or decrease in a health state over the years?
- ◆ Does one geographic area have a higher frequency of disease than another?
- ◆ What characteristics of people with a particular condition distinguish them from those without the condition?
- ◆ What factors need to be present to cause disease or injury?
- ◆ Is one treatment or program more effective than another in changing the health of affected people?
- ◆ Why do some people recover from a disease and others do not?

The ultimate goals of epidemiology are to “determine the extent of disease in a population, identify patterns and trends in disease occurrence, identify the causes of disease, and evaluate the effectiveness of prevention and treatment options” (Aschengrau & Seage, 2008, p. 33). With knowledge regarding the scale and nature of human health problems, solutions to prevent disease can be sought, thereby contributing to the improved health of the entire population.

Epidemiology offers community health nurses a specific methodology for assessing the health of aggregates. Furthermore, it provides a frame of reference for investigating and improving clinical practice in any setting. For example, if a community health nursing goal is to lower the incidence of sexually transmitted diseases (STDs) in a given community, such a prevention plan requires information about population groups. How many STD cases have been reported in this community in the past year? What is the expected number of STD cases (the morbidity rate)? Which members of the community are at highest risk of contracting STDs? To be effective, any program of screening, treatment, or health promotion regarding STDs must be based on this kind of information about population groups. Whether the community health nurse’s goals are to improve a population’s nutrition, control the spread of human immunodeficiency virus (HIV), deal with health problems created by a flood, protect and promote the health of battered women, or reduce the number of automobile crash injuries and fatalities at a specific intersection, epidemiologic data are essential.

## HISTORICAL ROOTS OF EPIDEMIOLOGY

The roots of epidemiology can be traced to Hippocrates, a Greek physician who lived from about 460 to 375 BCE and who is sometimes referred to as the first epidemiologist.

Hippocrates and other members of the Hippocratic School believed that disease not only affects individuals but also affects the masses. This was one of the earliest associations of the occurrence of disease with lifestyle and environmental factors, specifically geographic location (Lawson & Williams, 2001). Not until the late 19th century however, did modern epidemiology come into existence.

An **epidemic** refers to a disease occurrence that clearly exceeds the normal or expected frequency in a community or region. In past centuries, epidemics of cholera, bubonic plague, and smallpox swept through community after community, killing thousands of people, changing the community structure, and altering the lifestyle of masses of people. When an epidemic, such as the bubonic plague (also called pneumonic plague or the Black Death) or acquired immunodeficiency syndrome (AIDS), is worldwide in distribution, it is called a **pandemic**.

Epidemic and pandemic diseases clearly prompted the development of epidemiology as a science. Epidemiology became a distinct branch of medical science through its concern with massive waves of infectious diseases. In 1348 and 1349, the Black Death (likely caused by the bacillus *Yersinia pestis*) swept through continental Europe and England, killing millions of people. In England alone, the epidemic resulted in the deaths of 30% to 60% of the population (Theilmann & Cate, 2007).

The plague continued in Europe, but with less force, for three centuries and then waned, only to reappear in an epidemic in Hong Kong in 1894. Discovery of the plague bacillus was first attributed to Shibasaburo Kitasato (1852–1931), a Japanese bacteriologist (Solomon, 1997). Procedural issues with Kitasato’s work however, eventually resulted in the attribution to Alexandre Yersin (1863–1943), who worked in Hong Kong at the same time (Solomon, 1997). The name of the bacillus, *Yersinia pestis* reflects his acknowledged discovery. Within 4 years, another scientist, Paul-Louis Simond, had traced the bacillus life cycle from rats to fleas to humans; he postulated that the bite of a *Yersinia*-infected flea caused plague in humans. Although viewed with skepticism, by 1906 the scientific community finally accepted the route of disease transmission described by Simond and others (Simond, Godley, & Mouriquand, 1998). With this combined knowledge, intervention was now possible, and public health officials declared war on rats, seeking to make ships and wharf buildings rat-proof.

One early example of a community-wide campaign against rats occurred after the outbreak of plague in California in 1900 (Evans, 1939). The campaign proved successful, and bolstered confidence in efforts to control disease outbreaks by attacking the likely source. Understanding the role that rats played in the transmission of the disease led to an effective approach for disease control. Unfortunately, plague has not been eradicated, and wild rodents, especially ground squirrels, as well as rabbits and domestic cats, remain a natural reservoir of the plague bacillus (Heymann, 2004). Cases still occur occasionally in the western half of the United States, and there are sporadic outbreaks in South America. The disease is an ongoing threat in major areas of Asia and Africa, especially in rural regions. In Europe, the area near the Caspian Sea continues to harbor wild rodent plague (Heymann, 2004). The continuing presence of a disease or infectious agent in a given geographic area, such as

plague in Vietnam or malaria in the tropics of Brazil and Indonesia, means that the disease is **endemic** to that area.

As the threat of the great epidemic diseases declined, epidemiologists began to focus on other infectious diseases, such as diphtheria, infant diarrhea, typhoid, tuberculosis, and syphilis. They also studied diseases linked to occupations, such as scurvy among sailors and scrotal cancer among chimney sweeps. In recent years, epidemiologists turned to the study of major causes of death and disability, such as cancer, cardiovascular disorders, AIDS, violence, mental illness, accidents, arthritis, and congenital defects.

### Florence Nightingale: Nurse Epidemiologist

Nursing's epidemiologic roots can be traced to Florence Nightingale (1820–1910). Her detailed records, morbidity (sickness) statistics, and careful description of the health conditions among the soldiers in the Crimean War represent one of the first systematic descriptive studies of the distribution and patterns of disease in a population. She used wedge-shaped graphs that were shaded and colored to illustrate preventable deaths of the hospitalized Crimean soldiers, compared with hospitalized soldiers in England at the time. The sophisticated level of detail in her studies heralded her as the first nurse researcher. Changes made according to her suggestions, which are common knowledge now—establishing a clean environment, providing edible foods, cleaning wounds and using new bandages, and separating infectious soldiers from injured soldiers—brought dramatic proof of the authenticity of her observations and knowledge. Forty-four of every 100 British troops were dying in the Crimea before Nightingale instituted environmental and nutritional changes in the hospital and field. When her work was finished, the mortality (death) rate was only 2% (Gabriel & Metz, 1992).

### William Farr

Nightingale's epidemiologic approach grew from her decades-long collaboration with friend and colleague William Farr (Kudzma, 2006). Farr, a physician and self-taught mathematician, is considered one of the founders of modern epidemiology (Aschengrau & Seage, 2008). As head of the Office of the Registrar General for England and Wales (Kudzma, 2006), he developed a “more sophisticated system for coding medical conditions than was previously in use” (Friis & Sellers, 2004, p. 31). Arguments for the health care reforms Nightingale sought were bolstered by her collaboration with Farr. With Nightingale's data on the frequency of mortality among groups and Farr's broader population statistics, it was now possible to make “comparisons to the population at risk as a whole” (Kudzma, 2006, p. 63). The professional liaison between Nightingale and Farr is a wonderful example of collaborative practice in addressing public health; the merging of expertise from these two disciplines resulted in much more than either could accomplish individually.

Nightingale's use of statistical data, along with her commitment to environmental reform, strongly influenced nursing's evolution into a profession whose service addressed public health problems as well as hospital care (Kopf, 1978). As nursing has evolved, public health nurses have been increasingly challenged to intervene at the aggregate level, using epidemiologic approaches to address the needs of high-risk groups and populations.

### Eras in the Evolution of Modern Epidemiology

Modern epidemiology can be described as having four distinct eras, each based on causal thinking, sanitary statistics, infectious-disease epidemiology, and chronic-disease epidemiology. In light of new research, the eco-epidemiology era is currently emerging.

Early causal thinking was dominated by the *miasma theory*, which had its origins in the work of the Hippocratic School and was formally developed in the early 1700s. This theory held that a substance called *miasma* was composed of malodorous and poisonous particles generated by the decomposition of organic matter and was the cause of disease. Prevention based on this theory attempted to eliminate the sources of the miasma or polluted vapors. Despite its base on faulty reasoning, this type of prevention had positive consequences because it made people aware that decaying organic matter can be a source of infectious diseases. This theory dominated until the first half of the 19th century. Nightingale herself never accepted the link between microorganisms and disease (Kudzma, 2006) and based her practice on this same approach. Her work in the Crimea, with its emphasis on sanitation, had positive results nonetheless.

Similarly, the pioneering work of John Snow in identifying the source of cholera in England in the mid 1800s was based on a faulty assumption that the climate was involved. Even so, he was able to trace the source of the infectious agent to the water supply and brought public attention to the link between sanitary conditions and disease. We owe much to these individuals; that they didn't understand the exact mechanisms in disease causation does not diminish their pioneering work in applied epidemiology.

The era of infectious-disease epidemiology was dominated by the *contagion theory* of disease, which developed by the mid 18th century. Prompted by the development of increasingly sophisticated microscopes, this theory attempted to identify the microorganisms that cause diseases as a first step in prevention. It inspired various theories of immunity, and even prompted some initial attempts at vaccination against smallpox. Additionally, once an agent had been identified, measures were taken to contain its spread. Fumigating ships to kill rats, protecting wharf buildings and human habitations from rats, and removing rat food supplies from easy access were all measures taken to protect the public by further preventing the spread of plague bacilli. Based on the work of Louis Pasteur, Jakob Henle, and Robert Koch, the contagion theory was refined and became best known as the *germ theory of disease* (Aschengrau & Seage, 2008), which was predominant from the late 19th century through the first half of the 20th century (Lawson & Williams, 2001).

In the era of infectious-disease epidemiology, scientists viewed disease in terms of a simple cause-and-effect relationship. Finding a single cause (plague bacilli) and attacking it (eliminating rats) seemed to be the solution for preventing many diseases. In the case of bubonic plague, this approach appeared to be quite effective. However, scientific research eventually revealed that disease causation was much more complex than first suspected. For example, although most members of a group might be exposed to the plague, many did not contract it.

With bubonic plague, as with many other infectious diseases, the characteristics of the host can determine both the spread of the disease and its individual impact. Not everyone

in a population is at equal risk; it is now known that untreated bubonic plague has a case-fatality rate of 50% to 60%; meaning that about half of those who contract the disease and are not treated will eventually die (Heymann, 2004). Furthermore, the agent and course of transmission can be quite complex. Although a flea carries the bacilli from rats to humans in bubonic plague, many infectious diseases spread directly from one human being to another. Finally, the environment must be considered as part of the cause of disease. Evidence suggests that the plague originated in the high plains of Asia and spread to other parts of the world. However, questions remain as to whether the bacillus spread from rats to ground squirrels or had always been part of the squirrels' ecology.

After World War II, the causative agents of major infectious diseases were identified, methods of prevention were recognized, and antibiotics and chemotherapy were added to the arsenal to fight communicable diseases. The focus then became understanding and controlling the new chronic disease epidemics. Researchers completed case-control and cohort studies (discussed later) that linked the causative factors of cholesterol levels and smoking with coronary heart disease and associated smoking with lung cancer. Today, the major causes of mortality in the United States are noninfectious diseases. Chronic diseases of the heart, cancer, and stroke alone account for nearly 60% of deaths; accidents (including road traffic injuries), suicide, and homicide account for another 6.5% (Miniño, Heron, & Smith, 2006). These major health problems are not caused by infectious agents.

We are entering a new era of *eco-epidemiology*, distinguished by transforming global health patterns and technological advances. **Global health patterns**, the route, form, and virulence in which diseases appear in countries around the world, with consideration of environmental, ecologic, human, technologic, and political factors, are in transformation. The West Nile virus, severe acute respiratory syndrome (SARS), and the HIV epidemic illustrate this transformation. In most cases, causative organisms and critical risk factors are known, yet diseases occur, spread, and suddenly appear in countries or regions previously free of them. We

know which social behaviors need to change, but we are at a loss about how to create a climate of permanent change, even when entire populations are at stake. For example, we know how to prevent the transmission of HIV, yet thousands of new cases are reported each year. How can preventive practices be promoted in populations at risk for communicable diseases? The same is true for many current chronic diseases. How many nurses smoke? Do you exercise as you know you should? Do you know your cholesterol level, and eat appropriate foods accordingly? What are we missing to effectively change social behaviors?

Developments in technology drive research, primarily in biology and biomedical techniques and in information system capabilities. For example, the possibility now exists through DNA studies to recognize both viral and genetic components in insulin-dependent diabetes. HIV, tuberculosis, and other infections can be tracked from person to person through identifying the molecular specificity of the organisms, and a gene to track and mark one form of breast cancer has been identified. On a broader scale, using new technology, we are now able to track the geographic distribution of disease and correlate that data with other important health risks. For instance, using these geocoding systems, overweight and obesity in children can be correlated with other factors, such as after-school recreation opportunities, distribution of fast food restaurants, farmer's markets, or socioeconomic status. Recognizing the power of such capability, one of the goals of Healthy People 2010 (U.S. Department of Health and Human Services [USDHHS], 2000) was to use geocoding at all levels (national, state, and local). In the Healthy People 2010 Mid-course Review, this goal was revised to: "increase the proportion of major national health data systems that use geocoding to promote nationwide use of geographic information systems (GIS)" (USDHHS, 2006, p. 23.13). Even with the removal of the state and local emphasis, with a baseline of 50% in 2000, the national target of this goal is 100% by 2010. The possibilities of learning through technology have just begun in this current epidemiologic era. Table 7.1 summarizes the four eras in the evolution of modern epidemiology.

**TABLE 7.1 Eras in the Evolution of Modern Epidemiology**

Era	Paradigm	Analytic Approach	Prevention Approach
Sanitary statistics (1800–1850)	Miasma: poisoning from foul emanations	Clustering of morbidity and mortality	Drainage, sewage, sanitation
Infectious disease epidemiology (1850–1950)	Germ theory: single agent related to specific disease	Laboratory isolation and culture from disease sites and reproduce lesions	Interrupt transmission (vaccines, isolation, and antibiotics)
Chronic disease epidemiology (1950–2000)	Exposure related to outcome	Risk ratio of exposure to outcome at individual level in populations	Control risk factors by modifying lifestyle (diet), agent (guns), or environment (pollution)
Eco-epidemiology (emerging)	Relations within and between localized structures organized in a hierarchy of levels	Analysis of determinants and outcomes at different levels of organization using new information systems and biomedical techniques	Apply both information and biomedical technology to find leverage at efficacious levels

## CONCEPTS BASIC TO EPIDEMIOLOGY

The science of epidemiology draws on certain basic concepts and principles to analyze and understand patterns of occurrence among aggregate health conditions.

### Host, Agent, and Environment Model

Through their early study of infectious diseases, epidemiologists began to consider disease states generally in terms of the *epidemiologic triad*, or the *host, agent, and environment model*. Interactions among these three elements explained infectious and other disease patterns.

#### Host

The **host** is a susceptible human or animal who harbors and nourishes a disease-causing agent. Many physical, psychological, and lifestyle factors influence the host's susceptibility and response to an agent. Physical factors include age, sex, race, and genetic influences on the host's vulnerability or resistance. Psychological factors, such as outlook and response to stress, can strongly influence host susceptibility. Lifestyle factors also play a major role. Diet, exercise, sleep patterns, and healthy or unhealthy habits all contribute to either increased or decreased vulnerability to the disease-causing agent.

The concept of resistance is important for public health nursing practice. People sometimes have an ability to resist pathogens. This is called *inherent resistance*. Typically, these people have inherited or acquired characteristics, such as the various factors mentioned earlier, that make them less vulnerable. People who maintain a healthful lifestyle may not contract influenza even if exposed to the flu virus. Resistance can be promoted through preventive interventions that support a healthful lifestyle. For example, one study found that regular use of a multivitamin in the periconceptual period reduced the risk of preeclampsia by 45% ( $n = 1,835$ ); but only in those women who were not overweight (Bodnar, Tang, Ness, et al., 2006). If confirmed by additional studies, multivitamin use could be recommended as a preventive measure for those women planning pregnancies. These findings can also be viewed as supporting efforts to reduce overweight and obesity in women of child-bearing age.

#### Agent

An **agent** is a factor that causes or contributes to a health problem or condition. Causative agents can be factors that are present (e.g., bacteria that cause tuberculosis, rocks on a mountain road that contribute to an automobile crash) or factors that are lacking (e.g., a low serum iron level that causes anemia or the lack of seat belt use that contributes to the extent of injury during an automobile crash).

Agents vary considerably and include five types: biologic, chemical, nutrient, physical, and psychological. Biologic agents include bacteria, viruses, fungi, protozoa, worms, and insects. Some biologic agents are infectious, such as influenza virus or HIV. Chemical agents may be in the form of liquids, solids, gases, dusts, or fumes. Examples are poisonous sprays used on garden pests and industrial chemical wastes. The degree of toxicity of the chemical

agent influences its impact on health. Nutrient agents include essential dietary components that can produce illness conditions if they are deficient or are taken in excess. For example, a deficiency of niacin can cause pellagra, and too much vitamin A can be toxic. Physical agents include anything mechanical (e.g., chainsaw, automobile), material (rock slide), atmospheric (ultraviolet radiation), geologic (earthquake), or genetically transmitted that causes injury to humans. The shape, size, and force of physical agents influence the degree of harm to the host. Psychological agents are events that produce stress leading to health problems.

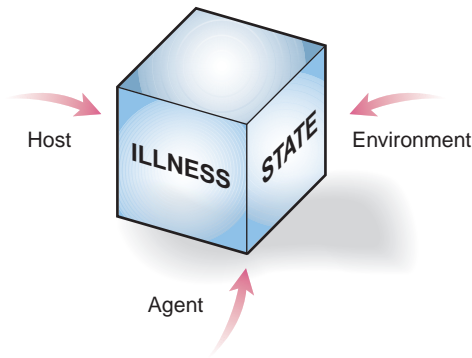

Agents may also be classified as infectious or noninfectious. Infectious agents cause communicable diseases, such as AIDS or tuberculosis—that is, the disease can be spread from one person to another. Certain characteristics of infectious agents are important for community health nurses to understand. Extent of *exposure* to the agent, the agent's *pathogenicity* (capacity to cause disease in the host), its *infectivity* (capacity to enter the host and multiply), its virulence (severity of disease), *toxigenicity* (capacity to produce a toxin or poison), *resistance* (ability of the agent to survive environmental conditions), *antigenicity* (ability to induce an antibody response in the host) (Fris & Sellers, 2004), and its structure and chemical composition all influence the effect of the agent on the host. (Chapter 8 examines the subject of communicable disease in greater depth.) Noninfectious agents have similar characteristics in that their relative abilities to harm the host vary with type of agent and intensity and duration of exposure.

#### Environment

The **environment** refers to all the external factors surrounding the host that might influence vulnerability or resistance. The physical environment includes factors such as geography, climate and weather, safety of buildings, water and food supply, and presence of animals, plants, insects, and microorganisms that have the capacity to serve as reservoirs (storage sites for disease-causing agents) or vectors (carriers) for transmitting disease. The psychosocial environment refers to social, cultural, economic, and psychological influences and conditions that affect health, such as access to health care, cultural health practices, poverty, and work stressors, which can all contribute to disease or health.

Host, agent, and environment interact to cause a disease or health condition. For example, the agent responsible for Lyme disease is the spirochete *Borrelia burgdorferi*; humans of all ages are susceptible hosts, along with dogs, cattle, and horses. Ticks that feed on wild rodents and deer transfer the spirochete to human hosts after feeding on them for several hours. Environmental factors, such as working or playing in tick-infested areas, influence host vulnerability. The host, agent, and environment model, shown in Figure 7.1, offered the epidemiologists who first studied Lyme disease in 1982 a plan for intervention. As soon as the agent was identified, measures could be taken to keep the spirochete from infecting human hosts, such as wearing protective clothing or tick repellent in tick-infested areas and promptly removing the attached ticks (Heymann, 2004).

In another example, the West Nile virus, which was widespread in Africa and the Middle East, arrived in the United States in 1999 and began to spread (Heymann,

**FIGURE 7.1** Epidemiologic triad. Epidemiologists study the causal agent, the susceptible host, and environmental factors that contribute to an illness, an injury, or a wellness state. Intervention may focus on any of these three to prevent the spread of illness or to improve health in a population.

2004). The first reported cases were in New York, where 45 people were infected. In that year, the region experienced a total of 59 hospitalized cases of West Nile disease, resulting in seven deaths. By 2006, West Nile virus had been reported in 43 states and the District of Columbia, with a total of 4,269 cases and 177 deaths (Centers for Disease Control and Prevention [CDC], 2007b). As of mid-2007, only Alaska and Hawaii had no confirmed presence of the virus in humans, birds, animals, or mosquitoes.

The encephalitis-causing disease is transmitted by a mosquito bite. The virus survives winter in the body of the adult *Culex* mosquito (Heymann, 2004). The infected mosquito bites a bird and infects it. Other mosquitoes bite the bird and in turn become infected. The infected mosquitoes pass the virus on to birds, humans, or horses. Many dead birds in an area may mean that the virus is circulating between the bird and mosquito populations and should be reported. In humans and animals with intact immune systems, the virus is usually

destroyed in the bloodstream. If the virus survives in the body, it can infect membranes around the spinal cord and brain and cause encephalitis. Those at highest risk are the elderly, children, and people with impaired immune systems.

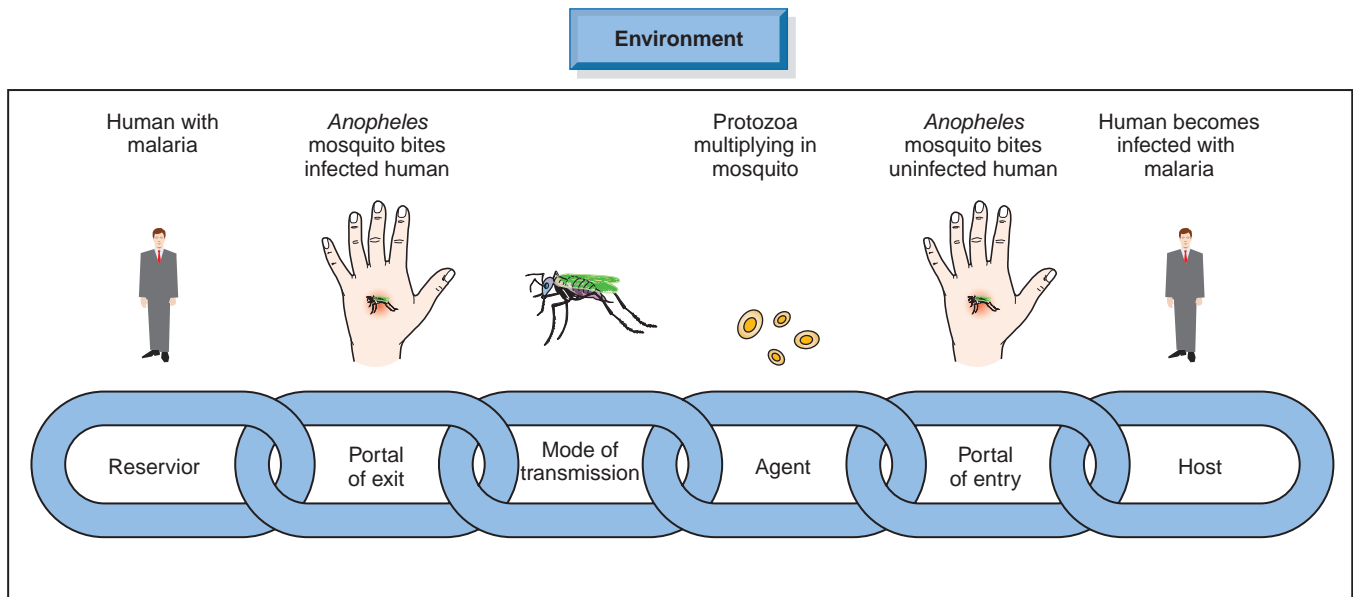

Prevention includes avoiding mosquito bites by applying insect repellent containing N,N-diethyl-meta-toluamide (DEET) when outdoors; wearing long-sleeved clothing and long pants treated with DEET-containing repellents; staying indoors at dawn, dusk, and in the early evening; eliminating standing water sources where mosquitoes lay their eggs; reporting dead birds; and ensuring that an organized mosquito control program exists in the area (CDC, 2004a). Using the model in Figure 7.1, can you categorize each of these six recommendations by their target (host, agent, or environment)?

**Causality**

**Causality** refers to the relationship between a cause and its effect. A purpose of epidemiologic study has been to discover causal relationships to understand why conditions develop and offer effective prevention and protection. As scientific knowledge of health and disease has expanded, epidemiology has changed its view of causality. The following section discusses some of those changes in thinking that began in the 1960s and are continually refined to this day.

**Chain of Causation**

As the scientific community’s thinking about disease causation and the tripartite model (host-agent-environment) grew more complex, epidemiologists began to use the idea of a chain of causation (Fig. 7.2). The chain begins by identifying the reservoir (i.e., where the causal agent can live and multiply). With plague, that reservoir may be other humans, rats, squirrels, and a few other animals. With malaria, infected humans are the major reservoir for the parasitic

**FIGURE 7.2** Chain of causation in infectious disease.

agents, although certain nonhuman primates also act as reservoirs (Heymann, 2004). Next, the agent must have a portal of exit from the reservoir, as well as some mode of transmission. For example, the bite of an *Anopheles* mosquito provides a portal of exit for the malaria parasites, which spend part of their life cycle in the mosquito's body; the mosquito in this case is the mode of transmission. The next link in the chain of causation is the agent itself. Malaria, for example, actually consists of four distinct diseases caused by four kinds of microscopic protozoa (Heymann, 2004). The next link is the portal of entry. In the case of malaria, the mosquito bite provides a portal of exit as well as a portal of entry into the human host.

The box surrounding the chain of causation in Figure 7.2 represents the environment, which can have a profound influence at almost any point along the chain. Consider the impact of environmental factors on the 1934–1935 malaria epidemic in Ceylon (an island country in the Indian Ocean off southern India). Historically, malaria occurred frequently in the dry northern area, where sparse vegetation allowed pools of water to be exposed to the sun, providing excellent breeding grounds for the *Anopheles* mosquito. In contrast, the more populous southwestern area usually had heavy monsoon rains and was relatively free from malaria. In 1934, however, a severe drought changed this environment drastically; throughout Ceylon, rivers almost dried up, leaving stagnant pools of water for mosquito breeding. Widespread crop failure caused the population to become badly undernourished, which added to conditions that would foster a malaria epidemic. The epidemic occurred in October 1934, affecting 2 to 3 million people and causing 80,000 deaths. The environment must certainly be seen as a major part of this causal chain (Burnet, 1962).

Another tragic example of the influence of environment on the causal chain occurred in the African country of Rwanda in July of 1994. Civil war caused a large percentage of the population to flee in the face of mass genocide of “unprecedented swiftness” that left up to 800,000 dead (U.S. Department of State, 2007). Hundreds of thousands of people filled refugee camps to overflowing, with over 50,000 deaths in the first month alone (Connolly et al., 2004). Conditions of squalor and poor sanitation led to contaminated water and resulted in a large-scale epidemic of cholera, a severe form of bacterial dysentery. Relief workers had limited supplies of intravenous or oral rehydration solutions and could do little to help. Thousands lost their lives. The unstable political environment, unsanitary conditions, scarcity of clean water, and malnourishment were all part of the causal chain.

### Causation in Noninfectious Disease

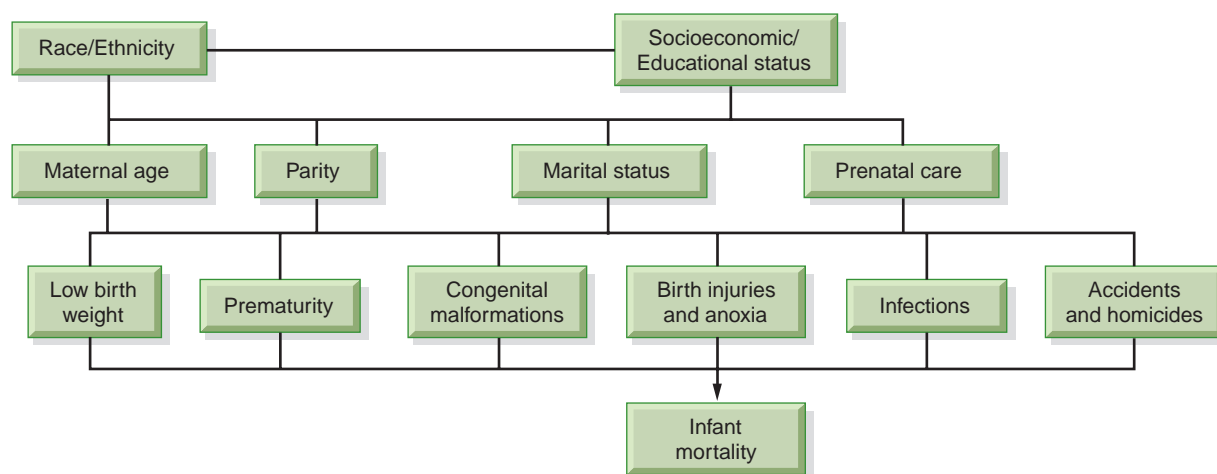

With the availability of vaccines and antibiotics in the United States and the developed world, attention shifted to the causes of noninfectious diseases such as cancer and diabetes. A new causal paradigm was clearly needed. The linear thinking embodied in models such as the *chain of causation* were insufficient in understanding the causes of these emerging health threats. Beginning in the 1950s, there was a growing interest in the role smoking played in the development of lung cancer. In 1964, the publication of *Smoking and Health: Report of the Advisory Committee to the Surgeon General of the Public Health Service* con-

cluded that smoking caused lung and laryngeal cancer in men (U.S. Public Health Service [USPHS], 1964). The Committee's conclusions were based on review of over 7,000 articles and utilized five criteria for judging the significance of the link between smoking and lung cancer (Friis & Sellers, 2004).

One year later, Sir Austin Bradford Hill proposed expanding those criteria to nine when evaluating the relationship between environmental exposure and potential health outcomes. Although these guidelines are often viewed as necessary for causal attribution, Hill stressed that they were a tool, not strict criteria (Legator & Morris, 2003). The elements added by Hill included biologic gradient, plausibility, experiment, and analogy. The criteria can be used with infectious disease, yet their significance lies with attributing cause in noninfectious disease. Each of the nine elements is summarized below (Aschengrau & Seage, 2008; Friis & Sellers, 2004):

1. *Strength of association*: This refers to the ratio of disease rates in those with and without the suspected causal factor. A strong association would be noted if disease rates are much higher in the group with the factor than in the group without it.
2. *Consistency*: An association is demonstrated in varying types of studies among diverse study groups (i.e., replication).
3. *Specificity*: A cause leads to one effect (not always the case in noninfectious diseases).
4. *Temporality*: Exposure to the suspected factor must precede the onset of disease (i.e., time order or time sequence).
5. *Biological gradient*: This relationship is demonstrated if, with increasing levels of exposure to the factor, there is a corresponding increase in occurrence of the disease (i.e., dose–response relationship).
6. *Plausibility*: The hypothesized cause makes sense based on current biologic or social models (i.e., it is possible).
7. *Coherence of explanation*: The hypothesized cause makes sense based on current knowledge about the natural history or biology of the disease (i.e., scientific knowledge).
8. *Experiment*: Experimental and nonexperimental studies support the association (e.g., reduced tobacco use in a population should lead to reduced lung cancer rates).
9. *Analogy*: Similarities between the association of interest and others (e.g., potential links to birth defects from new drugs is a concern since we already recognize this potential from the use of the drug thalidomide).

Based on the work of Hill and others, a basis was formed to critically assess causality in noninfectious diseases, as well as in new and emerging infectious diseases. The elements described by Hill are still utilized by epidemiologists and provide the fundamental principles community health nurses can use to evaluate evidence of disease causation in all types of published reports, both scientific and lay. In health education, these principles can be utilized to teach disease causation risk, especially when the evidence is not yet complete. For instance, a pregnant teen asks a nurse if

**FIGURE 7.3** Web of causation for infant mortality, based on information available from birth and death certificates. From Anderson, E.T., & McFarlane, J. (2003). *Community as partner*, 4th ed. Philadelphia: Lippincott Williams & Wilkins, with permission.

she should drink diet soda while she is pregnant. The nurse can share with her that the evidence to date supports the safety of artificial sweeteners for most adults (experiment), but that it is probably not wise to drink diet soda while pregnant. When she asks why (since there isn't any reported risk), the nurse can respond that any chemical has the potential to cause harm (plausibility and analogy), and the effects on a growing fetus (biologic gradient) are often unknown until decades later (temporality and experiment).

### Multiple Causation

As health care professionals began to understand the complexity of many of the infectious and noninfectious disease threats, they came to realize that causation was never completely straightforward. Even with long-recognized contagious diseases like cholera, the organism was only part of the equation. Factors such as availability of clean water, the number of trained nurses and doctors, the overall nutrition of the population, and even political upheaval could influence the spread of disease and the number who ultimately died. Causation was beginning to be viewed as multifactorial. Fortunately, with recognition of the complexity of each health threat, came multiple opportunities to find solutions. The following section discusses the complexity of causal factors on health outcomes and implications for reduced morbidity and mortality.

### Web of Causation

In the 1960s, the concept of multiple causation emerged to explain the existence of health and illness states and to provide guiding principles for epidemiologic practice. A causal paradigm that gained attention was referred to as the *web of causation*. The implication was that intervention (or breaking of the web at any point nearest to the disease) could profoundly impact the development of that disease (Aschengrau & Seage, 2008). This was a significant shift in thinking about disease and health, positing that the combination of multiple factors was the deciding factor in the

development of poor outcomes. This refinement in causal thinking also provided opportunities for health care interventions at a variety of levels. Another common term used for this approach is *causal matrix*.

Utilizing the multicausal approach, Figure 7.3 depicts a causal matrix for infant mortality. Data from birth and death certificates were used to identify the complex interactions among multiple causal factors that produce a negative health condition leading to infant mortality. Another example (Fig. 7.4) shows a web of causation for automobile crashes. All of the numerous factors involved must be considered when diagramming a web of causation. Speed, faulty equipment, heavy traffic, confusing traffic patterns, road construction, poor visibility, weather conditions, driver inexperience, and drinking or drug use, in any combination, can cause an automobile crash.

All health conditions can be diagrammed to depict a matrix of causation. A communicable disease with one clearly identified organism as the agent has the ability to be diagrammed based on factors such as availability of emergency services (treatment), diagnostic skill of health professionals (early diagnosis), availability of medications and vaccines to treat the disease (reduced morbidity), and community communication networks (public awareness). Any of these factors could greatly influence the progression of disease within the community.

*Association* is a concept that is helpful in determining multiple causality. Events are said to be associated if they appear together more often than would be the case by chance alone (see Perspectives). Such events may include risk factors or other characteristics affecting disease or health states. Examples are the frequent association of cigarette smoking with lung cancer, obesity with heart disease, and severe prematurity with infant mortality. The study of associated factors suggests possible causality and points for intervention. Contemporary epidemiologists continue to explore new and more comprehensive ways of viewing health and illness. The associations among lifestyle, behavior, environment, and stress of all kinds and the ways in which they affect health states are gaining importance in epidemiology.

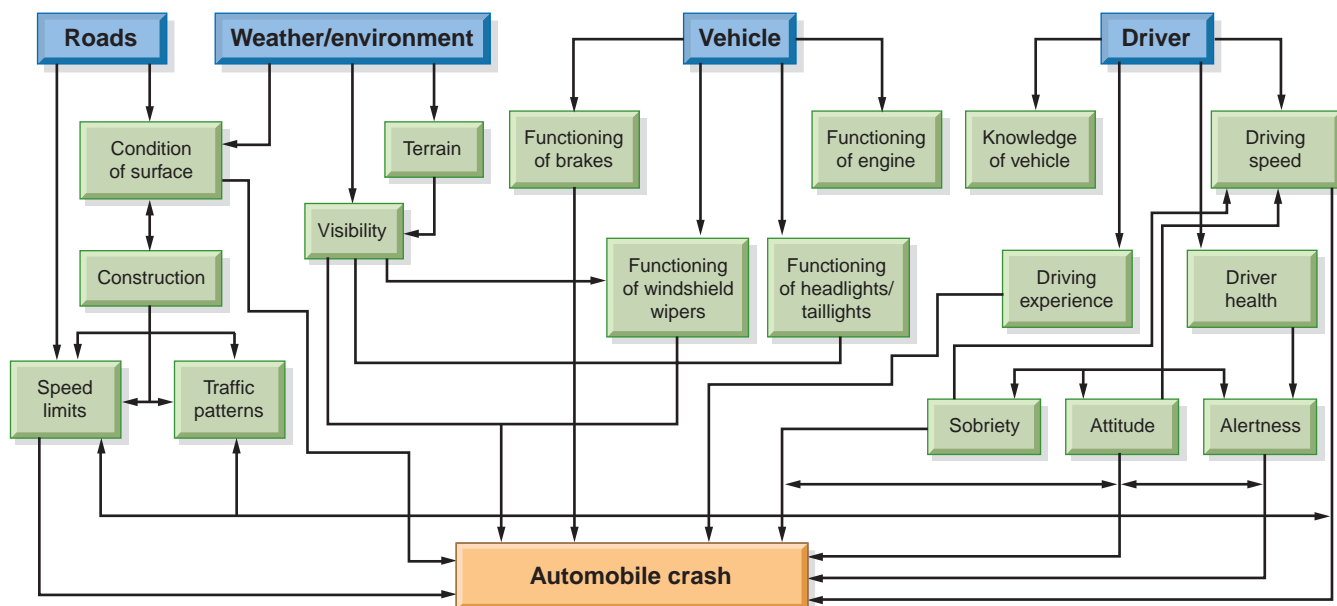

FIGURE 7.4 Web of causation for automobile crashes.

In the host, agent, and environment model, a shifting emphasis of investigation over time may be noted. Early epidemiologists worked to identify and manage the causative agent; the focus of concern was the disease state. The emphasis then shifted to the host: Who was susceptible? What characteristics led to susceptibility? Through immunization and health promotion, efforts were made to improve host resistance. Increasingly, however, public health workers came to realize the limitations imposed on individual control of health. Even individuals who are in the best of health cannot withstand toxic agents in the workplace—for example, nuclear wastes in the atmosphere from power plant accidents—or other debilitating conditions created by modern society. More and more, public health professionals are studying the environment and looking for methods to change conditions that contribute to illness.

## Immunity

**Immunity** refers to a host's ability to resist a particular infectious disease-causing agent. This occurs when the body forms antibodies and lymphocytes that react with the foreign antigenic molecules and render them harmless. For public health nursing, this concept has significance in determining which individuals and groups are protected against disease and which may be vulnerable. Four types of immunity are important in community health: passive immunity, active immunity, cross-immunity, and herd immunity.

### Passive Immunity

Passive immunity refers to short-term resistance that is acquired either naturally or artificially. Newborns, through maternal antibody transfer, have natural passive immunity that lasts up to 1 year for certain diseases (CDC, 2007a). This maternally provided protection seems to work best with measles, rubella, and tetanus, and less well with other

diseases (e.g., polio and pertussis). Artificial passive immunity is attained through inoculation with antibody products to provide temporary resistance. Examples of such products include immune globulin (hepatitis A and measles), hyperimmune globulins (hepatitis B, rabies, tetanus, and varicella), and hyperimmune serum (equine antitoxin for use with botulism and diphtheria). These products are used to boost a susceptible person's immunity, and administration must be repeated periodically to maintain immunity levels (CDC, 2007a).

### Active Immunity

*Active immunity* is long-term and sometimes lifelong resistance that is acquired either naturally or artificially. Naturally acquired active immunity comes through host infection. That is, a person who contracts a disease often develops long-lasting antibodies that provide immunity against future exposures. Artificially acquired active immunity is attained through vaccine inoculation. Such vaccines are prepared from killed (inactivated) or live attenuated (weakened) organisms administered to artificially produce or increase immunity to a particular disease (CDC, 2007a). The concept of active immunity underlies public health immunization programs that have successfully kept polio, diphtheria, smallpox, and other major diseases under control worldwide.

### Cross-immunity

*Cross-immunity* refers to a situation in which a person's immunity to one agent provides immunity to a related agent as well. The immunity can be either passive or active. Sometimes, infection with one disease, such as cowpox, gives immunity to a related disease, such as smallpox. The concept of cross-immunity has also been useful in the development and administration of vaccines. Inoculation with a vaccine

## PERSPECTIVES STUDENT VOICES

### Vaccine Adverse Event Reporting System— Example of Epidemiological Surveillance

I graduated in 2006 and started working in the emergency department (ED) of our local hospital. All through school I knew the ED was exactly where I wanted to work. Just about every course I took brought me that much closer to my dream . . . with one exception—Public

Health Nursing. It just didn't interest me—and it didn't seem to have much relevance to working as an ED nurse. Six months after I graduated, my view changed.

My community is pretty rural—we have a great hospital, but it's small and we don't have all the specialty areas available, such as pediatric surgeons. At about 0300, we had a 4-month-old come in a great deal of distress; vomiting and crying inconsolably. While I was interviewing the mother, she said he had been a very healthy baby up until about 8 hours ago and had even been seen by his pediatrician a few days earlier for his regular check-up. She handed me his immunization record as proof. We ended up airlifting the baby to the nearest children's hospital when it seemed likely that he had intussusception, which is a folding of the bowel on itself and pretty serious. After the child and the mother were gone, I realized that I still had the child's immunization record and hadn't yet looked at it either. I called the other hospital to tell them I had the immunization record and that I could fax over a copy. The nurse I spoke with asked me which immunizations the child had recently received. Thinking he just wanted to see if the child was up-to-date, I told him he just had a well-child visit a few days ago. He persisted and told me he needed to know the exact dates and which vaccines were given. As I read through the list, I realized I wasn't familiar with one of the vaccines and asked him what it was. He explained that it was the rotavirus vaccine and had been licensed about 10 months ago—adding that an earlier vaccine had been pulled off the market in 1999 due to an association with

intussusception. He had my attention! The nurse wanted to know if the lot numbers for the vaccines were on the record—and they were. I asked if he thought the child's condition was due to the vaccine—he didn't believe so, but that he would be making a VAERS report on the case once the physician confirmed the diagnosis and the lab's findings were back. I didn't know what this VAERS report was but thanked him and went to fax the immunization copy. I had a break coming up, so I went online to see what this report was. Turns out that VAERS stands for the *Vaccine Adverse Event Reporting System* and anyone (even parents) can make a report, if they think that a health condition might be the result of an immunization. The report can be made by phone or online at [www.vaers.hhs.gov](http://www.vaers.hhs.gov). The system monitors reports from all over the country to determine if there might be a problem with a particular vaccine. As I read more, I found out that the system is designed so that epidemiologists can look at the information and determine if there is a real association; they don't want to leave a vaccine on the market if it's potentially dangerous or pull vaccines off unnecessarily. The old vaccine for the rotavirus was pulled off the market after reports came in from VAERS and other sources. While I was sitting there taking this all in, I started recognizing that I had encountered two public health situations with just this one patient, and I had missed both of them. The first was assuming that because the child had a well-child check-up that he was up-to-date with his immunizations (I should have checked the record). The second was disease surveillance—if I had paid attention to the current recommendations for the rotavirus vaccine, I might have been alert to the possible connection with intussusception with the old vaccine and been aware of the VAERS system. Since that night, I have been following the reports on the vaccine's safety, and so far it looks like the association with intussusception is no more than would be expected in unvaccinated children—but I'll keep checking. I'm now the nurse that everyone comes to for information on vaccines, the need to make sure all the children we treat are up-to-date, and how to provide data to help monitor potential problems with vaccines. Who knew you could use public health nursing skills in an ED?

—Minerva G., RN/BSN (a.k.a. PHN)

made from one disease-causing organism can provide immunity to a related disease-causing organism. Field trials in Uganda and Papua, New Guinea and a study in India in the 1990s examined the administration of bacille Calmette-Guérin (BCG) vaccine, which is used to prevent tuberculosis, to people who had been exposed to Hansen disease (leprosy). The vaccine against *Mycobacterium tuberculosis* appeared to provide these individuals with a degree of cross-immunity to the related infectious agent, *Mycobacterium leprae*, and prevented their contracting disease (Heymann, 2004).

### Herd Immunity

*Herd immunity* describes the immunity level that is present in a population group. A population with low herd immunity

is one with few immune members; consequently, it is more susceptible to a particular disease. Nonimmune people are more likely to contract the disease and spread it throughout the group, placing the entire population at greater risk. Conversely, a population with high herd immunity is one in which the immune people in the group outnumber the susceptible people; consequently, the incidence of a particular disease is reduced (Friis & Sellers, 2004). The level of herd immunity may vary with diseases. For instance, a level of community immunity of between 85% and 90% may be necessary for rubella, but for diphtheria a level of 70% may be effective (Friis & Sellers, 2004). Mandatory preschool immunizations and required travel vaccinations are applications of the herd immunity concept.

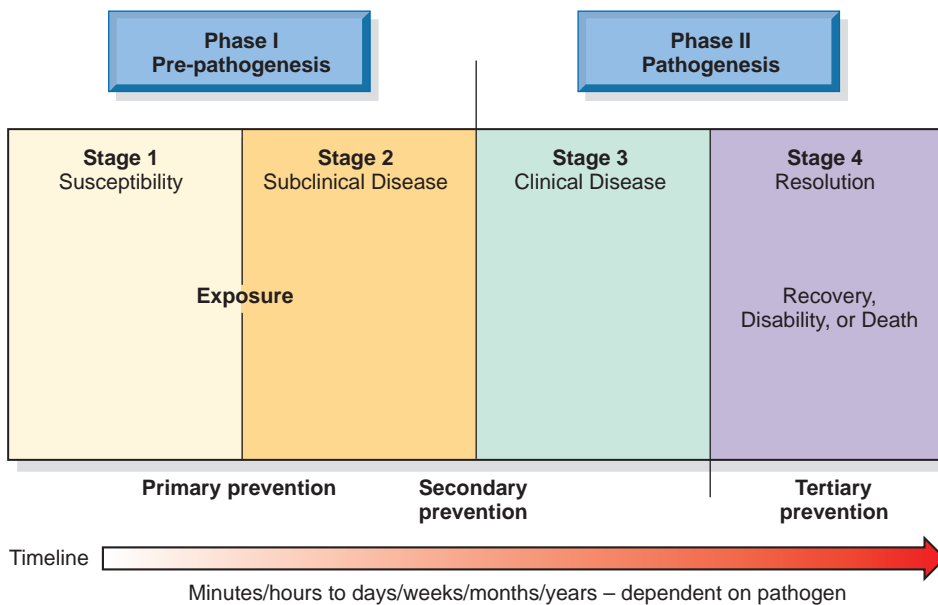

## Risk

To determine the chances that a disease or health problem will occur, epidemiologists are concerned with **risk**, or the probability that a disease or other unfavorable health condition will develop. For any given group of people, the risk of developing a health problem is directly influenced by their biology, environment, lifestyle, and system of health care (Dever, 1984; Lalonde, 1974). A person's inherited health capacity, the environment lived in, the person's lifestyle choices, and the quality and accessibility of the health care system either negatively or positively affect health, thereby increasing or decreasing the likelihood that a health problem will occur. Negative influences are called *risk factors*. For example, low-birth-weight babies (biology, environment, and system of health care) tend to be at greater risk for health problems, as are people who smoke cigarettes, have diets high in cholesterol, and are sedentary (lifestyle). The degree of risk is directly linked to susceptibility or vulnerability to a given health problem.

Epidemiologists study populations at risk. A *population at risk* is a collection of people among whom a health problem has the possibility of developing because certain influencing factors are present (e.g., exposure to HIV) or absent (e.g., lack of childhood immunizations, lack of specific vitamins in the diet), or because there are modifiable risk factors present (e.g., cardiovascular disease). A population at risk has a greater probability of developing a given health problem than other groups do. Epidemiologists measure this difference using the *relative risk ratio*, which statistically compares the disease occurrence in the population at risk with the occurrence of the same disease in people without that risk factor.

$$\text{Relative risk ratio} = \frac{\text{Incidence rate in exposed group}}{\text{Incidence rate in unexposed group}}$$

- Stage 1** – Host and environment factors influence population's vulnerability
- Stage 2** – Invasion by causative agent; people are asymptomatic
- Stage 3** – Disease or condition evident in population
- Stage 4** – Disease or condition concludes in renewed health, disability, or death

If the risk of acquiring the disease is the same regardless of exposure to the risk factor studied, the ratio will be 1:1, and the relative risk will be 1.0. A relative risk greater than 1.0 indicates that those with the risk factor have a greater likelihood of acquiring the disease than do those without it; for instance, a relative risk of 2.54 means that the exposed group is 2.54 times more likely to acquire the disease than the unexposed group. This statistic may be used, for example, to compare the incidence of heart disease among smokers (smoking is a risk factor) with the incidence among non-smokers, assuming that all other factors are the same. The relative risk ratio assists in determining the most effective points for community health intervention in regard to particular health problems. It also provides a more easily understood method for explaining the risk of certain behaviors in the development of illness or injury to the public.

## Natural History of a Disease or Health Condition

Any disease or health condition follows a progression known as its **natural history**; this refers to events that occur before its development, during its course, and during its conclusion. This process involves the interactions among a susceptible host, the causative agent, and the environment. The natural progression of a disease occurs in four stages as they affect a population—susceptibility, preclinical (subclinical) disease, clinical disease, and resolution (Fig. 7.5). The last stage, resolution, includes recovery, disability, or death (Gerstman, 2003).

### Susceptibility Stage

The first stage is *susceptibility*. During this state, the disease is not present and individuals have not been exposed. However,

**FIGURE 7.5** Natural history stages of a disease or health condition. Adapted From: Gerstman, B.B. (2003). *Epidemiology kept simple: An introduction to traditional and modern epidemiology*, 2nd ed. Hoboken, NJ: Wiley-Liss, Inc.

host and environmental factors could very likely influence people's susceptibility to a causative agent and lead to development of the disease. For example, college students with poor eating habits and fatigue from lack of sleep during final examinations present risk factors that promote the occurrence of the common cold. "If exposure to an agent occurs at this time, a response will take place. Initial responses reflect the normal adaptation response of the cell or functional system (e.g., the immune system). If these adaptation responses are successful, then no disease occurs and the process is arrested" (Valanis, 1999, p. 22). In 1994, the overcrowded conditions and poor sanitation of Rwandan refugee camps in Africa, described earlier, as well as refugees' stress, fatigue, and malnutrition, made them extremely vulnerable to contracting cholera and other diseases. However, in a later tragedy in Kosovo in 1999, the thousands of refugees fleeing for their lives from Yugoslavian Serbs were housed in refugee border camps with adequate supplies and services, and many found temporary or permanent refuge in other countries, including the United States. They endured a shorter period of stress and fatigue with better nutrition than the refugees in Rwanda; as a result, malnutrition was not as rampant. Because improved conditions in refugee camps eliminated major outbreaks of cholera and other diseases, susceptibility to disease in the group as a whole was reduced. Nevertheless, the psychological trauma from the attempts at "ethnic cleansing" of the people in Kosovo remained an existing health problem for years.

### Subclinical Disease Stage

The stage of *subclinical disease* begins when individuals have been exposed to a disease but are as yet asymptomatic. It is followed by an *incubation period*, during which the organism multiplies to sufficient numbers to produce a host reaction and clinical symptoms. Vulnerable children who have been exposed to chickenpox (varicella) but do not yet display signs of fever or lesions are in this stage. For diseases caused by infectious agents, the incubation period is relatively short, hours to months. One noteworthy exception to this is infection with HIV, which has an incubation period of 1–3 months, with progression to AIDS (Acquired Immuno-deficiency Syndrome) from 1 year to 15 years or longer (Heymann, 2004). In other conditions caused by noninfectious agents, the time from exposure to onset of symptoms, known as the *induction period* or *latency period*, is often years to decades. For example, children exposed to radiation may have a 5-year latency period for leukemia. Lung cancer caused by exposure to asbestos may have a latency period of 40 years between exposure and detection of the disease.

### Clinical Disease Stage

During the *clinical disease stage*, signs and symptoms of the disease or condition develop. In the early phase of this period, the signs may be evident only through laboratory test findings, such as tubercular lesions on radiographs or pre-malignant cervical changes evident on Papanicolaou (Pap) smears. Later in this stage, acute symptoms are clearly visible, as in the case of widespread enterocolitis in a salmonellosis (food poisoning) outbreak. In this early clinical stage or early discernible lesions stage, evidence of the disease or condition is present and diagnosis occurs.

### Resolution Stage

In the *resolution stage*, the disease or health condition causes sufficient anatomic or functional changes to produce recognizable signs and symptoms. Disease severity may vary from mild to severe. The disease may conclude with a return to health, a residual or chronic form of the disease with some disabling limitations, or death. This can also be called the *advanced disease stage*, because the disease or condition has completed its course.

Community health nurses can intervene at any point during these four stages to delay, arrest, or prevent the progression of the disease or condition. Primary, secondary, and tertiary prevention can be applied to each of the stages (see Levels of Prevention Pyramid).

### Epidemiology of Wellness

The public health science of epidemiology has traditionally studied the occurrence of disease and health problems. Because of their devastating effect on the health of populations, infectious diseases such as plague, cholera, and AIDS, as well as chronic illnesses such as heart disease or cancer, and fatal or debilitating injuries all require a continued epidemiologic focus. Nonetheless, the need to examine the epidemiology of wellness grows increasingly urgent, for if we continually examine and uncover new health promotion practices and encourage them, we can focus on wellness at the ideal primary level of prevention.

Epidemiology has moved from concentrating only on illness to examining how host, agent, and environment are involved in wellness at various levels. In response to an escalating need for improved methods of health planning and health policy analysis, epidemiology has developed more holistic models of health (Dever, 1984, 1991). These evolving epidemiologic models are organized around four attributes that influence health: (1) the physical, social, and psychological environment; (2) lifestyle with its self-created risks; (3) human biology and genetic influences; and (4) the system of health care organization. In the United States, *Healthy People 2010* (USDHHS, 2000) and greater recognition of the importance and cost-effectiveness of illness prevention and health promotion are driving new efforts to develop policy and research initiatives for public health (see Display 7.1).

Wellness models that at first focused on individual behavior now include approaches that encompass aggregates. A variety of wellness models can be found for groups of seniors (see Chapter 24), in occupational health settings (see Chapter 31), at innovative schools where wellness programs for children and teens are initiated (see Chapter 22), and throughout the services provided for beginning and growing families (see Chapter 21). Programs designed for aggregates focus on a wellness approach to growth and development. Examples include programs for pregnant teens and for infant and child development (e.g., Healthy Start, Head Start) that are funded by state and federal monies. Societal changes, such as the aging population, the communication revolution, the global economy, environmental threats, technology development, and the holism and wellness movements are driving these new approaches.

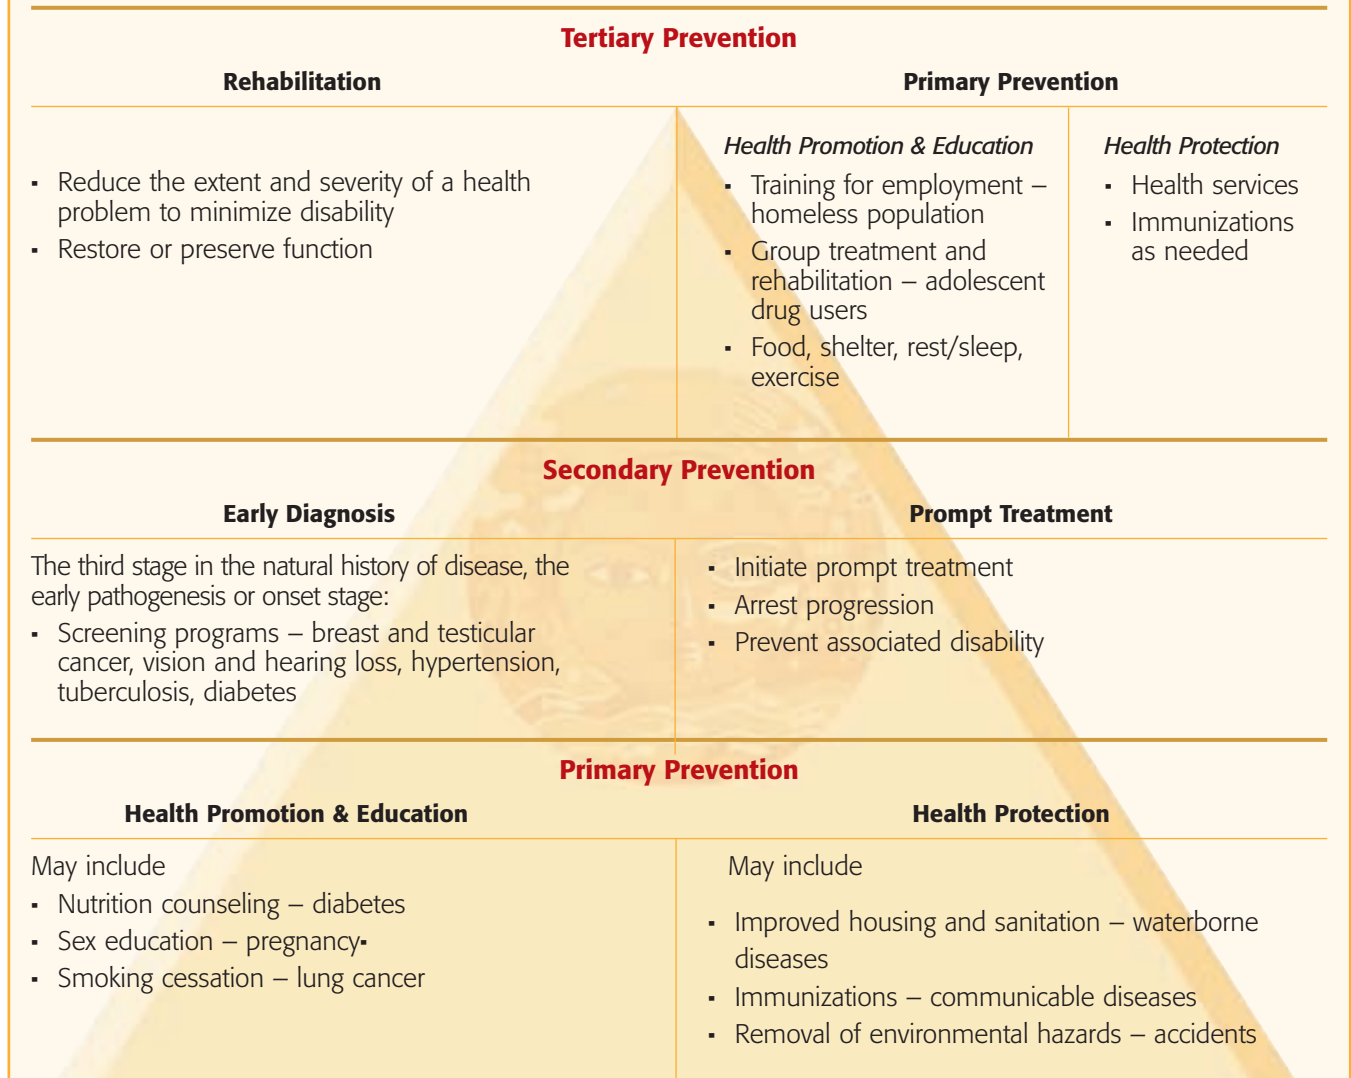

The four stages of the natural history of disease can apply to an understanding of any health condition, including wellness states. In stage one, *susceptibility*, people can become amenable

## LEVELS OF PREVENTION PYRAMID

**SITUATION:** Apply the levels of prevention during the four stages of the natural history of a disease to eradicate or reduce risk factors (examples of possible conditions provided).

**GOAL:** Using the three levels of prevention negative health conditions are avoided, or promptly diagnosed and treated, and the fullest possible potential is restored.

to healthier practices and improved health system organization. In stage two, *subclinical*, a community can learn about these health-promoting behaviors. Stage three, *clinical disease stage*, could be a period of trying out the beneficial policies and activities, and stage four, *resolution*, could encompass full adoption and a higher level of well-being for the community. This approach has important implications for preventive and health-promotion practices in community health nursing.

Community health nursing can play a primary role in the investigation and identification of factors that not only prevent illness but also promote health. This means sharpening skills in epidemiologic research to uncover the factors

that contribute to a full measure of healthful living. The time for an epidemiology of wellness has come.

### Causal Relationships

One of the main challenges to epidemiology is to identify causal relationships in disease and health conditions in populations. As was previously suggested, the assessment of causality in human health is difficult at best; no single study is adequate to establish causality. Causal inference is based on consistent results obtained from many studies. Frequently, the accumulation of evidence begins with a clinical

## DISPLAY 7.1

## HEALTHY PEOPLE 2010 & MIDCOURSE REVIEW—EPIDEMIOLOGICAL FOCUS (OBJECTIVE SHORT TITLES AND OBJECTIVES)

### Data & Information Systems

#### 23-2. *Public Access to Information and Surveillance Data*

(Developmental) Increase the proportion of Federal, Tribal, State, and local health agencies that have made information available for internal or external public use in the past year based on health indicators related to *Healthy People 2010* objectives.

#### 23-3. *Use of Geocoding in Health Data Systems*

Increase the proportion of major national health data systems that use geocoding to promote nationwide use of geographic information systems (GIS).

#### 23-4. *Data for All Population Groups*

Increase the proportion of population-based Healthy People 2010 objectives for which national data are available for all population groups identified for the objective.

#### 23-6. *National Tracking of Healthy People 2010 Objectives*

Increase the proportion of Healthy People 2010 objectives that are tracked regularly at the national level.

#### 23-7. *Timely Release of Data on Objectives*

Increase the proportion of Healthy People 2010 objectives for which national data are released within 1 year of the end of data collection.

### Public Health Organizations

#### 23-14. *Access to Epidemiology Services*

Increase the proportion of Tribal, State, and local public health agencies that provide or assure comprehensive epidemiology services to support essential public health services.

### Prevention Research

#### 23-17. *Population-based Prevention Research*

(Developmental) Increase the proportion of Federal, Tribal, State, and local health agencies that conduct or collaborate on population-based prevention research.

observation or an educated guess that a certain factor may be causally related to a health problem.

A **cross-sectional study** (which explores a health condition's relation to other variables in a specified population at a specific point in time) can show that the factor and the problem coexist. For example, one study compared the incidence of gonorrhea in a 55-block area in urban New Orleans with a "broken window index," which measured housing quality, abandoned cars, graffiti, trash, and public school deterioration (Cohen et al., 2000). The broken window index predicted the variance for gonorrhea rates more accurately than did a poverty index measuring income, unemployment, and low education.

A **retrospective study** (which looks backward in time to find a causal relationship) allows a fairly quick assessment of whether an association exists. Looking back at the use of lead in interior paint in the United States, history shows that even though the particular dangers to children were documented in English-language literature as early as 1904, the U.S. lead industry did nothing to discourage the use of lead paint on interior walls and woodwork. In fact, some paint companies (e.g., Dutch Boy Paint) used children in their advertising through the 1920s (Markowitz & Rosner, 2000). Not until the 1950s did the industry adopt a voluntary standard limiting the amount of lead in interior paints, and then only under increasing pressure. Not until 1978 was interior lead paint prohibited.

A **prospective study** (which looks forward in time to find a causal relationship) is crucial to ensure that the presumed causal factor actually precedes the onset of the health problem. The prospective approach is concerned with current information and provides a direct measure of the variables in

question. For example, the U.S. Nurses Health Study provided an opportunity for a prospective analysis of the association between night shift work and sleep deprivation and the risk of developing Parkinson disease. In a sample of nearly 85,000 registered nurses, those with 15 or more years of night shift work had a 50% lower risk of developing the disease than those nurses who never worked the night shift. Increased sleep duration was positively associated with disease risk. The data suggest one of two options: that night shift work is protective against the development of Parkinson disease or that low tolerance for night shift work is an indicator of the disease (Chen, Schernhammer, Schwarzschild, & Ascherio, 2006). Studies such as these provide a mechanism to evaluate a variety of factors that precede the development of disease and then assess issues of association and ultimately causation.

Finally, if ethically possible, an **experimental study** (in which the investigator controls or changes factors suspected of causing the condition and observes results) is used to confirm the associations obtained from observational studies (in which the investigator merely observes data or people without controlling or changing any factors). It often requires many years to accumulate enough evidence to suggest a causal relationship.

Epidemiologically, a causal relationship may be said to exist if two major conditions are met: the factor of interest (causal agent) is shown to increase the probability of occurrence of the disease or condition as observed in many studies in different populations, and evidence suggests that a reduction in the factor decreases the frequency of the given disease. The synthesis of data begins by selecting as many of the various types of epidemiologic studies of the problem as

possible. After those studies that are not methodologically sound are discarded, the studies are reviewed. The better the data meet the criteria outlined by Hill (discussed earlier), the more likely it is that the factor of interest is one of several causes of the disease (strength of association, consistency, specificity, time sequence, biologic gradient, plausibility, coherence, experiment, and analogy).

The goal of any epidemiologic investigation is to identify causal mechanisms that meet these nine criteria and to develop measures for preventing illness and promoting health. The community health nurse may need to gather new data for this type of investigation, but pertinent existing data should be thoroughly examined first. This type of information can be obtained by the community health nurse from a variety of sources, which are discussed in the next section.

## SOURCES OF INFORMATION FOR EPIDEMIOLOGIC STUDY

Epidemiologic investigators may draw data from any of three major sources: existing data, informal investigations, and scientific studies. The public health nurse will find all three sources useful in efforts to improve the health of aggregates.

### Existing Data

A variety of information is available nationally, by state, and by section, such as county, region, or urbanized area. This information includes vital statistics, census data, and morbidity statistics on certain communicable or infectious diseases. Local health departments often can provide these data on request. Public health nurses seeking information on communities may find local health system agencies helpful. These agencies collect health information for groups of counties within states and interact with health planning authorities at the state level. They have access to many types of information and can give advice on specific problems.

### Vital Statistics

*Vital statistics* refers to the information gathered from ongoing registration of births, deaths, adoptions, divorces, and marriages. Certification of births, deaths, and fetal deaths are the most useful vital statistics in epidemiologic studies. The community health nurse can obtain blank copies of a state's birth and death certificates to become familiar with the information contained in each (Displays 7.2 and 7.3). Much more information is recorded than the fact and cause of death on the death certificate. Birth certificates also can provide helpful information (e.g., weight of the infant, amount of prenatal care received by the mother), which can be used to identify high-risk mothers and infants.

Sources for vital statistical information include state websites on the Internet, local and state health departments, city halls, and county halls of records (see list of Internet resources at the end of this chapter). Statistics regarding general morbidity and mortality for specific states are located in the aggregate from the Centers for Disease Control and Prevention (CDC) at the national level (National Center for Health Statistics). State statistics are obtained from state health departments, and county information (spe-

cific cities or census tracts) can be obtained from either the state or the county health department.

### Census Data

Data from population censuses taken every 10 years in many countries are the main source of population statistics. This information can be a valuable assessment tool for the community health nurse who is taking part in health planning for aggregates. Population statistics can be analyzed by age, sex, race, ethnic background, type of occupation, income gradient, marital status, educational level, or other standards, such as housing quality. Analysis of population statistics can provide the community health nurse with a better understanding of the community and help identify specific areas that may warrant further epidemiologic investigation. Data from the U.S. Census Bureau is found on its website (see the Internet section at the end of this chapter) and is an easily accessed source of population-level data.

### Reportable Diseases

Each state has developed laws or regulations that require health organizations and practitioners to report to their local health authority cases of certain communicable and infectious diseases that can be spread through the community (Heymann, 2004). This reporting enables the health department to take the most appropriate and efficient action. All states require that diseases subject to international quarantine regulations be reported immediately. However, many of these diseases (e.g. plague, cholera, yellow fever, and polio) are virtually unknown now in developed countries (World Health Organization [WHO], 2007). Health care professionals have not had experience identifying another reportable disease, smallpox, because no cases have been reported since 1977 (CDC, 2004b). In 1980, the World Health Organization (WHO) declared the global eradication of smallpox after more than 10 years of international effort. (Chapter 17 discusses the concern over the use of smallpox as a bioterrorism threat.) Numerous other diseases under surveillance by WHO (e.g., tuberculosis, malaria, viral influenza, and severe acute respiratory syndrome [SARS]) must also be reported (WHO, 2007). Other reportable diseases (numbering between 20 and 40 in each state) are usually classified according to the speed with which the health department should be notified. Some should be reported by phone or e-mail, others weekly by regular mail. They vary in potential severity from varicella (chickenpox) to rabies and include AIDS, encephalitis, meningitis, syphilis, and toxic shock syndrome. Community health nurses should obtain the list of reportable diseases from their local or state health department office. Following-up on occurrences of these diseases is a task frequently assigned to public health nurses working for local health departments. Chapter 8 includes an example of a Confidential Morbidity Report (CMR) used to report and track communicable diseases at the local, regional, and national level.

### Disease Registries

Some areas or states have disease registries or rosters for conditions with major public health impact. Tuberculosis and rheumatic fever registries were more common when these

	33. REGISTRAR'S SIGNATURE						34. DATE FILED (Month, Day, Year)	

diseases occurred more frequently. Cancer registries provide useful incidence, prevalence, and survival data, and assist the community health nurse in monitoring cancer patterns within a community. Community health nurses can access these registries through state health department websites. At the federal level, the Agency for Toxic Substances and Disease Registry (ATSDR, n.d.) maintains three registries of major public concern: the World Trade Center Health Registry (comprehensive and confidential health survey of those directly exposed to fallout and debris on Sept. 11, 2001), the Tremolite Asbestos Registry (asbestos exposure in Libby, Montana), and the National Exposure Registry (listing of persons exposed to certain hazardous substances).

### Environmental Monitoring

State governments, through health departments or other agencies, now monitor health hazards found in the environment. Pesticides, industrial wastes, radioactive or nuclear materials, chemical additives in foods, and medicinal drugs have joined the list of pollutants (see Chapter 9 for a detailed discussion). Concerned community members and leaders view these as risk factors that affect health at both community and individual levels. Public health nurses can also obtain data from federal agencies such as the Food and Drug Administration (FDA), the Consumer Product Safety Commission, the Environmental Protection Agency (EPA), and, as previously mentioned, the ATSDR.

### National Center for Health Statistics Health Surveys

The National Center for Health Statistics (NCHS) furnishes valuable health prevalence data from surveys of Americans. Published data are also frequently available for regions. The National Health Interview Survey (formerly known as National Health Survey) was established by Congress in 1956 and provides a continual source of information about the health status and needs of the entire nation (NCHS, 2007a). The National Health Interview Survey includes interviews from approximately 43,000 households each year and provides information about the health status and needs of the entire

country (NCHS, 2007a). The National Nursing Home Survey primarily samples institutional records of hospitals and nursing homes; it provides information on those who are using these services, along with diagnoses and other characteristics (NCHS, 2007b). The National Health and Nutrition Examination Survey (NHANES) reports physical measurements on smaller samples of the population and augments the information provided by interviews. It also provides prevalence information on injuries, diseases, and disabilities that appear frequently in the population. The National Survey of Family Growth (NSFG) focuses on fertility and family planning as well as other aspects of family health (NCHS, 2007b). Other studies investigate vital statistics events and characteristics of ambulatory patients in physicians' community practices.

Each of these nationally sponsored efforts suggest ways in which community health nurses can examine health problems or concerns affecting their communities (see From the Case Files). Interviews, physical examinations of subsets of community members, and surveillance of institutions, clinics, and private physicians' practices can be carried out locally after needs are identified and funds made available. Other sources may be found in data kept routinely but not centrally on the health problems of workers in local industries or the health problems of schoolchildren; a key issue for many community health nurses. Existing epidemiologic data can be used to plan parent education programs, health promotion among students, and almost any other type of service.

Another service of the CDC is its important publication, the *Mortality and Morbidity Weekly Report (MMWR)*. This publication presents weekly summaries of disease and death data trends for the nation. It includes reports on outbreaks or occurrences of diseases in specific regions of the country and international trends in disease occurrences that may affect the U.S. population. Most health departments subscribe to this publication, which provides important information both for epidemiologists and community health nurses.

### Informal Observational Studies

A second information source in epidemiologic study is informal observation and description. Almost any client group encountered by the community health nurse can trigger such

## From the Case Files

I am one of only four Public Health Nurses in our county—which is not many considering that our service area is very large, very rural, and very poor. Before I came, which was about 10 years ago, they had at least 10 nurses, and the population was maybe half of what it is now. We have growing numbers of residents with tuberculosis (TB), high teenage pregnancy, too many low-birth-weight babies, and to top it off, many of our residents lack health insurance. The county is in a budget crisis (again), and public health is high on the list for further reductions. I have been asked to speak at the next county supervisors meeting about what Public Health Nurses do and basically fight to keep us in the budget. I don't have much time to pull together information to give them, and will only have about 15 minutes for the presentation. They are all business owners, so I know they will appreciate data. I know other counties have all their morbidity and mortality figures online, but not here. Where to even start?

In preparing for this presentation, what specific types of data would you recommend to this nurse? What would be the sources of this data? Are those sources from local, state, or national resources? How could Healthy People 2010 and the Midcourse Review help frame this presentation?

a study. If, for example, the nurse encounters an abused child at a clinic, a study of the clinic's records to screen for additional possible instances of child abuse and neglect could lead to more case findings. If several cases of diabetes come to the attention of a nurse serving on a Navajo reservation, a widespread problem might come to light through informal inquiries about the incidence and age at onset of the disease among this Native American population. In a study of culture, sexuality, and women's agency in the prevention of HIV/AIDS, two researchers explored the awareness among women in southern Africa of the HIV epidemic and methods they might use to protect themselves from the virus. Interviews and informal field observations were carried out over a 7-year period at five sites "that were selected to reflect urban and rural experiences, various populations, and economic and political opportunities for women at different historical moments over the course of the HIV epidemic" (Susser & Stein, 2000, p. 1042). The findings indicated that most women saw themselves as active participants in the search for a way to protect themselves in sexual situations and were not helpless victims. At all sites over the 7 years, women desired to control their own bodies and felt they had the right to use the female condom. However, political and economic concerns, combined with historically powerful patterns of gender discrimination and neglect of women's sexuality, were considered to be the main barriers to the development and distribution of methods that women could control. Collecting such information and complementing it with existing data about a population served by a community health nurse could lead to improved women's health promotion practices to prevent HIV/AIDS in the United States. Informal observational study often raises questions and suggests hypotheses that form the basis for designing larger-scale epidemiologic investigations, such as this study in Africa.

### Scientific Studies

The third source of information used in epidemiologic inquiry involves carefully designed scientific studies. The nursing profession has recognized the need to develop a systematic body of knowledge on which to base nursing practice. Already, systematic research is becoming an accepted part of the community health nurse's role. Findings from epidemiologic studies conducted by or involving nurses are appearing more frequently in the literature. For example, concern about testicular cancer and the patterns of testicular self-examination (TSE) among young adult men was the impetus for a nurse to conduct a study between 1999 and 2001 among 191 men attending occupational health fairs in the American Midwest (Wynd, 2002). The nurse learned that 64% rarely or never performed TSE and 36% practiced TSE monthly or every few months. Those who infrequently performed TSE more often were African American or Hispanic and had less than a college education. Factors associated with infrequent TSE practice included less satisfaction with job assignment and with life in general; greater worries interfering with daily life; more serious family problems involving spouse, children, or parents; and fewer people to turn to for support. In another study, concern regarding negative birth outcomes prompted exploration on the association between maternal chronic disease and preterm birth (PTB), low birth weight (LBW), and infant mortality

(Graham, Zhang, & Schwalberg, 2007). Working in collaboration with other health professionals, the nurse researcher examined birth and death certificates between 1999 and 2003 in a cohort of over 200,000 singleton infants born to African American and White mothers. The research showed that, irrespective of maternal race, chronic hypertension and diabetes were significantly associated with at least one negative birth outcome. Concerning too was the finding that, for African American mothers, cardiac disease was strongly associated with LBW and PTB (Graham et al.). Systematic studies such as these, as well as informal studies and existing epidemiologic data, can provide the community health nurse with valuable information that can be used to positively affect aggregate health.

## METHODS IN THE EPIDEMIOLOGIC INVESTIGATIVE PROCESS

The goals of epidemiologic investigation are to identify the causal mechanisms of health and illness states and to develop measures for preventing illness and promoting health. Epidemiologists employ an investigative process that involves a sequence of three approaches that build on one another: descriptive, analytic, and experimental studies. All three approaches have relevance for community health nursing (see Chapter 4 for a more detailed description).

### Descriptive Epidemiology

**Descriptive epidemiology** includes investigations that seek to observe and describe patterns of health-related conditions that occur naturally in a population. For example, a community health nurse might seek to learn how many children in a school district have been immunized for measles, how many home births occur each year in the county, how many cases of STDs have occurred in the city in the past month, or how many automobile crashes have occurred near the community high school. At this stage in the epidemiologic investigation, the researcher seeks to establish the occurrence of a problem. Data from descriptive studies suggest hypotheses for further testing. Descriptive studies almost always involve some form of broad-based quantification and statistical analysis.

### Counts

The simplest measure of description is a count. For example, an epidemiologic study to assess the impact of the varicella vaccine (licensed in 1995) on death due to the disease, examined data from the NCHS (1990–2001) Multiple Cause-of-Death Mortality Data (Nguyen, Jumaan, & Seward, 2005). Data from the period prior to and following vaccine availability showed that varicella-related deaths dropped by more than 45%, from an average 145 per year between 1990 and 1994 to 66 per year during 1999–2001. The findings also showed that varicella-related deaths declined among children and adults (20–49 years) alike and for all racial and ethnic groups. As positive as these results were, reported deaths occurred among those who were eligible to receive the vaccine and not among those with high-risk conditions such as HIV, as might be expected. The most current figures from the NCHS reflect an even more precipitous drop, with 19 reported varicella-related deaths during 2004 (NCHS, 2006).

Obtaining a count of this type always depends on the definition of what is being counted and when it was counted. This particular count, for example, utilizes a large database that takes time to be made public and therefore may not provide a current picture of actual deaths. Use of this type of data should always consider the time delay involved. If a community health nurse needs more current information within a specific community or state, hospital records or death certificates may be another source. However, before making use of any statistics, whether from official state offices, the Census Bureau, or a health agency, it is necessary to determine what the information represents.

### Rates

**Rates** are statistical measures expressing the proportion of people with a given health problem among a population at risk. The total number of people in the group serves as the denominator for various types of rates. To express a count as a proportion, or rate, the population to be studied must first be identified. For instance, total West Nile virus fatalities in the United States for 2006 were 177 out of 4,269 confirmed infections (CDC, 2007b). If those deaths are considered in relation to the total number of cases in the country, there will be one rate; if, however, those fatalities are considered in relation to the total population, there will be a quite different rate. It is important when reviewing rates that you understand which measures are being compared.

In epidemiology, the population represents the universe of people defined as the objects of a study. Because it is often difficult, if not impossible, to study an entire population, most epidemiologic studies draw a sample to represent that group. Sometimes, it is important to seek a random sample (in which everyone in the population has an equal chance of selection for study and choice is made without bias). At other times, a sample of convenience (in which study subjects are selected because of their availability) is sufficient. In many small epidemiologic studies, it may be possible to study almost every person in the population, eliminating the need for a sample. Several rates have wide use in epidemiology. Those most important for the public health nurse to understand are the prevalence rate, the period prevalence rate, and the incidence rate.

**Prevalence** refers to all of the people with a particular health condition existing in a given population at a given point in time. The *prevalence rate* describes a situation at a specific point in time (Friis & Sellers, 2004). If a nurse discovers 50 cases of measles in an elementary school, that is a simple count. If that number is divided by the number of students in the school, the result is the prevalence of measles. For instance, if the school has 500 students, the prevalence of measles on that day would be 10% (50 measles/500 population).

$$\text{Prevalence rate} = \frac{\text{Number of persons with a characteristic}}{\text{Total number in population}}$$

In the study of varicella deaths, on the other hand, the investigators had a count for 1-year periods from 1991 to 2001 (Nguyen et al., 2005). Rather than portraying only 1 day, this number covered an extended period of time (1 year). The

prevalence rate over a defined period of time is called a *period prevalence rate*:

$$\text{Period prevalence rate} = \frac{\text{Number of persons with a characteristic during a period of time}}{\text{Total number in population}}$$

Not everyone in a population is at risk for developing a disease, incurring an injury, or having some other health-related characteristic. The *incidence rate* recognizes this fact. **Incidence** refers to all new cases of a disease or health condition appearing during a given time. Incidence rate describes a proportion in which the numerator is all new cases appearing during a given period of time and the denominator is the population at risk during the same period. For example, some childhood diseases give lifelong immunity. The school children who have had such diseases would be removed from the total number of children at risk in the school population. Three weeks after the start of a measles epidemic in a school, the incidence rate describes the number of cases of measles appearing during that period in terms of the number of persons at risk:

$$\frac{200}{1,000} \text{ or } \frac{200 \text{ new cases}}{1,000 \text{ persons at risk}}$$

The health literature is not always consistent in the use of the term *incidence*; sometimes, this word is used synonymously with *prevalence rates*, and the reader must take this into consideration.

$$\text{Incidence rate} = \frac{\text{Number of persons developing a disease}}{\text{Total number at risk per unit of time}}$$

Another rate that describes incidence is the attack rate. An *attack rate* describes the proportion of a group or population that develops a disease among all those exposed to a particular risk. This term is used frequently in investigations of outbreaks of infectious diseases such as influenza. If the attack rate changes, it may suggest an alteration in the population's immune status or that the disease-causing organism is present in a more or less virulent strain.

### Computing Rates

To make comparisons between populations, epidemiologists often use a common base population in computing rates. For example, instead of merely saying that the rate of an illness is 13% in one city and 25% in another, the comparison is made per 100,000 people in the population. This population base can vary for different purposes from 100 to 100,000. To describe the **morbidity rate**, which is the relative incidence of disease in a population, the ratio of the number of sick individuals to the total population is determined. The **mortality rate** refers to the relative death rate, or the sum of deaths in a given population at a given time. Display 7.4 includes formulas for computing rates commonly used in community health.

The goal of descriptive studies is to identify the patterns of occurrence of any health-related condition. They can be *retrospective* (identify cases and controls, then go back to review existing data) or *prospective* (identify groups and exposure factors, and then follow them forward in time).

## DISPLAY 7.4

## COMMON EPIDEMIOLOGIC RATES

## General Mortality Rates

$$\text{Crude Mortality Rate} = \frac{\text{Number of Reported Deaths During 1 Year}}{\text{Estimated Population as of July 1 of Same Year}} \times 100,000$$

$$\text{Cause-Specific Mortality Rate} = \frac{\text{Number of Deaths From a Stated Cause During 1 Year}}{\text{Estimated Population as of July 1 of Same Year}} \times 100,000$$

$$\text{Case Fatality Rate} = \frac{\text{Number of Deaths From a Particular Disease}}{\text{Total Number With the Same Disease}} \times 100$$

$$\text{Proportional Mortality Ratio} = \frac{\text{Number of Deaths From a Specific Cause Within a Given Time Period}}{\text{Total Deaths in the Same Time Period}} \times 100$$

$$\text{Age-Specific Mortality Rate} = \frac{\text{Number of Persons in a Specific Age Group Dying During 1 Year}}{\text{Estimated Population of the Specific Age Group as of July 1 of Same Year}} \times 100,000$$

## Specific Rates for Maternal and Infant Populations

$$\text{Crude Birth Rate} = \frac{\text{Number of Live Births During 1 Year}}{\text{Estimated Population as of July 1 of Same Year}} \times 1,000$$

$$\text{General Fertility Rate} = \frac{\text{Number of Live Births During 1 Year}}{\text{Number of Females Aged 15–44 as of July 1 of Same Year}} \times 1,000$$

$$\text{Maternal Mortality Rate} = \frac{\text{Number of Deaths From Puerperal Causes During 1 Year}}{\text{Number of Live Births During Same Year}} \times 100,000$$

$$\text{Infant Mortality Rate} = \frac{\text{Number of Deaths Under 1 Year of Age for Given Year}}{\text{Number of Live Births Reported for Same Year}} \times 1,000$$

$$\text{Perinatal Mortality Rate} = \frac{\text{Number of Fetal Deaths Plus Infant Deaths Under 7 Days of Age During 1 Year}}{\text{Number of Live Births Plus Fetal Deaths During Same Year}} \times 1,000$$

In a descriptive study of child abuse, for example, the investigator would note the age, gender, race or ethnic group, and physical and emotional conditions of the children affected. In addition, data would be collected that described the economic status and occupation of parents, the location and setting of abusive behavior, and the time and season of the year when abuse occurred. In the retrospective study on reported varicella deaths, the investigators described the age, sex, ethnic background, and birthplace of victims and other information, such as whether varicella was an underlying or contributing cause of death (Nguyen et al., 2005). Describing facets of these deaths provides information for further study and suggests avenues for intervention or prevention.

### Analytic Epidemiology

A second type of investigation, **analytic epidemiology**, goes beyond simple description or observation and seeks to identify associations between a particular human disease or health problem and its possible causes. Analytic studies tend to be more specific than descriptive studies in their focus.

They test hypotheses or seek to answer specific questions and can be retrospective or prospective in design. Analytic studies fall into three types: prevalence studies, case-control studies, and cohort studies.

### Prevalence Studies

When examining prevalence, it is helpful to remember that the health condition may be new or may have affected some people for many years. A **prevalence study** describes patterns of occurrence, as in the study of varicella-related deaths. It may examine causal factors, but a prevalence study always looks at factors from the same point in time and in the same population. Hypothesized causal factors are based on inferences from a single examination and most likely need further testing for validation.

### Case-control Studies

A **case-control study** compares people who have a health or illness condition (number of cases with the condition) with those who lack this condition (controls). These studies begin

with the cases and look back over time (retrospectively) for presence or absence of the suspected causal factor in both cases and controls. In a case-control study to explore the risks of delivering a small-for-gestational-age (SGA) infant based on certain occupational patterns, women delivering single births between 1997 and 1999 were interviewed by telephone after delivery (Croteau, Marcoux, & Brisson, 2006). Comparisons between the cases and controls revealed that irregular and shift work increased the risk of a SGA birth, but that changing those occupational patterns before 24 weeks could reduce the risk substantially. In a case-control study, the two groups should share as many characteristics as possible, to isolate possible causes. In the study by Croteau and colleagues, the control group mothers were randomly selected from all singleton births during that same period and in the same region of the country. In this way, differences between the cases (SGA births) and those with a normal-weight infant are more easily identified.

### Cohort Studies

A **cohort** is a group of people who share a common experience in a specific time period. Examples are a group of the elderly or the employees of an industry. In epidemiology, a cohort of people often becomes a focus of study. Cohort studies, rather than measuring the relationship of variables in existing conditions, study the development of a condition over time. A cohort study begins by selecting a group of people who display certain defined characteristics before the onset of the condition being investigated. In studying a disease, the cohort might include individuals who are initially free of the disease but are known to have been exposed to a particular factor. They would be observed over time to evaluate which variables were associated with the development or nondevelopment of the disease. These types of studies are often utilized with environmental hazard exposures, as with the World Trade Center Health Registry, the Tremolite Asbestos Registry, and the National Exposure Registry discussed earlier (ATSDR, n.d.). All of these registries provide the capability to conduct a cohort study on postexposure disease development and enable those affected to access the most current information on their exposure risks.

In 1993, the Women's Health Study, a 10-year national longitudinal, experimental, cohort study involving nearly 40,000 female health professionals was initiated (clinicaltrials.gov, 2007; Nabel, 2005). Sponsored by the National Heart, Lung, and Blood Institute and the National Cancer Institute, it consisted of a randomized trial evaluating the benefits and risks of low-dose aspirin and vitamin E in the prevention of cancer and cardiovascular disease. Depending on the random assignment of the women, participants took 100 mg of aspirin or placebo and 600 IU of vitamin E or placebo every other day. This was a double-blind study: neither the participants nor the researchers knew which subjects were taking the study drugs or placebos. The study has been funded through 2009 to provide observational follow-up of study participants. The only positive results to date show that women over age 65 may benefit from low-dose aspirin to prevent strokes. The aspirin regimen was not effective in preventing a first heart attack or death from cardiovascular causes. The research findings support adopting healthy lifestyle habits including "eating for heart health, getting regular physical activity, maintaining a

healthy weight, not smoking, and controlling high cholesterol levels, high blood pressure, and diabetes" (Nabel, 2005). With respect to cardiovascular health and vitamin E, there was no demonstrated benefit or risk.

In practice, the various types of studies just discussed are frequently mixed. A case-control study may include description and analysis with a retrospective focus; a cohort study may be conducted prospectively or retrospectively. The Women's Health Study just discussed is an example of a case-control study, a cohort study, and an experimental study. Flexibility is essential to allow the investigator as much freedom as possible in choosing the most useful methodology.

### Experimental Epidemiology

**Experimental epidemiology** follows and builds on information gathered from descriptive and analytic approaches. It is used to study epidemics, the etiology of human disease, the value of preventive and therapeutic measures, and the evaluation of health services (Valanis, 1999). In an experimental study, the investigator actually controls or changes the factors suspected of causing the health condition under study, then observes what happens to the health state. In human populations, experimental studies should focus on disease prevention or health promotion rather than testing the causes of disease, which is done primarily on animals.

Experimental studies are carried out under carefully controlled conditions. The investigator exposes an experimental group to some factor thought to cause disease, improve health, prevent disease, or influence health in some way (as in the Women's Health Study). Simultaneously, the investigator observes a control group that is similar in characteristics to the experimental group but without the exposure factor.

The public health nurse should be alert for opportunities to conduct experimental studies in the course of working with groups. A study need not be elaborate to provide important data for future nursing practice. For example, a community health nurse can provide focused instruction to 20 new mothers encouraging them to breast-feed and then compare the health of their infants with infants of 20 mothers in the same service area who use formula.

A nurse can look at the number of automobile crashes at an intersection where there is a traffic light compared with a similar intersection that has stop signs. Based on the results of the investigation, the nurse may bring the information to the city council and petition for a stop light at the intersection. Study results can be used to bring about change in the community and are not limited to communicable or chronic diseases. Improving community safety is also an essential outcome.

An expanding area of experimental epidemiology involves the use of computers to simulate epidemics. With mathematical models, it is possible to determine the probabilities of various aspects of disease occurrence. This approach is making an increased contribution to epidemiologists' knowledge of etiology and prevention.

Occasionally, an experiment occurs naturally, thus affording the researcher the chance to make important discoveries. John Snow discovered such a "natural experiment" in London in 1854 (as discussed earlier in the chapter). In his seminal study of an epidemic of cholera, he observed

one group that contracted the disease and another that did not. Closer inspection revealed that the major difference between these groups was their water supply. Eventually, the spread of cholera was traced to the water supply of the group with the high morbidity rate (Valanis, 1999).

A *community trial* is a type of experimental study done at the community level. Geographic communities are assigned to intervention (experimental) or nonintervention (control) groups and compared to determine whether the intervention produces a positive change in the community. Community trials can be extremely expensive and are not undertaken unless there is substantial evidence that the intervention will make a difference at the aggregate level. There are times when these community trials occur spontaneously, and it is important for the community health nurse to recognize these opportunities. For instance, one community public health department institutes an aggressive campaign to educate health care workers on the signs of elder abuse. Selecting a similar community where that level of training is not available, the community health nurse can then compare the rates of elder abuse reporting between these two communities. If you were conducting this research, what outcome would you expect in the community with the enhanced training? Where could you obtain this information? Think about what other measures you might be interested in comparing between these two communities.

## CONDUCTING EPIDEMIOLOGIC RESEARCH

The community health nurse who engages in an epidemiologic investigation becomes a kind of detective. First, there is a problem to solve, a puzzle to unravel, or a question to answer. The nurse begins to search for basic information, for clues that might help answer the question. Information is never self-explanatory, and, like a detective, the nurse must analyze and interpret every additional clue. Slowly, there is a narrowing of possible suspects until the causes of a disease, the consequences of a prevention plan, or the results of treatment are identified. On the basis of this investigation, the nurse can draw further conclusions and make new applications to improve health services.

As discussed previously, epidemiologic studies are a form of research. The steps outlined here are similar to those discussed in Chapter 4. Epidemiologic research involves seven steps. Everything from an informal study in the course of nursing practice to the most comprehensive epidemiologic research project can be undertaken with these steps:

1. Identify the problem.
2. Review the literature.
3. Design the study.
4. Collect the data.
5. Analyze the findings.
6. Develop conclusions and applications.
7. Disseminate the findings.

Each step is considered here in the context of a single nursing study that examined receipt of lead-poisoning prevention information by parents of children enrolled in one state's Medicaid program (Polivka, 2006). Although research as a community health nursing role is covered in a separate chapter, the analysis of one epidemiologic study reinforces the integration of research in the nurse's role.

## Identify the Problem

Community health nurses are constantly confronted with threats to the health and well-being of the community. Almost daily, questions are raised, puzzles presented, and problems identified. Pregnant women who smoke or use cocaine threaten the health of their unborn children: What can be done to reduce this behavior? Rape is increasing: What can be done to prevent such violence or to bring aid to victims? Children are injured and die from bicycle accidents: Why do these occur and how can they be prevented? Many farm workers have been killed or injured in farm equipment accidents: What can be done to prevent them? Any threat to the health of a group offers fertile ground for epidemiologic investigation.

One nurse researcher was concerned with lead-poisoning prevention education among parents of young children. To explore this issue, the researcher sought to examine parental receipt of educational materials on lead-poisoning prevention, as well their preferred method of receiving that information (Polivka, 2006). Using a cross-sectional design, parents of 1- to 2-year-old children who were enrolled in the Medicaid program were mailed a survey developed by the researcher. From the nearly 90,000 children meeting the study criteria, a sample of 1,656 was selected, which allowed for a low but realistic 24% return rate. The response rate ( $n = 532$ ) was actually higher than predicted, and the majority of the respondents reported receiving lead-poisoning prevention information. Of concern, however, was that only 28% reported receipt of some type of reminder to have their child's blood drawn for a lead level assessment. The findings also indicated that most respondents preferred to receive lead-poisoning prevention information from brochures/pamphlets (71%) or directly from health care providers (48%).

## Review the Literature

All too often, after identifying a problem, health professionals rush to take immediate action without reviewing solutions that have been tried previously. Every epidemiologic investigation should begin with a review of the literature. Even discovering that little research has been done on the problem can be valuable information. Conversely, if many studies have already been conducted in the area, this information can help narrow the study to areas not previously investigated or allow researchers to replicate earlier studies to confirm findings in a different setting. One of the most valuable sources in the literature is the review article, which essentially summarizes all the research that has been conducted on a subject.

A review of the literature often suggests hypotheses from discoveries made in other studies. In the lead-poisoning prevention education survey, a review of the literature provided helpful background information (Polivka, 2006). The literature review also revealed that other studies have found varied levels of receipt of lead-poisoning prevention education among parents and caregivers, from as low as about 30% to as high as 60%.

## Design the Study

The first step in designing a study is to formulate one or more specific questions to answer or hypotheses to test.

Sometimes, the question or hypothesis emerges from the review of the literature; it also may be developed through the researcher's own analysis and hunches. It is a good idea to write out one or more hypotheses to test or questions to answer. In the lead-poisoning education survey, the researcher did not explicitly state a hypothesis; however, in previous focus groups conducted by the researcher and a colleague, "parents revealed they had little knowledge regarding the sources of lead poisoning, and they preferred to receive information via videos and television ads" (Polivka & Gottesman, 2005). This piece of information helped inform the current study and the current research questions:

- ◆ Have parents received lead-poisoning prevention information or reminders about lead testing?
- ◆ With whom have parents talked about lead poisoning?
- ◆ How would parents prefer to receive lead-poisoning prevention education? (Polivka, 2006, p. 53)

The next step is to plan what study type (descriptive, analytic, or experimental) or combination of study types, best suits the goals of the research and how the study will be conducted. Will the data be collected retrospectively from existing records, or will new data be collected? Who will conduct interviews? What kinds of data will be needed to measure the outcomes of intervention? Polivka (2006) used a retrospective analytic approach in the design of this cross-sectional survey. A mailed survey was selected as an effective means to sample the population of interest.

## Collect the Data

The survey tool used in the Polivka (2006) study was a researcher-developed instrument that was assessed for both face and content validity by a team of experts in the field. The next step was to pilot test the survey tool with individuals similar to the target population. In this case, the researcher used a small group of women who were enrolled in the WIC program (Special Supplemental Nutrition Program for Women, Infants, and Children, U.S. Department of Agriculture) and revised the survey based on their suggestions.

Following review by a human subjects committee, the survey was mailed to the identified parents along with a cover letter and stamped preaddressed envelope. To increase the return rate from the parents, a small incentive was included in the survey, and a thank-you card and reminder to return the survey (for nonrespondents) was mailed out 1 week later. For those not returning surveys after 3 to 7 weeks, another survey was sent out in hope of increasing the rate of return. For those who completed the survey, a small thank-you gift was mailed out. The steps taken by the researcher were all important to achieving a return rate of 32%, well over the expected rate of 24%.

As in the Polivka (2006) study, it is useful to perform a pilot study that pretests an interview guide, questionnaire, or treatment. If one wishes to interview women about battering during pregnancy, it might be useful to prepare a guide and interview one or two people, then revise the guide on the basis of the experience. If development of a questionnaire to assess the nutritional needs of elderly people living alone is

part of the study design, it would be helpful to test the survey on some volunteers to determine its clarity and relevance. And, if the study is to provide a specific treatment such as coaching, teaching, or demonstration, it is important to practice it on a small group of people with characteristics similar to those of the subjects. In community health nursing, data collection often can occur as part of ongoing practice. Unless the study has been carefully designed, however, data may be collected for months or years, only to discover that important questions have been omitted.

## Analyze the Findings

In most epidemiologic studies, data analysis consists of summarizing the findings, computing rates and ratios, and displaying the findings in tables and graphs. At this stage, the data are used to address the original question or test the original hypothesis. Was the hypothesis supported or not supported by the data? Summarized data can also generate more questions or indicate areas that warrant further investigation. For example, in the Polivka (2006) study, 60% of the parents reporting receipt of some type of lead-poisoning prevention information tended to be over age 25, unmarried, and with more than a high school education. These results certainly suggest that younger parents and those with less education should be a target of educational interventions to address lead-poisoning prevention. Moreover, any educational materials developed should keep in mind the reading capability of those parents.

## Develop Conclusions and Applications

Stating conclusions is an outcome of analysis and interpretation. The investigators summarize the results and their meaning for the purpose of making this information useful to other health services providers. Many times, research has direct practical application for improving health services, continuing or discontinuing services, or conducting future research. It is also important to describe mistakes made and lessons learned about study design and other aspects of the research, to assist future investigators.

In the Polivka study, the researcher suggests that "public health nurses need to collaborate with other health care providers in implementing individual, community, and system level lead-poisoning prevention educational interventions for parents of at-risk children" (2006, p. 55). Citing the continued need for efforts to reduce lead-poisoning and the Healthy People 2010 goal of eliminating lead poisoning in U.S. children (USDHHS, 2000), the author also states that "public health nurses can be pivotal in educational reminder efforts by determining specific targeted population segments and identifying appropriate educational methods for those segments at the individual, community, and system levels" (Polivka, p. 56). The author had clearly outlined the leadership role that community health nurses can and should take to reach this national goal.

## Disseminate the Findings

Finally, research findings should be shared. Information gained from epidemiologic studies must be disseminated throughout the professional community to strengthen the

knowledge base for improved practice and to promote future research. In the lead-poisoning prevention education study, the author selected a well-known nursing journal; one that specifically focuses on public health nursing practice. Careful selection of this specialty venue helps assure that those practicing in community and public health nursing are more likely to read the article. The author's use of the term *lead poisoning* in the title of the article was also very important for dissemination. Nurses interested in lead poisoning are very likely to have this article selected in a database reference search, such as the Cumulative Index to Nursing & Allied Health Literature (CINAHL), based on the use of that term alone.

## Summary

Epidemiology is the study of the distribution and determinants of health, health conditions, and disease in human population groups. It shares with community health nursing the common focus of the health of populations. It is a specialized form of scientific research that can provide public health professionals with a body of knowledge on which to base their practice and methods for studying new and existing problems. To understand epidemiology, one must first understand some basic epidemiologic concepts: the host, agent, and environment model; causality; immunity; the natural history of disease or health conditions; risk; and prevention strategies.

Community health nurses can use three sources of information when conducting epidemiologic investigations: existing epidemiologic data, informal investigations, and carefully designed scientific studies.

Epidemiology employs three investigative approaches: descriptive studies, analytic studies, and experimental studies. Although studies can be either retrospective or prospective, some merely describe existing conditions (descriptive studies), whereas others seek to explain causes (analytic studies). Experimental studies seek to confirm causal relationships identified in descriptive and analytic studies. Analytic studies can be of three types: prevalence, case-control, or cohort. In practice, all these types of studies often become combined in various ways. They also make use of quantitative concepts such as count, prevalence rate, incidence rate, mortality rate, and various types of morbidity (sickness) rates.

Epidemiologic research includes seven steps:

1. Identify the problem, which is usually a threat to the population's health.
2. Review the literature to determine what other studies have found.
3. Carefully design the study.
4. Collect the data.
5. Analyze the findings.
6. Develop conclusions and applications.
7. Disseminate the findings.

Thinking epidemiologically can significantly enhance community health nursing practice. Epidemiology provides both the body of knowledge—information on the distribution and determinants of health conditions—and methods for investigating health problems and evaluating services. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Identify an aggregate-level health problem in your community. Using the host, agent, and environment model, explain who is the host, what are the causative agents, and what environmental factors have promoted or delayed the development of the problem.
2. Select an aggregate health (wellness) condition, such as preschoolers' normal growth and development or elders' healthy aging, and list all the causal factors that might contribute to this healthy state. Now, plot these schematically in a diagram to show the web of causation model for this condition.
3. Using the same health condition that you selected in the previous exercise, describe the natural history of this condition, outlining its four stages. Identify three preventive nursing interventions, one for each level of prevention that could apply to this condition.
4. Select an article that reports an epidemiologic study from a recent nursing or public health journal, and record your responses to the following questions:
  - What prompted the study, and what was its purpose?
  - Was it descriptive, analytic, or experimental research?
  - Was the study design retrospective or prospective?
  - Why did the investigators choose this design?
  - What existing sources of epidemiologic data did this study use? List all sources specifically, such as *Morbidity and Mortality Weekly Report* or incomes by household in census data.
  - What were the study findings? Identify the population group that will benefit from this research.
5. Interview one or more practicing public health nurses in your community, and identify an aggregate-level problem that needs epidemiologic investigation. Propose a rough draft study design to research this problem.

## Communicable Disease Control

### LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Describe the nurse's role in communicable disease control.
- ◆ Describe the three modes of transmission for communicable diseases.
- ◆ Explain the strategies used for the three levels of prevention in communicable disease control.
- ◆ Explain the significance of immunization as a communicable disease control measure.
- ◆ Differentiate between human immunodeficiency virus (HIV) infection and acquired immunodeficiency syndrome (AIDS).
- ◆ Describe major issues that affect the control and elimination of tuberculosis (TB).
- ◆ Discuss specific ways to prevent sexually transmitted diseases, including HIV/AIDS.
- ◆ Identify six globally emerging communicable diseases.
- ◆ Discuss the global and national trends and issues in communicable disease control.
- ◆ Discuss the consequences of biologic terrorism with weapons such as anthrax and smallpox.
- ◆ Discuss ethical issues affecting communicable disease and infection control.

*“Illness is the doctor to whom we pay most heed; to kindness, to knowledge, we make promise only; pain we obey.”*

—Marcel Proust

### KEY TERMS

Acquired  
immunodeficiency  
syndrome (AIDS)  
Active immunity  
Communicable disease  
Direct transmission  
Fomites  
Herd immunity  
Human immunodeficiency  
virus (HIV)  
Immunization  
Incubation period  
Index case  
Indirect transmission  
Infectious  
Isolation  
Passive immunity  
Quarantine  
Reservoir  
Ring vaccination  
Screening  
Surveillance  
Vaccine  
Vector

 **Communicable** diseases pose a major threat to public health and are of significant concern to community health nurses. A **communicable disease** is one that can be transmitted from one person to another, is caused by an agent that is **infectious** (capable of producing infection), and is transmitted from a source, or **reservoir**, to a susceptible host (Heymann, 2004). The majority of communicable diseases that the community health nurse will encounter and investigate are considered infectious; other diseases are not infectious, but are just as potentially problematic to a community. An example of a noninfectious disease is Lyme disease. The infections or diseases that are investigated are reportable through a process mandated by the individual state in which the nurse practices (Heymann, 2004).

Knowledge of communicable diseases is fundamental to the practice of community health nursing because these diseases typically spread through communities of people. Understanding the basic concepts of communicable disease control, as well as the numerous surrounding issues, helps a community health nurse work effectively to prevent and control communicable disease in populations and groups. It also helps nurses teach important and effective preventive measures to community members, advocate for those affected, and protect the well-being of uninfected persons (including nurses themselves).

In the last century, numerous changes occurred in the lives of people globally, as well as nationally, related to issues of public health. Achievements in health, safety, longevity, and disease control improved the lives of many populations in developed nations, and with the work of many global organizations, will continue to improve for developing nations as well. With progress, come challenges and concerns related to community health nursing services (Centers for Disease Control [CDC] 1999b; World Health Organization [WHO], 2003b), such as:

- ◆ Higher morbidity among various age and population groups related to communicable diseases, rather than death.
- ◆ Continuing disproportionate morbidity and mortality among lower socioeconomic populations.
- ◆ Emergent, newly identified, or reemerging diseases related to changing environments, global mobility, and need for space. Examples of these are hantavirus, severe acute respiratory syndrome (SARS), and West Nile virus.
- ◆ Development of multidrug resistant (MDR) strains of bacteria and viruses that pose significant occupational health challenges as well as practice issues for health workers.
- ◆ Rising fear of terrorist attacks utilizing biologic agents.
- ◆ Ongoing public empowerment through education regarding healthy life practices, and current health research associated with disease and cancer prevention through diet, immunization, and the environment.

This chapter provides you with valuable information to better understand the communicable disease burden in your community. It describes ways to plan and implement appropriate prevention interventions, including immunization of children and adults, environmental interventions, community

education, screening programs, and disease case/source investigation and contact finding. Ethical issues of communicable disease control are also discussed. A list of communicable disease information sources useful to you, the public health nurse, is provided at the end of this chapter.

## BASIC CONCEPTS REGARDING COMMUNICABLE DISEASES

Communicable diseases have challenged health care providers for centuries. They have led to the development of countless nursing and medical preventive measures, from simple procedures such as handwashing, sanitation, and proper ventilation to the research and development of vaccines and antibiotics (CDC, 1999b).

### Evolution of Communicable Disease Control

Because preventive measures have greatly reduced the spread of communicable diseases, many people consider communicable diseases to be a threat of the past. Yet this is not the reality. Communicable diseases, particularly those of epidemic and pandemic probability, such as TB, influenza, or acquired immunodeficiency syndrome (AIDS), continue to cost millions of lives and billions of dollars to the global human society every year (WHO, 2003b).

As mentioned in Chapter 7, the first documented global threat from a communicable disease began in the 13th century in the form of bubonic plague. It was responsible for killing 25% of the population in some European countries over the years following the Crusades and during the years of exploration and trade by ship—in the 1400s to 1600s.

As commerce and industry continued to grow, people migrated from rural areas to towns and cities. However, health and hygiene practices that worked in remote areas did not transfer to the new urban settings. In tenements and overcrowded parts of towns, water for drinking easily became contaminated with human waste; mounting garbage and trash, unable to be composted or buried as was done in farming communities, created a rich habitat for rodents and other animals and insects, encouraging them to breed and become vectors for many communicable diseases.

Not until the 1700s and 1800s were the causative organisms for various infectious diseases recognized through the assistance of increasingly sophisticated microscopes. With these discoveries came early attempts to create ways to prevent the spread of such organisms, either by decreasing their power or by eliminating them. Pasteurization of milk was invented, and efforts to eliminate rats from ships and food storage areas began. These measures commenced a global effort to eliminate communicable diseases (Weatherall, Greenwood, Chee, & Wasi, 2005).

One disease, smallpox, is a classic example of a communicable disease control success story. For centuries, the infectious disease of smallpox killed millions of people and scarred survivors for life—in fact, it is thought that smallpox is responsible for more deaths than any other infectious disease (Children's Hospital of Philadelphia, 2007). Smallpox first responded to a crude vaccine that was developed in the 18th century, almost accidentally, when Dr. Edward Jenner noted that milkmaids seemed to be unaffected by the illness when it swept through the English countryside every few

years. He posited that the mild infections they incurred while milking cows and coming in contact with the blisters on cow's udders gave them protection from the more serious smallpox infections. He injected fluid from the cows' blisters into volunteers, including his own young son (Children's Hospital of Philadelphia, 2007). Notable people of the time withstood the months-long after effects of the smallpox vaccine, including the family of our second president, John Adams (McCullough, 2001). The vaccine was studied and perfected and was used globally for decades. A major worldwide eradication campaign began in 1967. The last naturally acquired case of smallpox in the world occurred in October 1977; global eradication was certified 2 years later by the World Health Organization (WHO) and confirmed by the World Health Assembly in May 1980. Since then, no cases of smallpox have been identified in any country (Heymann, 2004).

However, the threat of biologic warfare using smallpox or other disease organisms raises concerns about how to prepare for the future. A smallpox immunization program began in 2002 with President George W. Bush being immunized. The plan was to follow with military personnel, health care providers, and then voluntary immunization among the general population. In 2002, the Centers for Disease Control and Prevention (CDC) issued guidelines for state and local health departments to develop smallpox response plans. The plans were to include a mass vaccination strategy in the event of an outbreak (CDC, 2002).

### Community Health Nurse and Reporting Communicable Disease

Most health departments or districts have PHNs who work in disease control and prevention. Some agencies utilize a combination of nurses, epidemiologists, and communicable disease investigators. Each state has a state-level department of health services, which is either the primary or guiding agency for local disease control policies that are mandated through the health and safety codes of each state. States utilize the national reportable disease list as the guidance for state reportable diseases and may add to this list as they choose, reflecting the types of conditions that are unique to a state or region of the United States (CDC, 2006g). The CDC is the federal agency that provides guidance and recommendations for each state health department to utilize in developing individual state recommendations for the local agencies. The CDC is also available to each individual citizen via phone or the internet ([www.cdc.gov](http://www.cdc.gov)).

The local health department/agency is the initial point of notification of a communicable disease investigation. The notifications may come from a laboratory, which is a mandated reporter of infectious reportable diseases and must report both to the ordering physician as well as to the health department. The physician is also a mandated reporter, and must complete the state's Confidential Morbidity Report (CMR) (see Fig. 8.1). Each local health department/agency will investigate the specific disease using a protocol set either by the state or local health officer (CDC, 2006g).

### Global Trends—Achievements and Challenges

During the last several decades, substantial progress has been made in controlling some major infectious diseases

around the world, although other diseases have not been as well managed. The following are some of the major accomplishments, as well as continuing dilemmas:

- ◆ WHO's Expanded Program on Immunization (EPI) was launched in 1974. As a result, by 2005, more than 78% of the world's children had been immunized against diphtheria, tetanus, whooping cough (pertussis), poliomyelitis, measles, and TB, compared with fewer than 5% in 1974 (WHO, 2005).
- ◆ Eradication of *smallpox* was achieved in 1980.
- ◆ The tropical disease *yaws* has virtually disappeared. The first *yaws* campaign was launched in Haiti in 1950, and by 1965, 46 million people in 49 countries had been successfully treated with penicillin. The disease is no longer a significant problem in most of the world.
- ◆ Improved sanitation and hygiene has decreased outbreaks of *relapsing fever*, transmitted by lice and fleas.
- ◆ The elimination of polio has been a goal since the 1988 Global Polio Eradication Initiative was developed by WHO (2006c). Achievement of this goal was earmarked for the year 2000, and it was looking like it might happen (WHO). As of 2003, only six of the original 125 countries were still experiencing polio—Nigeria, India, Pakistan, Niger, Afghanistan, and Egypt. By the end of 2003, India reported a reduction in cases from previous years to 225 cases—an all-time low. Unfortunately, in August of 2003, several northern states in Nigeria suspended their vaccination campaign, citing issues with what they believed to be problems with the vaccine. Because of this deferment of vaccinations, another outbreak occurred, which led to the disease being imported to once polio-free regions of Africa. Through the efforts and diplomacy of WHO, trust was regained, leading to a swift resurrection of the vaccination campaign (WHO, 2006c).
- ◆ The global threat of *plague* has declined in the last 40 years, largely as a result of the use of antibiotics and insecticides (Heymann, 2004).
- ◆ *Leprosy* (Hansen disease), once a major communicable disease, is almost eliminated. In 1966, there were 10.5 million reported cases worldwide. As of 2002, only 620,000 cases were diagnosed worldwide. The WHO will no longer consider leprosy a public health problem when fewer than one case per 10,000 population occurs—a goal that has been achieved in 110 of 122 endemic countries (Heymann, 2004).

Some major communicable diseases and areas of concern remain, including the following:

- ◆ *Malaria* remains a major threat, even though the mortality rate has improved in the last 25 years. In 1954, there were 2.5 million deaths annually and 250 million cases of malaria worldwide; in 2002, there were an estimated 1 million deaths and 300 to 500 million cases yearly (WHO, 2006d). Tropical Africa has 90% of the cases, and malaria is endemic in 92 countries (Heymann, 2004).
- ◆ *Cholera* was mainly confined to Asia in the early 20th century, but has been spread worldwide by

**CONFIDENTIAL MORBIDITY REPORT**

NOTE: For STD, Hepatitis, or TB, complete appropriate section below. Special reporting requirements and reportable diseases on back.

**DISEASE BEING REPORTED:** \_\_\_\_\_

REMARKS \_\_\_\_\_

FIGURE 8.1 Confidential Morbidity Report.

global travel in the second half of the century. In countries where communities lack sanitary drinking water and sewage disposal, as well as safe food-handling practices, the rates can be very high. This disease can be lethal to the very young, elderly, and those with compromised health, as dehydration from the loss of fluids from diarrhea and vomiting can occur rapidly. Vaccine development, improved sanitation, and education regarding food handling are ongoing strategies being utilized in the cholera-endemic regions of the world (WHO, 2006a).

- ◆ *Tuberculosis* has made a powerful resurgence in the last three decades as many countries let their control programs become complacent. In 1993, WHO declared TB a global emergency. One-third of the incidence of TB in the last 5 years can be attributed to human immunodeficiency virus (HIV) infection. Drug-resistant strains of the TB bacillus have infected up to 50 million people worldwide. Each year, 8 million people develop TB, and 1.8 million die of the disease. The highest incidence rates are found in Africa and Southeast Asia (Borgdorff, Floyd, & Broekmans, 2002; CDC, 2006o).
- ◆ *Yellow fever* is endemic in tropical regions of South American and Africa. Integration of yellow fever vaccination into the regular childhood immunization schedule and mosquito abatement efforts are key to decreasing this disease (Heymann, 2004).

Global successes and failures in the control of communicable diseases are affected by many factors. First, the geopolitical nature of an area influences who can respond when a communicable disease occurs in a country. Second, the natural and manmade resources of an area influence the health status of the population before a disease strikes, contributing to both disease resistance and the ability to survive once a communicable disease is contracted. This is one reason that poorer nations have higher incidences and greater numbers of deaths from communicable diseases. Finally, weather and climate factors can influence health and illness. For example, both droughts and floods can lead to crop failure and subsequent famine, which directly affect an individual's ability to fight disease or recover (Weatherall et al., 2005).

## National Trends

At the national level, for several decades in the late 20th century, medical research and funding focused on major chronic diseases such as arteriosclerosis and cancer. During those years, it seemed that the war against communicable disease was being won, and the nation became complacent about communicable diseases (CDC, 1999a).

## New, Emerging, and Reemerging Diseases

In the early 1980s, HIV/AIDS had emerged as a new and devastating disease. But because of the political atmosphere of the time, valuable time was lost in recognizing the potentially deleterious effects that this disease would cost in human suffering and lives lost. Not only was this new

epidemic ignored, but at the same time, it was also discovered that many children were not being immunized against communicable diseases—U.S. rates were as high as those in poorer nations. Tuberculosis was also coming back with a vengeance, and in many cases was resistant to the recognized treatment (Fauci, 2005).

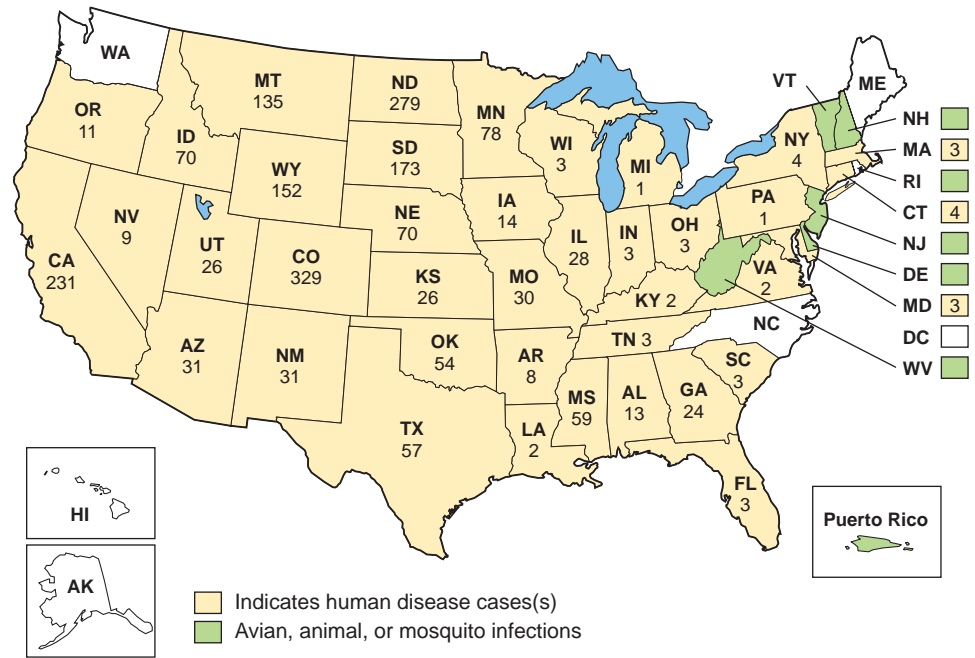

Clearly, communicable diseases will always present challenges to health care. Pathogens that are considered to be under control because they respond well to current treatment can mutate and produce new, virulent, and resistant strains. Diseases that have been almost eliminated can emerge again if public health efforts slacken; and diseases that are eradicated in the United States can revisit this country on any one of the international flights arriving each day at our airports. As a result, present concerns focus on three types of communicable disease: new diseases, emerging diseases, and reemerging diseases (Fauci, 2005).

Some communicable diseases have been affecting us for centuries or millennia, but a major new disease, HIV/AIDS, which is discussed in this chapter and in more detail in Chapter 26, was first recognized only in 1981. Legionnaires' disease, which was first detected in Philadelphia in 1976, occurred sporadically in other countries since then. In 1999, West Nile virus was first diagnosed in the United States in New York City. In subsequent years, surveillance programs were developed to track West Nile virus activity as it crossed the country. In 2005, as more cases were confirmed, West Nile virus disease in humans became a reportable disease (CDC, 2006g). In 2006, West Nile virus activity reflected mild to severe symptoms in 4,052 human cases and resulted in 146 deaths nationally. These diseases are disturbing reminders that new threats to public health are always on the horizon (see Fig. 8.2).

*Emerging diseases* are diseases rarely or never before seen in the United States. These diseases may also be new to public health officials in other countries. Emerging diseases occurring in the United States include Hantavirus, seen in the southwestern region in 1993; and typhoid, seen in a native Nigerian in New York City in 1994. Typically, diseases that are uncommon in the United States, such as malaria, plague, Lassa fever, cholera, and yellow fever, accompany people as they travel from one country to another on airlines and cruise ships. Sudden acute respiratory syndrome (SARS) emerged in 2003, causing a worldwide panic and a crisis for health care systems. Global travel patterns enabled this infectious agent to spread quickly to other countries from its epicenter in China (Murphy, 2006). Dr. Mohammad Akhter, while serving as executive director of the American Public Health Association, said "the [CDC] is just like the Justice Department before 9/11. It only comes in to investigate once a crime has been committed" (Mullins, 2002).

*Reemerging diseases* are those communicable diseases that have been endemic in some parts of the world, but are now endemic in more countries and are increasing to epidemic proportions in others. Often, the resurgence is caused by the emergence of new, drug-resistant strains of a familiar organism, such as the MDR TB bacillus. *Staphylococcus aureus* infections now are characterized by some strains so powerful that they no longer respond to vancomycin. Fortunately, the infection still responds to two new antibiotics, but those could also lose effectiveness. This is a watershed

**FIGURE 8.2** 2007 West Nile Virus activity in the United States (reported to the CDC as of September 18, 2007).

Map shows the distribution of avian, animal, or mosquito infection occurring during 2007 with number of human cases if any, by state. If West Nile virus infection is reported to CDC from any area of a state, that entire state is shaded.

moment in the fight to stay ahead of communicable diseases. In addition to *S. aureus* and the TB bacillus, the list of antimicrobial-resistant organisms includes strains of *Haemophilus influenzae*, *Neisseria gonorrhoeae*, *Bordetella pertussis*, and *Streptococcus pneumoniae*. Tuberculosis is currently the communicable disease that affects the greatest number of people in the United States in regard to strains of drug-resistant microbes.

### Healthy People: The Prevention Agenda for the Nation

The *Healthy People 2010* document (U.S. Department of Health and Human Services [USDHHS], 2000) groups the nation's health objectives somewhat differently from its predecessor, *Healthy People 2000* (USDHHS, 1991). Nevertheless, many objectives still focus on infectious diseases and immunizations, aiming to decrease morbidity and mortality from infectious diseases and to increase the number of immunized children and adults. In addition, the document attempts to guide the nation toward health with goals and objectives that include new focus areas such as arthritis, osteoporosis, chronic back conditions, chronic kidney diseases, respiratory diseases, vision and hearing, medical product safety, health communication, and public health infrastructure.

*Healthy People 2010* objectives were formulated with input from more than 350 national and 250 state public health, medical, and environmental agencies, in addition to lay advisors from around the country. These collaborators began to meet in 1996 to design the structure and content of the document. During its development, the Office of Disease Prevention and Health Promotion accepted electronic comments at

its website and in writing, making this truly a document of the people. With so many people involved, achievement of the document's goals is much more likely.

### Modes of Transmission

As discussed in Chapter 7, the reservoir of infection can be a person, animal, insect, or inanimate material in which the infectious agent lives and multiplies and which serves as a source of infection to others. Transmission of a communicable disease can occur by direct, indirect, airborne, or vector methods.

#### Direct Transmission

**Direct transmission** occurs by immediate transfer of infectious agents from a reservoir to a new susceptible host. It requires direct contact with the source, through touching, biting, kissing, or sexual intercourse—that is, contact with oral secretions, blood, or other potentially infectious fluid, such as the drainage from a skin lesion. Coughing or sneezing secretions into the face of a susceptible individual can directly transmit respiratory infections, such as measles or pertussis. Close proximity is required—about 3 feet—to transmit an organism from one person to another (National Institutes of Health [NIH], 2006).

#### Indirect Transmission

**Indirect transmission** occurs when the infectious agent is transported within contaminated inanimate materials such as air, water, or food. It is also commonly referred to as *vehicle-borne transmission*. Chapter 9 describes both the government's

role and the nurse's role in helping to prevent food and water contamination by infectious agents (NIH, 2006).

### Food- and Water-related Illness

Reportable food- or water-related illness can include infections from bacterial agents such as *Salmonella*, *Shigella*, *E. coli* 0157, and *Campylobacter*; the protozoan agent *Giardia*; and the viral agent hepatitis A. The contamination can occur at the source (e.g., contamination by animal into the food or water chain) or through unsanitary food handling practices, which are referred to as the *fecal–oral route*. Ingestion of the pathogenic organism sets in motion the events of a food- or water-related illness (CDC, 2005d).

Most commonly, exposure to infectious food or water results in symptoms related to gastrointestinal function, including diarrhea, nausea, vomiting, stomach cramps, and bloating. Fever accompanies these infections as well. Onset of symptoms may occur within a few hours after exposure or not until days or even weeks later, depending on the organism. This time interval between exposure and onset of symptoms is called the **incubation period**.

Bacterial contamination of food resulting in human illness occurs as a result of either infection or intoxication. Infection occurs through ingestion of food contaminated with adequate doses of *Salmonella*, *Shigella*, *E. coli*, or other pathogens. The cycle begins when the infectious agent multiplies and grows in the food medium. The agent subsequently invades the host after ingestion of the food. Infection then occurs—which is the entry and development or multiplication of an infectious agent in the body. Infection is usually accompanied by an immune response, such as the production of antibodies with or without clinical manifestation. The infectious organism produces illness by direct irritation of the normal gastrointestinal mucosa. By contrast, intoxication is caused by the production of toxins as a by-product of the normal bacterial life cycle. This commonly occurs when cooked food is left standing at room temperature. It is ingestion of the toxin, rather than the microbe itself, that produces the illness (CDC, 2005d).

The distinction between infection and intoxication is relevant for a number of reasons. Toxins may be difficult to isolate and identify, particularly in the absence of the bacteria; some suspected food-borne illnesses go unidentified for this reason. Although the bacteria may be killed after heating of foodstuffs before consumption, some bacteria-produced toxins are stable at normal cooking temperatures, so that food cannot be rendered safe. Bacteria established in the human gastrointestinal system may require medical treatment to be eradicated. In contrast, individuals with food intoxication typically require essentially supportive care while in the process of ridding themselves of the toxin (CDC, 2005d).

The most important aspects of food- or water-related diseases for nurses in community health may be, first of all, recognizing that outbreaks of illness affecting large numbers of people continue to occur fairly regularly, despite well-recognized standards for decontamination of water supplies and safe commercial food preparation. Second, such outbreaks may not be detectable by local surveillance means because of individuals' mobility or the routine transportation of foods from one

#### DISPLAY 8.1

### CORRECT METHODS FOR PRESERVING THE SAFETY AND CLEANLINESS OF FOOD

#### Before handling food:

- Wash hands and all food preparation surfaces and utensils thoroughly with soap and water.

#### When preparing food:

- Wash foods that are to be eaten raw and uncooked thoroughly in clean water. This includes foods that are to be peeled that grow on the ground or come in contact with soil.
- Cook all meat products thoroughly.
- Do not allow cooked meats to come in contact with dishes, utensils, or containers used when the foods were raw and uncooked.

#### When storing leftover foods:

- Cool cooked foods quickly; store under refrigeration in clean, covered containers.

#### When reheating leftover foods:

- Heat foods thoroughly. Bacteria contaminating food grow and multiply in a temperature range between 39°F and 140°F.

state to the other (CDC, 2005d). For example, an outbreak of *E. coli* 0157 was associated with spinach grown in one state and sold nationally. This illness outbreak was detected through identification in multiple state laboratories and compared through sentinel disease detection centers. It was then traced back to the source—through local investigations of ill persons (CDC, 2006i). Third, such outbreaks can serve to remind all community health practitioners of the continuing need to teach and observe the most basic methods for preventing food and water contamination. Display 8.1 summarizes correct methods for maintaining the safety and cleanliness of food.

### Vector Transmission

When transmission occurs through a **vector** (a nonhuman carrier such as an animal or insect), it is known as vector-borne transmission. Common vectors include bats, fleas, lice, mosquitoes, raccoons, rats, skunks, squirrels, and ticks. During vector-borne transmission, the infectious agent may be transported mechanically without multiplication or change, or the infectious agent may develop biologically before passage to a susceptible host.

Diseases transmitted through vectors prove challenging in communicable disease control, because individuals who become infected typically have no direct personal contact with other infected persons. Rather, isolated cases occur within areas inhabited by the vector. Nevertheless, vector-borne diseases have significantly affected human history. Louse-borne typhus and flea-borne plague together were responsible for a majority of the devastating epidemics that occurred over the last 600 years. Currently, mosquito-borne malaria and snail-borne schistosomiasis cause major human suffering for hundreds of millions of people in tropical settings every year (Heymann, 2004).

Control strategies directed toward vector-borne diseases typically involve community education and environmental measures to hinder the vector from reaching the host (see Chapter 9). Control strategies may include:

- ◆ Minimizing the population of insect vectors (e.g., by spraying insecticides to kill mosquitoes)
- ◆ Educating the public to the natural habitat of the vector to reduce the population density
- ◆ Exterminating rodents that carry diseases, such as rats
- ◆ Using barriers between the susceptible human and the vector, such as mosquito nets or screened windows to control malaria or protective clothing and sprays against tick-borne diseases
- ◆ Educating the public about preventive and protective measures, including actions to take when attacked by the vector to prevent disease from developing

In the United States, vector-borne illnesses have received renewed attention with accumulating information about Lyme disease, caused by a bacterium *Borrelia burgdorferi* that is transmitted to humans by a tick vector. Lyme disease results in symptoms of varying severity, including rash, joint pain, progressive weakness, vision changes, and other neuromuscular dysfunction. Other vector-borne diseases receiving attention in the 1990s included tick-borne fevers (e.g., Rocky Mountain spotted fever and relapsing fever) and rabies, whose vector usually is an infected domestic animal, bat, skunk, or raccoon. As mentioned earlier, West Nile virus was first seen in the United States in 1999. Occasionally, imported vector-borne tropical diseases, including malaria and dengue fever, are reported (Heymann, 2004).

### Airborne Transmission

Airborne transmission occurs through droplet nuclei—the small residues that result from evaporation of fluid from droplets emitted by an infected host. Sneezing and coughing are common examples of airborne transmission. They may also be created purposely by atomizing devices or accidentally in microbiology laboratories. Because of their small size and weight, they can remain suspended in the air for long periods before they are inhaled into the respiratory system of a host. Airborne transmission can also occur in dust. Small particles of dust from soil containing fungus spores may cling to clothing, bedding, or floors. Alternatively, the spores may become separated from dry soil by the wind and then be inhaled by the host (CDC, 2006b).

## PRIMARY PREVENTION

In the context of communicable disease control, two approaches are useful in achieving primary prevention: Education using mass media, and targeting health messages to aggregates and immunization.

### Education

Health education in primary prevention is directed both at helping at-risk individuals understand their risk status and at promoting behaviors that decrease exposure or susceptibility.

Chapter 11 deals more extensively with the concepts of learning theory and the variety of health education approaches and materials available to community health nurses today.

### Use of Mass Media for Health Education

All people need to be informed about the risks of communicable diseases. Often, use of health marketing techniques through mass media can be an effective way to reach the largest number of people (Rall & Meyer, 2006; Renaud et al., 2006). Additionally, many target groups, such as low-income and racially and ethnically diverse communities at high risk for communicable diseases, are very hard to reach one-on-one. Media can be an effective method to reach them. To disseminate public health information to large numbers of people, mass media plays four major roles:

1. *Use the media as a primary change agent:* Community education programs can successfully increase knowledge about communicable diseases and preventive measures.
2. *Use the media as a complement to other disease prevention efforts:* The media can effectively model preventive behaviors, such as condom use and drug abstinence.
3. *Use the media as a promoter of communicable disease control programs:* The media can help to increase participation of community members in primary prevention services.
4. *Use the media to promote disease prevention messages:* The media can contribute to the creation of a social environment that promotes health (e.g., increasing acceptance of regular condom use in the prevention of sexually transmitted diseases [STDs]).

The body of literature on mass communication for promoting health and preventing disease through the voluntary adoption of healthy behaviors is growing rapidly (Rall & Meyer, 2006; Renaud et al., 2006). Television, as a significant medium, reaches into most American homes, and public health campaigns are creatively designed to reach the target audiences.

The urgency to combat AIDS, as well as other life-threatening diseases, provides a strong rationale and impetus for developing effective disease prevention and control messages for dissemination through the media.

Messages need to be tailored to the specific characteristics of target audiences and the media channels to which the audiences are exposed. Disadvantaged or stigmatized groups, such as the poor, ethnic minorities, gay men, injection drug users, and prostitutes, are more vulnerable to infectious diseases and need mass media messages targeted to them. Those people who watch more television and listen to more radio respond to health promotion messages received through these media more often than groups who do not (CDC, 2006f).

Behavioral change is essential to control the spread of communicable diseases, and that change depends on successful communication between community health providers and target audiences, using the most appropriate media possible. Participation in media and education efforts depends on the awareness of target groups (e.g., injection drug users) about available programs and how to access them. Carefully and thoughtfully designed disease prevention messages

disseminated through the media are a reliable and effective way of reaching hard-to-reach populations.

### Targeting Meaningful Health Messages to Aggregates

To effectively deliver a communicable disease prevention message, the message must reach the target (at-risk) population. This requires correct identification of the characteristics of the target audience in terms of educational level, salience of the issue, involvement of the target audience with the issue, and access of the target audience to the media channels used. Cultural issues affect people’s interpretation of messages and must be considered in the presentation of a disease-prevention message to ethnic and racial minority groups (Rall & Meyer, 2006; Renaud et al., 2006). Principles for adapting health messages to specific population subgroups include:

1. Develop educational materials from the community perspective, reflecting respect for community values and traditions, relevance to community needs and interests, and participation of the community in the preparation and use of the materials.
2. Ensure that materials are an integral part of a health education program, supported by other components of intervention—materials should not stand alone.
3. Materials must be related to the delivery of health services that are available, accessible, and acceptable to the target population.
4. All materials must be pretested and have demonstrated attractiveness, comprehension, acceptability, ownership, and persuasiveness.
5. Materials must be distributed with instructions for their use (i.e., how, when, and with whom they are to be used).

### Immunization

Control of acute communicable diseases through immunization has been a common practice since the 19th century in the United States. **Immunization** is the process of introducing some form of disease-causing organism into a person’s system to promote the development of antibodies that will resist that disease. In theory, this process makes the person immune to that particular infectious disease (i.e., able to resist a specific infectious disease-causing agent). That immunization requirements are acceptable in American society today is evidence that high levels of immunization in school children and aggressive enforcement of school immunization requirements, starting in the late 1970s, have not met widespread opposition. This continues to be true even during the last decade, when common immunizations have been changed and the number of immunizations has increased.

The schedule for administration of vaccines officially changes every January. In 2004, the CDC conducted the National Immunization Survey. Overall, 77.2% of children 18 to 35 months of age at the time of the survey had received all of the recommended immunizations (National Center for

Health Statistics, 2004). Adolescent vaccination, however, has lagged behind the rates achieved by younger children over the last decade. Barriers that must be overcome include lack of parental knowledge, inadequate access to medical care, and inadequate or no insurance coverage (National Foundation for Infectious Diseases, 2005). With adults, good progress has been made. Influenza vaccine coverage rates increased from 42% in 1991 to 65% in 2003, and pneumococcal vaccine coverage rates increased from 21% to 34% over the same period (CDC, 2005g).

The statutes that exist to ensure adequate immunization levels at the time of school entry place the school in the role of a controlling agency, whereas public health departments and private health care providers are authorized to administer the required vaccines (see Chapter 22). An emerging drawback of this mechanism is that many parents delay immunizations until the child’s fifth year (Scutchfield & Keck, 2003). Preschool-age children represent a major proportion of all cases of vaccine-preventable diseases and are the group at highest risk for infection. A national objective stated in *Healthy People 2000* (USDHHS, 1991) was for 90% of American children to be vaccinated by their second birthday with four doses of DTaP, three doses of polio, and one dose of the combined measles, mumps, and rubella vaccine. *Healthy People 2010* (USDHHS, 2000) reinforced this goal by including an objective for reducing or eliminating all indigenous cases of vaccine-preventable disease (Table 8.1).

Although childhood immunization rates historically have been lower in minority populations compared with the White population, rates for minority preschool children have been increasing at a more rapid pace, and the gap has significantly

**TABLE 8.1** *Healthy People 2010 Vaccine-preventable Disease Objectives*

Disease	2003	2010 Target
Congenital rubella syndrome	0	0

narrowed (CDC, 2005b; CDC, 2006h). The National Immunization Survey has documented substantial progress toward achieving 1996 Childhood Immunization Initiative coverage goals by racial and ethnic groups. However, efforts to increase vaccination coverage need to be intensified, particularly for children living in poverty (CDC, 2006h)

It is critical to discover the social and cultural characteristics affecting health status, attitudes about preventive measures, behaviors in seeking services, acceptability of interventions, and perceptions of health care providers that determine parental action in having a child immunized in a regular and timely fashion (see From the Case Files I, and Display 8.2). This is a unique area of health care delivery, one in which nurses must rely on parental initiative to obtain a form of care for the well child that may be perceived as

producing pain and temporary illness for no observable benefit (CDC, 2006h).

### Vaccine-preventable Diseases

Vaccine-preventable diseases (VPD), such as hepatitis B, *H. influenzae* type b, measles, polio, diphtheria, pertussis, and chickenpox, are diseases that can be prevented through immunization. Immunity may be either passive or active.

**Passive immunity** is short-term resistance to a specific disease-causing organism; it may be acquired naturally (as with newborns through maternal antibody transfer) or artificially through inoculation with pooled human antibody (e.g., immune globulin) that gives temporary protection. **Active immunity** is long-term (sometimes lifelong) resistance to a

## From the Case Files I

### Personal Belief Exemption and Immunization

A whooping cough outbreak occurred in a small rural county last year. Whooping cough or pertussis is a vaccine-preventable disease. It is highly contagious, and most devastating to the very young and very old. In this community, the population is not very ethnically diverse, but it is philosophically diverse. Many community members are against vaccinating their children. The outbreak of pertussis occurred in a small charter school, with the majority of the children unvaccinated for reasons of personal belief. Personal belief exemption is an option for a family. Unfortunately, with a large unvaccinated population, as in this school, the spark of a contagious, vaccine-preventable infection can spread rapidly. This is what happened at this school, with 22 cases among children and family members. The school had to be closed a week early for winter break to help halt the spread. Three waves of illness occurred in this school from November to April.

One might think that the entire problem lies with the group of individuals who will not vaccinate their children, but this is not what was discovered upon investigation. The issue of personal belief exemption was discussed among public health nurses and school nurses in this community. We discussed the issue with parents and teachers at the charter school. The two highlights from our discussions were that parents either signed the exemption out of true conviction or out of frustration that the school was hounding them to get their child vaccinated. For whatever reason, some parents just cannot seem to make the time to get the necessary immunizations completed. These parents tend to be the high-risk families who keep a school nurse busy. It was discovered that in some of the schools with high-risk families, the personal belief exemption was signed in order to not be pestered any longer.

So, which group do you extend your efforts to as a public health nurse? The answer is both. The parents who will not vaccinate their children will not be convinced otherwise. Parents who chose the easy way out may need more assistance. Here was the solution that the county's immunization coordinator came up with. Utilizing the community's immunization coalition and the school nurses, it was determined that the school secretaries needed an inservice on how to properly offer the exemption to a family and what information parents would need to make an informed decision before signing the exemption.

The immunization coordinator developed an education tool that explained the parent responsibility to the community at large if their child were to become ill with a vaccine-preventable illness. The document covered points, such as the family having a medical plan with their physician, learning how to care for and isolate the child, working with a public health nurse, and so on (see Display 8.2). The school secretaries were asked to give this document to parents who were interested in exempting, along with community resource information as to where to send families who may not have access to affordable immunizations.

The parents at the charter school were very accepting of the information on what to do for an ill child, and the school secretaries expressed relief regarding dealing with parents who may want to exempt out for convenience rather than conviction. In time, we should be able to see if this approach has improved vaccination rates in the community.

## DISPLAY 8.2

## WHAT PARENTS SHOULD KNOW WHEN SIGNING A PERSONAL BELIEFS AFFIDAVIT EXEMPTION OF IMMUNIZATION

1. Measles, mumps, rubella, chicken pox, pertussis, diphtheria, polio, Haemophilus influenza type b, hepatitis A, and hepatitis B are infectious to others and are avoidable through immunization.
2. Please educate yourself to the symptoms and possible complications that can arise from a vaccine-preventable disease. Information for parents about these diseases may be found at the National Immunization Program site <http://www.cdc.gov/nip/> or by calling the Nevada County Public Health Department (530) 265-1450.
3. These diseases have many symptoms that require close monitoring and care so that complications are minimized. It is essential to have a plan of care, coordinated with your health care provider, to act upon the mildest to most severe symptoms of the disease.
4. The school or school nurse is responsible for maintaining a list of the school children who have parent-signed exemption to immunization for medical, religious, or personal belief. This list allows the school nurse to quickly identify any child who is at risk of exposure to a vaccine-preventable disease.
5. An unimmunized child will be excluded from school by the County Health Officer when a vaccine-preventable disease is identified in the school. The ill child will also be excluded from school.
6. When a child is excluded from school, it is the responsibility of the parent or guardian to keep the child isolated\* from the public at large to prevent spread of infection to the community.
7. Vaccine-preventable diseases are considered **reportable communicable diseases** under the Health and Safety Codes of California. If your child contracts one of these diseases, a Public Health Nurse will contact you. Be prepared to provide information about the illness to the investigator. **This information is confidential.**
8. The parent or guardian is also at risk of contracting any of these diseases when exposed to an ill child. If unimmunized, the parent or guardian may also be considered exposed and incubating the disease, since this may continue the cycle of infection to others. This in turn requires that the parent or guardian remain in isolation from the community through the incubation period.
9. The child who is exposed to the disease may be offered preventive medication or immunization to prevent the disease from occurring—either may keep the child from being excluded from school.

Date

\*The isolation time frame is determined by the county health officer. Isolation means that the exposed or ill child cannot leave home except for medical care. **No social gatherings!**

specific disease-causing organism; it also can be acquired naturally or artificially. Naturally acquired active immunity occurs when a person contracts a disease and develops long-lasting antibodies that provide immunity against future exposure. Artificially acquired active immunity occurs through inoculation with a vaccine, such as the diphtheria, pertussis, tetanus vaccination series given to children. A **vaccine** is a preparation made from a live organism or an inactivated form of the organism. Live attenuated vaccines are made from weakened wild virus organisms that are used to create an immune response in the recipient. It only takes a small amount to initiate an immune response, and the organisms must replicate to be effective. Inactivated vaccines are made from a viral organism that has been inactivated by heat or chemicals. These vaccines cannot replicate in the recipient (CDC, 2007a).

Because of the success of immunization strategies, few practicing nurses in the United States today have treated clients with tetanus or diphtheria, or even measles (although some have cared for clients with residual polio disabilities). However, VPDs still exist in force in the developing world, and outbreaks occur in the United States in groups of non-immunized or susceptible populations. For example, certain people are medically exempt from immunization, and others decline immunization for religious or personal reasons. Even with global and national efforts at reducing and eliminating VPDs, some national goals have not been met. In fact, statistics for some diseases have gotten worse. Rates of

immunization coverage have declined in some areas, with subsequent increases in VPDs (e.g., pertussis). Pertussis has become endemic, with frequent outbreaks (Broder et al., 2006).

### Schedule of Recommended Immunizations

A schedule for the administration of childhood vaccinations, based on recommendations by the Advisory Committee on Immunization Practices (ACIP), the American Academy of Pediatrics (AAP), the American Academy of Family Physicians (AAFP), and the CDC, is published annually (Table 8.2). The CDC also provides “catch-up” schedules for children not receiving their first immunizations at birth, according to the standard schedule. Current recommendations call for a child to receive 10 different vaccines or toxoids (many in combination form and all requiring more than one dose) in six or seven visits to a health care provider between birth and school entry, with boosters in the preteen to early teen years (CDC, 2007b).

Factors influencing the recommended age at which vaccines are administered include the age-specific risks of the disease, the age-specific risks of complications, the ability of persons of a given age to produce an adequate and lasting immune response, and the potential for interference with the immune response acquired from passively transferred maternal antibodies. In general, vaccines are recommended for the youngest age group at risk whose members are known to develop an acceptable antibody response to vaccination (CDC, 2007a).

Range of recommended ages

Catch-up immunization

Certain high-risk groups

This schedule indicates the recommended ages for routine administration of currently licensed childhood vaccines, as of December 1, 2006, for children aged 0–6 years. Additional information is available at <http://www.cdc.gov/nip/recs/child-schedule.htm>. Any dose not administered at the recommended age should be administered at any subsequent visit, when indicated and feasible. Additional vaccines may be licensed and recommended during the year. Licensed combination vaccines may be used whenever any components of the combination are indicated and

other components of the vaccine are not contraindicated and if approved by the Food and Drug Administration for that dose of the series. Providers should consult the respective Advisory Committee on Immunization Practices statement for detailed recommendations. Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS). Guidance on how to obtain and complete a VAERS form is available at <http://www.vaers.hhs.gov> or by telephone, 800-822-7967.

1. Hepatitis B vaccine (HepB). (Minimum age: birth)

At birth:

- Administer monovalent HepB to all newborns before hospital discharge.
- If mother is hepatitis surface antigen (HBsAg)-positive, administer HepB and 0.5 mL of hepatitis B immune globulin (HBIG) within 12 hours of birth.
- If mother's HBsAg status is unknown, administer HepB within 12 hours of birth. Determine the HBsAg status as soon as possible and if HBsAg-positive, administer HBIG (no later than age 1 week).
- If mother is HBsAg-negative, the birth dose can only be delayed with physician's order and mother's negative HBsAg laboratory report documented in the infant's medical record.

After the birth dose:

- The HepB series should be completed with either monovalent HepB or a combination vaccine containing HepB. The second dose should be administered at age 1–2 months. The final dose should be administered at age ≥24 weeks. Infants born to HBsAg-positive mothers should be tested for HBsAg and antibody to HBsAg after completion of ≥3 doses of a licensed HepB series, at age 9–18 months (generally at the next well-child visit).

4-month dose:

- It is permissible to administer 4 doses of HepB when combination vaccines are administered after the birth dose. If monovalent HepB is used for doses after the birth dose, a dose at age 4 months is not needed.

2. Rotavirus vaccine (Rota). (Minimum age: 6 weeks)

- Administer the first dose at age 6–12 weeks. Do not start the series later than age 12 weeks.
- Administer the final dose in the series by age 32 weeks. Do not administer a dose later than age 32 weeks.
- Data on safety and efficacy outside of these age ranges are insufficient.

3. Diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP). (Minimum age: 6 weeks)

- The fourth dose of DTaP may be administered as early as age 12 months, provided 6 months have elapsed since the third dose.
- Administer the final dose in the series at age 4–6 years.

4. Haemophilus influenzae type b conjugate vaccine (Hib). (Minimum age: 6 weeks)

- If PRP-OMP (PedvaxHIB® or ComVax® [Merck]) is administered at ages 2 and 4 months, a dose at age 6 months is not required.
- TriHibit® (DTaP/Hib) combination products should not be used for primary immunization but can be used as boosters following any Hib vaccine in children aged ≥12 months.

5. Pneumococcal vaccine. (Minimum age: 6 weeks for pneumococcal conjugate vaccine [PCV]; 2 years for pneumococcal polysaccharide vaccine [PPV])

- Administer PCV at ages 24–59 months in certain high-risk groups. Administer PPV to children aged ≥2 years in certain high-risk groups. See *MMWR* 2000;49(No. RR-9):1–35.

6. Influenza vaccine. (Minimum age: 6 months for trivalent inactivated influenza vaccine [TIV]; 5 years for live, attenuated influenza vaccine [LAIV])

- All children aged 6–59 months and close contacts of all children aged 0–59 months are recommended to receive influenza vaccine.
- Influenza vaccine is recommended annually for children aged ≥59 months with certain risk factors, health-care workers, and other persons (including household members) in close contact with persons in groups at high risk. See *MMWR* 2006;55(No. RR-10):1–41.
- For healthy persons aged 5–49 years, LAIV may be used as an alternative to TIV.
- Children receiving TIV should receive 0.25 mL if aged 6–35 months or 0.5 mL if aged ≥3 years.
- Children aged <9 years who are receiving influenza vaccine for the first time should receive 2 doses (separated by ≥4 weeks for TIV and ≥6 weeks for LAIV).

7. Measles, mumps, and rubella vaccine (MMR). (Minimum age: 12 months)

- Administer the second dose of MMR at age 4–6 years. MMR may be administered before age 4–6 years, provided ≥4 weeks have elapsed since the first dose and both doses are administered at age ≥12 months.

8. Varicella vaccine. (Minimum age: 12 months)

- Administer the second dose of varicella vaccine at age 4–6 years. Varicella vaccine may be administered before age 4–6 years, provided that ≥3 months have elapsed since the first dose and both doses are administered at age ≥12 months. If second dose was administered ≥28 days following the first dose, the second dose does not need to be repeated.

9. Hepatitis A vaccine (HepA). (Minimum age: 12 months)

- HepA is recommended for all children aged 1 year (i.e., aged 12–23 months). The 2 doses in the series should be administered at least 6 months apart.
- Children not fully vaccinated by age 2 years can be vaccinated at subsequent visits.
- HepA is recommended for certain other groups of children, including in areas where vaccination programs target older children. See *MMWR* 2006;55(No. RR-7):1–23.

10. Meningococcal polysaccharide vaccine (MPSV4). (Minimum age: 2 years)

- Administer MPSV4 to children aged 2–10 years with terminal complement deficiencies or anatomic or functional asplenia and certain other high-risk groups. See *MMWR* 2005;54(No. RR-7):1–21.

The Recommended Immunization Schedules for Persons Aged 0–18 Years are approved by the Advisory Committee on Immunization Practices (<http://www.cdc.gov/nip/acip>), the American Academy of Pediatrics (<http://www.aap.org>), and the American Academy of Family Physicians (<http://www.aafp.org>).

Recommendations for vaccine administration may be revised in light of specific circumstances. For example, it is now recommended that infants receive hepatitis B vaccine at birth, whether or not their mothers have a positive or negative response to the hepatitis B surface antigen. This approach will catch any infants born to mothers who lack prenatal testing, or who may live in households with individuals with unknown hepatitis B status (CDC, 2005a). Rotavirus—a diarrheal illness of infants—can safely be prevented by the use of a new vaccine RotaTaq, approved in February 2006 (CDC, 2007a). It has been reintroduced into the childhood immunization schedule recommendations.

### **Assessing Immunization Status of the Community**

Determining the immunization status of children in a community can be a time-consuming but worthwhile task. Community health nurses may consider assessing groups of children with some common characteristics, such as children served by the Women, Infants, and Children program (WIC), those served by private medical providers, or those attending public schools in various neighborhoods. Because all children attending school in the United States must show proof of immunization upon school entry, review of immunization records at school can provide a means of retrospectively determining the proportion of these children whose immunizations were up to date at age 3 months or at age 2 years. It is strongly recommended that retrospective school vaccination record surveys be done as a means of estimating current levels of immunization status and monitoring trends over time. If no unusual immunization events occur in the intervening period, this retrospective record review gives a reasonable estimate of current immunization status of those age groups in the community. In addition, such a record review targeting children who were not up-to-date on their immunizations before school entry helps identify younger siblings who may also not be up-to-date (American Academy of Pediatrics [AAP], 2003).

With increasing numbers of children entering day care services in the preschool years, more states now require immunizations for preschool children, often including immunization against influenza, which is not presently required for older age groups. Preschool or day care center operators now obtain information about immunization status of this younger cohort, a group that previously often escaped surveillance and immunization initiatives (AAP, 2003).

Of interest to community health nurses, the ACIP and CDC in 2006 expanded the group of children eligible for influenza vaccine coverage under the Vaccines for Children (VFC) program. The resolution extends VFC coverage for influenza vaccine to all VFC-eligible children aged 6 to 59 months, as well as VFC-eligible children aged 2 to 18 years who are household contacts of children younger than 2 years of age. This resolution became effective in June 2006, so that flu vaccine could be administered during the 2006–2007 influenza vaccination season and subsequent seasons. These changes were expanded because of the increased risk for influenza-related hospitalizations among those younger than 59 months of age (CDC, 2006k).

Other community settings in which community health nurses may identify underimmunized children include homeless shelters and other public service settings or agencies

used by families and children, including local religious centers. A family with one underimmunized child may have underimmunized children of other ages, as well as any number of other unmet preventive health care needs that the community health nurse can help address (AAP, 2003).

### **Herd Immunity**

**Herd immunity** is central to understanding immunization as a means of protecting community health. As described in Chapter 7, herd immunity is the immunity level present in a particular population of people (Heymann, 2004). If few immune persons exist within a community, herd immunity is low, and the spread of disease is more likely. Vaccination of more individuals in the community, so that a high proportion has acquired resistance to the infectious agent, contributes to higher herd immunity. High herd immunity reduces the probability that the few unimmunized persons will come in contact with one another, making spread of the disease less likely. Outbreaks may occur if the immunization rate falls to less than 85% (Scutchfield & Keck, 2003) or if nonimmunized susceptible persons are grouped together rather than dispersed throughout the immunized community (see Evidence-Based Practice).

### **Barriers to Immunization Coverage**

Improving immunization coverage requires examination of the reasons why children are not immunized. Many barriers exist. They include religious, financial, social, and cultural factors, as well as philosophical objections and provider limitations that form barriers to adequate immunization coverage.

#### **Religious Barriers**

The right to religious freedom gives some groups of individuals in the United States the constitutional right to exemption from immunization if they object to vaccination on religious grounds. Children from these families are identified at school entry. Such exemptions must be specifically enacted by law and, although it is not necessary to belong to a specific denomination, courts have required those seeking exemption to demonstrate that such belief against immunization is sincere and that no clear danger exists from the particular disease. Problems arise when members of exempted groups are found together in school or community settings, raising the risk of disease spread because of a lower herd immunity (Heymann, 2004).

#### **Financial Barriers**

Until recently, finances may have been a significant factor for immunization delays in families with limited incomes. Such families may have had more immediate priorities than vaccinations for an otherwise well child. In the late 1990s, two major initiatives significantly improved the financing of childhood immunizations. The VFC program and the Child Health Insurance Program (CHIP) cover children on Medicaid, uninsured children, and American Indian and Alaska Native children (USDHHS, 2006). In addition, underinsured children who receive immunizations at federally qualified health centers and rural health clinics are covered. These initiatives should eliminate low income as a barrier.

## EVIDENCE-BASED PRACTICE

### “Cocooning” to Protect Unvaccinated Infants

Over the past several years, a method known as *cocooning* has gained increased attention as a means to prevent communicable diseases, such as influenza and pertussis, in unvaccinated and incompletely vaccinated individuals. Children who are at high risk for infection, but not old enough to receive the current influenza vaccine, would be one of the target groups for this approach. Theoretically, by having all close family contacts immunized, the belief is that the risk of infection can be greatly reduced. This concept has been promoted in a variety of venues, including the Centers for Disease Control and Prevention (CDC) (2006) and the U.S. Food and Drug Administration (2006). Using the concept of herd immunity, this approach seems to hold great promise. The Cocooning Project at Renouin Regional Medical Center was the first in the nation to launch this innovative program in 2006 (CDC, 2006). The program provides immunizations for pertussis and influenza to all family contacts of babies born at the medical center.

The actual effectiveness of this program, however, has yet to be demonstrated. A literature search on this topic yielded only one discussion article regarding this type of intervention, and it cast some doubt on whether it can be an effective approach. De Serres and Duval (2005) note that less than half of the pertussis deaths in the United States had a traceable source of infection within their household contacts; meaning that other sources of infection are problematic. The 2006 proceedings of the Advisory Committee on Immunization Practices (CDC, 2006, p. 44) also noted that solid evidence has not yet been produced. Although the approach may have merit, the evidence is not yet apparent. In planning for an immunization program such as this, the public health nurse must approach this situation with cau-

tion. A number of questions must be addressed in considering whether cocooning is a viable option in a community: (a) Does this approach actually reduce infections in the target population and where is the evidence? (b) What is the risk to the household members being vaccinated? (c) What is the cost of this program? and (d) Are there unintended consequences from this approach, such as delayed immunizations in the target population?

Innovations are an important source of improved health-promoting practices and should not be discouraged, but as always, solid research evidence is vital. With limited health care dollars, efforts must target the most cost effective and proven methods possible. Only time and research will show whether cocooning can be an effective tool in the public health arsenal.

### Social Barriers

Educational levels, transportation problems, as well as access to and overcrowding of facilities pose further barriers to adequate immunization coverage. The formidable quantities of paperwork involved in obtaining the informed consent of parents may be intellectually intimidating as well as time-consuming. Working parents may find it difficult, if not impossible, to reach an immunization clinic with their child during working hours. Requirements for appointments (instead of walk-in clinics) or for a physical examination before vaccination may present additional deterrents. Pockets of need continue to exist in areas of every major city where substantial numbers of underimmunized children live. These areas are of great concern because, particularly in large urban areas with traditionally underserved populations, a great potential exists for disease outbreaks (USDHHS, 2000).

### Cultural Barriers

Meeting the immunization needs of minority groups may involve cultural barriers related to differing concepts of

health care and preventive measures among cultures. Language barriers may lead parents to feel confused, overwhelmed, and unable to access services. Depending on how long a family has resided in the United States and their level of active sponsorship, parents may not be familiar with expectations of the health care system in regard to their actions on behalf of the well child (Kennedy, Brown, & Gust, 2005).

### Philosophical Objections

Many affluent, well-educated, caring parents have philosophical objections to immunization. They fear harm to their children, as has periodically been reported in the media. Parents may object to one or more of the vaccines, or prefer to delay or separate the vaccines; this puts the child “behind” on immunizations, according to the AAP schedule. Community health nurses should be aware that caring parents are talking about these issues, reading about them, and trying to make informed decisions about them (Kennedy et al., 2005). When possible, it may be helpful to offer information or websites that address the many myths surrounding childhood

immunizations (see the Internet resources at the end of this chapter for more information).

### Provider Limitations

Another barrier to immunization coverage is provider limitations. Health care providers may have contact with an eligible child, yet may fail to offer vaccination. This occurs when providers see children for different reasons and do not review their immunization records, thus missing the opportunity to provide vaccination services at what may be a very convenient time for parents. Sometimes, children come for immunization services and receive some vaccines but not others, although the safety and efficacy of administering multiple vaccines on the same occasion are well established and recommended by the CDC. Providers may erroneously defer administration of a vaccine based on a condition (e.g., symptom of illness) that is not a true contraindication to immunization. To address this particular issue, the CDC has developed guidelines for providers showing misconceptions concerning contraindications to vaccination (Table 8.3). Another provider limitation or barrier to timely immunization coverage is that few providers have the initiative and resources to establish a uniform system for recall and notification when the next immunization is due. In the United States, even clients of private providers often are not encouraged or assisted to maintain their own copies of personal written medical records (Margolis et al., 2001; Szilagyi et al., 2002).

### Planning and Implementing Immunization Programs

Immunization programs targeting specific subgroups can be effective if they include the following: (a) community assessment parameters by race or other cultural groupings in the planning phase; (b) assessment of specific characteristics of the groups such as language, child care practices, preventive health behaviors, extreme poverty, or high illiteracy; and (c) appropriate planning decisions to deal with these potential barriers. Successful outreach efforts are motivated by the desire to reach the target population, even if specific or unusual accommodations must be made. Clinics can be scheduled and held at times and places specifically intended to make the service more accessible and convenient to the target group (Szilagyi et al., 2002). Materials should be designed and presented with the needs and abilities of target parents in mind. Interpreters must be provided as needed (Talking Quality.gov, 2006). Display 8.3 outlines the necessary steps and considerations for administering immunization clinics in community settings.

### Adult Immunization

Many people erroneously assume that vaccinations are for children only. Well-advertised influenza vaccination campaigns in recent years have, to some extent, helped to correct this notion. However, media coverage about the adverse effects of such vaccination has done little to increase either community or provider enthusiasm about adult vaccination in general. Adults are at increased risk for many VPDs, and approximately 45,000 adult deaths each year are associated with complications from pneumococcal disease and

influenza (CDC, 2006k). As the nation's population ages, increasing numbers of adults will be at risk for these major causes of death and illness.

Adults may require vaccination for a variety of reasons. Occupational exposure to blood, blood products, or other potentially contaminated body fluids provides the basis for Occupational Safety and Health Administration (OSHA) requirements for hepatitis B vaccine. All persons should receive tetanus vaccine every 10 years unless they experience major or contaminated wounds. If such a wound is sustained, the individual should receive a single booster of a tetanus toxoid on the day of the injury if more than 5 years has elapsed since the last tetanus toxoid dose.

In addition to the previously mentioned influenza and pneumonia vaccinations, the newly licensed version of the childhood diphtheria/tetanus/acellular pertussis (DTaP) vaccine—tetanus/diphtheria/acellular pertussis (Tdap)—is available for 11- to 64-year-olds and will now make an impact upon pertussis disease in the community (CDC, 2007b). Other reasons for promoting the necessity of adult vaccination include history of high-risk conditions, such as heart disease, diabetes, and chronic respiratory diseases; international travel; and suspected failure of earlier vaccines to produce lasting immunity. Table 8.4 displays the *Healthy People 2010* objective for influenza and pneumonia vaccines for people older than 18 years of age (USDHHS, 2000).

Substantial numbers of VPDs still occur among adults despite the availability of safe and effective vaccines (CDC, 2006h). At least six factors contribute to low vaccination levels among adults:

1. Limited comprehensive vaccine delivery systems are available in the public and private sectors.
2. Although statutory requirements exist for vaccination of children, no such requirements exist for all adults.
3. Vaccination schedules are complicated because of detailed recommendations that may vary by age, occupation, lifestyle, or health condition.
4. Health care providers frequently miss opportunities to vaccinate adults during contacts in offices, outpatient clinics, and hospitals.
5. Comprehensive vaccination programs have not been established in settings where healthy adults congregate (e.g., the workplace, senior centers).
6. Clients and providers may fear adverse effects after vaccination.

### International Travelers, Immigrants, and Refugees

As Americans interact more and more with their neighbors in other parts of the world, the incidence of Americans with tropical or imported diseases also rises. Within 36 hours of beginning a trip, any destination in the world can be reached. That amount of time is within the incubation period of most infectious diseases, and microbial agents are rapidly spread around the globe.

Information necessary for a potential traveler to travel to new and exotic places, remain healthy, and return healthy is available from a number of sources. At a minimum, all

<sup>a</sup>**Contraindications.** A contraindication is a condition in a recipient that increases the risk for a serious adverse reaction. A vaccine will not be administered when a contraindication is present. Consult the MMWR article, “General Recommendations on Immunizations” for a full definition including examples.

<sup>b</sup>**Precautions.** A precaution is a condition in a recipient that might increase the risk for a serious adverse reaction or that might compromise the ability of the vaccine to produce immunity. Injury could result, or a person might experience a more severe reaction to the vaccine than would have otherwise been expected; however, the risk for this happening is less than expected with a contraindication. Under normal circumstances, vaccinations should be deferred when a precaution is present. However, a vaccination might be indicated in the presence of a precaution because the benefit of protection from the vaccine outweighs the risk for an adverse reaction. Consult the MMWR article, “General Recommendations on Immunizations” for a full definition including examples.

<sup>c</sup>Events or conditions listed as precautions should be reviewed carefully. Benefits and risks of administering a specific vaccine to a person under these circumstances should be considered. If the risk from the vaccine is believed to outweigh the benefit, the vaccine should not be administered. If the benefit of vaccination is believed to outweigh the risk, the vaccine should be administered. Whether and when to administer DTaP to children with proven or suspected underlying neurologic disorders should be decided on a case-by-case basis.

<sup>d</sup>Hepatitis B vaccination should be deferred for infants weighing  $< 2,000$  grams if the mother is documented to be hepatitis B surface antigen (HbsAg)-negative at the time of infant's birth. Vaccination can commence at chronological age 1 month. For infants born to HbsAg-positive women, hepatitis B immunoglobulin and hepatitis B vaccine should be administered at or soon after birth regardless of weight. See MMWR article, “General Recommendations on Immunizations” text for details.

<sup>e</sup>Acetaminophen or other appropriate antipyretic can be administered to children with a personal or family history of seizures at the time of DTaP vaccination and every 4–6 hours for 24 hours thereafter to reduce the possibility of post-vaccination fever (Source: American Academy of Pediatrics. Active immunization. In Pickering LK, ed. *2000 Red Book: Report of the Committee on Infectious Diseases*, 25th ed. Elk Grove Village, IL; American Academy of Pediatrics, 2000.)

<sup>f</sup>MMR and varicella vaccines can be administered on the same day. If not administered on the same day, these vaccines should be separated by  $\geq 28$  days.

<sup>g</sup>Substantially immunosuppressive steroid dose is considered to be  $> 2$  weeks of daily receipt of 20 mg or 2 mg/kg body weight of prednisone or equivalent.

<sup>h</sup>Measles vaccination can suppress tuberculin reactivity temporarily. Measles-containing vaccine can be administered on the same day as tuberculin skin testing. If testing cannot be performed until after the day of MMR vaccination, the test should be postponed for  $> 4$  weeks after the vaccination. If an urgent need exists to skin test, do so with the understanding that reactivity might be reduced by the vaccine.

<sup>i</sup>See text for details.

<sup>j</sup>If a vaccinee experiences a presumed vaccine-related rash 7–25 days after vaccination, avoid direct contact with immunocompromised persons for the duration of the rash.

## DISPLAY 8.3

## ADMINISTRATIVE ASPECTS OF IMMUNIZATION PROGRAMS

**Study the Target Community**

- Assess disease incidence and level of immunization coverage.
- Identify the target group.
- Assess conditions in the community: Is the target group scattered or localized?
- Assess level of community involvement and awareness of the problem.
- Identify means of communicating with target group: Through the media or through leaders or other.
- Consider political and social structure of the community. Identify important leaders.
- Identify sites for immunization clinics that are appropriate, accessible, and available.

**Plan the Immunization Program**

- Review budget for immunization services.
- Determine goals for clinic performance or outcome measures.
- Communicate with target group to notify them of need and promote involvement and participation.
- Estimate needs for vaccines and supplies and obtain them. Plan care of vaccines before, during, and after clinic.
- Develop team coordination among staff.
- Plan clinic logistics: Available supply of needed materials, medical waste disposal, anaphylaxis supplies, records and means of clinic registration, staffing, floor plan for traffic control and efficient management of crowds.
- Prepare staff with information regarding objectives for clinic, criteria for who shall not be immunized,

mechanisms for referral of clients with other health needs.

**Publicity**

- Inform target group of date, location, and times of immunization clinic.
- Provide information on reasons for and benefits of (and contraindications to) immunization.
- Encourage parents to bring existing immunization records to clinic.
- Provide contact information for those with questions or inquiries.

**Immunization Clinic**

- Registration system and records (for parent and clinic) ready.
- Registrar or assistant(s) ready to assist parents not familiar with language of paperwork.
- Parent education: informed consent, reporting of adverse reactions, date next vaccine due.
- System for call-back, follow-up.
- System for dealing with other health issues and/or adverse events.

**Evaluation of Program**

- Assess numbers of immunizations given in relation to goals.
- Assess suitability of approach in identification of target group, selection of sites, means of communication with group, availability of resources, and so forth.
- Invite parental as well as community and staff feedback.
- Evaluate results in relation to expenditures.

**TABLE 8.4** *Healthy People 2010 Target for Influenza and Pneumonia Immunization in Adults*

*Objective:* Increase to 90% the rate of immunization coverage among adults 65 years of age or older; 60% for high-risk adults 18 to 64 years of age.

Recommended Immunization	1998 (unless noted)	Target 2010
<b>Noninstitutionalized adults 65 years of age or older</b>		
Influenza vaccine	64%	90%
Pneumococcal vaccine	46%	90%
<b>Noninstitutionalized high-risk adults 18 to 64 years of age</b>		
Influenza vaccine	26%	60%
Pneumococcal vaccine	13%	60%
<b>Institutionalized adults (persons in long-term or nursing homes)</b>		
Influenza vaccine	59% (1997)	90%
Pneumococcal vaccine	25% (1997)	90%

Retrieved July 13, 2008 from [http://www.healthpeople.gov/documents/html/volume1/14\\_immunization.htm](http://www.healthpeople.gov/documents/html/volume1/14_immunization.htm)

- Age-adjusted to the year 2000 standard population.
- National Nursing Home Survey estimates include a significant number of residents who have an unknown vaccination status.

international travelers must take steps to be adequately immunized as required by international health practices. These steps include being immunized with the recommended vaccines for the particular area of the world, having the necessary chemical prophylaxis on hand (i.e., antimalarial medications as prescribed), and being knowledgeable about food and water hygiene precautions as well as basic first aid for the care of simple injuries (CDC, 2005e). Every year, travelers who neglect to take the recommended travel vaccines or medications end up with generally preventable illnesses, which can cost them time, money, and their health. In many major cities of the United States, one finds tropical medicine or travelers' medicine specialists who can assist in adequate preparation for travel (CDC, 2005e).

Refugees and international travelers who arrive in the United States are often unfamiliar with U.S. health systems, health precautions, and practices. Refugees and immigrants must follow prescribed guidelines for their acculturation, including extensive health screening mandated by U.S. immigration laws. More than ever before, community health nurses have professional contact with these new Americans, whether close to their time of arrival or later, in schools, immunization clinics, or other locations. Visitors from other countries may also require the assistance of other community health professionals. For this reason, community health nurses are encouraged to develop and maintain a global perspective on communicable diseases

(CDC, 2006d). See Chapter 16 for more information on global health.

## SECONDARY PREVENTION

Two approaches to secondary prevention of communicable disease are possible: screening, and disease case and contact investigation with partner notification.

### Screening

The term **screening** is used in community health and disease prevention to describe programs that deliver a testing procedure to detect disease in groups of asymptomatic, apparently healthy individuals. Common screening measures can include: (a) prenatal hepatitis B, (b) urine chlamydia and gonorrhea, and (c) Mantoux tuberculin skin tests for TB infection. For HIV, several screening tests are available—including oral fluids testing, rapid finger stick, or the more sensitive screening enzyme immunoassay (EIA). All of these must be confirmed by a supplemental test such as the Western blot or an immunofluorescence assay (IFA) when positive results appear on screening tests (CDC, 2006j). All screening tests are discussed later in this chapter. Screening is a secondary prevention method because asymptomatic cases can be discovered and provided with prompt early treatment.

It is important to remember that the screening itself is not diagnostic, but rather seeks to identify those persons with positive or suspicious test findings who then require further medical evaluation or treatment. As a community health nurse working with clients in a screening setting, you must be prepared to clearly and correctly explain to individuals that screening tests are not definitive and that positive findings require subsequent investigation before diagnostic conclusions can be drawn.

### Criteria for Screening Tests

Some important criteria are used in deciding whether to carry out a screening intervention in a community. They include validity and reliability, and predictive value and yield.

#### Validity and Reliability

The screening test must be valid and reliable. *Validity* refers to the test's ability to accurately identify those with the disease. *Reliability* refers to the test's ability to give consistent results when administered on different occasions by different technicians.

#### Predictive Value and Yield

The *predictive value* of a screening test is important for determining whether the screening intervention is justified. *Yield* refers to the number of positive results found per number tested. The predictive value and the yield of screening tests become important in planning screening programs for communicable disease detection and prevention because they can help planners locate screening efforts in areas or within population groups that are known to be at high risk for the disease. The predictive value of screening tests increases as the prevalence of the disease increases. For example, a screening test for syphilis targeted at the popula-

tion associated with crack houses in a particular city would have greater predictive value and yield than a screening test for syphilis given to the city population at large.

Epidemiologic criteria for screening interventions for the detection of health problems include:

1. Is the disease an important public health problem?
2. Is there a valid and reliable test?
3. Is there an effective and tolerable treatment that favorably influences the early stages of the disease?
4. After a positive screening result, are facilities for diagnosis and treatment available and accessible?
5. Is there a recognizable early asymptomatic or latent stage in the disease?
6. Do clear guidelines for referral and treatment exist?
7. Is the total cost of the screening justifiable compared with the costs of treating the disease if left undiscovered?
8. Is the screening test itself acceptable?
9. Will screening be ongoing?

The ethics or values represented by these statements include a clear and unwavering respect for the dignity and worth of individuals across racial, gender, religious, sexual, tribal, ethnic, and geographic lines. They include a commitment to ensuring that resources are allocated to areas where they will have the most benefit in preventing disease and premature death. They speak to respect for the individual receiving the screening service, in that the person should take on the burden of diagnosis only if access to acceptable further intervention exists.

Socioeconomically disadvantaged persons are often at greatest risk for disease, yet they are the least likely to receive screening services because of financial barriers, including lack of health insurance coverage for preventive care (Coughlin, 2006).

### Case and Contact Investigation, Partner Notification

Another secondary prevention approach is known as case and contact investigation with partner notification. In this approach, the community health nurse investigates a reported communicable disease case to discover and notify those who have had contact with the infected person, such as with TB reactors, and to notify partners in the case of STDs. The objective of a contact investigation and partner notification is specifically to reach contacts of the **index case** (diagnosed person) before the contacts, in turn, become infectious (CDC, 2006j). Therefore, the rapidity with which contact investigation can be accomplished is vital.

*Healthy People 2010* (USDHHS, 2000) guidelines differentiate between two types of partner notification. *Patient referral* describes those clients who voluntarily advise their partners of the risk of disease and the need for contact with a health provider. *Provider referral* describes the community health workers who contact individuals exposed to the index case and either assist the individual in obtaining medical care or strongly encourage them to seek appropriate medical care. In both types of notification, clients need information and encouragement as well as assurance of confidentiality (Hogben et al., 2004).

Not all individuals who have a disease can accurately identify the persons with whom they have had close or intimate contact. This is particularly the case with STDs associated with drug use and the selling of sex for drugs. It is also true in situations involving highly mobile or transient people whose lifestyles preclude establishing relationships that can be traced or followed. These problems lead to the need for alternative approaches in finding contacts or new cases, including the provision of screening activities in locations where people with similar risky lifestyle behaviors are likely to congregate. It further points to the critical need for tests that provide reliable results very rapidly, because it may not be possible to locate the person for follow-up 24 hours or 2 weeks later (CDC, 2007b).

Contact investigation is most commonly practiced today in STD and TB control programs. The same interviewing and data collection techniques can transfer to use with food-borne illness or other disease outbreak control efforts. Understanding the disease being investigated, incubation period, various stages of infection (active or latent), and urgency of evaluation and treatment are important considerations in determining the timeline of the investigation (Dato, Wagner, & Fapohunda, 2004).

### Tertiary Prevention

The approaches to tertiary prevention of communicable disease include isolation and quarantine of the infected person and safe handling and control of infectious wastes.

### Isolation and Quarantine

Communicable disease control includes two methods for keeping infected persons and noninfected persons apart to prevent the spread of a disease. **Isolation** refers to separation of the infected persons (or animals) from others for the period of communicability to limit the transmission of the infectious agent to susceptible persons. **Quarantine** refers to restrictions placed on healthy contacts of an infectious case for the duration of the incubation period to prevent disease transmission if infection should develop (Heymann, 2004).

### Safe Handling and Control of Infectious Wastes

Also important to the control of infection in community health is the proper disposition of contaminated wastes. The CDC has developed *universal precautions*, which encourage health care workers to think of all blood and body fluids, and materials that have come in contact with them, as potentially infectious. Although universal precaution observance is primarily considered while the nurse is giving hands-on treatment or care to a patient, keeping these principles in mind while making community health visits in the primary and secondary setting is paramount to the safety of both the client and the nurse (Heymann, 2004).

Universal precautions include the following:

- ◆ Hand-washing after contact with the client or with potentially contaminated articles and before care of other clients
- ◆ Discarding or bagging and labeling of articles contaminated with infectious material before it is sent for decontamination and reprocessing
- ◆ Isolation based on the mode of transmission of the specific disease, which may include strict isolation, contact isolation, respiratory isolation, TB isolation (acid-fast bacilli [AFB] isolation), enteric precautions, or drainage/secretion precautions

The Environmental Protection Agency (EPA, 2007) defines infectious waste as waste capable of producing an infectious disease. The agency notes that for waste to be infectious, it must contain pathogens with sufficient virulence and quantity so that exposure to the waste by a susceptible host could result in an infectious disease. EPA requirements for medical waste disposal are for waste to be segregated into categories of (a) used and unused sharps, (b) cultures and stocks of infectious agents, (c) human blood and blood products, and (d) human pathologic, isolation, and animal waste. Although incineration has long been recognized as an efficient method for disposing safely of sharps and other contaminated medical waste, fewer incinerators are available now because of increasing regulation of emissions, and particularly those regulations related to burning chemical wastes (Occupational Safety and Health Administration, 2006).

Four key elements of an infectious waste management program are applicable to community practice:

1. Health professionals must be able to correctly distinguish waste that poses a significant infection hazard from other biomedical waste that poses no greater risk than general municipal waste, and such infectious waste must be clearly defined.
2. The waste management program must have administrative support and authority to institute practice guidelines and provide the containers and other resources needed for safe disposal of infectious wastes.
3. Handling of the infectious wastes must be minimized. Containers should be rigid, leak resistant, and impervious to moisture; they should have sufficient strength to prevent rupture or tearing under normal conditions; and they should be sealed to prevent leakage. Containers for sharps must also be puncture resistant.
4. An enforcement or evaluation mechanism must be in place to ensure that the goal of reducing the potential for exposure to infectious waste in the community is met.

## MAJOR COMMUNICABLE DISEASES IN THE UNITED STATES

Community health nurses encounter several communicable diseases in their practice. Many are reportable, but some are not—although they are just as transmittable to others as the reportable infections. As mentioned previously, each state department of health has the capacity to determine which diseases will be reportable based upon the federal reportable disease list. These diseases are frequently diagnosed and treated in the community care setting rather than the hospital. The most commonly reported diseases are the STDs: chlamydia, gonorrhea, and syphilis are reportable in all states; and genital herpes and human papillomavirus (HPV) genital warts are not reportable in all states. Hepatitis,

HIV/AIDS, influenza (seasonal and avian), pneumonia, and TB are mandated reportable diseases. The following sections discuss some of the more common communicable diseases, but the list is not inclusive of all that are reportable. Diseases are presented in groups by similarity, rather than by virulence or prevalence.

## Chlamydia

*Chlamydia trachomatis* (CT) infections are the most commonly reported notifiable STD in the United States. Since 1994, CT has made up the largest proportion of all STDs reported to the CDC. In women, chlamydial infections, which are usually asymptomatic, may result in pelvic inflammatory disease (PID)—a major cause of infertility, ectopic pregnancy, and chronic pelvic pain (CDC, 2005h). Chlamydia is a sexually transmitted bacterial infection of great concern, with 436,350 cases reported to the CDC in 1997, 702,093 in 2000, and 976,445 in 2005. The number of cases has increased primarily because of an increase in recognition, testing, and mandatory reporting by the states in the past two decades (CDC, 2005h; Heymann, 2004).

Until recently, chlamydia was probably the least recognized of the STDs. Only since 2000 has reporting of chlamydia been required by all states, including the District of Columbia (CDC, 2005h). People with uncomplicated infection are quite often symptom free until late and serious complications occur. Women and children typically are the most adversely affected, particularly in terms of sequelae, including PID, ectopic pregnancy, infertility, infant conjunctivitis, and infant pneumonia (Heymann, 2004).

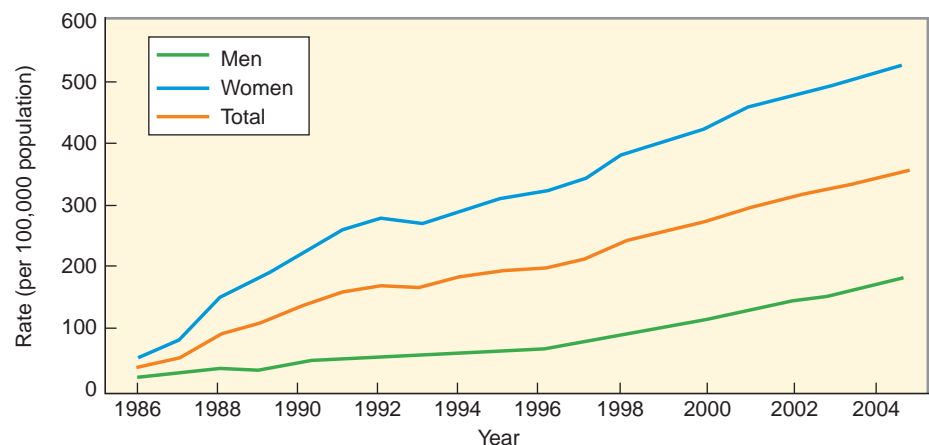

Screening programs have been extremely effective in reducing the chlamydia burden in groups that are screened regularly. One of the goals of *Healthy People 2010* is to reduce the prevalence of CT infections among young people (15 to 24 years of age) to no more than 3.0%, but as of 2004, the average was 6.3% (CDC, 2005h). In 2004, the reported rate of chlamydial infection among women in the United States (485 cases per 100,000) was nearly four times higher than the reported rate among men (147 cases per 100,000); however, this difference probably reflects a greater number of women being screened for this disease (CDC, 2005h). The lower rate among men suggests that many of the sex partners

of women with chlamydia are not diagnosed or reported. However, with the use of the highly sensitive nucleic acid amplification tests for testing urine, symptomatic and asymptomatic men are now regularly being diagnosed with chlamydial infection (CDC, 2005h). As a result of increased screening efforts in many settings outside of the medical office, reported rates of chlamydia continue to increase (Fig. 8.3).

Control of chlamydial infections of the cervix is considered key to effective reduction in the rates of PID, particularly among teenage women. A recent investigation of people in a health maintenance organization (HMO) demonstrated that screening and treatment of cervical infection reduces the likelihood of PID (CDC, 2005k). In one study of teen and young adult men who had their urine screened for chlamydia (Ku et al., 2002), 3.1% of the teenagers (age 15 to 19 years) and 4.5% of the young adults (age 22 to 26 years) had chlamydial infections. Also, the great majority of the participants were asymptomatic. The federal government reports that almost half of reported cases are 15- to 19-year-old girls, and an additional one-third of cases are women between the ages of 20 and 24 (Agency for Healthcare Research and Quality [AHRQ], 2001).

Barriers exist to successful prevention, diagnosis, and treatment of chlamydia. As noted, many people who are diagnosed with chlamydia are asymptomatic and often report their use of prophylactic protection during sexual intercourse as sporadic. In the study by Ku and colleagues (2002), the number of reported partners per year was about three for both age groups. Another major barrier to effective control is lack of compliance with the required 7-day treatment regimen of doxycycline (100 mg twice a day) or tetracycline four times a day. The use of azithromycin (1 g in a single dose) is also highly effective and leads to better compliance as on-the-spot treatment in the clinic setting is possible.

“Patient-delivered partner treatment” has been shown to be more effective than encouraging the patient to notify their partner(s) to seek testing and treatment. However, for men who have sex with men, this practice is not as customary, as there may be other co-infection issues that need evaluation and treatment as well (CDC, 2006m; Schillinger et al., 2003). To minimize the risk for reinfection, clients should be instructed to abstain from sexual intercourse until all of their sex partners have been treated. Clients do not need to be retested for chlamydia after completion of treatment with

**FIGURE 8.3** Chlamydia rates: Total and by sex: United States, 1986–2005.

NOTE: As of January 2000, all 50 states and the District of Columbia had regulations requiring the reporting of chlamydia cases.

doxycycline or azithromycin unless symptoms persist or reinfection is suspected. A test of cure may be considered 3 weeks after completion of treatment with erythromycin (CDC, 2006m). Condom use is important in decreasing the spread of chlamydia infection.

Prenatal screening of pregnant women can prevent chlamydial infection among neonates. Neonatal *C. trachomatis* infection may involve the mucous membranes of the eye, oropharynx, urogenital tract, and rectum. It is most often recognized by the presence of conjunctivitis, which develops 5 to 12 days after birth. Chlamydia is the most frequent identifiable infectious cause of ophthalmia neonatorum. Chlamydia also is a common cause of subacute, afebrile pneumonia with onset at 1 to 3 months of age. Either of these conditions may be observed when you are making a home visit for post-delivery, family follow-up (CDC, 2005h).

## Genital Herpes

Genital herpes is an STD caused by the herpes simplex viruses, type 1 (HSV-1) and type 2 (HSV-2). Most cases of genital herpes are caused by HSV-2. Most individuals have no or only minimal signs or symptoms from HSV-1 or HSV-2 infection. Primary and recurrent infections occur, with or without symptoms, and first occurrences may take up to 2 or 4 weeks to heal. In women, sites of primary disease are the cervix and the vulva. Recurrent disease generally involves the vulva, perineal skin, legs, and buttocks. In men, lesions appear on the penis, and in the anus and rectum of those engaging in anal sex. Typically, another outbreak can appear weeks or months after the first, but it almost always is less severe and briefer than the first outbreak. The infection can remain in the body indefinitely, and the number of outbreaks will decrease over a period of years (Heymann, 2004).

Nationwide, at least 45 million people ages 12 and older, or one of five adolescents and adults, have had genital HSV infection. Genital HSV-2 infection is more common in women (approximately one of four women) than in men (almost one of five). This may be due to male-to-female transmissions being more likely than female-to-male transmission. Generally, a person can only get HSV-2 infection during sexual contact with someone who has a genital HSV-2 infection. Transmission can occur from an infected partner who does not have a visible sore and may not know that he or she is infected (CDC, 2006m).

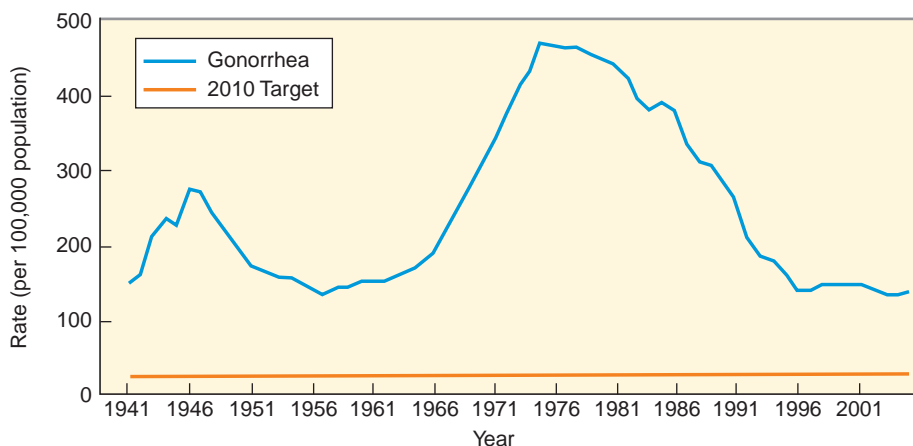

Most people infected with HSV-2 are not aware of their infection. However, if signs and symptoms occur during the first outbreak, they can be quite pronounced. The first outbreak usually occurs within 2 weeks after the virus is transmitted. Other signs and symptoms during the primary episode may include a second crop of sores, and flu-like symptoms, including fever and swollen glands. Most individuals with HSV-2 infection may never have sores, or they may have very mild signs that they do not even notice or that they mistake for insect bites or another skin condition (CDC, 2006m).

Health care providers can diagnose genital herpes by visual inspection if the outbreak is typical, and by taking a sample from the sore(s) and testing it in a laboratory. HSV infections can be difficult to diagnose between outbreaks. Blood tests, which detect HSV-1 or HSV-2 infection, may be helpful, although the results are not always clear (Heymann, 2004).

Three antiviral medications provide clinical benefit for genital herpes: acyclovir, valacyclovir, and famciclovir. Each is given orally for 7 to 10 days for a first clinical episode; for recurrent genital herpes, the recommended regimen is similar doses given twice daily. The drugs have been shown to reduce shedding of the virus, diminish pain, and accelerate healing. Intravenous acyclovir therapy is provided for clients who have severe disease or complications that necessitate hospitalization, such as disseminated infection, pneumonitis, hepatitis, or complications of the central nervous system (e.g., meningitis, encephalitis). These antiviral medications can shorten and prevent outbreaks during the period when the person takes the medication. In addition, daily suppressive therapy for symptomatic herpes can reduce transmission to partners (CDC, 2006m).

## Gonorrhea

The overall rate of gonorrhea in the United States has decreased to 115.5 cases per 100,000 in 2005, compared with the 1997 case rate of 122.7 cases per 100,000. The causative agent is gonococcus bacteria—*Neisseria gonorrhoeae*. Consistently, the highest rates have been among women age 15 to 19 years (624.7 cases per 100,000) and 20- to 24-year-old men (436.8 cases per 100,000) (CDC, 2005i). Overall, we have yet to reach the *Healthy People 2010* target of 19 cases per 100,000 (Heymann, 2004; USDHHS, 2000) (see Fig. 8.4).

NOTE: The Healthy People 2010 target for gonorrhea is 19.0 cases per 100,000 population.

**FIGURE 8.4** Gonorrhea rates: United States, 1941–2005 and the Healthy People 2010 target.

Antimicrobial resistance continues to be a concern in treating gonorrhea. Overall, 15.9% of isolates collected in the United States in 2004 from 28 Gonococcal Isolate Surveillance Project (GISP) STD clinic sites were resistant to penicillin, tetracycline, or both. Resistance is more prevalent on the West Coast and in Hawaii (California Department of Health Services, STD Guidelines [CADHS], 2004). Globally, the prevalence of drug-resistant strains of gonococcal infections in developing countries are a cause for added concern (Indian Council of Medical Research, 2006).

Gonorrhea commonly manifests in men as a purulent drainage from the penis, accompanied by painful urination within 2 to 7 days after an infecting exposure. In women, the symptoms may be so mild as to go unnoticed. Progression of untreated gonorrhea in women can lead to serious reproductive system involvement causing PID and subsequent infertility. Treatment for gonorrhea will vary across the country due to the antibiotic resistance seen on the West Coast and among men who have sex with men. The recommended treatment regimen will need to reflect the surveillance data related to drug susceptibility. The practitioner must be vigilant in questioning recent travel or local acquisition of the infection and base treatment choice on this information (CDC, 2005i; Heymann, 2004). Because treatment failure with the combined ceftriaxone/doxycycline regimen is rare, a follow-up test of cure is not considered essential except for pregnant women, who should have a culture performed.

## Syphilis

Syphilis, a genital ulcerative disease, manifests in several forms during the life cycle of the disease. Approximately 3 weeks after exposure, a primary lesion called a *chancre* characteristically appears as a painless ulcer at the site of initial invasion of the causative organism *Treponema pallidum*, a spirochete. This first stage is considered primary syphilis. After 4 to 6 weeks, the chancre heals without treatment, to be replaced by the development of a more generalized secondary skin eruption, classically appearing on the soles of the feet and palms of the hands, often accompanied by fatigue. This stage is secondary syphilis. These secondary manifestations resolve spontaneously, and a latent period follows, which may last from weeks to years. These stages are latent, late latent, and tertiary or neurosyphilis. Unpredictably, severe, systemic involvement with disability, or even death may occur. Transmission of untreated syphilis can occur in any stage (Heymann, 2004).

Syphilis is the first STD for which control measures were developed and tested. The incidence of primary syphilis cases in the United States decreased between 1990 and 2000, from 50,000 to 5,979 reported cases. But, an increase occurred between 2000 and 2004, mainly among men. An increase in primary syphilis cases reported in 2005 was 8,724. Between the years 2003 and 2004, the rate among women has remained the same, and the highest rate remains among men having sex with men. Syphilis contributes to HIV transmission in those parts of the country where rates of both infections are high. Only in the South do rates remain higher than the rest of the United States, with an average rate of 3.6 cases per 100,000 people. The target for 2010 is 0.2 cases per 100,000, and the opportunity exists to eliminate syphilis within the U.S. borders (CDC, 2005j).

Elimination of syphilis would have far-reaching public health implications because it would remove two devastating consequences of the disease—increased likelihood of HIV transmission and compromised ability to have healthy babies due to spontaneous abortions, stillbirths, and multisystem disorders caused by congenital syphilis acquired from mothers with syphilis. (USDHHS, 2000, Section 25, p. 18)

Treatment of early primary, secondary, and early latent syphilis is generally accomplished through antibiotic therapy. The specific treatment is a long-acting penicillin G (benzathine penicillin), 2.4 million units given in a single intramuscular dose on the day of diagnosis. Clients should be reexamined serologically at 3 and 6 months after treatment to ensure cure; however, the single-dose treatment is considered effective therapy even if the client fails to return (Heymann, 2004).

## Viral Warts

Condyloma acuminata, verruca vulgaris, papilloma venereum, and the common wart are all forms of a viral disease manifested by a variety of mucous membrane and skin lesions (Heymann, 2004). All are transmitted by direct contact, but condyloma acuminata, or genital warts caused by HPV, are usually sexually transmitted.

Researchers have identified more than 100 types of papilloma viruses, and at least 30 of these types of the virus are sexually transmitted. Several of the subtypes of HPV are associated with cervical dysplasia and genital cancers, which can occur 5 to 30 years after the initial infection, accounting for more than 90% of cervical cancers (CDC, 2006c). The CDC estimates that about 6.2 million Americans get a new genital HPV infection each year.

Sexually active individuals are at risk for contracting any one or several of the types of genital warts that exist. Because few produce the actual bumpy, visual signs of warts, and some produce no notable symptoms, many cases go undiagnosed. This asymptomatic state leads to ongoing transmission between or among sexual partners (CDC, 2006m). Sexually active women can be diagnosed at the time of Papanicolaou smear (Pap) during the woman's health examination. This test can detect abnormal cytologic changes, and viral tests can be performed on the sample to determine the presence of HPV. Biopsy of the site may also be needed to examine the tissue more thoroughly (CDC, 2006m).

Treatment depends on the size and location of the warts. Even though the warts may be removed, the viral infection can't be cured, which is why the warts often return. Some of the medications used to treat genital warts cannot be used during pregnancy, so it is important for clients to tell their doctors if they could be pregnant. Small warts may be treated with medications applied to the skin. In some cases, applying liquid nitrogen (cryotherapy) to warts will freeze the tissue and make warts disappear. Some larger warts require laser treatment or surgical removal (CDC, 2006c; CDC, 2006m).

A vaccine released in 2006 has the potential to impact the rates of cervical cancer caused by HPV in women. The vaccine, Gardasil, protects against four HPV types (6, 11, 16, and 18), which together cause 70% of cervical cancers and 90% of genital warts. The vaccine is available to females between the ages of 9 and 26 years. The vaccine is not available to males at this time, although studies are under way

(CDC, 2006c). Some states now require this vaccine for girls enrolled in middle schools.

## Hepatitis

Of five viral hepatitis infections that constitute serious liver disease, three commonly reported types are hepatitis A, B, and C. The number of people being infected with hepatitis is globally epidemic. Nationally, substantial progress is being made in the elimination of hepatitis viruses through the primary prevention practices of education and immunization for forms A and B.

### Hepatitis A

Hepatitis A, caused by infection with the hepatitis A virus (HAV), occurs worldwide and is sporadic and epidemic, with cyclic recurrences affecting children and young adults most frequently. Case rates are high in Central and South America, the Caribbean, Mexico, Asia (except Japan), Africa, and southern and eastern Europe. Hepatitis A is identified by the presence of immunoglobulin M (IgM) antibodies against HAV in the serum of acutely or recently ill individuals (Heymann, 2004). The disease is transmitted from person to person by the fecal–oral route and is characterized by the abrupt onset of symptoms including fever, malaise, anorexia, nausea, and abdominal discomfort, followed by jaundice in more severe cases. Mild illnesses last 1 to 2 weeks, but more severe cases last 1 month or longer. It is generally a self-limited disease that does not result in chronic infection or chronic liver disease (Heymann, 2004).

Where environmental sanitation conditions are poor, infection is common and occurs at an early age. In the United States, most cases are transmitted in day care centers among diapered children, to household and sexual contacts of acute cases, and among travelers to countries where the disease is endemic. At times, common-source outbreaks are related to contaminated water, food contaminated by infected food handlers, raw or undercooked shellfish harvested from contaminated water, or contaminated produce, such as lettuce or strawberries (CDC, 2005e; Fiore, 2004).

Inactivated hepatitis A vaccines are prepared from formalin-inactivated, cell-culture–derived HAV and have been available in the United States since 1995 (CDC, 2007a). Administered in a two-dose series, these vaccines induce protective antibody levels in virtually all adults, providing the opportunity to eliminate this disease as a public health problem in the United States. The vaccine is recommended as a routine VFC vaccine and, as of 2005, is now available for children older than 12 months (CDC, 2007a). A combined hepatitis A and B vaccine has been developed for adults. Community health nurses play an important role in the prevention (pre-travel vaccination) and control of this disease, including case investigation, education, and identifying exposed contacts who need referral or assistance in obtaining postexposure prophylaxis and vaccination (CDC, 2006e).

### Hepatitis B

Hepatitis B is a serious disease caused by a virus that attacks the liver. The virus, called hepatitis B virus (HBV), can cause lifelong infection, cirrhosis (scarring) of the liver, liver

cancer, liver failure, and death. In very few cases, the infection will resolve, providing immunity (Heymann, 2004).

Hepatitis B is a global problem, with 66% of the world's population living in areas where high levels of infection by HBV occur. More than 2 billion people (one-third of the world's population) have evidence of resolved or current HBV infection, and 350 million people are chronic carriers of the virus. HBV causes 60% to 80% of all cases of primary liver cancer, which is one of the three top causes of cancer deaths in East Asia, Southeast Asia, the Pacific Basin, and sub-Saharan Africa (Heymann, 2004).

In the United States, cases of HBV are related to exposures common in certain high-risk groups, including injection drug users and homeless youth (Beech, Myers, & Beech, 2002), heterosexuals with multiple partners, homosexual men, incarcerated populations, and clients and staff in institutions for the developmentally disabled (Charuvastra et al., 2001).

The symptoms of HBV range from unnoticeable to fulminating, and include anorexia, vague abdominal discomfort, nausea and vomiting, and rash, often progressing to jaundice. The diagnosis is confirmed by the presence of specific antigens or antibodies (or both) to HBV in serum (Heymann, 2004).

Vaccination is the most effective way of preventing HBV transmission. Following WHO recommendations, 158 member states have integrated hepatitis B vaccine into their national immunization programs. The WHO and the United Nations Children's Fund (UNICEF) have sought means to help the poorest and neediest countries procure the vaccine. Effective implementation of this strategy could effectively eliminate transmission of hepatitis B by the year 2025 (WHO, 2005).

Community health nurses have an important role in the prevention and control of hepatitis B. Most importantly, this role includes teaching that encourages immunization compliance and consistent adherence to universal precautions (discussed earlier), especially for people in high-risk lifestyles or occupations (CDC, 2006a).

### Hepatitis C

Hepatitis C was first identified in 1989 and has already become a major public health problem. It causes a complex infection of the liver and is one of the leading known causes of liver disease in the United States. It is a common cause of cirrhosis and hepatocellular carcinoma, as well as liver transplantation. It is believed that at least 4 million people in this country are infected with HCV. The incidence is not well known, but prevalence studies have led the WHO to estimate that 200 million people worldwide and 4 million people in the United States are infected with the hepatitis C virus (HCV) (NIH, 2002).

Hepatitis C is more widespread than AIDS, and many infected people are unaware that they are infected (Lauer & Walker, 2001). About 170 million people are chronic carriers, at risk for development of liver cirrhosis and liver cancer. In the United States, four times as many people have contracted HCV as have contracted HIV infection. Approximately 30,000 new acute infections and 8,000 to 10,000 deaths occur each year, and hepatitis C has become a leading reason for liver transplantation (Sarbah & Younossi, 2000).

Symptoms are similar to those of hepatitis A and B, and may be unrecognizably mild to fulminating. Diagnosis depends on the demonstration of antibody to HCV, and a

screening test for blood donors was established in 1992 (Heymann, 2004). Before this test, HCV was the most common cause of posttransfusion hepatitis worldwide, accounting for approximately 90% of cases in the United States. The incidence of hepatitis C in the United States is highest in injection drug users (approximately 60%), hemophilia patients, and hemodialysis patients; it is also more frequently found among heterosexuals with multiple sexual partners, homosexual men, and health care workers than in the general public. Tattooing and body piercing provide an additional source of HCV transmission, and the exact role of tattooing is being studied. HCV testing is recommended for the following groups (Hench & Simpkins, 2002):

- ◆ People who inject nonprescribed drugs, including those who injected once or a few times in the past and do not consider themselves drug users
- ◆ Clients who received transfusions or organ transplants before 1992 and recipients of blood from a positive donor
- ◆ People with selected medical conditions, including recipients of clotting factors before 1987, people undergoing chronic hemodialysis, and those with persistently elevated alanine aminotransferase levels
- ◆ Those exposed to HCV-positive sources, such as needlesticks, sharps, or mucosal exposures
- ◆ Children born to HCV-positive women (after 12 months in order to make sure maternal antibodies have dissipated)

A community health nurse's role includes case-finding, encouraging testing for people who received blood transfusions before 1992, and reinforcing universal precautions (see earlier discussion), along with strong nursing assessment skills and compassion. There is no vaccine, and chronic hepatitis C is a life-altering event; clients need emotional support, and community health nurses can provide this support, as well as education for clients and families. New drugs and clinical trials are being continually introduced, and nurses can provide up-to-date information.

## HIV/AIDS

The **human immunodeficiency virus (HIV)** is a retrovirus that attacks the body's immune system. Two types have been identified: type 1 (HIV-1) and type 2 (HIV-2). These viruses are relatively distinct serologically and geographically, but they have similar epidemiologic characteristics. The pathogenicity of HIV-2 appears to be less than that of HIV-1 (Heymann, 2004). Twenty-five years have passed since the identification of this infection, and it is viewed by many to be a chronic, manageable disease process; however, in most of the world, HIV continues to devastate populations of people who do not have access to life-extending medical care and medications. This section explores the acute nature of the infection, surveillance, investigation, and education. The chronic nature of this illness, along with treatment and disease management is discussed in Chapter 26.

**Acquired immunodeficiency syndrome (AIDS)** is a severe, life-threatening condition, representing the late clinical stage of infection with HIV, in which there is progressive damage to the immune and other organ systems—particularly the central nervous system. Most people infected with

HIV remain symptom free for long periods, but viral replication is active during all stages of infection. AIDS eventually develops in almost all HIV-infected people who are not receiving antiretroviral therapy (ART) or highly active antiretroviral therapy (HAART), from months to 17 years after infection—with a median of 10 years (CDC, 2005f).

In recent years, the incidence of HIV infection among heterosexuals has grown. In the 1980s, most HIV infections occurred in men who had sex with men and in injection drug users. When HIV entered the country's blood supply, it affected transfusion patients, hemophiliacs, and other persons who received infected blood or blood products. As more women of childbearing age became infected, newborns were at increased risk for acquiring HIV infection. Today, almost all infections in infants and children are caused by transmission from the mother before or during birth. Today, most new cases of HIV/AIDS are transmitted through heterosexual or homosexual contact, the sharing of HIV-contaminated needles and syringes, or during the perinatal period from mother to child (CDC, 2006n).

HIV/AIDS was recognized as an emerging disease 25 years ago, and it has rapidly established itself throughout the world, creating a global pandemic. It is now prevalent in virtually all parts of the world (CDC, 2005f). An estimated 39.5 million adults and children worldwide were living with HIV/AIDS in 2006, with 1 million of them in the United States (CDC, 2006n).

## Populations at Risk

AIDS was first recognized as a distinct syndrome in 1981. During the early years, it was seen as a disease of male homosexuals, intravenous drug abusers, and people with a history of multiple blood transfusions. The at-risk population for HIV/AIDS now includes people with a large number of sexual partners, adolescents, injection drug users and their sexual partners, homosexual men and their male or female partners, people who exchange sex for drugs or money, and people already infected with an STD (CDC, 2005f). Sexual transmission of HIV is closely associated with other STDs, particularly those that have an ulcerative phase, including syphilis. With belated but growing global awareness, the AIDS epidemic is recognized as a universal threat to the health and well-being of individuals and populations.

Adolescents and young adults are considered to be at particular risk for HIV infection because many of them engage in high-risk behaviors, believing they are invulnerable to infection. In addition to the considerable risks posed by potential HIV infection, other adverse outcomes related to early initiation of sexual activity include higher levels of all STDs (Quander, 2001).

## Prevention Education

National HIV prevention and intervention efforts depend on two important factors: self-perception of risk, and adoption of risk-reducing behaviors in response to awareness of the risk. Consequently, education about HIV/AIDS, including safe sex and injection drug use behaviors, has become the key to prevention. Public health workers seek to identify and intervene with the at-risk population, providing counseling and prevention education as well as testing services. The

primary purposes of counseling are to prevent further spread of HIV infection and, whenever possible, to slow the progression of HIV infection to AIDS. HIV counseling can help uninfected people initiate and sustain behaviors to reduce their risk of infection, help infected people adopt behaviors to reduce the risk of transmission to others, encourage spouses and partners of infected people to adopt safe behaviors, and help infected people take better care of themselves. Properly using condoms, reducing the number of sexual partners, and abstaining from injection drug use all decrease, but do not eliminate, the risk of HIV infection (CDC 2006j).

The role of a community health nurse may vary from state to state regarding surveillance, investigation, and contact notification. Only 33 states and territories have confidential name-based reporting systems, others have unique identifier reporting mechanisms. Both types of surveillance systems require physicians or medical practitioners to complete a reporting document with vital information regarding exposure risks, dates of testing, diagnosis, treatment, opportunistic illnesses, and patient identification (unique or named-based). From this information, the nurse may be able to facilitate ongoing community services, either through direct patient contact or the patient's medical provider. Partner notification is on a case-by-case basis, depending upon which system is in place in each state (CDC, 2006j).

## Sexually Transmitted Disease Prevention and Control

Human history has been shaped by disease, and all historical events played a part in creating the preconditions for epidemics. Of all the communicable diseases, perhaps none are as closely interrelated with human activities and attitudes as STDs. Many have occurred in epidemic proportions; most have existed for centuries.

Sexually transmitted diseases are those infections that are spread by transfer of organisms from person to person during sexual contact. Sexually transmitted diseases are of critical importance in any discussion of communicable disease control because, as a single class of disease, gonorrhea, CT, syphilis, HIV, and hepatitis B are among the top ten diseases reported for 2004 (most current national data) (CDC, 2006n). The STDs discussed in this section included gonorrhea, syphilis, chlamydia, genital herpes, and HPV (genital warts). AIDS, of course, is an STD, as is hepatitis B, although transmission of these diseases can also occur through intravenous drug use, transfusion of blood products before 1986, or needle-stick injury (CDC, 2006n).

Of further concern to community health nurses is the fact that women and children suffer an inordinate STD burden. Aside from the risk of AIDS and subsequent death, the most serious complications of STDs are PID, sterility, ectopic pregnancy, blindness, cancer associated with HPV, fetal and infant death, birth defects, and mental retardation. The medically underserved, particularly the poor and marginalized, as well as ethnic and racial minorities, shoulder a disproportionate share of this problem—experiencing higher rates of disability and death than the population as a whole. Some notable disproportionately affected groups are sex workers, adolescents and adults in detention, and migrant workers (USDHHS, 2000). However, STDs can affect teen and young women who do not plan on becoming sexually active. Sexual

violence and sexual coercion are significant problems for America's young women. Studies show that not all sexually experienced young females enter a sexual relationship as a willing partner (Hanson, 2002) and that sexual assault or date rape is not uncommon on high school and college campuses.

*Healthy People 2010* guidelines identify the availability and quality of public services for STD as key factors in reducing the spread of STDs and preventing complications (USDHHS, 2000). Effective health promotion approaches in the community must include STD prevention in the curricula of middle and secondary schools. Preventing the initiation of sexual activity early in life results in a decreased number of sexual partners over a person's lifetime, and education is needed to assist youth in cognitively establishing the behavioral link between sexual activity and STD exposure.

In addition to the need for more innovative and effective sexual health promotion approaches in school settings, a number of recommendations have been made for improvements in current delivery systems (USDHHS, 2000):

- ◆ The number of clinics offering STD screening, diagnosis, treatment, counseling, and referral services should increase substantially to improve access to comprehensive services.
- ◆ Increased allocation of resources must be directed to the quality-of-life issues that operate in young adults' lives and contribute to inappropriately early initiation of unprotected sexual activity.
- ◆ Improved collaboration is needed among health care providers, community health departments, and community health nurses in case management regarding medical treatment, follow-up strategies to confirm cure, and notification and treatment of sexual partners.

Changes in behavior require diverse and multidisciplinary interventions over an extended period. Such interventions must integrate the efforts of parents, families, schools, religious organizations, health departments, community agencies, and the media. The goals of educational programs should be to provide adolescents with the knowledge and skills they need to refrain from sexual intercourse, and to increase the use of condoms as well as other contraceptive measures among those unwilling to postpone onset of sexual activity. Parent-child conversations about sexual matters are associated with delays in the initiation of sexual activity and with increased use of contraceptives by adolescents who engage in sexual intercourse. Additional recommendations to promote sexual health in adolescent populations include: (a) innovations for early detection and treatment of STDs among teenagers, (b) specialized training for clinicians providing health services for adolescents, (c) school education combined with accessible clinical services, and (d) behavioral interventions to prevent exposure to and acquisition of STDs (CDC, 2006n; USDHHS, 2001).

## Influenza (Seasonal, Avian) and Pandemic Preparedness

Influenza (flu) is identified as an acute communicable viral disease of the respiratory tract characterized by fever, headache, myalgia, prostration, coryza, sore throat, and cough. Influenza A virus causes the most severe and widespread disease

(pandemics); influenza B causes milder disease outbreaks, and influenza C is connected with only sporadic cases of milder respiratory disease. Influenza is usually seasonal in nature, but may be found year round if testing is done. Seasonal flu preparedness is in the form of vaccine preparation, utilizing the previous year's flu strain information to calculate the next year's subtype through complex formulations done globally and nationally by public health authorities (CDC, 2006k; Kilbourne, 2006).

Influenza derives its importance from the rapidity with which epidemics evolve, the widespread morbidity, and the seriousness of complications, namely pneumonias (Heymann, 2004). Influenza, an Italian word that means *influence of the cold*, has been recognized since 412 BCE and was first described by Hippocrates. It existed throughout the early centuries, and about 30 possible pandemics have been documented in the past 400 years. Three have occurred in the 20th century—in 1918, 1957, and 1968. The 1918 “Spanish flu” pandemic was the most devastating, killing more than 20 million people worldwide from 1918 to 1920 (Kilbourne, 2006). This pandemic occurred because the new virus was easily transmitted from person to person, and the general population had not been previously exposed to this subtype of influenza.

Influenza infections occur primarily in the winter months, affecting individuals in all age groups and causing approximately 20,000 deaths and 110,000 hospitalizations annually in the United States (CDC, 2006k; Prisco, 2002). Children have the highest rates of infection, but individuals age 65 years and older and those with medical conditions who are at risk for complications have the highest rates of serious morbidity and mortality. Older adults account for more than 90% of the deaths attributed to influenza and pneumonia (CDC, 2006k; Prisco, 2002).

Influenza immunization is available every flu season; vaccines are closely matched to the circulating strains of the virus. Children younger than 2 years of age are at substantially increased risk for influenza-related hospitalizations. The key CDC (2006k) recommendations include providing vaccine to:

- ◆ Children 6 months to 59 months
- ◆ Women who will give birth or be pregnant during the influenza season
- ◆ Persons 50 years old or older
- ◆ Children and adolescents (aged 6 months–18 years) who are receiving long-term aspirin therapy and, therefore might be at risk for Reye syndrome after influenza infection
- ◆ Adults and children with medical conditions that put them at risk for poor outcomes if influenza is contracted
- ◆ Adults or children with any respiratory condition that would be compromised further by influenza infection
- ◆ Nursing home or other long-term care facility residents with chronic health conditions
- ◆ Health care workers

The injectable influenza vaccine is inactivated. The nasally inhaled version is a live attenuated vaccine (CDC, 2006k). In the elderly, immunization may be less effective in preventing illness, but may reduce the severity of disease. With vaccination, the incidence of complications among the elderly is reduced by 50% to 60%, and death by approxi-

mately 80% (Heymann, 2004). The vaccine should be given every year *before* influenza is expected in the community (i.e., November to March in the United States). For those living or traveling outside the United States, timing of the immunization should be based on the seasonal patterns of influenza in the area to which they are traveling (CDC, 2005e).

Community health nurses play a major role in primary prevention. Influenza vaccination clinics are frequently planned and organized by or with the local public health agency, with the injections usually administered by community health nurses. Health departments typically schedule vaccination clinics in line with the state recommendations and provide these services with minimal monetary charge to the at-risk community members. Private entities, such as pharmacies or home care agencies, often choose to provide vaccine for profit at venues around the community. Private physicians and HMOs provide immunization for their patients or members. The community influenza clinic is a primary prevention activity often occurring during the fall of each year (CDC, 2006k).

In 1997, a new influenza virus called A(H5N1) was identified in chickens in Hong Kong. This virus produces a strain of avian influenza, which is common in wild birds and domestic poultry. Although the Hong Kong avian strain caused numbers of human cases of avian flu, the transmission was from direct exposure to infected poultry, not through human-to-human transmission (Kilbourne, 2006). Infected poultry were exterminated before the avian flu could mutate into a human-to-human subtype. In 2003, this strain of avian flu reemerged worldwide, in both domestic chicken flocks and wild fowl, spread by bird-to-bird transmission following bird migration patterns (WHO, 2007). Although human illness has been documented, it has not occurred through person-to-person contact. It is feared, however, that a mutation could change the mode of transmission, and this situation is being closely watched worldwide.

Sources of influenza virus include swine, birds, and poultry, and many types of flu can pass from animals to humans. Influenza virus mutate readily; it is possible that the A (H5N1) subtype could mutate to jump species from bird to swine and then to man, considering that many types of swine flu are readily passed to humans (Kilbourne, 2006).

Pandemics occur when a flu subtype has not circulated previously (new strain) or has reemerged in a population that has never been exposed (Kilbourne, 2006). If the A (H5N1) subtype mutates, for example, it could then be available for human-to-human infection and thus spark a possible pandemic (Kilbourne, 2006).

The WHO Network for Global Influenza Surveillance, which involves 116 national influenza centers worldwide, maintains constant vigilance for new influenza viruses. FluNet is an Internet-based tool for worldwide influenza surveillance. This program allows for the electronic submission of influenza data from participating global laboratories. Only designated users can submit data, but the results—graphics, maps, and tables of influenza activity on a global scale—are available to the general public. As new data arrive and are verified, the maps and tables are revised to give users an up-to-date overview of the influenza situation. FluNet has expedited the sharing of information on influenza patterns and virus strains, and is becoming an

essential tool in preparing for and preventing influenza pandemics. Collaborating Influenza Surveillance Centers have created a task force of influenza experts to develop a plan for the global management and control of such a pandemic, and world public health leaders work diligently to prevent another influenza pandemic similar to the devastating outbreak of 1918 (WHO, 2006b). It is unknown when or where the next flu epidemic or pandemic will occur, but the CDC has charged the individual states with the duty to develop statewide plans that can be used by individual counties as templates for countywide preparedness (Kilbourne, 2006).

## Pneumonia

Pneumonia is a pulmonary infection that causes inflammation of the lobes of the lungs, bronchial tree, or interstitial space. The causative organism can be viral (50% of all cases), bacterial, or fungal (Schultz, 2002). Symptoms of pneumonia include sudden onset with a shaking chill, fever, pleural pain, dyspnea, a productive cough of “rusty” sputum, and tachypnea. The onset is less abrupt in elderly individuals, and the diagnosis may need to be confirmed by radiographic studies. In infants and young children, fever, vomiting, and convulsions may be the initial symptoms.

Community-acquired pneumonia is a significant cause of morbidity and mortality. It is the sixth leading cause of death and the first leading cause of infectious death in the United States. An increased incidence of pneumonia often accompanies epidemics of influenza. An estimated 3 million cases occur yearly, with approximately 20% requiring hospital admission, and 50,000 deaths occurring yearly from bacterial pneumonia (Schultz, 2002). Hospital admissions and mortality related to pneumonia are far more common among people older than age 65; the mortality rate is approximately 50%. This is not a reportable infectious disease, but, nevertheless, it can have a great impact upon the community (Heymann, 2004).

The incidence of pneumonia is highest in winter. Pneumonia is spread by droplets, by direct oral contact, and through **fomites**, which are any inanimate objects freshly soiled with respiratory discharges. People most susceptible to pneumonia are the elderly and people with a history of chronic diseases, a compromised immune system, or any condition affecting the anatomic or physiologic integrity of the lower respiratory tract.

Primary prevention is the best course of action, and includes a pneumococcal vaccine, especially for the high-risk groups, ages 2 years old and up. High-risk groups include those with chronic diseases, immune-suppressing health conditions, or those who are asplenic. Reimmunization is recommended only for high-risk children, or adults over 65 years who had their first vaccination before age 65. The vaccine is not effective in children younger than 2 years of age and is not recommended for the healthy population between the ages of 2 and 65 years. For these people, education about preventing pneumonia is a major part of the community health nurse’s role (CDC, 2007a).

Secondary prevention includes the early diagnosis and prompt treatment of affected individuals. Antimicrobial agents such as penicillin and erythromycin are the drugs of first choice for treating pneumonia.

## Tuberculosis

Tuberculosis is a disease primarily of the lungs and larynx, caused by the mycobacterium tuberculosis complex, *M. africanum*, *M. tuberculosis*, and *M. canettii*, all gram-positive bacilli. Tuberculosis can also infect other parts of the body, when it is referred to as *extrapulmonary TB* (outside of the lungs). Tuberculosis has two stages: latent infection, which is noninfectious to others, and active disease, which is highly infectious to others. Tuberculosis is airborne, and is spread by droplet nuclei, sprayed from the mouth by coughing, sneezing, laughing, yelling, singing, or any way in which air is expelled vigorously from the lungs through the mouth. Infection occurs after inhaling the bacilli exhaled by the person with active TB. The incubation time for TB is approximately 10 to 12 weeks. The Mantoux TB skin test is the acceptable screening test for this infection. A positive test result depends upon the situation and the state in which the test is performed (Heymann, 2004).

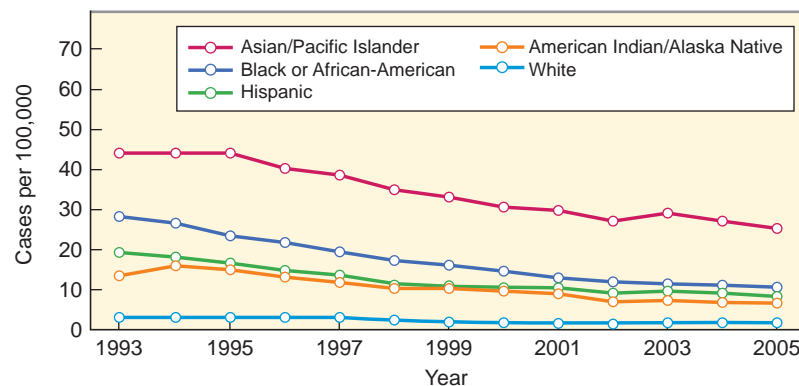

Exposure to TB does not lead to actual disease in all cases. A long latent period may persist for many years (even for a lifetime) before the infected person develops disease and becomes infectious. The probability of becoming infected depends primarily on the amount of exposure to air contaminated with *M. tuberculosis*, the proximity to the infectious person, and the degree of ventilation. Most individuals exposed to people with TB do not become infected. Of those who do, all but about 5% to 10% will remain disease free, perhaps for a lifetime. The remaining 90% harbor the organism; although they are not infectious, they represent a persistent pool of potential cases in a population. The likelihood of being among the 10% who develop clinical infectious disease is variable, depending on the initial dose of infection and certain other risk factors. Groups at increased risk include children younger than 3 years of age, adolescents, young adults, the aged, and the immunosuppressed (CDC, 2006l; Heymann, 2004).

Once almost eradicated, TB has reemerged as a serious public health problem. In 2005, the CDC reported that the number of cases had decreased by 44%. Between 1993 and 2003, there was a decrease in active TB cases from 25,108 to 14,840. As of 2005, the total number of active TB cases was listed as 14,097 (CDC, 2005c). Although this is good news, there is evidence of sharply disparate rates among minority populations—the number of active TB cases among African Americans was 3,954 (28%), Hispanic Americans had 4,043 cases (29%), and Asian Americans reported 3,209 cases (CDC, 2006i) (see Fig. 8.5). In addition, the worldwide TB situation has worsened over the past two decades, especially in Africa because of the HIV/AIDS epidemic (a fatal association exists between TB and HIV/AIDS). The rate of TB among children is increasing, and there has been a proliferation of MDR strains, especially in Eastern Europe, where the deterioration of the health infrastructure presents a significant threat not only to clients but also to their caregivers (Borgdorff et al., 2002).

## Incidence and Prevalence

Roughly one-third of the world’s population is infected with *M. tuberculosis*. These 2 billion people have the potential for developing active TB at some point in time. Each year,

**FIGURE 8.5** Tuberculosis case rates by race/ethnicity.

\*All races are non-Hispanic. In 2003, Asian/Pacific Islander category includes persons who reported race as Asian only and/or Native Hawaiian or Other Pacific Islander only.

\*\*Updated as of April 6, 2007, CDC.

8 million people worldwide develop active TB, and 1.8 million people die from it. Approximately 80% of TB cases are found in 23 countries; the highest incidence rates are in Africa and Southeast Asia (Borgdorff et al., 2002). In the United States, 10 to 15 million people are infected with *M. tuberculosis* without displaying symptoms (latent TB), and about 1 in 10 of these individuals will develop active TB at some time in their lives. This makes TB the leading infectious killer of adults, despite the fact that effective anti-TB treatment has existed since the 1940s. Tuberculosis is also a leading cause of death among people infected with HIV (Heymann, 2004; “WHO Reviews,” 2002).

### Surveillance

In the past, TB was called *consumption*, *wasting disease*, and the *white plague*. This disease has been one of the greatest scourges since times before recorded history. It was the leading cause of death in the United States through the 1930s because no cure was available. A diagnosis of TB was a slow death sentence, and the best chance of recovery was rest, sunshine, and plenty of food. Consequently, sanatoriums—rest homes where patients followed a prescribed routine every day—were built and were occupied for months until the patient recovered or died.

**Surveillance** of a disease refers to the continuous scrutiny of all aspects of occurrence and spread of the disease that are pertinent to effective control (Heymann, 2004). In 1953, when uniform national surveillance for TB was initiated, there were more than 84,000 TB cases in the United States. With the introduction of effective antibiotics in the 1940s to 1960s, there was a 73% decline in the number of TB cases, and it was thought that the problem of TB had been solved. From 1953 through 1984, the number of TB cases decreased by an average of 6% each year, and in 1985 they reached an all-time low of 22,201. The decrease in the number of TB cases contributed to medical and political complacency that resulted in a lack of progress in the development of new approaches and tools to control TB, and the disease is now resurging (Cowie, Field, & Enarson, 2002). In fact, TB dramatically increased in developing countries, prompting the WHO in 1993 to declare TB a “global emergency” at a time when many Western countries were anticipating the impending elimination of the disease (WHO, 2003a).

### Populations at Risk

Minority populations tend to be at greater risk for TB. An increasing percentage of U.S. TB cases are occurring among people who were born in Asian, African, or Latin American countries, where TB rates are five to 30 times higher than in the United States. In the 1990s, TB cases among U.S.-born individuals declined 38%, whereas the number of TB cases among foreign-born persons in the United States increased by 6%. The TB case rate for foreign-born individuals has remained at least four to five times higher than for the U.S.-born, and the proportion of U.S. cases occurring in foreign-born persons has increased steadily since the mid-1980s, reaching 46% in 2000 (Saraiya et al., 2002). Tuberculosis disease cases occur predominantly among the following groups: foreign-born persons (46%), the elderly (23%), homeless people (5%), and individuals infected with HIV (8%). Higher incidences of TB are found among low-income people, persons with alcohol or drug abuse problems, the underserved, the malnourished, people in correctional facilities, people with other medical conditions, and individuals working where people at risk for TB are grouped together (e.g., homeless shelters, drug treatment centers, health care facilities). Tuberculosis rates are highest among refugees and immigrants, and noncompliance with treatment in all groups is a major factor in continued transmission of the disease, as well as in development of MDR organisms.

HIV infection is the strongest known risk factor for the development of TB. Immune-suppressed individuals, such as those with AIDS, can develop fulminant active TB within weeks after exposure to the mycobacterium, and the disease progresses much faster than in those with a normal, competent immune system. Consequently, a suspected case of TB in a person with AIDS is usually treated immediately, without waiting for the results of sputum tests or chest radiography.

During the last 20 years, the incidence of HIV infection has shifted from a predominantly homosexual, White, middle-class male population to a more impoverished, heterosexual, inner-city minority population with a high prevalence of *M. tuberculosis* infection. Consequently, the incidence of HIV-related TB mortality has risen. The risk of HIV-infected clients for TB infection is further complicated by the possible false-negative reactions of the tuberculin skin test resulting from the client’s impaired immunity (Desvarieux, Hyppolite, Johnson, & Pape, 2001).

Increasing numbers of TB cases among children are especially worrisome because they point to escalated transmission in the United States. Cases in children most often result from recent infection, in contrast to cases among older adults, which may develop as a result of infection occurring many years previously. Tuberculosis among children suggests rising case rates among persons of reproductive age who have contact with and transmit infection to susceptible children. This underscores the need to investigate the child's household and community contacts for untreated disease. Likewise, when adult active TB cases are identified, it is essential to evaluate child contacts of the infected person (CDC, 2005c).

Among children with active TB, minority groups account for a vast majority of the cases. Girls have a much higher incidence during elementary and high school years than do boys of the same age. Susceptibility in children and adolescents peaks during infancy and again in puberty. Infants show decreased ability to localize infection and have limited stores of acquired antibodies. The occurrence of TB infection and disease in children provides important information about its spread in homes and communities. For example, if a child has TB infection or disease, it must have been transmitted relatively recently; therefore, the person who transmitted the TB may still be infectious. Other adults and children in the household or community have probably been exposed, and, if infected, others may develop TB disease in the future (CDC, 2005c).

### Prevention and Intervention

Tuberculin testing, the standard method for evaluating TB infection, is a simple skin test that measures—by visible reaction—whether the body has had immunologic experience with *M. tuberculosis* (Table 8.5). From there, evaluation procedures determine the classification status of the

disease, ranging from 0 to 5. The two most used terms are *infected without current disease* (classification 2) and *with current TB disease* (classification 3) (Table 8.6). The skin test itself is not diagnostic of disease. The Mantoux test delivers 0.1 mL of PPD (purified protein derivative) by intradermal injection. Because the dose is measured at the time of injection, the Mantoux test is considered to be more reliable than other methods, like the TB Tine test (CDC, 2005c). Interpretation of the tuberculin test is critical to subsequent evaluation of the client's status. The interpretation of this screening method must be as sensitive as possible while maintaining specificity for exposure.

The community health nurse may encounter an individual who, at the time of the TB skin test, discloses having had the bacillus Calmette-Guerin vaccine (BCG) in her home country. The BCG vaccine is an attenuated strain of *M. bovis* (bovine strain), which is not used in the United States. The efficacy of the BCG vaccine is questionable, as the protective value wanes over time and there is no consistency in how the vaccine is made. Because of these shortcomings, BCG is recommended in the United States *only* for infants and children with negative skin tests who (a) are at high risk for intimate and prolonged exposure to persistently untreated or ineffectively treated people with infectious pulmonary TB and cannot be removed from the source of exposure or placed on long-term preventive therapy, or (b) are continuously exposed to persons with TB who have bacilli resistant to both isoniazid and rifampin.

Successful interventions require TB control programs to focus resources on high-risk people, including contacts of people recently diagnosed as having TB disease. Also targeted for prevention efforts are members of racial and ethnic minorities and people born in countries where TB prevalence is high. People with TB infection who have conditions placing them at increased risk for active TB (e.g., HIV infection) also require special attention.

TABLE 8.5 Classification of the Tuberculin Skin Test Reaction

 5 or more millimeters	 10 or more millimeters	 15 or more millimeters
An induration of <b>5 or more millimeters</b> is considered positive in <ul style="list-style-type: none"> <li>• HIV-infected persons</li> <li>• A recent contact of a person with TB disease</li> <li>• Persons with fibrotic changes on chest radiograph consistent with prior TB</li> <li>• Patients with organ transplants</li> <li>• Persons who are immunosuppressed for other reasons (e.g., taking the equivalent of &gt;15 mg/day of prednisone for 1 month or longer, taking TNF-alpha antagonists)</li> </ul>	An induration of <b>10 or more millimeters</b> is considered positive in <ul style="list-style-type: none"> <li>• Recent immigrants (&lt;5 years) from high-prevalence countries</li> <li>• Injection drug users</li> <li>• Residents and employees of high-risk congregate settings</li> <li>• Mycobacteriology laboratory personnel</li> <li>• Persons with clinical conditions that place them at high risk</li> <li>• Children &lt;4 years of age</li> <li>• Infants, children, and adolescents exposed to adults in high-risk categories</li> </ul>	An induration of <b>15 or more millimeters</b> is considered positive in any person, including persons with no known risk factors for TB. However, targeted skin testing programs should only be conducted among high-risk groups

**TABLE 8.6 Classification System for Tuberculosis (TB)**

Class	Type	Description
0	No TB exposure	Not infected: no history of exposure, negative reaction to tuberculin skin test (TST) or negative in vitro laboratory diagnostic tests.
1	TB exposure	No evidence of infection: history of exposure and negative reaction to TST or negative in vitro LTBI laboratory diagnostic tests.
2	Latent TB infection, no disease	Positive TST or positive in vitro LTBI laboratory diagnostic tests, negative bacteriologic studies (if done) and no clinical and/or radiographic evidence of active TB. Patients with isolated calcified granulomas (calcified solitary pulmonary nodules), calcified hilar lymph nodes, or pleural thickening are generally classified as TB 2.
3	TB, clinically active	Laboratory, clinical, bacteriologic, and/or radiographic evidence of current disease.
4	Tuberculosis, not clinically active	History of previous episode(s) of TB,  <b>or</b> Abnormal stable radiographic findings in a person with positive reaction to TST ( $\geq 5$ mm) or positive in vitro LTBI laboratory diagnostic tests and negative bacteriologic studies (if done) and no clinical and/or radiographic evidence of current disease.
5	TB suspect	Diagnosis pending. Diagnosis of TB being considered, whether or not treatment has been started, pending completion of diagnostic procedures. Persons should not be in this class more than 3 months. When diagnostic procedures have been completed, the person should be placed in one of the preceding classes.

From Centers for Disease Control & Prevention (CDC). (2002). *Core curriculum on tuberculosis. Chapter 2*. Retrieved August 13, 2008 from [http://www.cdc.gov/TB/pubs/corecurr/Chapter\\_2/Chapter\\_2\\_Classification\\_System.htm](http://www.cdc.gov/TB/pubs/corecurr/Chapter_2/Chapter_2_Classification_System.htm)

According to the CDC Division of TB Elimination (DTBE) (2005c), a well-functioning TB control program is the best way to prevent TB and the emergence of drug resistance to TB. This program should ideally strive for:

- ◆ Standardized public health practices
- ◆ Prompt sputum conversion in people with active disease
- ◆ Identification of contacts of people with active TB to identify and treat other cases and people recently exposed
- ◆ A high completion-of-therapy rate within 1 year after diagnosis
- ◆ Assurance of adequate funding and a dedicated TB control infrastructure

One of the most effective ways to achieve a high completion-of-therapy rate is through directly observed treatment (DOT). In endemic countries, such as Africa, directly observed treatment short-course (DOTS) is used. This strategy assures treatment success because the client takes the medication in the presence of a health care worker. The American Thoracic Society and the CDC propose treating all patients with DOT because it reduces the sources of infection in the community (Jasmer et al., 2004; Potter, Rindfleish, & Kraus, 2005).

This labor-intensive approach has proved effective for the most difficult of TB cases in the United States. The more difficult clients are those who do not realize their personal or social responsibility for health and those who do not have the resources to focus on health when there are other stressors or diversions in their life. For these reasons,

clients such as alcohol and drug abusers, transient homeless people, and low-income people may become the source for new cases of TB. DOT therapy ensures that clients take a daily or intermittent dose of prescribed medication, locating them wherever they may be—in neighborhood bars, sleeping on the sidewalk, in a homeless shelter, or in a drug rehabilitation center. Most health departments and TB control programs have a percentage of their clients receiving DOT therapy, with licensed staff or community health workers assigned to administer the TB drug regimen. These ancillary staff members are often former program participants, trained and supervised by professional health workers (Jasmer et al., 2004; Potter et al., 2005). A program like DOTS needs sustained political commitment, with the governments of nations recognizing the long-term benefits of providing the resources and staff necessary to ensure its proper implementation.

Commitment and flexibility on the part of health care providers and services can substantially enhance medication compliance. Significant improvement in compliance has been demonstrated with programs designed to provide DOT therapy for all clients, using community-based health workers who meet with clients in residences, at job sites, and at other local venues. In addition, new variations on the standard treatment regimens are being researched. Approaches include allowing individuals to take larger medication doses on a twice-weekly schedule, or providing an observed medication program for a limited period, followed by a course of self-administered medication with periodic reevaluation by health care providers (CDC, 2006p).

## Multidrug-resistant Tuberculosis

Epidemiologists and communicable disease specialists cite a number of factors that contribute to the development and spread of TB strains resistant to one or more of the standard arsenal of TB drugs. Strains now exist that are resistant to as many as nine of 11 standard anti-TB drugs. In South Africa, an area that has been hard-hit with HIV/AIDS and TB, officials are now combating extremely drug-resistant tuberculosis (XDR-TB) that has killed close to 200 people in a few months, most of them with HIV (WHO, 2006e). Chief among the factors contributing to drug resistance seems to be the political and social response to declining rates of TB over past decades, which has resulted in funding cuts for surveillance, treatment, and research, and a premature sense that TB was defeated. On an individual case basis, the most common means by which resistant organisms are acquired is by noncompliance with therapy for the full, recommended period. Public health departments with limited resources have been unable to provide the intensive follow-up necessary to ensure that people who essentially feel well continue taking their medication (which may produce unpleasant although usually mild and manageable side effects) for the length of time considered necessary to achieve cure. Public health officials face a challenge and need to network effectively to provide continuous case management for highly mobile and often disenfranchised infected minority populations (Jasmer et al., 2004; Potter et al., 2005).

When candidates for drug therapy are identified, it is essential to provide program support to ensure that the maximum number of individuals comply with their medication regimen for the full duration of therapy. Isoniazid therapy for individuals who are infected with TB but have no evidence of active disease has been shown to be highly effective in preventing progression to infectiousness and clinical symptoms. Isoniazid is also a key component of the treatment for active disease (CDC, 2005c).

## Clients with HIV and Tuberculosis

HIV infection is associated with an increased possibility of developing primary TB after exposure to a source. Someone with latent TB infection and HIV infection is up to 800 times more likely to develop active TB disease during her lifetime than someone without HIV (AVERT, 2007). The connection between TB and HIV/AIDS is dramatic, with one-third of the incidence of TB in the last 5 years attributed to HIV. In the United States, it is estimated that 26% of adult TB cases are attributable to HIV infection (CDC, 2005c).

People with HIV infection should be given high priority for preventive therapy, regardless of their age. For HIV-infected people, preventive therapy consists of isoniazid daily for up to 1 year (the usual regimen for preventive therapy is 6 months). These clients must be monitored closely for effectiveness of the preventive therapy and for tolerance to isoniazid. This drug has the capacity to develop adverse reactions or negative side effects. Isoniazid can cause hepatitis or damage the liver; close monitoring and regular follow-up are necessary to detect early symptoms such as nausea, vomiting, abdominal pain, fatigue, and dark urine signifying bleeding. Any combination of these symptoms is sufficient to initiate liver function tests (Springhouse, 2006).

As mentioned earlier, HIV-positive clients may not have the ability to react to a skin test for TB because of a weakened immune system. Therefore, other methods to determine TB status are employed. If it is determined that TB disease is present, HIV-infected clients should begin a regimen of drugs according to the schedule used by their physicians or clinics. The clients should be closely monitored for response to treatment; if they do not seem to be responding, they should be reevaluated.

Community health nurses have a responsibility to help HIV-infected clients experience a successful TB treatment regimen. Caregiving includes observing for adherence to treatment, administering medications (either directly through DOT or through DOT supervision by ancillary staff), observing for signs and symptoms of adverse reactions, monitoring for overall health and well-being, educating, and making referrals as needed.

## Infectious Diseases of Bioterrorism

Information about anthrax and smallpox is presented here because of the threat that these diseases present to the community as weapons of terrorism (see Chapter 17 regarding disasters and terrorism). Because community health nurses work in the community, they are in a position of responsibility to allay fears, provide correct information, and to help people in the decision-making process regarding immunization in regard to possible terrorist attacks. Although other disease-causing organisms may be weaponizable, anthrax and smallpox have a history of use as terrorist weapons and will be discussed here (Secor-Turner & O'Boyle, 2006).

### Anthrax

Shortly after the terrorist attacks of September 11, 2001, the U.S. population was further terrorized by anthrax. Several people who handled or delivered mail inhaled and touched anthrax spores concealed in envelopes. Many acquired anthrax, and deaths were reported. The pervasiveness of the fear this act created was felt nationwide. No person or country has yet claimed responsibility, or has been accused with spreading the causative organism.

In nature, anthrax is primarily a disease of herbivores, with humans and carnivores as incidental hosts. There are infrequent and sporadic human infections in most industrialized countries. It is an occupational hazard among workers who process animal hides, hair, bone and bone products, and wool in some countries. In fact, it has been called *wool sorter disease* and *ragpicker disease* (Heymann, 2004).

In humans, anthrax is an acute bacterial disease that affects mainly the skin or respiratory tract. The two main forms—cutaneous anthrax and inhalation anthrax—account for most human anthrax cases. The case-fatality rate for cutaneous anthrax is 5% to 20%. Skin becomes itchy where exposed, a lesion becomes papular and then vesicular, and in 2 to 6 days a depressed black eschar, surrounded by extensive edema, develops. The infection may spread to the lymph system and cause septicemia. With inhalation anthrax, the initial symptoms are mild and non-specific but progress to respiratory distress. Fever and shock follow in 3 to 5 days, and death is the expected outcome (Heymann, 2004).

The causative organism, *Bacillus anthracis* is a gram-positive, encapsulated, spore-forming agent found in livestock and wildlife as the main reservoirs. The incubation period is short (hours to 1 week), and most cases occur within 48 hours after exposure. Transmission from person to person is rare, but articles and soil contaminated with spores may remain infective for decades (Heymann, 2004).

An anthrax vaccine exists, and all lots of this vaccine are owned by the Department of Defense. Troublesome side effects (fatigue, muscle or joint pains, and mental impairment) are experienced by 5% to 35% of recipients, and six doses are required over an 18-month period in addition to yearly booster doses. The vaccine was approved in 1970 for the treatment of cutaneous anthrax and has been administered primarily to members of the armed forces. However, it is not licensed for use with aerosol exposure, the form of anthrax that would be faced in a terrorist attack. Vaccination for anthrax remains voluntary (Nass, 2002).

### Smallpox

Smallpox is a disease from our history books. In fact, the last case of smallpox was reported in 1978, and in 1980 WHO declared the disease eliminated worldwide. However, as recently as 1966, the disease was widespread in 31 countries. Some 10 to 15 million people were contracting smallpox annually, 2 million people died each year, and millions more were permanently disfigured or blinded (Sibley, 2002). By the late 1970s, just over one decade later, the global eradication campaign had pushed smallpox to the brink of extinction. The last known naturally occurring case of smallpox was in Somalia in 1977. Officially, the smallpox virus presently exists at only two places: the CDC in Atlanta and the State Research Centre of Virology and Biotechnology, Koltsovo, Novosibirsk Region, Russian Federation (Heymann, 2004; Sibley, 2002).

In the United States, routine vaccination against smallpox ended in 1972, and the smallpox vaccine has not been available for general distribution since May 1983. Few health care practitioners today have seen cases of smallpox or have administered the vaccine. In 2002, community health nurses in some communities became involved in the primary prevention of smallpox and learned the intricate techniques of smallpox vaccination and treatment of vaccine side effects in preparation for immunization of large portions of the population. That year, voluntary smallpox vaccinations were resumed for the first time in three decades (Spake, 2002). Initially, key military units were inoculated, beginning in 2002, followed by “first responders” such as emergency health care providers and health department personnel. The general public is not currently targeted for immunization (Veenema & Toke, 2006).

The plan for smallpox preparedness utilized the previously successful **ring vaccination** strategy—containing an outbreak by rapidly isolating and vaccinating people who have had close, face-to-face contact with the victim. This method refers to concentric rings, with those in the center ring being closest to the victim. Nonetheless, it is not clear whether any groups other than the United States and Russia possess the virus; furthermore, the rate of transmission of smallpox is complex and is contingent on many social and biological factors. “Therefore, it’s difficult both to determine how real the threat is and to calculate a meaningful

risk–benefit ratio in regard to compulsory mass vaccination” (Veenema, 2002, p. 35). However, one bright spot with smallpox prevention is that people who come in contact with a victim can receive protection if they are vaccinated within up to 7 days after exposure. This is unlike other VPDs and provides a window of time to reach exposed people (California Department of Health Services [CDHS], 2003).

Smallpox vaccination has risks. It is not a benign vaccine, and some experts allege that the morbidity associated with the vaccine has been understated (Veenema, 2002). One to 2 deaths per 1 million recipients of the vaccine can be expected, in addition to hundreds of cases of generalized vaccinia, eczema vaccinatum, and postvaccinal encephalitis (Heymann, 2004). Less severe but more common side effects include the formation of satellite lesions, regional lymphadenopathy, fever, headache, nausea, muscle aches, fatigue, and chills. In addition, the vaccine is contraindicated for the immunosuppressed, those with eczema, pregnant women, and infants younger than 1 year (Bicknell, 2002).

The variola virus causes smallpox and is transmitted from person to person. Initial infection begins with a febrile prodromal period that occurs 1 to 4 days before the onset of the rash. Fever is 101°F or higher, and victims experience at least one of the following: prostration, headache, backache, chills, vomiting, and severe abdominal pain. These physical symptoms are followed by the classic smallpox lesions—characterized as deep-seated, firm/hard, round, well-circumscribed vesicles or pustules. The lesions are in the same stage of development, anywhere on the body. Practitioners must prepare to recognize and differentiate smallpox from other diseases. The smallpox lesion can be confused with other conditions, such as varicella (chicken pox), disseminated herpes zoster, impetigo, drug eruptions, contact dermatitis, scabies, or disseminated HSV. Accurate diagnosis depends on the practitioner’s skill to clearly recognize the classic smallpox lesion, identify that the lesions are in the same stage of development, and get an accurate history of prodromal symptoms (Heymann, 2004).

Community health nurses must raise their awareness and bioterrorism preparedness. As advocates for clients, families, groups, aggregates, and populations, community health nurses can do the following (Veenema, 2002):

- ◆ Become knowledgeable about the infectious agents that pose the most significant threats of being used in cases of bioterrorism (e.g., anthrax, botulism, plague, smallpox).
- ◆ Implement educational programs designed to inform the public of the potential consequences of the smallpox vaccine and of mass vaccination.
- ◆ Stay current on evolving vaccination policies, evaluating their potential impact on community health.
- ◆ Get involved in the national smallpox vaccination policy debate.
- ◆ Participate in designing bioterrorism disaster response plans within your professional organizations and at the state and local level; anticipate the challenges associated with the plans.
- ◆ Assist your facility in preparing for the responsibilities it would assume in the event of a change in national policy mandating universal smallpox vaccination.

- ◆ Be ready to participate in the design and implementation of large-scale immunization programs.
- ◆ Explore and educate yourself about voluntarily taking the vaccine if you work in a high-risk (first-response) clinical practice, such as an outpatient clinic or health department.

## GLOBAL ISSUES IN COMMUNICABLE DISEASE CONTROL

Our planet has many common concerns, and communicable disease control is one of them. A new issue is the increasing number of emerging communicable diseases occurring globally. New diseases bring new challenges in case investigations, surveillance, and control. To conquer these challenges, community health nurses are assisted by the steps of the nursing process.

### Globally Emerging Communicable Diseases

Emerging diseases are those that either have newly appeared or are rapidly increasing in incidence or geographic range. Most emerging diseases are not caused by genuinely new pathogens; rather, ecologic, environmental, and demographic factors place nonimmune people in increased contact with a pathogen or its host, or promote the pathogen's dissemination. As mentioned earlier in this chapter, the current volume, speed, and reach of international travel make the emergence of communicable diseases truly a global problem. The following is a brief profile of some old and new emerging infectious diseases. (See Chapter 16 for more on global health issues.)

*Ebola hemorrhagic fever*, a severe acute viral illness with sudden onset of fever, malaise, myalgia, headache, pharyngitis, vomiting, diarrhea, and a maculopapular rash, has been confined to countries in tropical Africa. It was first identified in 1976, in the Democratic Republic of the Congo, where the case-fatality rate has ranged from 50% to 90%. Person-to-person transmission occurs by direct contact with infected blood, secretions, organs, or semen. People of all ages are susceptible (Heymann, 2004).

*Legionnaires' disease* (legionellosis) is a form of a potentially fatal pneumonia caused by bacteria that contaminate the water in air-conditioning systems, faucets, and humidifiers. It was first identified at a convention of members of the American Legion, held in Philadelphia, Pennsylvania, in 1976. It is characterized by anorexia, malaise, myalgia, and headache; within 1 day, there is a rapidly rising fever associated with chills, a nonproductive cough, abdominal pain, and diarrhea. The case-fatality rate has been as high as 39% in hospitalized clients and higher among those with compromised immune systems. The disease occurs more frequently with increasing age, with most patients being older than 50 years of age (Heymann, 2004).

*Hantavirus* is an old virus with a newly recognized clinical illness. It first occurred in Manchuria before World War II. In 1951, it was recognized in Korea. It is considered a major, expanding public health problem in China, with 40,000 to 100,000 cases reported annually. It was first seen in the United States in 1993, in the area where Utah, Colorado, New Mexico, and Arizona meet; 28 people died from hantavirus infection. The severe form of the disease is endemic

in Eurasia and Scandinavia. Deer mice appear to be the reservoir, and transmission is by way of aerosolization of infected droppings. It is an acute viral disease characterized by abrupt onset of fever, low back pain, varying degrees of hemorrhagic manifestations, renal involvement, hypotension, and shock. Prevention is focused on rodent control, and surveillance for the infection in wild rodents (Heymann, 2004).

*E. coli O157:H7* was first identified as a pathogen in the United States in 1982. An outbreak of severe bloody diarrhea was traced to contaminated hamburgers. In January 1993, a large outbreak caused by this *E. coli* strain affected 700 people who ate undercooked hamburgers in the Puget Sound area of Washington. Other outbreaks have been caused by unpasteurized milk and by apple cider made from apples contaminated by cow manure. More recent outbreaks have included fresh spinach grown in California. Children younger than 5 years of age are most susceptible and are at greatest risk of developing hemolytic-uremic syndrome as a complication.

*E. coli* infections are recognized to be an important problem in Europe, South Africa, Japan, South America, and Australia. Humans may serve as a reservoir for person-to-person transmission. Primary prevention can be accomplished by following federal guidelines, which require commercially prepared meat to be cooked to an internal temperature of 140°F, and by safe and hygienic cooking practices at home. Raw meats should be kept separated from fruits, vegetables, and cooked meats during preparation; separate cutting boards should be used, and they should be cleaned with soap and hot water and rinsed using a bleach solution (Heymann, 2004).

*Lyme disease* was first discovered in the United States in the 1970s when an unusually high incidence of children developed rheumatoid arthritis in Lyme, Connecticut. It is an infection caused by a spirochete called *Borrelia burgdorferi* and is characterized by a distinctive skin lesion, systemic symptoms, and neurologic, rheumatologic, and cardiac involvement occurring over a period of months to years. A bite from a tick that can be carried by dogs and cats passes the disease to humans. All 48 contiguous states have reported cases, but it is most prevalent in the Northeast. It is the most common tick-borne disorder in the United States. Lyme disease is treatable and is not communicable from person to person. Primary prevention includes educating the public about the mode of transmission and being aware of high-risk areas. In wooded, brushy, and tall-grass areas, people should walk in the middle of trails, wear a long-sleeved shirt, wear a hat, spray tick repellent on clothes and shoes, and wear long pants tucked into high socks. They should check for ticks after an outing. Light-colored clothing makes it easier to see ticks. If a tick is found, it should be removed with forceps (tweezers), trying not to crush the tick's body, and pulling it straight out of the tissue it adheres to (Heymann, 2004).

*Dengue fever*, an acute febrile viral condition, is not transmitted from person to person but through the bite of an infected mosquito. Symptoms include sudden onset beginning with fever, severe headache, myalgia, arthralgia, retro-orbital pain, anorexia, gastrointestinal disturbances, and rash. Children have milder symptoms than do adults. The prevalence has increased as a result of increasing worldwide urbanization during the last few decades. Dengue and dengue hemorrhagic fever (DHF) have been reported from more than 100 countries in the world, but not in Europe. These two diseases often occur in massive epidemics, most

recently in 1996, when severe epidemics were reported in 27 countries in the Americas and in Southeast Asia. Outbreaks of DHF were recently reported in Brazil, Cuba, India, and Sri Lanka. The WHO strategy of control is based on prevention of transmission by controlling the vector mosquito. Such measures start with eliminating areas for breeding, such as small pools of stagnant water, even in empty flowerpots or abandoned tires (Heyman, 2004; WHO, 2002).

### Other Diseases

In 1996, England reported the first cases of new-variant Creutzfeldt-Jakob disease (a fatal neurologic condition), probably related to eating contaminated beef. In 1997, cases of *S. aureus* with reduced susceptibility to vancomycin occurred in Japan and the United States, raising concern for a return to the preantibiotic era. In that same year, an outbreak of avian influenza in Hong Kong raised concerns about a potential pandemic; it was the first time an avian influenza virus had infected humans (Kilbourne, 2006). In 2002, SARS, an atypical pneumonia with a 10% fatality rate, was recorded in mainland China, Taiwan, and Hong Kong. By June of 2003, more than 8,400 cases and 772 deaths were reported in 13 countries (WHO, 2004).

## Global Response to Communicable Diseases

Communicable diseases are not limited to specific regions of the world; they are the problem of all people. In 1996, WHO focused on completing the unfinished business of eradication and elimination of specific diseases; tackling “old” diseases, such as TB and malaria, and the problem of antimicrobial resistance, as well as combating newly emerging diseases. The WHO continues to focus on safeguarding the gains already achieved, which depends largely on sharing health and medical knowledge, expertise, and experience on a global scale. During the 50 years of its existence, WHO has taken a three-pronged approach to communicable diseases: case-finding, surveillance and control, and elimination and eradication (WHO, 2004).

*Case-finding* is an important beginning to communicable disease control and eventual eradication. Because of the changing nature of the world’s demographics, use of space, and accelerating technology, old or once unknown diseases are reemerging, and others are being seen on our planet for the first time. Differentiation of one set of symptoms from those of another disease is an essential first step in case-finding. Once a disease has been identified, all cases need to be found through the traditional case-finding methods of contact investigation. Each contact leads to another piece of information and becomes part of communicable disease detective work.

Once a disease has been identified and is known to exist in a particular community, the steps of *surveillance and control* begin. Questions need to be answered and acted upon: How is the disease spread? What must be done to reduce the impact of the source? Do infected persons need to be isolated? Does the disease respond to antimicrobial therapy? Weekly, monthly, and yearly documentation of disease frequency and distribution is gathered and shared globally. Control measures then begin. Some developing countries may need more technical and financial support to

achieve control. The cost of locating cases, eliminating vector pools, and providing immunizations and/or treatment can be a burden beyond the capabilities of poorer nations.

Effective surveillance and control can lead to the goal of *elimination and eradication* of a disease in many cases. We have been successful with smallpox and are closing in on polio. Within the next 25 years, other diseases, such as measles and TB, have the potential for elimination. Global collaboration, using the strengths from all nations, is needed to achieve these goals.

## USING THE NURSING PROCESS FOR COMMUNICABLE DISEASE CONTROL

As mentioned in Chapters 4 and 7, the nursing process has steps similar to the research process and the epidemiologic process when approaching any health problem or condition. Therefore, using the nursing process to achieve communicable disease control should be an important and natural process for community health nurses.

### Assessment

The first step of the nursing process, assessment, aligns itself with case-identification and case-finding in communicable disease control. The community health nurse must use all assessment skills and tools available during contact with clients, so as not to overlook the possibility of a communicable disease. Assessment must be comprehensive, producing physical, social, and environmental data. There is no place for assumption. At times, a nurse can become lulled into the usual patterns of inquiry, and this oversight may prove fatal to the client. An example follows:

“Baby Josephine is irritable,” says the mother. “Well, babies sometimes are,” says the nurse. “How are you feeding her? Show me how you hold her. Does she sleep well? Try rocking her in the rocking chair before bedtime. And burp her more frequently. I’ll check back with you in 2 weeks.” Did the nurse record the baby’s temperature, look at her for a rash, compare present weight with last weight, ask about bowel habits or vomiting, inquire about illnesses in the family, check on breast-feeding technique or watch while the mother demonstrated formula preparation, inspect the family’s water source, ask about other foods the baby is eating, and so forth?

Broader inquiry into such a simple statement from the mother in this example may lead to the discovery of a life-threatening, undiagnosed communicable disease.

Assessment in the broader, community health nursing role may involve assessing a community’s need for communicable disease surveillance and new or improved control programs. Nurses are in the community and can get a feel for the increasing or decreasing numbers of communicable diseases. They are often the first ones to know of a new outbreak of communicable disease in the community.

### Planning

The planning step in the nursing process involves different activities, depending on whether the planning is for an individual, family, group, or entire community. At the individual level, the nurse may assist a client with a communicable

disease to get immunizations or definitive treatment. Or, the nurse may assist the client in ways to care for the communicable disease symptoms that provide relief and comfort and reduce the chance of transmitting the disease to others in the family or community. When working with families, the nurse's actions are similar to those with individual clients and include assisting the family in getting available and needed immunizations, controlling the disease if present, limiting it to the people already exposed, and getting appropriate treatment and meaningful rehabilitation, if needed. With groups and communities, planning includes the collaboration of many different groups. Whether an immunization clinic is proposed or a flu shot day is planned for senior citizens, there are location, staff, and supplies to prepare, which may include writing grants, establishing contracts, and training and orienting staff, before implementation can begin.

## Implementation

During the implementation step, the nurse actually takes the action that was identified as necessary during assessment and planned for with clients and others in collaboration. In the implementation step, the nurse may actually deliver the service or may supervise other staff or volunteers. On a large scale, such as with the implementation of a new immunization clinic, the fact that this will be an ongoing service has to be considered in an agency's budget. Staff turnover issues, relief when an absence occurs, and continuous formative (during the implementation process) evaluation of the services with minor changes to improve day-to-day operation can be introduced.

Implementing plans with small groups or families may involve arranging for transportation, so that several people can get to the immunization site or can be seen by a primary care provider. It may include gathering stool samples for laboratory analysis from a family recovering from a *Salmonella* infection. Education on primary prevention of future infections is an essential part of the implementation phase. Agency record keeping, state-required contact investigation, and reporting cases of communicable diseases are essential in this phase. Figure 8.1 is an example of a reporting form.

## Evaluation

Evaluation is an essential step in the nursing process with all conditions, diseases, and services community health nurses provide. When dealing with communicable diseases, it is most important to determine whether actions have achieved the established goals. Have the outcomes been accomplished? Are all family members immunized? Are all family members free of the disease? Do families know how to prevent this and other diseases from occurring or recurring? Does the community have the communicable disease services it needs? Is the community free of the disease? What needs to be done now to keep the community safe from communicable diseases? Are there funding issues, programs nearing completion that need support, or growth of services needed that can be addressed before a critical need occurs? These are examples of questions that need answers during evaluation. The community health nurse who is concerned with the health and safety of the community follows the steps of the nursing process to achieve healthy community goals.

## ETHICAL ISSUES IN COMMUNICABLE DISEASE CONTROL

When working to effectively control communicable diseases in communities and population groups, it is important to ensure that the activities undertaken are ethically sound and justified. It is important in communicable disease control to consider the ethical aspects of access to disease prevention and treatment services; enforced compliance with preventive measures; screening programs; privacy, confidentiality, and discrimination; and issues involving the health worker employee who is infected with or is a carrier of an infectious agent.

On a larger scale are ethical dimensions related to the cause and elimination of barriers to accessibility of drugs in developing countries. Making the inexpensive measles vaccine available to children in African villages, providing effective malaria treatment for people in South Asia, applying DOTS protocols for use in rural Brazil, and making ART and HAART drugs available to people with HIV/AIDS in developing countries (NIH, 2001) are examples of these issues (see Chapters 4 and 16 for further discussion).

## Health Care Access in Communicable Disease Control

Access to health care means that people needing services find them available, acceptable, appropriate, and unrestricted by barriers to use. Such access has been advocated as an essential public health value, yet the global economy has been experiencing rising inequality, with income gaps between and within countries continuing to widen (Casas-Zamora & Ibrahim, 2004).

It would be misleading to say that rates of communicable diseases in population subgroups provide reliable indicators of health care access. The issue is significantly compounded when health care providers miss opportunities to vaccinate and when parents, who have the means, fail to seek out services to ensure that immunizations are up-to-date. It is clear that, in the absence of access to health care services, opportunities for people to receive the information and services necessary to prevent transmission and progression of infectious diseases are sharply curtailed (CDC, 2004).

## Enforced Compliance

Legally, the responsibilities of public health officials in communicable disease control include the police power to enforce compliance with treatment or restrict the activity of infectious people to protect the welfare of others (Heymann, 2004). In disease prevention, completely voluntary measures to encourage healthier lifestyles tend to be ineffective.

Regulations that enforce compliance with disease prevention strategies are a justifiable restriction if the measures proposed are demonstrably effective and grounded in ethical principles. Coercion must be of the mildest sort compatible with achieving the goals of the regulation. Information must be provided to allow consumers to see the consequences of deleterious habits and the value choices that must be made. Inducements should be favored over disincentives. Regulation should be confined to actions with direct public impact and should be limited severely in matters that are personal and private (CDC, 2006d).

## Confidentiality, Privacy, and Discrimination

To carry out communicable disease interventions, client needs for confidentiality and privacy must be ensured. Screening and other interventions must take place in a physical setting that does not allow overt differentiation between those clients with positive and negative results. As agency and national data systems and programs continue to evolve, it is essential to make confidentiality and data protection measures clear priorities. As many as 60 to 100 people are thought to have access to any average hospital record. Anonymity is frankly incompatible with early intervention. Two areas of current practice that may benefit from closer ethical scrutiny in regard to protection of privacy are contact investigation in STD programs and school-based screening for pediculosis (head lice).

Human society has a longstanding aversion to infectious diseases. Ostracism, which in the past included people with leprosy and other contagious conditions, has shifted to discrimination against people with TB, AIDS, head lice, and other current forms of communicable disease. Such discrimination should be of as much concern in the public health field as in the legal sector (CDC, 2006j).

Passage of the Americans with Disabilities Act in 1990 has resulted in legal protections for people diagnosed with communicable diseases who suffer discrimination, regardless of status of infectiousness. The issue of confidentiality has always been a major concern in contact investigation. It continues to be a source of debate in balancing the values of protection of the individual with protection of the public's health. The identity of the individual must be protected to the maximum extent possible, and any breaches of confidentiality must be clearly justified on the basis of a threat to the safety of an individual. That is, failure to provide essential information must jeopardize the well-being of the exposed person or contact. It is important to ensure that accessible services exist for the exposed partner or contact in the event that, as a result of screening intervention, they are burdened with the emotional, physical, and financial consequences of diagnosis (CDC, 2006j).

## Summary

Communicable diseases pose a major threat to the public's health and have done so since the beginning of humankind. In today's world, such diseases are transmitted globally as the result of mobile populations, increased urbanization, and international travel. These diseases are transmitted through direct contact from one person to another or indirectly through contaminated objects (air, water, food) or a vector (animal or insect). Communicable diseases affect all types of people and have worldwide significance.

Ideally, prevention of communicable diseases is accomplished through primary prevention methods such as utilizing mass media education campaigns, one-on-one education, and immunization. Knowledge of VPDs, the schedule of vaccinations, a community's immunization status, herd immunity, barriers to immunization coverage, planning and implementing immunization programs, adult immunizations, and the immunization needs of international travelers, immigrants, and refugees have been discussed.

Secondary prevention activities of screening and contact investigation and casefinding are the steps to be taken when primary prevention activities have failed. Tertiary prevention is needed to ensure additional people are not infected. This is accomplished through isolation and quarantine, universal precaution practices among health care workers, and the safe handling and control of infectious wastes.

Becoming familiar with the major communicable diseases affecting our nation is essential baseline information for community health nurses. Tuberculosis, resurging since the 1980s, may be one of the biggest public health problems in the new millennium. Nurses must be aware of the populations at risk, how the disease is prevented, and the use of appropriate interventions during diagnosis and treatment. Issues compounding the control of TB are twofold: increasing infections with MDR strains, and the increasing number of people with TB and HIV/AIDS, making diagnosis and treatment more complicated.

A second major disease, HIV/AIDS, was first identified in the 1980s. In the last 25 years, 36 million people worldwide have become infected. With the success of antiviral drugs, HIV/AIDS is becoming a chronic disease for clients in industrialized nations, with an average life expectancy of 10 to 15 years after diagnosis. Africa is deeply affected by the massive numbers of women and children who are HIV positive, without access to the life-prolonging drugs available to people in developed nations.

Sexually transmitted diseases threaten the health and lives of millions of citizens. At risk are the sexually active, particularly adolescents and young adults, as well as minorities, women of childbearing age, and children born exposed to an STD. Control of STDs can be accomplished through effective screening, treatment, contact investigation, and aggressive public education. Several common STDs were discussed, including gonorrhea, syphilis, chlamydia, genital herpes, and anogenital viral warts.

Hepatitis is more common than HIV, and can lead to life-threatening events, such as cirrhosis and liver cancer. Yet, these diseases do not garner the attention they need. Most of the public is unaware of the types of hepatitis, prevention, transmission, and treatment. Vaccines for two of the forms (hepatitis A and hepatitis B) are now available, and hepatitis B vaccine is required in the routine childhood vaccine schedule.

Influenza and pneumonia are "old" diseases that are causing newly increased morbidity and mortality in the United States. These diseases cause the most morbidity and mortality in the frailest citizens—the very young and the very old—although vaccines are available to prevent them. A national objective for 2010 is to increase the immunized population, achieving a herd immunity to prevent such diseases.

Smallpox (an eradicated disease) and anthrax have been identified as potential bioterrorism weapons. The community health nurse has several areas of responsibility in regard to bioterrorism. First, the nurse must know the signs and symptoms of potential infectious diseases used as weapons. Also, the nurse has a responsibility to the community to allay fears about bioterrorism and to provide information about prevention. Finally, community health nurses and other nurses are becoming technically skilled in providing smallpox vaccine as the nation prepares for possible bioterrorism at home or during war.

Several emerging or new diseases are occurring globally. Such diseases as Ebola, hantavirus, *E. coli*, Legionnaires' disease, Lyme disease, dengue fever, Creutzfeldt-Jakob disease, antibiotic resistant *S. aureus*, SARS, and avian influenza are occurring in increasingly alarming numbers. It may not be unusual for community health nurses to come across these diseases in their practice.

Internationally, the WHO has been working for 50 years to make the world a healthier place in which to live. By providing all nations with the technical support, resources, and education they need, the WHO is aggressively tackling communicable diseases. Case-finding, surveillance, control, elimination, and eradication are steps toward meeting WHO's goals for communicable diseases.

Community health nurses use the nursing process in their important role with regard to all populations at risk for communicable diseases. Nurses concerned with communicable disease control must recognize who is at risk, where the potential reservoirs and sources of infectious disease agents are located, what environmental factors promote their spread, and what are the characteristics of vulnerability of community members and groups—particularly those subject to intervention. Community health nurses must work collaboratively with other public health professionals to establish immunization and education programs, improve community infection control policies, and develop a broad range of services to populations at risk.

Ethical issues in communicable disease and infection control include access to health care, enforced compliance, the justifiability of screening, preservation of confidentiality and privacy, and the avoidance of discrimination against infected people. ■

### ACTIVITIES TO PROMOTE CRITICAL THINKING

- Interview a professional in your local or state health department who works in communicable disease control. Determine (a) how she conducts communicable disease surveillance, (b) what diseases must be reported in your state, and (c) which communicable diseases are posing the greatest threat to the health of your state's citizens.
- Compare a recent issue of *Mortality and Morbidity Weekly Report* with the same issue published a year earlier, in terms of cases of specific notifiable diseases in the United States. Which diseases appear to be increasing? Decreasing? Select one disease and read at least one recent publication on this subject to determine the reasons for its rise or decline.
- Determine, through your local health department, what percentage of preschool children are immunized in your city or county. Is this a safe level of herd immunity? Propose some recommendations for preserving or raising this level.
- Select one high-risk population discussed in this chapter and list the factors that make this group vulnerable to communicable disease. Use at least one other published source to enhance your understanding. Propose one nursing intervention (such as a specific screening or educational program) and outline how it might be accomplished.
- Interview a professional who works in STD services or with the HIV-infected population. Determine what methods she uses for contact investigation. How does this health care worker preserve privacy and confidentiality? What measures have proved most effective in reaching contacts? What is your evaluation of their success?
- Access the CDC through the Internet (<http://www.cdc.gov>) and browse the site to learn about its various services. Are there special travelers' warnings in certain countries at this time? What are some of the CDC's current concerns regarding communicable diseases? Select a communicable disease and identify the number of cases presently reported. Return to the same website 1 month later. Has the incidence of the disease increased or decreased?

## Environmental Health and Safety

### LEARNING OBJECTIVES

*Upon mastery of this chapter, you should be able to:*

- ◆ Discuss the importance of applying an ecologic perspective to any investigation of human–environment relationships.
- ◆ Explain the concepts of prevention and long-range environmental impact and their importance for environmental health.
- ◆ Identify at least five global environmental concerns and discuss hazards associated with each area.
- ◆ Relate the effect of the described hazards on people’s health.
- ◆ Discuss appropriate interventions for addressing these health problems, including community health nursing’s role.
- ◆ Describe how national health objectives for the year 2010 target environmental health.
- ◆ Describe strategies for nursing collaboration and participation in efforts to promote and protect environmental health.

*“When we try to pick out anything by itself, we find it hitched to everything else in the Universe.”*

—John Muir, 1911

### KEY TERMS

Built environment  
Contaminant  
Deforestation  
Demographic entrapment  
Desertification  
Ecologic perspective  
Ecosystem  
Environmental health  
Environmental impact  
Environmental justice  
Extinction  
Global warming  
Pollution  
Toxic agent  
Wetlands

 Our environment—the conditions within which we live and work, including the quality of our air, water, food, and working conditions—strongly influences our health status. Consequently, the study of environmental health has tremendous meaning for community health nurses. Broadly defined, **environmental health** is concerned with assessing, controlling, and improving the impact people make on their environment and the impact of the environment on them. The field of environmental health is concerned with all elements of the environment that influence people's health and well-being. The conditions of workplaces, homes, or communities, including the many chemical, physical, and psychological forces present in the environment that affect human health, are important considerations.

Different environments pose different health problems and benefits. Consider the effects of climate change, soil erosion, and insect invasions on a rural community or the effects of industrial toxic wastes, auto emissions, and airport noise on urban residents. The health effects of a hot, dry climate are different from those of an arctic area, and the environmental conditions of an industrialized nation are dramatically different from those of a developing country.

This chapter describes conceptual and theoretic approaches to environmental health and examines historical perspectives, global environmental health issues, and the primary environmental areas of concern to community health nurses. Those primary environmental areas include air pollution, water pollution, contaminated food, waste disposal, insect and rodent control, and specific hazards in the home, worksite, and community. The role of the public health nurse in efforts to mitigate or remove environmental toxins and other hazards is stressed.

## CONCEPTS AND THEORIES CENTRAL TO ENVIRONMENTAL HEALTH

Assessing environmental health means more than looking for illness or disease-causing agents; it also means examining the quality of the environment. Do the conditions of both the manmade and the natural environment combine to provide a health-enhancing milieu? Are people's surroundings safe and life-sustaining? Are they clean and aesthetically enriching? Is the environment not only physically but also psychologically health-enhancing? To answer these questions and gain greater understanding, the nurse needs to consider the conceptual and theoretic approaches that are essential to assessing and controlling environmental health.

### Preventive Approach

The study of environmental health has become increasingly complex as people's influence on the environment has increased. With the unprecedented advances in science and technology that have taken place in the past few decades, society's ability to affect the environment has expanded, and the implications of these effects are not fully comprehended. New forms of energy, new synthetic chemical substances, and genetic engineering research bombard us with such rapidity that it is almost impossible to anticipate all the potential side effects on the environment and, in turn, on people's health. For each advance and presumed improvement, the toll to be paid is often unknown until years or even decades later. In many

cases, unfortunately, the risks have been known but ignored. For example, lead was recognized in the 19th century as a hazard, and white lead-based interior paint was banned in parts of Europe in the early 1900s. Despite this, it wasn't until 1978 that lead-based paint and lead-based paint products were finally banned in the United States (Wigle, 2003). The cost, just in terms of lost potential for those poisoned with lead can never be adequately measured. The impact of nearly 75 years of lead paint use is felt even to this day.

For these reasons, the concept of prevention is vital to environmental health. Scientists must use foresight as they design innovations; government agencies, business organizations, and citizens must play watchdog; and those concerned with human and environmental health must monitor new developments and intervene to prevent problems from occurring. Health practitioners need to determine causal links between people and their environment, with an eye to improving the health and well-being of both. Nurses must be particularly aware of environmental factors that have the potential to either promote or adversely affect the health of communities. All three levels of prevention (primary, secondary, and tertiary) must be employed, but most important is primary prevention. Prevention of a disease or *hazard* (a source of danger and risk particularly affecting human health) from occurring at all has the greatest benefit to the community.

Although small-scale preventive and health-promoting measures, such as safety education in the home or workplace, are important, the larger environmental problems ultimately place many, if not all, members of a given community at risk. Community health nurses can develop an understanding of these environmental threats, as well as the collaborative skills needed to work with other members of the public health team to prevent or alleviate them.

### Ecologic Perspective

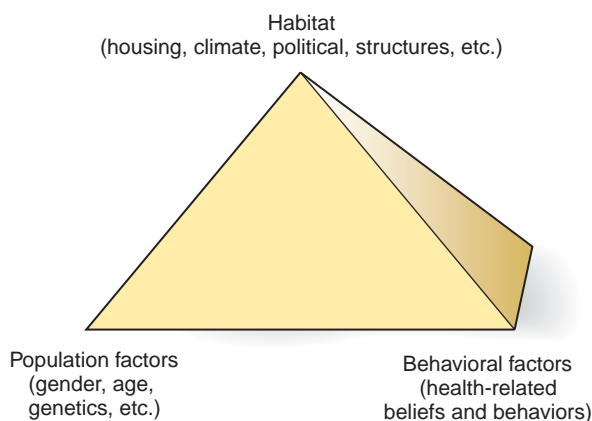

It is important to consider issues of environmental health from an **ecologic perspective**, keeping in mind the total relationship or pattern of relationships among people and their environment. Even when environmental health efforts focus on a specific health hazard or single environmental factor that poses a health threat, a broad view of human–environment relationships must be maintained. In most cases, a single causal factor cannot be isolated, because there may be many causal relationships. An example is childhood asthma; although the exact causes are not known, factors such as allergens (e.g., dust mites), irritants (e.g., tobacco smoke, air pollution), weather, exercise, and infections can induce symptoms (National Library of Medicine, 2007a). The risk of developing the disease is further increased with family history (genetics) and poverty (environment). These various causal mechanisms join to increase the risk for the development of asthma, with no single mechanism being sufficient. This relationship has been referred to as the *causal pie model* (Rothman & Greenland, 2005).

An **ecosystem** is a community of living organisms and their interrelated physical and chemical environment. Within an ecosystem, any manipulation of one element or organism may have hazardous effects on the rest of the system. Therefore, no one factor, whether organism or substance, can be viewed in isolation. For example, in produce processing,

there are several points at which contamination can occur: at production and harvest (growing, picking, and bundling); during initial processing (washing, waxing, sorting, and boxing); during distribution (trucking); and during final processing (slicing, squeezing, shredding, and peeling). Several different pathogens are associated with a variety of food-borne diseases from produce and animals grown and raised in the United States, Mexico, and Central America (U.S. Department of Agriculture [USDA], 2006). Pathogens may have been introduced in the irrigation water, with the fertilizer, or from lack of field sanitation during production and harvest; from contaminated wash water and handling at initial processing; from contaminated ice and dirty trucks during distribution; or in the final processing from dirty wash water, improper handling, or cross-contamination. By taking an ecologic approach to the study of environmental health, the community health nurse acknowledges that people can affect their environment, and the environment can affect them. Preventive and health-promoting measures may be applied to all aspects of the environment, as well as to the people in it. Humans share this planet with millions of other living creatures, and we must consider the ecologic balance and anticipate the far-reaching consequences of our actions before introducing environmental change through contaminants or toxic agents. A **contaminant** is organic or inorganic matter that enters a medium, such as water or food, and renders it impure. A **toxic agent** is a poisonous substance in the environment that produces harmful effects on the health of humans, animals, or plants.

Using a model similar to the epidemiologic triad introduced in Chapter 7, a triangle of human disease ecology is created. This model stresses the links between habitat, population, and behavior (Fig. 9.1). *Habitat* includes aspects of the environment in which people live, including housing, workplaces, communication systems, flora, fauna, climate, topography, services, and economic and political structures of societies and local communities. *Population* factors include the characteristics of the population (age, gender, and genetic predisposition), which help to determine health status and disease susceptibility. *Behavioral* factors include health-related beliefs and behaviors, which are shaped by a range of social and economic factors. The

**FIGURE 9.1** The triangle of human disease ecology. Adapted from Curtis, S., & Tacket, A. (1996). *Health and Societies: Changing Perspectives*. London: Arnold.

triangular relationship among these factors suggests that no real boundaries exist between them and that the health of populations is a result of the interaction of all factors. It also indicates that action on one part of the system in isolation is unlikely to be effective without complementary action on other relevant factors.

**Environmental justice** is a movement that has sought to ensure that no particular part of the population is disproportionately burdened by the negative effects of pollution. The U.S. Environmental Protection Agency (EPA) uses the following definition:

Environmental Justice is the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. . . . It will be achieved when everyone enjoys the same degree of protection from environmental and health hazards and equal access to the decision-making process to have a healthy environment in which to live, learn, and work. (2006b)

Industrial plants, waste facilities, and other potential polluters are more likely to be situated in poorer communities, and pollutants from these facilities can make the people who live there ill. The problem is even more pronounced with respect to the poor in developing countries; little global attention is rarely paid them until catastrophe strikes (Butler & McMichael, 2006). One of the world's worst industrial cataclysms occurred in Bhopal, India, in 1984, when methylisocyanate was uncontrollably released from a Union Carbide plant. The initial result was at least 3,800 people dead and over half a million people exposed. Well over 100,000 still suffer the after-effects of exposure (Bhopal Medical Appeal, n.d.; Butler & McMichael, 2006). It is very possible that, as poor countries industrialize and embrace Western development and consumerism, more disasters will occur. However, action can be taken in advance to prevent such incidents. Environmental legislation, preventive maintenance strategies, worker-training programs, environmental education programs, research on product safety, development of systematic hazard-evaluation models, and emergency planning are all examples of possible preventive activities.

In the United States, it is not unusual to identify communities that are exposed to higher levels of pollutants than others. Often, members of these communities are not well equipped to deal with pollution problems because of their limited involvement in the political process. In addition, they may not be aware of their exposure to pollutants and may be more vulnerable to health problems because of poor nutrition and inadequate health care.

*Aesthetics* is the appreciation of beauty that is culturally pleasing to the person observing the person, place, or thing. Even accounting for cultural differences, some things exist, such as a woodland path, a rocky beach, or a colorful sunset, that most people would find aesthetically pleasing. How does the aesthetics or beauty of our environment affect us? People themselves are the best sources for ideas regarding the things that they cherish as being beautiful. However, an environment that is well-landscaped and free of waste material, clutter, and foul smells can contribute to the inhabitants' well-being.

## PERSPECTIVES: STUDENT VOICES

I am definitely not an activist by any stretch of the imagination—at least I wasn't until a few months ago. One of my first public health nursing course assignments was to look into the smoke detector requirements in our community. I actually picked this project because it sounded easy—after all, doesn't everyone have a smoke detector in their home? Granted, I know that there is a problem with people removing batteries from them; but if they have a fire, that's their fault, right? Well, did I have a lot to learn! It turns out that smoke detectors are only good for about 8 years before they need to be replaced, and you need more than one in a house or apartment, especially inside each bedroom and right outside that area. To make matters worse, our city only requires multiple smoke detectors in housing built after 1992! So, if you live in older rental housing, like many of our elderly, poor, and even college students, the owners don't need more than one to be within code! This is scary and worse, it is perfectly legal. A few of the other students in the class took an interest in this, and we wrote a letter to our city council. It has taken some time, but it looks like they may be able to change the codes. You can be certain that I will be watching to make sure they do! Who would have guessed . . . I've become an activist! I guess I have what it takes to be a public health nurse after all.

*Anna M., Nursing Student*

The benefits of aesthetically pleasing surroundings are difficult to measure. Nevertheless, we know how good it makes us feel when we experience it, that we would like to linger there longer, and that we would not like to let it disappear. If people were able to feel this way about their home, their neighborhood, and their community, the world would be a more harmonious and healthier place.

A related issue concerns the **built environment**. The term refers “to urban areas and structures (e.g., roads, parks, and buildings) constructed by human beings, as opposed to undeveloped, rural areas” (Friis, 2007, p. 74). Increasingly, the built environment is thought to be a force of either positive or negative impact on the health of populations. For instance, the massive migration out of the cities that began in the 1950s and continues to the present has had a dramatic impact on both the environment and, inadvertently, the health of the population. As more and more land is developed and agricultural areas are converted to housing, the need for increased use of automobiles follows. With the automobile use comes the added impact of increased air pollution. Add to that the lack of services (schools, stores, recreation, and faith communi-

ties) within walking distance and normal daily physical activity is impeded, which can lead to overweight and obesity. This is a simplistic example, but it points out how unintended consequences can result from the environment we live in. Many communities are now looking for ways to discourage overdependence on automobiles and to encourage physical activity. They are planning new developments with major services that are easily accessible by walking, bicycling, or public transportation. One possible by-product of these efforts may be the strengthening of community ties. Although long thought to be unhealthy environments, cities actually encourage walking, and residents in poor neighborhoods tend to walk more than those in more affluent areas (Vlahov, Galea, & Freudenberg, 2005). With collaborative efforts by all stakeholders, our communities can become more health-promoting and life-enhancing to all residents.

### Long-range Environmental Impact

When studying environmental health, it is important to consider the effect of positive or negative changes on the environment and on the people, animals, and plants living in it. This **environmental impact** must be viewed not only in terms of its consequences for people living now but also in terms of long-range impact on the human species. One must consider the health of future generations as well as present ones. Considerations should include food and fuel limitations of the natural environment, attendance to conservation through balancing of present and future needs, and prevention of the consequences of environmental abuse. This last point broadens the focus even more. Certainly, one should determine how current practices and toxins are hurting humans today, but it is also imperative to discover what threats they pose to the biosphere and thus to future generations—their long-range environmental impact. For example, carbon monoxide gas given off by factories and automobiles is toxic and can be lethal, causing dizziness, headaches, and lung diseases in humans who inhale it at certain concentrations. It has also been found to contribute to the formation of ground-level ozone, more commonly referred to as *smog* (EPA, 2007e), posing a serious ecologic threat both now and in the future. The National Institute of Environmental Health Sciences (NIEHS) 2006–2011 Strategic Plan calls for increased research and partnerships with industry to find effective means to better protect the health of the public (NIEHS, 2006). Efforts such as these will help policy makers weigh the possible environmental risks of any new industrial or business facility against its potential job and tax benefits for local citizens.

### EVOLUTION OF ENVIRONMENTAL HEALTH

Environmental influences on health have been present throughout human history. Interactions with the environment, and the conditions of that environment, have shaped humans' mental, emotional, and physical health since the beginning of time. From ancient tribal practices of burial of excreta to modern-day sewage treatment, humans have been concerned with how the environment would provide for their needs and affect their well-being.

## Global Perspective

In an effort to promote human health, people have taken steps to control, alter, and adapt to their environment. Demonstrations of this concern go back to Biblical times, when the Israelites observed strict rules governing food preparation, practiced sanitation, and quarantined people with infectious diseases (e.g., leprosy). For example, rules governing the proximity of tanneries, furnaces, animal slaughterhouses, and cemeteries served to protect the village water supply (Novick & Morrow, 2008).

As populations became more settled and urbanized, many different environmental health concerns developed. Community actions to deal with these developments have been recorded as far back as 2500 BCE. Archaeologists have discovered remnants of sophisticated water and waste systems in ancient cities of northern India and in the Middle Kingdom of Egypt. Early Roman engineers built aqueducts for supplying fresh water, and they developed management operations for overseeing water and sewage systems. (The use of lead pipes by the Romans in their water delivery systems likely resulted in chronic lead poisoning and may have contributed to the downfall of the empire [Friis, 2007]). Many of the innovations in sanitation brought to Europe by the Romans were lost for centuries. Ultimately, the decline in sanitary conditions would prove a breeding ground for major outbreaks of diseases such as plague and cholera.

A major environmental issue in the medieval world was the spread of infectious diseases brought about by the growth of cities, increased trade, and wars. The most severe infectious diseases were outbreaks of leprosy and bubonic plague during the 13th and 14th centuries (McGrew, 1985; Zgodzinski & Fallon, 2005). As leprosy spread and peaked in Europe in the early 13th century, people recognized a connection between the environment and spread of the disease. They instituted epidemic control by isolating people with signs of the disease and checking newcomers to the community (Novik & Morrow, 2008). Therefore, long before science had discovered the true causes of these diseases, people were instinctively changing or avoiding harmful environmental circumstances in an effort to promote health. Simple city ordinances restricted locals from washing their clothes or tanners from cleaning their skins in rivers that supplied drinking water. A law passed in London in 1309 governed the disposal of waste into the Thames River. Similarly, people passed rules governing the sale of old or spoiled meat to local residents, and “in Basel, leftover fish were displayed at a special inferior food stall and sold only to strangers” (McGrew, 1985, p. 139). This early concern for sanitary conditions became a major focus in public health, reaching its peak between 1840 and 1880.

The sanitary movement, which began about 1830, called for societal transformation to create a truly healthful environment that emphasized bathing, clean water, and controlled human waste disposal (Zgodzinski & Fallon, 2005). During the middle to late 1800s, Florence Nightingale in England and Dr. Ignaz Semmelweiss in Vienna pioneered the promotion of clean hospital and surgical conditions to prevent illness (Friis & Sellers, 2004; Nightingale, 1860/1969). Oliver Wendell Holmes made the connection

between exposure to sepsis and maternal infection in Boston in 1843 (Holmes, 1843/1909–1914). John Snow first documented environmental spread of disease in London in 1849 when he linked the spread of cholera with contaminated drinking water (Aschengrau & Seage, 2008). The work of Pasteur and Koch demonstrated the role of bacteria in disease (Zgodzinski & Fallon, 2005). All of these, in addition to greater use of the microscope, shed further light on the relationship of the environment to health.

Awareness of the environmental impact on health was first documented in the *Report on the Sanitary Condition of the Labouring Population of Great Britain* by Edwin Chadwick in 1842 (Hanley, 2006; Library of Congress, 2007). This document addressed the necessity for a healthy environment. About the same time, a similar report called *Report of the Sanitary Commission of Massachusetts* was published in the United States (1850). This document, often referred to as the *Shattuck Report* after the chairman of the commission, Lemuel Shattuck, provided original insights into environmental health issues, including smoke prevention, urban planning, and sanitation programs (Gordon, 2002; Wilcox, 2005). These documents marked the first organized concern for public health and environmental health controls. Since that time, the focus has gradually expanded from sanitation to the problems generated by advances in technology, chemical production, and pollution, which are discussed in this chapter.

An important international agency, the World Health Organization (WHO), was created in 1948 and has helped to identify and address world health problems, including issues of environmental concern. Because many modern technological discoveries cause far-reaching health hazards that affect the environment and the health of the entire global population, this organization and others like it will play increasingly important roles in the future.

## National Perspective

In the United States, all levels of government have worked diligently to assess, prevent, and correct environmental health hazards. The major environmental health efforts of the federal government have come primarily since the early 1970s. Local governments assume responsibility for proper waste disposal, pure water supply, and efficient sanitary and safety conditions within the community. State governments, represented by different agencies, handle broader issues that deal with the creation of state regulations, policies, and supervision of local health efforts. The federal government is charged with establishing and enforcing health standards and regulations (Mays, 2008). During the past several decades, the public concern for human health in relation to the environment, as well as concern for the environment itself, has stimulated increased government actions. The Environmental Protection Agency (EPA) was established in 1971 and was given extensive authority over all environmental concerns and protection of public health. The Food and Drug Administration (FDA) was established within the U.S. Public Health Service in 1968; the Occupational Safety and Health Administration (OSHA), for regulation, and the National Institute for Occupational Safety and Health

## DISPLAY 9.1

## HEALTHY PEOPLE 2010 OBJECTIVES RELATED TO ENVIRONMENTAL HEALTH

**Goal:** Promote health for all through a healthy environment.

**Number Objective Short Title**

**Outdoor Air Quality**

- 8-1 Harmful air pollutants
- 8-2 Alternative modes of transportation
- 8-3 Cleaner alternative fuels
- 8-4 Airborne toxins

**Water Quality**

- 8-5 Safe drinking water
- 8-6 Waterborne disease outbreaks
- 8-7 Water conservation
- 8-8 Surface water health risks
- 8-9 Beach closings
- 8-10 Fish contamination

**Toxics and Waste**

- 8-11 Elevated blood lead levels in children
- 8-12 Risks posed by hazardous sites
- 8-13 Pesticide exposures
- 8-14 Toxic pollutants
- 8-15 Recycled municipal solid waste

**Healthy Homes and Healthy Communities**

- 8-16 Indoor allergens
- 8-17 Office building air quality

- 8-18 Homes tested for radon
- 8-19 Radon-resistant new home construction
- 8-20 School policies to protect against environmental hazards
- 8-21 Disaster preparedness plans and protocols
- 8-22 Lead-based paint testing
- 8-23 Substandard housing

**Infrastructure and Surveillance**

- 8-24 Exposure to pesticides
- 8-25 Exposure to heavy metals and other toxic chemicals
- 8-26 Information systems used for environmental health
- 8-27 Monitoring environmentally related diseases
- 8-28 Local agencies using surveillance data for vector control

**Global Environmental Health**

- 8-29 Global burden of disease
- 8-30 Water quality in the U.S.–Mexico border region

U.S. Department of Health and Human Services. (2000). *Healthy People 2010: Understanding and improving health* (2nd ed.). Washington, DC: U.S. Government Printing Office.

(NIOSH), for research, were both established in 1970. The Public Health Service, under the U.S. Department of Health and Human Services (USDHHS), has helped to focus environmental control efforts through development of objectives published in 1979 and again in 1991. Its 1991 document, *Healthy People 2000*, listed objectives in major target areas. In the 2000 follow-up document, *Healthy People 2010*, objectives for improvement in environmental health parameters continued (Display 9.1).

Private business has become more conscious of health and safety issues, following enhanced legislation such as the Products Liability Law and product monitoring by the U.S. Consumer Product Safety Commission (CPSC). Private business and industry have often been accused of having total disregard for the health of the environment and its effect on human health, but this image seems to be slowly changing. Many companies, when confronted by concerned environmentalists or consumer protection groups that have formed in recent years, have been forced to change their practices. Boycotts of products, listings of environmentally conscientious firms, and general public outrage have put a stop to many harmful practices. A number of companies have been concerned for some time with the environmental impact of their business operations; they have sought not only reduction of health hazards but also ways to promote environmental and public health. Timber companies, for example, have actively engaged in reforestation projects. Private business has been a major contributor to many non-profit, environmentally concerned projects and agencies, such as the Sierra Club.

Maintaining a healthy environment and balanced ecology and promoting the health of those living in it remain challenging. Past efforts to accomplish these goals have been only partially successful. However, increased public awareness and concern for future generations have exerted tremendous pressure to create new and more effective legislative acts and activities (Display 9.2).

## MAJOR GLOBAL ENVIRONMENTAL CONCERNS

The global perspective, and specifically the national perspective, of environmental health provides a picture of humankind's attempts to protect populations. However, for much of our world's history, protecting people, other living beings, or the Earth itself has not been a priority or even a concern. Because of this history, major global environmental concerns now face the world, including overpopulation, ozone depletion, global warming, deforestation, wetlands destruction, desertification, energy depletion, inadequate housing, aesthetics, and environmental justice issues (Friis, 2007).

### Overpopulation

Human population took hundreds of thousands of years to reach 1 billion in the 1800s and until 1960 to reach 3 billion. Less than 50 years later, it has more than doubled to 6.7 billion. Every 11 years, the world gains 1 billion people. Assuming that overall fertility rates continue to decline as

1976	Toxic Substances Control Act		
1977	Clean Water Act		
1979	U.S. Department of Health and Human Services helped to focus environmental control efforts		

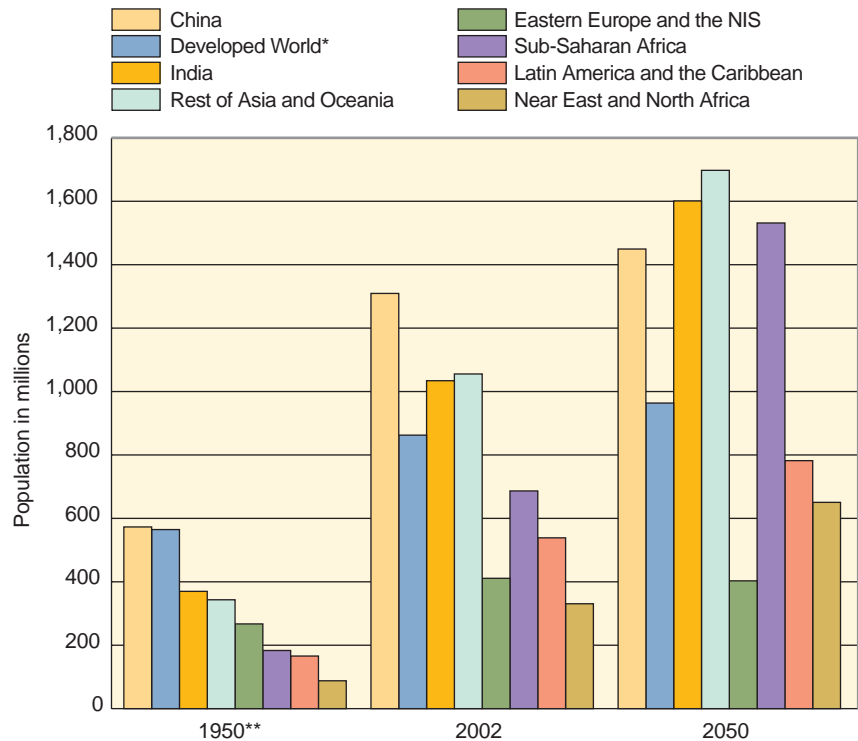

they have since the 1970s, by 2050 there may still be well in excess of 9.2 billion inhabitants of Earth. If however, the fertility rates remain constant, the population could reach 11.9 billion (Population Action International, 2007a, 2007b). The environmental impact of continued growth could translate into increasing food scarcity, water shortages, and depletion of other vital resources, ultimately threatening our very survival (Friis, 2007). Uncontrolled population growth is indisputably a public health issue.

The burden of population growth is being carried by the poorest developing countries, such as those in Sub-Saharan Africa, India, and Asia. According to the U.S. Census Bureau, the less-developed countries of Asia and Oceania (excluding India and China) will be more populous than any other region in the world by 2050 (Fig. 9.2). Long the most populated country in the world, at present growth rates, China will likely be eclipsed by India in 2037. Between one-third and one-half of the population in most developing countries is younger than 15 years of age, in part because advances in public health have lowered mortality among all age groups, but especially among infants and children. Globally, nearly one-third of the population is younger than 15 years (U.S. Census Bureau, 2007).

Until most recently, the elderly population (those 65 years and over) made up a relatively small percentage of the world's population. In 2002, this age group accounted for approximately 7% of the overall population. Compare that to projections for 2050, when the absolute number is expected to be tripled, bringing the percentage up to nearly 17% (U.S. Census Bureau, 2004). The growth in the population over 65 will increasingly strain existing health care, pension, and social service systems (Research Brief, 2005).

In some nations, the population is projected to shrink. If low fertility rates continue in Germany, Italy, Russia, and Spain for instance, their populations will decrease by anywhere from 2% to 10% by the year 2025. In contrast, countries such as Nigeria, Zambia, and Jordan have high fertility rates, and it is likely that their populations will increase by 30% to 60% over the same period (U.S. Census Bureau, 2005).

What do these statistics and trends mean for the health of populations and the ecosystem? When a population exceeds the ability of its ecosystem to either support it or acquire the support needed, or when it exceeds its ability to migrate to other ecosystems in a manner that preserves its standard of living, the population is said to be experiencing **demographic entrapment**. Such a population faces the four tragedies of

**FIGURE 9.2** Regional Distribution of Global Population: 1950, 2002, and 2050. Population rankings of major world regions continue to shift in favor of developing regions. From U.S. Census Bureau. *International Population Reports WP/02. Global population profile: 2002*. Washington, DC: U.S. Government Printing Office.

\* "Developed World" refers to North America (excluding Latin America and the Caribbean), Western Europe, Japan, Australia, and New Zealand. Rest of Asia and Oceania refers to Asia excluding Japan, China, and India plus Oceania excluding Australia and New Zealand. NIS indicates the New Independent States of the former Soviet Union.  
 \*\* Current boundaries.

entrapment. Depending on cultural, political, and ecologic factors, it can starve, die from disease, slaughter itself or others, or be supported indefinitely by aid from others.

### Government's Role

The government has a responsibility to prevent a population from exceeding the limits of the nation's resources and boundaries. The possible methods of preventing overpopulation, or solutions to it, are controversial, depending on one's culture, religious beliefs, and personal values and convictions. Ideally, the political system governing a country has a responsibility to provide a well-formed infrastructure of health and safety services for its population; economic development that provides employment, housing, and services; and political strength to provide stability to the nation. Many countries with unstable political systems are unable to deal effectively with overpopulation issues.

Where countries experience a decline in population, as is currently occurring in the European Union (EU), efforts have been undertaken to implement pronatalist policies. A growing aging population and a shrinking workforce are seen as threatening EU goals of full employment, economic growth, and social cohesion. Immigration may slow but not mitigate the problem and is not seen as a feasible long-term solution. Faced with one of the lowest birth rates in Europe, France instituted generous child-care subsidies and rewards for families having at least three children (Research Brief,

2005). Population stability clearly has an impact on developing and developed societies alike.

### Nurse's Role

Public health professionals, including community health nurses, have a responsibility in the area of overpopulation, both globally and locally. Productive interventions include the following: (a) teaching families that birth spacing improves child and maternal survival and that a planned family is the best environment for a child's development; (b) preventing high-risk pregnancies, such as those among teens and adult women who are infected with the human immunodeficiency virus (HIV) or have the acquired immunodeficiency syndrome (AIDS); (c) preventing the growing epidemic of HIV/AIDS; (d) providing family planning education to prevent worldwide deaths from unsafe abortions; and (e) providing prenatal care—because healthy mothers equal healthy children. These are key areas in which public health efforts can reap major rewards for families.

### Air Pollution

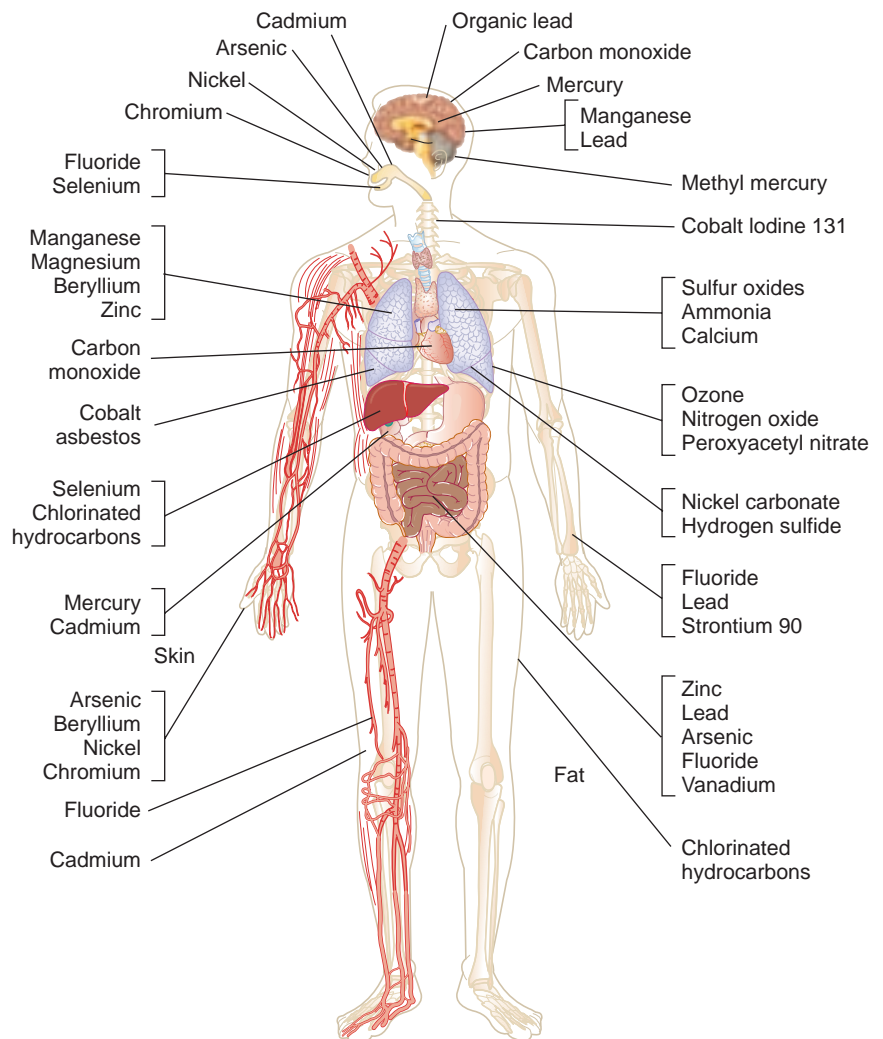

For many centuries, people have known that air quality affects human health. In Europe and America in the 1800s and early to middle 1900s, documented episodes of concentrated air pollution due to thermal atmospheric inversion caused many reported deaths. **Pollution** refers to the act of contaminating

or defiling the environment to the extent that it negatively affects people’s health. Air pollution is now recognized as one of the most hazardous sources of chemical contamination. It is especially prevalent in highly industrialized and urbanized areas where concentrations of motor vehicles and industry produce large volumes of gaseous pollutants.

Air pollution is a global problem. Recognizing the threat, the WHO published the first global standards for air quality in 2005 (WHO, 2006). Outdoor air pollution contributes to cardiovascular and respiratory diseases and is believed responsible for nearly 1 million lung cancer deaths yearly. With respect to children, infant mortality in the first year of life, bronchitis, asthma, and reduced lung development are additional health threats (Licari, Nemer, & Tamburlini, 2005). In Europe, outdoor air pollution and specifically particulate matter, is believed to cause 13,000 deaths per year among children younger than 4 years of age (WHO, 2006). U.S. children as well suffer disproportionately from the effects of both indoor and outdoor air pollution. One result of air pollution, asthma, accounts for 14 million lost school days each year and is the third leading cause of hospitalizations for children under 15 years; sadly, the number of U.S. children dying from asthma nearly tripled from 93 deaths in 1979 to 266 in 1996 (CDC, 2007a).

In the U.S., guidelines developed by the EPA serve to both regulate and monitor pollutants (EPA, 2006a). From 1980 to 2005, overall emissions of the six major pollutants measured by the federal government (carbon monoxide, nitrogen dioxide, ozone, particulate matter, sulfur dioxide, and lead) decreased substantially. However, the EPA also reported that in 2005 approximately 122 million people in the United States lived in counties where the air pollution levels exceeded the National Ambient Air Quality Standards (NAAQS) (EPA, 2006a). Airborne pollutants have adverse effects on many areas of human life; the costs to property, productivity, quality of life, and especially human health are enormous. The list of diseases and symptoms of ill health associated with specific air pollutants is lengthy, ranging from minor nose and throat irritations, respiratory infections, and bronchial asthma to emphysema, cardiovascular disease, lung cancer, and genetic mutations (Fig. 9.3).

As with other toxic chemicals, it is often difficult to establish a cause-and-effect relationship between air pollution and illness. A relatively short, high level of exposure is normally easier to identify. A number of poignant examples have occurred. One acute episode in Donora, Pennsylvania in 1948 caused 20 deaths, 400 hospitalizations, and nearly half of the town’s 14,000 residents were sickened. Industrial contaminants

**FIGURE 9.3** Body system targets of major air pollutants.

from iron and steel mills, coal-fired home stoves, and factory burning of coal combined with fog to create a deadly mix (Friis, 2007). Most affected by this disaster were residents over 55 years of age; those with existing heart or lung disease were most at risk for adverse outcomes (Friis). Another event occurred in London in 1952, when an atmospheric inversion trapped coal-burning smoke and fog over the city for almost a week. Between 4,000 and 8,000 people, mostly the elderly and those who were vulnerable because of respiratory and cardiac diseases, died as a result (Yassi et al., 2001). Although these disasters and others like them are dramatic and frightening, the effects of long-term exposure to low levels of pollution, such as environmental tobacco smoke exposure in the home (second-hand smoke), are perhaps even more threatening. Indoor air pollution is definitely more difficult to record, measure, understand, define, correlate, and control. It may be impossible to ever document the total effects.

Certain geographic areas are more susceptible to the ill effects of air pollution because of weather conditions or physical terrain. The episode in London occurred when a lack of wind combined with low temperatures to create a temperature inversion—a phenomenon in which air that normally rises is trapped under a layer of cold air, allowing air contaminants to build up to intolerable levels. Los Angeles, another city troubled by air pollution, is surrounded by mountains that prevent winds from clearing away smoke and fumes. A further condition occurs in urban areas: buildings create a “heat island effect,” in which warm air traps pollution in the atmosphere around the city. In examining the effects of air pollution, it is necessary to take into account the climate conditions and topography of an area.

**TABLE 9.1 The Air Quality Index (AQI)**

AQI Values	Levels of Health Concern	Colors
When the AQI is in this range. . .	. . .air quality conditions are. . .	. . .as symbolized by this color.
0–50	Good	Green
51–100	Moderate	Yellow
101–150	Unhealthy for Sensitive Groups	Orange
151–200	Unhealthy	Red
201–300	Very Unhealthy	Purple
301–500	Hazardous	Maroon

AIRNow. *Air Quality Index (AQI)—A Guide to Air Quality and Your Health*. <http://www.airnow.gov/index.cfm?action=static.aqi>

The EPA has developed a tool to provide the public with timely and easy-to-understand information on local air quality and whether air pollution levels pose a health concern. The Air Quality Index (AQI) lets the public know how clean the air is and whether they should be concerned for their health. The AQI is focused on health effects that can happen within a few hours or days after breathing polluted air (Table 9.1). Depending on the topography and general air flow patterns of the area, some communities use the index to inform the public as to

**EVIDENCE-BASED PRACTICE**

**Helping Reach the HP 2010 Goal of Reduced Environmental Tobacco Exposure for Young Children—But How?**

Environmental tobacco exposure (ETS), passive smoking, second-hand smoke—by any name, it is extremely harmful to young children. Their small size and lung capacity, coupled with rapid breathing rates as compared to adults, add to the risk of health problems, both short- and long-term. The problem is well known to public health nurses, but the question remains: How do you change adult behaviors so that fewer children are exposed? More and more public health nurses are looking to public policy change and community health education programs to address health problems such as this. A systematic review of literature regarding population-level options to support smoke-free homes found a correlation between comprehensive tobacco control programs and reduced prevalence of smoking in homes in Britain, the United States, Australia, and New Zealand (Thomson, Wilson, & Howden-Chapman, 2006). Most notably, efforts at reducing workplace smoking seemed to have a positive association with smoke-free homes. Chan and Lam (2006) implemented a simple health education program to reduce ETS in homes with sick children. Mothers were the target of this intervention, with reported

achievement of short-term motivation to reduce smoking exposure produced by fathers as well. Which approach, health education or policy change, do you think shows the most promise and why? Are there other sources of information to help guide you, such as systematic reviews? If you had 1 minute to present a case for a program to reduce ETS in homes to a politician, what would you say? What if you had that same short amount of time with a young mother who smokes? What would your 1-minute message be? How would you address privacy issues and right to self-determination?

when use of wood-burning fireplaces or burning of trash piles or leaves is ill-advised or illegal. In the San Francisco area, residents may ride free on public transportation on those days when the air quality is poor. This program is designed for both short- and long-term behavioral change to reduce air pollution (Bay Area Air Quality Management District, 2007).

### **Dusts, Gases, and Naturally Occurring Elements**

Dusts can contain numerous types of chemical irritants and poisons. Many hazardous dusts are associated with the workplace; for example, coal miners have developed black lung disease from inhaling coal dust, and a respiratory disease called silicosis is caused by exposure to silica dust (common in mining, sandblasting, and tunnel work). Dusts are also associated with farming and grain elevator work, as well as highway construction. Asbestos fibers, which are found in insulation and fireproofing materials, textiles, and many other products, have been associated with lung cancer. Although people who smoke are at 30 times greater risk of developing lung cancer than those who do not smoke, environmental tobacco smoke (ETS) is estimated to cause approximately 3,000 lung cancer deaths in nonsmokers each year, and 150,000 to 300,000 infants and children younger than 18 months of age experience lower respiratory tract infections annually because of exposure to second-hand smoke. In addition, asthma and other respiratory conditions are triggered or worsened by tobacco smoke (USDHHS, 2000).

Although much air pollution results from some type of human activity, naturally occurring elements, such as pollen from plants and flowers, ash from volcanic eruptions, and airborne microorganisms, can also have ill effects on health. A long list of gaseous pollutants, including sulfur oxides and nitrogen oxides produced by industrial emissions, pose additional problems for community health. Such gases cause respiratory disease, asphyxiation, and other problems in humans, and they can harm plant and animal life as well. Other gases, including chlorine, ozone, sulfur dioxide, and carbon monoxide, are all harmful to individual health, as well as to the broader environment and the ecosystem.

Radon is another gas that has been a topic of concern in recent years. This colorless, odorless, radioactive gas is formed by the breakdown of uranium in rock, groundwater, and soil in some geographic areas (Yassi et al., 2001). Radon is believed to be one of the leading causes of lung cancer, accounting for up to 20% of all lung cancers (Friis, 2007). Among nonsmokers, radon is the leading cause of lung cancer (EPA, 2007f), whereas lung cancer risk is increased 10-fold in smokers who are also exposed to radon in the home (EPA, 2007b). The link between radon exposure and lung cancer first came to light following studies of miners exposed to high levels of radon gas (Friis, 2007). Radon is a risk to all of us since it can seep into houses and public buildings through cracks in basement walls or through sewer openings, exposing people who inhabit, attend school, or work in the affected buildings. Furnaces and exhaust fans can help pull radon into a house, although the highest levels tend to be found in basements, where the gas enters. Home testing for radon was recommended by the EPA and the U.S. Public Health Service starting in 1988. Despite the health risks of radon exposure, a study to examine awareness of radon and its health consequences in low-income rural residents found

very troubling results. In an area at high risk for radon exposure, only 21% accurately assessed their own risk, over 52% were unsure about the causal nature of health problems from radon, and 39% disagreed that the long-term health of their children could be improved with reduced radon exposure (Hill, Butterfield, & Larsson, 2006).

*Healthy People 2010* (USDHHS, 2000) has two objectives focused on radon concerns. One goal is to increase the proportion of persons who live in homes tested for radon concentrations from 17% to 20%, and the other is to increase the number of new homes constructed to be radon-resistant from 1.4 million (in 1997) to 2.1 million by 2010. According to the EPA (2007h), radon-resistant construction techniques include installation of a gas-permeable layer beneath the slab or flooring system, plastic sheeting on top of the gas-permeable layer and under the slab, sealing and caulking of all openings in the concrete foundation, installation of a vent pipe from the gas-permeable layer to the outside of the house, and possibly the installation of a venting fan. Since 2001, 6% of new homes nationwide have been constructed with radon-reducing features. In areas with high radon risk (Zone 1), approximately 12% of new homes built incorporate the needed features (EPA, 2007h). Clearly, increased public awareness and action is needed (Fig. 9.4).

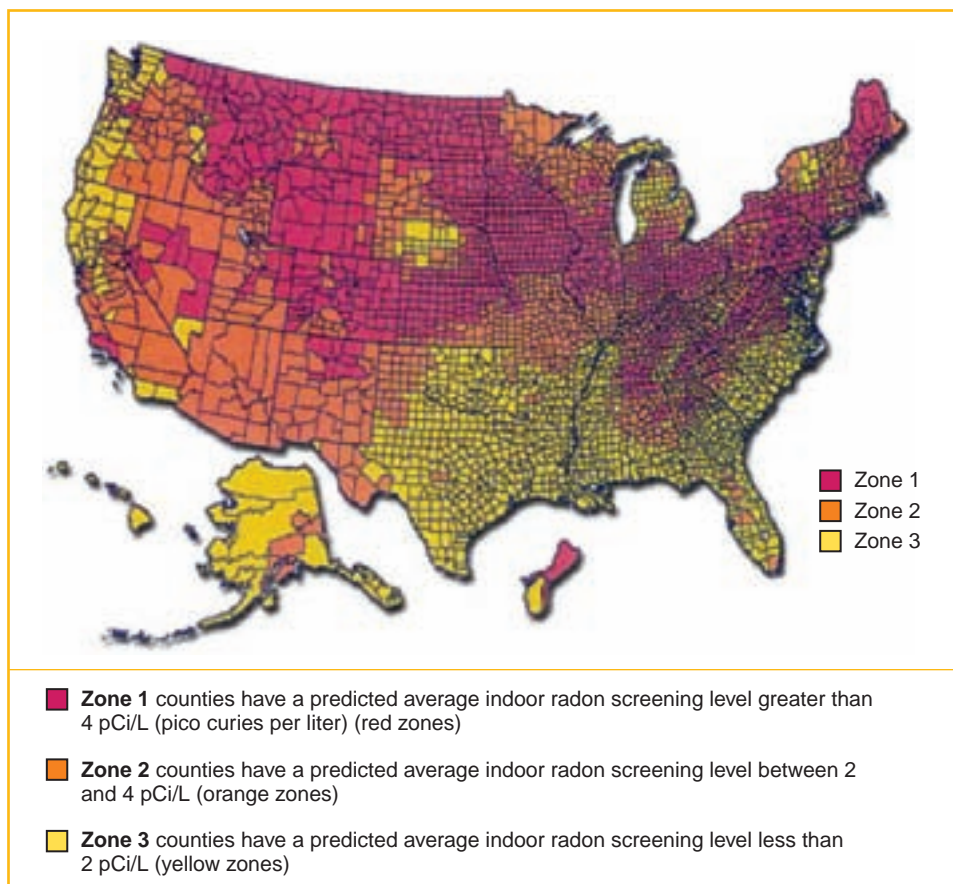

### **Acid Precipitation (Acid Rain)**

The emission of hazardous chemicals into the Earth's atmosphere has a serious effect on the environment. Air pollutants such as sulfur dioxide from power plant emissions or nitrogen oxides from motor vehicle exhaust combine with rainwater, snow, and other forms of precipitation to produce sulfuric and nitric acid, commonly called "acid rain" (EPA, 2007a; Friis, 2007). The problem has been most severe and most heavily documented in Canada (from emissions arising in the U.S. Midwest) and Scandinavia (from emissions arising in Germany and Britain). Similar situations occur in Russia and Eastern Europe and probably in China, India, and Central Asia. Acid rain can extensively alter the biology of small bodies of water (Yassi et al., 2001). Although acid rain does not seem to pose any direct danger to humans, it kills small forms of life and endangers forest and freshwater ecologies.

### **Ozone Depletion and Global Warming**

Two new and very threatening environmental hazards, stratospheric ozone layer depletion and global warming, are closely related. **Global warming** is the trapping of heat radiation from the Earth's surface that increases the overall temperature of the world, causing a "greenhouse effect." This warming is caused by carbon dioxide and other gases that enter the atmosphere through a depleted ozone layer and become trapped (Friis, 2007; Yassi et al., 2001). The direct health effects of ozone depletion include increased risks for skin cancer and cataracts. Greater indirect effects could result from global warming through damage to the food chain, an increase in the global population exposed to vector-borne diseases, raised ocean levels, and a variety of effects on crop production (Friis, 2007). Of additional concern, in 1995, at least 25 million people (sometimes called *environmental refugees*) could no longer support their families in their

**FIGURE 9.4** Environmental Protection Agency map of radon zones. From U.S. Environmental Protection Agency, <http://www.epa.gov/radon/zonemap.html>.

homelands because of drought, soil erosion, desertification, deforestation, and other environmental problems. By 2010, this number could well double, further stressing existing economic and environmental resources (Myers, 2005).

In the past, changes in the Earth's climate resulted from natural causes and enabled the evolution of species over hundreds of thousands of years. The accumulation of stratospheric ozone shields the Earth from damaging ultraviolet light, filtering and reducing the extent of radiation that reaches the Earth. Today, human activities are affecting our climate in serious and immediate ways. The ozone layer is being destroyed as a result of chemical interactions among air pollutants, primarily chlorofluorocarbons (CFCs). Most of these ozone-destroying chemicals and greenhouse gases are produced in the wealthier countries. Efforts to curb use of ozone-depleting gases in the U.S. and internationally is now having a measureable impact. Although the ozone is expected to continue to degrade over the next few years, gradual recovery is expected within 50 years (EPA, 2008); assuming continued worldwide efforts to phase out these chemicals are maintained.

### Government's Role

Government regulation of air pollution has been relatively slow in developing. In 1963, the U.S. federal government passed the first series of Clean Air Acts. These set standards for air quality

and industrial emissions and delegated funds to assist in pollution control programs. Although progress has been made, further public health efforts are needed to help identify pollution sources and related health hazards (see Display 9.2).

Even if the air is cleaner than it was 40 years ago, work remains to be done. In 2005, the EPA issued the Clean Air Interstate Rule (CAIR), designed to reduce power plant emissions by the largest amount in more than a decade. Currently, 28 states in the East, Southeast, and Midwest are covered by the rule. The health benefits are expected to exceed 25 times the cost of compliance, with results published in 2015 (EPA, 2005). This rule was enacted in conjunction with the Clean Air Mercury Rule, the first ever federally mandated requirements for reduced mercury emissions from coal-fired electric utilities. The automobile is a continued target of efforts to reduce pollutant production, and new steps will include reducing the sulfur content of gasoline, tightening emission standards, and removing loopholes that allow certain groups of vehicles to defy emission standards.

The EPA has identified ways in which people can help reduce greenhouse gases at home, work, school, and on the road. These are useful suggestions that the community health nurse can use and pass along to clients. Seven easy suggestions for the home include (EPA, 2007d):

1. Change five lights (e.g., replace five frequently used fixtures or bulbs with *Energy Star* options).

2. Look for *Energy Star* qualified products (e.g., lighting, home electronics, heating and cooling equipment, and appliances).
3. Heat and cool smartly (e.g., change filters regularly, install adequate insulation, have equipment serviced regularly).
4. Use green power (e.g., use electricity from renewable sources).
5. Reduce, reuse, and recycle (e.g., reduce waste generation and water consumption, participate in community recycling programs).
6. Be green in your yard (e.g., compost food and yard waste).
7. Calculate your household's *carbon footprint* (use EPA Personal Greenhouse Gas Emissions Calculator available at: [http://www.epa.gov/climatechange/wycd/calculator/ind\\_calculator.html](http://www.epa.gov/climatechange/wycd/calculator/ind_calculator.html)).

### Nurse's Role

Community health nurses can influence air quality through detection, community education, and lobbying for appropriate legislation. People are exposed to numerous impurities in the air in their homes and workplaces. Nurses can promote health by helping to detect indoor pollutants and informing people of existing or potential dangers. Many household products and building materials emit vapors that can cause problems. Cigarette smoke and cigar smoke are common indoor pollutants that can have ill effects on non-smokers as well as smokers. Infants and other vulnerable persons are at risk from such exposure (Friis, 2007; Wigle, 2003). Carbon monoxide poisoning may result from stove and furnace emissions or from car exhaust accumulating in a garage. Radon gas trapped in basements or tightly insulated homes is also a major concern. Nurses can assist with the prevention or elimination of these health hazards by ensuring that the indoor environment is well ventilated (oxygenated) and heating equipment properly maintained, and by looking for possible sources of pollution. Installation and maintenance of residential carbon monoxide detectors outside the sleeping area in every home should also be encouraged (U.S. Consumer Product Safety Commission, n.d.).

### Water Pollution

Water is such an essential element to human survival that the available quantity and quality of water within a community has become a prime environmental health issue. Water has many uses other than consumption by humans. It serves as a means of transportation. It cleans and cools the body or other objects. It is the basis for many forms of recreation and sports, such as swimming and boating, and it provides a vehicle for disposing of human and industrial wastes and controlling fires. Apart from serving human needs, water also acts as a medium for sustaining other living organisms, as a home to plant and animal life, and as a means of carrying and distributing necessary nutrients in the environment. Although nursing's environmental health role concerns the safe consumption of water by humans, it is important, taking an ecologic perspective, to keep in mind water's other uses and users.

Drinking water comes from two main sources: surface water (such as lakes and streams) and underground sources (called *groundwater*), which collects in areas known as *aquifers* and comes to the surface through wells and springs. In general, underground sources are thought to be less subject to contamination than surface sources, which are open to runoff from agricultural pesticides or industrial wastes. However, groundwater too may be contaminated if seepage occurs. It is important to recognize that public water supplies may originate from either surface or underground sources. Well water may refer to an individual residential well or to a large municipal facility. In the Middle Ages, disease epidemics spread as people drank water contaminated by human waste; this is still a problem today in developing countries and, at times, in other countries, if flooding occurs. Residential well water may contain fecal contaminants from improper septic tank drainage. Toxic agents that may affect groundwater include buried hazardous wastes, nitrate contamination of wells in rural areas, and arsenic in drinking water, which is linked to bladder, kidney, and liver cancers (Friis, 2007).

In most industrialized nations, lack of sufficient water for drinking has not been a serious issue. Areas with limited water supplies have devised facilities to store water during high-flow periods, so that it is available to satisfy the year-round needs of a given community. Adequate water supply to meet agricultural demands still has not been achieved, however.

The major concern with regard to water is purity. Every time you turn on the faucet in your home, workplace, or in the community, the expectation is that the water is clean, clear, and free of contamination. In the United States, we take it for granted that the water we drink is safe; this is not always the case. More concerning is that, in many parts of the world, access to safe sources does not exist. As much as 20% of the world's population may not have access to safe sources of drinking water (Friis, 2007). Water can be contaminated and made unsafe for drinking in many different ways. Three are discussed here.

1. Water may be infected with bacteria or parasites that cause disease. *Giardia lamblia* is a parasite that enters the water supply through contamination from human or wild animal feces. It can cause giardiasis, a gastrointestinal disease that results in diarrhea and malabsorption of nutrients. For example, beavers in the northern Cascade Mountains often contaminate water. Humans using the area for recreation must treat the water by boiling before drinking it. Water may also be contaminated with bacteria such as *Vibrio cholerae*, resulting in cholera, or with viruses leading to hepatitis A (Heymann, 2004).
2. Toxic substances, such as pesticides, are introduced by humans into water systems and constitute another form of water pollution. These substances may contaminate streams, lakes, and wells. Industrial pollutants may also enter drinking water through oil spills, careless dumping, or buried hazardous wastes that seep into underground water sources. Such wastes not only harm the quality of the water but also have been implicated in diseases such as leukemia. They can contaminate local fish and shellfish, making them unfit for consumption. One

such example is mercury, which, through bioaccumulation has reached levels in some seafood (shark, swordfish, king mackerel, and tilefish) that make them unsafe for consumption, especially by pregnant women, nursing mothers, and young children (U.S. Food and Drug Administration [FDA], 2004; Friis, 2007).

3. Pollutants may upset the ecosystem, affecting natural organisms that help purify water systems. Power plants or other industries dissipate excess heat into lakes and streams and cause water temperatures to rise. This *thermal pollution* kills off beneficial organisms in the water.

In response to the various potential water pollutants, most cities and local communities with public or semipublic water systems in operation have set up water testing and treatment purification centers to ensure safe drinking water. Unfortunately, testing for bacteria and toxins often does not occur until after illness has been reported. Another major problem arises in rural areas, where most water supplies are private and therefore not subject to systematic testing and treatment. Testing of water for coliforms as indicator organisms has proven useful (EPA, 2006c). Water frequently is treated with chlorine to disinfect it, but this has led to a small but potential risk of chloroform exposure, a by-product which is linked to small for gestational age (SGA) and preterm delivery (Wright, Schwartz, & Dockery, 2004).

Recreational uses of water, such as public swimming, have health implications. Lakes, oceans, rivers, and even hot tubs often carry infectious agents and result in a number of health problems including swimmers' itch; diarrheal diseases, such as cryptosporidiosis caused by a parasite; and the bacterial infection leptospirosis, which presents with fever and malaise and may progress to jaundice or meningitis (Heymann, 2004). Many disease outbreaks have been caused by polluted water systems serving campgrounds, parks, and other public areas. Between 2003 and 2004, the most commonly reported gastroenteritis outbreak associated with recreational water exposure was caused by cryptosporidium (Dziuban et al., 2006).

The marine ecosystem can be altered by any changes that affect the oceans, such as water temperatures at the surface, nutrient levels, winds, currents, and precipitation patterns. This can lead to possible increases in diseases transmitted from fish and shellfish, toxic "red tides" (Backer et al., 2005; Heymann, 2004), and a dormant form of cholera that develops when pH, temperature, salinity, and nutrient levels are insufficient (Hoskins, 2001). In addition, coming in contact with marine waters that are contaminated with domestic sewage can cause nonenteric illnesses among swimmers, including febrile respiratory illness from fecal streptococci and ear ailments from fecal coliform exposure.

### Government's Role

Most of the responsibility for maintaining water quality rests with state and local governments. The federal government took a needed step in 1974 by passing the Safe Drinking Water Act, which gave the EPA authority to establish water standards and to ensure that these standards were upheld. The federal government also provided funds to assist state and

local governments in this effort. In 2000, the EPA revised regulations on public notification to expedite sharing of vital information with the public. In fiscal year 1998 alone, 25% of the public water systems had violations requiring public notification. Of these 124,000 violations, the majority were for monitoring and testing violations, with 1.5% pertaining to real short-term health threats. In cases of acute health risks, water systems had 24 hours to notify affected populations (EPA, 2002). These long-awaited rules set the minimum requirements for healthy drinking water and helped to ensure the safety of drinking water supplies. However, policies related to groundwater quality protection need continued monitoring. Saltwater intrusion caused by excessive withdrawal of water from the aquifer can also threaten drinking water supplies in coastal areas (Friis, 2007). As in many communities across the country, almost half of all residential drinking water consumption in South Florida is used for landscape irrigation. With concern for continued viability of the water supply, many communities have implemented water use restrictions (South Florida Water Management District, 2007). With conservation, it is hoped that the progress of saltwater intrusion will be mitigated or reversed.

Globally, because of the enormous health problems in developing nations caused by unclean water, the WHO declared the 1980s as the International Clean Water Decade and established a goal to have safe drinking water for all by the year 1990. This goal was not met; only 50% of the world's population had a safe water supply in 1980, 55% in 1985, and 66% in 1990 (WHO, 2000). By 2002, the percentage had increased to 83%, yet slow progress in areas such as Sub-Saharan Africa tempered the achievement. In 2005, a new global initiative, the *International Decade for Action: Water for Life 2005–2015* was launched with the goal of increasing awareness of the basic need for safe drinking water and finding solutions to achieve global access (WHO, 2005). Efforts to address water purity globally continue to assume high priority, however the focus is shifting from drinking water quality alone toward overall improvement of the environment.

### Nurse's Role

What role can community health nurses play in the effort to keep water safe? As nurses work in a community, they can help by examining household or city drinking water. Is there a strange odor or discoloration? Are particles or sediment visible in the water? Being aware of drinking water quality and possible contaminants in a given locality alerts the nurse to consider a possible causal relationship if a problem exists. Asking clients to observe and report changes in water quality further assists the nurse in the monitoring process. If such changes occur, the proper authorities, such as health department officials, should be notified and water samples tested. Community health nurses can also be alert to increased incidence of illnesses that might be water related. For example, if several children exhibit similar symptoms, the nurse might inquire as to whether all have been swimming in the same pool or drinking from the same water fountain. Although water quality monitoring is ultimately the responsibility of environmental health authorities, it is incumbent on the nurse, as a collaborating member of the health team, to observe and report any information that would further the goal of safe and healthy water for communities.

## Deforestation, Wetlands Destruction, and Desertification

**Deforestation** is the clearing of tropical and temperate forests for cropland, cattle grazing, or urbanization. Elimination of these natural habitats is dooming some species of insects and animals to **extinction**, the loss of a species from the Earth forever. **Wetlands** are natural inland bodies of shallow water, such as marshes, ponds, river bottoms, and flood plains, which filter contaminated surface waters and support wildlife reproduction and growth. They can be as small as a neighborhood seasonal stream bed or as large as the Everglades in Florida. At one time, the Everglades covered the lower 20% of the state but, in 1948, the U.S. Army Corps of Engineers constructed an elaborate system of roads and water control structures that converted thousands of acres and ultimately led to urbanization and loss of much of the original habitat (National Park Service, 2000). Today, only 50% of the original wetlands still exist in South Florida. The destruction of this major U.S. wetland has caused numerous species of wildlife to disappear from the area or become extinct. There is discussion to reclaim some of the land and convert it back to much-needed wetlands. **Desertification** refers to the conversion of fertile land into desert, which is unable to support crop growth or wildlife.

Any natural or manmade process that changes life-supporting regions into land for other use or into barren wastelands upsets the ecosystem of the area. The destruction of forests and the upturning of Earth for urban sprawl uncovers organisms hidden for eons, to which humans and animals are then exposed. In addition, gases that were once absorbed by lost trees remain in the atmosphere and contribute to ozone depletion, which increases global warming. Deforestation, in turn, contributes to desertification, because forests provide protection for the surrounding topsoil by way of their roots, fallen leaves, and undergrowth. When this protection is lost, landslides and other geographic changes occur. Global temperature increases cause riverbeds to dry up and create desert areas that are unable to support the people who once inhabited them. Drought, famine, and starvation often follow in such areas. The loss of forests and wetlands, along with increasing desertification, affects millions of people each year, with a potential for catastrophic environmental damage in the future.

### Government's Role

Our government (both state and federal) has the power to make decisions that save the wetlands and forests in the United States. The decision to save these lands is made when constituents express their concern loudly enough for their congressperson or senator to hear and respond positively. Often, developers of housing and industrial facilities are more influential, and their interests prevail. If the importance of the wetlands and forests is not recognized where decisions are made, then they will be lost.

### Nurse's Role

Community health nurses can make a difference in this area. Perhaps no other person knows a community more intimately than the community health nurse. This role gives a valid voice of concern at the local level. By using leadership

and collaborative skills, the nurse can initiate grassroots efforts to save wetlands and forests in the community. Chapters 12 and 13 provide information for bringing about change, beginning at the local level.

## Energy Depletion

Most of the energy sources we use today are not renewable. Wood has been used for thousands of years and was our first fuel. It is still a primary source of home heating for most of the world's population (with resultant deforestation and air pollution). Natural gas for heat and fuel can be a highly efficient energy source, but pipelines must be built for hundreds or thousands of miles in some cases—a luxury that smaller and poorer countries cannot afford. Coal takes thousands of years to create, and although substantial reserves remain, not all coal extraction is environmentally or economically feasible (Energy Information Administration, 2007). Some countries do not have coal as a natural resource and have similar problems with natural gas.

Nuclear energy has been used for at least 50 years. This source of energy has been controversial since its first use, yet it has proved to be an effective power product. Nevertheless, there have been some near-disasters and real disasters caused by human error. In 1979, a nuclear power plant on Three Mile Island near Harrisburg, Pennsylvania, had a near-disaster in one of its cooling towers, with a partial meltdown of the core. Fortunately, the nuclear core was never exposed. This scare caused many people in the United States to lobby against nuclear power plants in their communities, and these protests have effectively stopped new construction (Friis, 2007). The largest radiation disaster occurred in April, 1986, at the Chernobyl nuclear power plant in Ukraine. Five million people in Ukraine, Belarus, and the Russian Federation were exposed to ionizing radiation. Twenty-eight of the 444 people at the plant who were directly exposed died within 3 months, and 300 were hospitalized. Psychological effects among people living in the surrounding areas resulted from the lack of information immediately after the accident, the stress and trauma of compulsory relocation, a break in social ties, and fear that radiation exposure could cause health damage in the future (Yassi et al., 2001). An increase in the incidence of childhood thyroid cancer has been noted, particularly in Belarus (Friis). The final impact in terms of increased cancer rates resulting from the breach may never be known. The area remains unsafe to enter today.

The building of nuclear power plants is only one community concern; the disposal of the nuclear waste products also raises environmental, safety, and ethical issues. The permanent disposal of all high-level radioactive waste falls under the regulations of the Nuclear Waste Policy Act of 1982. The act provides that all high-level waste will be disposed of underground and in a deep geologic repository, and that the Yucca Mountain, Nevada site is the current preferred site. The three federal agencies involved in the disposal are the Department of Energy, which develops permanent disposal capacity for spent fuel; the EPA, which develops environmental standards to evaluate the geologic repository; and the Nuclear Regulatory Commission, which develops regulations to implement the EPA safety standards and licensing of the repository (U.S. Nuclear Regulatory

Commission [NRC], 2007). The Yucca Mountain site was originally slated for licensing review in 2004, but legal challenges and financial complications have delayed that process (Yucca Mountain Information Office, 2007). With disposal issues and safety concerns at the forefront, the expansion of nuclear energy in the United States remains controversial.

### Government's Role

Other renewable sources of energy need to be discovered, rediscovered, or tapped. Newer and more “environmentally friendly” energy sources are used experimentally in limited areas. They include landfill gas recovery, solar power, and wind power. These sources can make a difference:

- ◆ The National Wind Coordinating Collaborative (2007), established by utility companies, consumers groups, state and federal regulators, and the U.S. Department of Energy, serves as a forum for discussions about the use and expansion of wind power. The stated goal of the organization is “self-sustaining commercial markets for wind power that is environmentally, economically, and politically sustainable.” Environmental impact issues, such as wildlife mortality and land use considerations are explored.
- ◆ The U.S. Department of Energy (DOE) is working closely with industry and universities to develop photovoltaic (PV) systems for harnessing the rays of the sun to generate power. As far back as the 1996 Olympics in Atlanta, the swimming competitions took place under lights powered by PV. Today, many emergency telephones along the nation’s highways are powered by PV systems, and efforts are underway to expand this energy source for utility power production (DOE, 2006).
- ◆ The DOE is working to address the need for growing and harvesting crops that can be turned into biomass fuels and to reclaim waste products from agricultural crops and forestlands for generating electricity. The agency currently supports five regional organizations to advance the use of biomass. Since 2002, 60 awards for biomass research and development have been supported by the federal government. In 2007, \$18 million was earmarked for these efforts (DOE, 2007a).
- ◆ The DOE also is involved in geothermal technology. One program *GeoPowering the West* is working with the western states, including Alaska and Hawaii, to dramatically increase the use of geothermal heat sources, including heat pump systems. The oldest and largest geothermal power complex in the United States is The Geysers. Located 100 miles north of San Francisco, it is a source of 725 megawatts of power, with plans to increase this amount by 80 megawatts by 2012 (DOE, 2007b).

It will take both a global effort to increase awareness and accompanying technology to use these energy sources in enough areas to make an environmental difference.

### Nurse's Role

A community health nurse may not have a direct role in the creation of new energy sources or the use of a particular source. However, the nurse can educate people about energy conservation, discuss alternative energy sources presently available in the community, and encourage people to become interested in and knowledgeable about the importance of the potential for energy depletion in the future.

Conservative use of existing energy sources can be a part of the community health nurse’s teaching with families in the community. In addition to saving precious energy resources, measures taken to cut energy use can save the family money on monthly utility bills. Conservation methods include ensuring that a home or apartment is well insulated and free from drafts; broken windows and improperly fitted windows or doors are repaired; caulking and weather stripping is used where needed; and heating and cooling of the home are modified by setting the thermostat at 68 degrees in the winter and no lower than 78 degrees in the summer. Families should be encouraged to wear warmer clothing or layers of clothing indoors in the winter and to dress in cool cotton garments in the summer. In the summer, encourage families to use indoor free-standing or ceiling fans, and to close blinds and curtains on the sunny sides of the house to help to keep it cooler.

In many communities, the utility company provides home energy inspections free of charge to help families recognize areas in their home where they are losing energy. Often, these programs provide funding to make the needed changes, especially among low-income families.

### Unhealthy or Contaminated Food

The food supply, and particularly the quality of that food, is affected by the environment, and numerous health hazards are associated with food. The community health nurse needs to ask how the environment influences the safety of food for human consumption. Three types of hazardous foods must be considered when examining food as a possible health problem: inherently harmful foods, contaminated foods, and foods with toxic additives.

### Inherently Harmful Foods

Poisonous foods, such as certain types of mushrooms or inedible berries, do not pose a serious threat to most people. The general public can identify and avoid harmful plants and substances, so poisonings are rare. There are, however, numerous household plants and outdoor flowers, shrubs, and trees that are poisonous if consumed. A searchable database of poisonous plants is available through Cornell University at: <http://www.ansci.cornell.edu/plants/alphalist.html>. Children in particular are at risk because some of these plants bear berries or colorful flowers that can capture a child’s interest, including the following examples (Texas A&M University, n.d.):

#### House Plants

- ◆ Hyacinth
- ◆ Dieffenbachia
- ◆ Elephant ear

#### Flower Garden

- ◆ Larkspur
- ◆ Lily-of-the-valley
- ◆ Iris

### Ornamental Plants

- ◆ Wisteria
- ◆ Azalea
- ◆ Yew
- ◆ Rhododendron

### Trees and Shrubs

- ◆ Oaks
- ◆ Elderberry
- ◆ Black locust

### Plants in Wooded Areas

- ◆ Jack-in-the-pulpit
- ◆ Mistletoe

### Plants in Fields

- ◆ Nightshade
- ◆ Buttercups
- ◆ Poison hemlock

## Contaminated Foods

Contaminated foods pose a more serious health problem. The Centers for Disease Control and Prevention (CDC) estimates that 76 million people in the United States experience food-borne illnesses each year, accounting for 325,000 hospitalizations and more than 5,000 deaths—an average of almost 100 deaths per week (National Institute of Allergy and Infectious Diseases [NIAID], 2007). Food may contain harmful bacteria that cause outbreaks of disease, such as *Salmonella enterica*, *Campylobacter jejuni*, *Clostridium botulinum*, *Shigella sonnei*, or *Escherichia coli* 0157:H7. These are the most common or serious of the more than 250 different known causes of food-borne diseases (Heymann, 2004; NIAID, 2007). Of these, salmonellosis is the most common (Friis, 2007).

There are other causes of foodborne illnesses. Parasitic transmission usually takes the form of trichinosis, which is caused by ingestion of *Trichinella spiralis* in undercooked pork and is rarely seen in the United States (Heymann, 2004). Various types of worm infestations have created serious health problems, particularly in developing countries. Viral food transmission is rare. Different types of chemical food contamination result from improper food handling or processing (e.g., dirty machines used in food processing factories), from use of pesticides and herbicides by farmers, and from polluted water (e.g., mercury in fish).

International trade and travel, together with changes in demographics, consumer lifestyles, food production, and microbial adaptation, have led to the emergence of new food-borne diseases. Globalization of the food supply means that people are exposed, through foods purchased locally, to pathogens native to remote parts of the world. As a result of international travel, people who are exposed to food-borne hazards in a foreign country may bring disease into their own country when they return, possibly exposing others in a location thousands of miles from the original source of the infection (Friis, 2007).

## Foods with Toxic Additives

A third health hazard from food comes from the intentional introduction of additives to food products. Because present-day consumers demand convenience foods and time-saving

devices—and businesses want to produce food items with long shelf-lives, enhanced flavor, and lasting, vibrant colors—many foreign chemicals and synthetic products have been added to foods. Animals that are raised for food, such as chickens, pigs, and beef cattle, are often fed or injected with substances to speed their growth. As consumers shift toward healthier eating, they do not know and are only starting to question the effects these additives may have over time. For example, red dye no. 2 once was added to improve the color of certain food products but has since been identified as carcinogenic. Preservatives and chemical flavorings such as saccharin have also proved hazardous in large doses. It is still questionable what small doses may do with prolonged use. More recently, questions have been raised about potential long-range effects of NutraSweet (aspartame), a sugar substitute. Furthermore, such natural flavor enhancers as salt and processed sugars appear in excessive quantities in some canned and packaged foods and are linked to unhealthy dietary consequences, such as hypertension or obesity. In small doses, these additives may not be harmful, but when additives are consumed in combination and over prolonged periods, they may create serious health consequences.

The most recently available sugar substitute *Splenda* (Sucralose) was first introduced in 1999 following FDA approval (McNeil Nutritionals, 2007). It is now found in a wide variety of foods, including snacks and treats for school-aged children, and is actively marketed to families with children. Although the substitute was tested in more than 100 scientific studies and approved by major organizations such as the Joint Food and Agriculture Organization/World Health Organization Expert Committee on Food Additives (JECFA), the Health Protection Branch of Health and Welfare Canada, and Australia's National Food Authority (McNeil Nutritionals), there are those who question the long-term safety of the additive and its effectiveness in reducing obesity. With respect to young children, a nutritionally sound and low-sugar diet would be far preferable to the use of artificial sweeteners.

## Food Irradiation

One promising tool for global food safety not yet mentioned is food irradiation. It is a process of imparting ionizing energy to food to kill microorganisms. Sometimes it is referred to as *cold pasteurization* (Friis, 2007). Just as with traditional heat pasteurization of milk, food irradiation can enhance the safety of foods such as meat, chicken, seafood, and spices, which cannot be pasteurized by heat without changing their nature to a cooked rather than a raw form. Irradiation is not a substitute for safe food handling and good manufacturing practices by processors, retailers, and consumers, but it is a method of promoting food safety that has been approved by some 50 countries worldwide. It has been applied commercially in the United States, Japan, and several European countries such as Belgium, France, and the Netherlands for many years—in some for longer than two decades.

Only certain ionizing energy sources can be used for food irradiation. Permitted gamma ( $\gamma$ ) sources are the isotopes cobalt 60 and cesium 137 (Friis, 2007). More recently, electron beams (e-beams) have become available as a source of ionizing energy in the United States and other countries. All of the previously mentioned organisms that cause food-borne diseases can be eradicated with the use of food irradiation. Although

**FIGURE 9.5** International symbol for irradiated food (Radura logo).

many questions have been raised about its safety and efficacy, food irradiation is an accepted practice globally (International Atomic Energy Agency [IAEA], 2005) and “after decades of research, development, public debate and consumer acceptance trials in many countries, irradiation has emerged as a safe and viable technology for ensuring the safety and quality of food and for combating food-borne diseases” (IAEA, n.d., p.2). The international symbol, the Radura logo, indicating that food has been irradiated can be seen in Figure 9.5.

### Government’s Role

It is the legal responsibility of food producers, processors, and manufacturers to guarantee the quality and safety of food products. However, conflicting motives, such as concern over loss of profit, often lead to careless or inadequate monitoring. Governmental regulatory agencies exist on the local, state, and federal levels to set standards and to control the quality of food sold to the public. Such public health authorities as the FDA, the U.S. Department of Agriculture, and the USDHHS are all necessary to help ensure the purity of commercial food products. Included in their jurisdiction is supervision of the food service industry. Licensing requirements, sanitation standards, and inspections serve as control measures.

Governmental agencies cannot cover all the bases, however. For example, inadequate inspection of the quality of commercial fish sold for food has led to numerous outbreaks of hepatitis A and other illnesses. With the wide variety of possible contaminants and potential dangers, consumers’ best protection lies in supervising their own food quality (see Internet Resources at the end of this chapter).

### Nurse’s Role

Community health nurses can have a significant impact through health education. Most bacterial and viral food-borne diseases can be prevented if people know and practice

proper cooking and storage of food as well as proper personal hygiene.

Nurses can teach the basics of keeping perishable products sufficiently refrigerated, discarding foods that may be old or spoiled, cooking foods thoroughly, and bringing water to a full boil when appropriate to be certain of eliminating microbes. A consumer education program that is sponsored by the Partnership for Food Safety Education is called Fight BAC! This is a public–private partnership of industry, government, and consumer groups created to educate the public about safe food handling to help reduce food-borne illness. Educational materials are available for use by teachers, health educators, and community health nurses when working with groups in the community (Partnership for Food Safety Education, 2006).

Nurses can emphasize washing and cleaning of produce and tools used in food processing, including the preparer’s own hands. Finally, nurses can educate people to watch for signs of contamination. A dented can, for example, may signal the presence of living bacteria that are using the oxygen within the container and contaminating its contents. Nurses can raise public awareness regarding the conditions of supermarkets, restaurants, and other food handlers. They can also help promote community standards, enabling legislation, and policies for safer food supplies.

### Waste Disposal

The United States generates more solid and hazardous waste per capita than any other industrialized nation. In 1990, each person in the United States produced, on average, 4.3 pounds per day of combustible or landfill-maintained waste. In 1995, this figure was 4.4 pounds per day, equivalent to 1,600 pounds of municipal solid waste each year. More frightening is the fact that U.S. industry produces the equivalent of more than 1 ton of *hazardous* waste per person each year. In addition, some 8.1 million tons of toxins were released into the air in 1993. The year 2010 target is 2.0 tons (USDHHS, 2000).

With the vast amounts of waste produced in the form of household garbage, human excreta, and agricultural and industrial byproducts, including hazardous chemical and radioactive substances, it is no wonder that waste management and disposal has become an important and pressing topic in recent decades. New technology has effectively addressed some of the problems, but there is still much need for improvement. Solid and hazardous wastes pose a wide range of public health concerns. Therefore, it is imperative that health officials, including community health nurses, become aware of the possible health hazards that these wastes present to individuals and to communities.

### Disposal of Human Waste

One of the oldest environmental health hazards comes from improper disposal of human excreta. Although industrialized nations have successfully addressed the problem, it continues to be widespread in developing nations and in rural, poverty-stricken communities. Human wastes, particularly feces, provide a perfect environment in which bacteria and disease-causing parasites can live and reproduce.

Therefore, contaminated drinking water, food grown in contaminated soil, and, of course, direct contact with the contaminated water or soil can cause infections. For example, hookworm, a problem in the United States in the early part of the 20th century, usually enters the body through the skin of bare feet (Heymann, 2004; Rockefeller Archive Center, n.d.).

### Disposal of Garbage

Dumping, burning, and burying are the most common solid-waste disposal methods. Dumping is problematic, because garbage dumps provide perfect conditions for the breeding of rats, flies, and other disease-carrying organisms and may potentially be a source of water contamination from runoff. Dumps are also eyesores that take up valuable land resources. Burning of waste reduces the volume of garbage, but it also produces noxious odors and pollutes the air. Sanitary landfills have generally replaced dumps as a more effective way to dispose of refuse by burying it. With proper handling, including covering and daily sealing (to prevent insect and rodent breeding), this method has proved satisfactory for solid waste.

### Disposal of Hazardous Waste

Disposal of toxic chemical and radioactive wastes produced by industry is another grave concern. The threat is serious, because one cannot be certain of all of the effects of these wastes or whether present methods of disposal are fool-proof. Furthermore, many of these wastes escape containment or accidentally leak into water systems and into the soil to contaminate drinking water and food.

In 1980, the federal government enacted the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), commonly referred to as the Superfund. Under the act, uncontrolled or abandoned hazardous-waste sites are cleaned up. In addition, the act provides for accidents, spills, and other emergency releases (Friis, 2007). Another feature of the act is the identification and prioritization of the most hazardous substances by the Agency for Toxic Substances and Disease Registry (ATSDR), in cooperation with the EPA. The agencies prepare the National Priorities List (NPL), which is used to identify those sites eligible for Superfund action (Friis, 2007). The top 20 hazardous substances from the 2005 list can be reviewed in Table 9.2.

Primary methods of hazardous waste disposal include burial in double-lined cells in landfills, surface impoundments for special treatment and storage, waste-injected underground steel- and concrete-lined wells, solid waste piles, and land treatment facilities. Some hazardous wastes are incinerated before disposal. With the disposal of hazardous waste, it is always a concern that storage containers may not be leak proof, and interference with dump sites or storage facilities may expose the environment to these toxic substances. Examples of chemical contamination have been discovered in communities such as Elizabeth, New Jersey; Times Beach, Michigan; and Love Canal, New York, where residents developed cancer and other health problems because of exposures to toxic chemicals. There is also the continuing problem of securing disposal sites for the increasing volume of hazardous wastes. Communities seek

**TABLE 9.2 Top 20 Hazardous Substances—2005 CERCLA Priority List**

1	Arsenic
2	Lead
3	Mercury
4	Vinyl chloride
5	Polychlorinated biphenyls
6	Benzene
7	Polycyclic aromatic hydrocarbons
8	Cadmium
9	Benzo(a)pyrene
10	Benzo(b)fluoromethane
11	Chloroform
12	DDT, p,p'-
13	Aroclor 1254
14	Aroclor 1260
15	Dibenzo(a,h)anthracene
16	Trichloroethylene
17	Dieldrin
18	Chromium, hexavalent
19	Phosphorus, white
20	DDE, p,p'-

the advantages of new technology but do not wish to bury the resulting wastes in their backyards. In many instances, legislators and public officials have faced serious conflict in their efforts to locate acceptable toxic waste dump sites.

With burgeoning industry and new technology in the world today, society has developed more sophisticated means of energy production, more labor-saving devices, and more practical and innovative products. This massive new product development has created a problem for the environment—how to handle the vast amount of waste created from discarded goods, by-products of production, and the “throwaway mentality.” For example, more than 3.5 million tons of disposable diapers, estimated to account for 1.4% of all municipal wastes, are dumped in landfills each year in the United States. Debate is ongoing as to whether reusable cloth diapers or one-time use diapers have a more negative environmental impact, but consensus is growing to support reusable diapers as the more environmentally friendly option (California Integrated Waste Management Board, 2007; National Geographic, 2006). With each child using between 5,000 and 8,000 diapers during the early years of life, the issue is of great importance. Additionally, the vast majority of disposable diapers are discarded directly into the trash instead of first flushing fecal material down the toilet.

Consequently, a large amount of raw, untreated sewage is ending up in landfills, with the potential for serious problems in the future. In the United States, modern landfills are designed to restrict leaching of contaminants directly into the groundwater, but this is not the case in all countries. Not only does the development of such products take an enormous toll on natural resources, but the quantity and nature of the resulting wastes also pose serious health hazards and environmental problems. Improper disposal of domestic products, such as toxic insect sprays, some household cleaners, partially used paint cans, used auto oil, and termite fumigation chemicals, causes health dangers (Calvert et al., 1998). The availability of toxic substances in the home is especially dangerous to young children. Estimates for 2001 are that nearly 40% of toxic agents most commonly ingested by children younger than 6 years of age included cosmetics, cleaning products, topical agents, pesticides, arts/crafts/office supplies, and hydrocarbons (Wilkerson, Northington, & Fisher, 2005).

### Government's Role

The government's role is to establish standards for safe waste disposal and to monitor and enforce compliance. In most modernized urban areas, the public sewage system handles waste by treating raw sewage and disposing of it into a body of water. In most instances in the United States, state health departments oversee proper waste treatment and disposal. In rural areas, where people often have private septic systems, the supervision of proper waste handling is difficult and not as consistent. Health workers in rural settings should be alert to the potential dangers posed by inconsistent monitoring. Communities across the country are beginning to address the issue of household hazardous waste by developing both disposal and recycling programs. These programs must meet or exceed current EPA guidelines (EPA, 2006d).

More research is needed to determine the effects of various disposal methods and to improve disposal practices. It is imperative that people not only learn how to dispose of wastes safely—to protect humans, the environment, and future generations—but that they also look seriously at other options. More emphasis must be placed on transforming waste into usable products, increasing the amounts and kinds of recycling done, and reducing the amount of refuse produced in the first place.

### Nurse's Role

Community health nurses can encourage the positive actions described by educating the public and lobbying for enabling legislation. Nurses can promote greater sensitivity among citizens to the problems of accumulating waste with its potential health hazards; encourage clients to buy products that can be recycled, and discourage use of aerosol spray containers, plastics, and other nonrecyclable items. Such information sharing occurs during home visits when conducting family and home assessments; during group educational opportunities that arise in apartment complexes or neighborhoods where several families are being served; with school children when the community health nurse is invited into the classroom by the teacher; or in conjunction with environmental health services when a community is blighted by waste management problems and the nurse

speaks to groups of parents, teens, or children. The possibilities are limited only by the nurse's imagination, priorities, community connections, and time constraints.

### Insect and Rodent Control

All human communities are affected by the insects and rodents living in their environment. On the least dangerous level, they can cause irritation (e.g., mosquito or flea bites) and discomfort (e.g., infestations of bedbugs or lice). They can also pose a direct threat to health through such things as attacks by diseased rats or squirrels. Insects and rodents can consume and, in turn, contaminate food. However, by far the most serious health hazard they impose is through their role as *vectors*—nonhuman carriers of disease organisms that can transmit these organisms directly to humans.

The most common vectors are mosquitoes, flies, ticks, roaches, fleas, rats, mice, and ground squirrels. All of these agents can serve as reservoirs for germs that they then transmit through physical contact with humans or by contaminating human foodstuffs or water. Cases of vector-spread diseases range from the 14th-century bubonic plague epidemic spread by rat fleas, which killed a quarter of the European population, to the mosquito-spread outbreaks of West Nile virus that began in New York in 1999.

### Government's Role

Vector surveys, research, and control are usually left to local and state health departments. These agencies have also implemented community awareness and pest control programs. Once vectors have been found, health workers can attempt to control them through many methods. Approaches used in the past included trapping of rodents, poisoning, spraying with pesticides, and eliminating areas where vectors breed (e.g., draining or filling marshes to control mosquito populations). In planning any approach, it is essential to consider the possible health hazards to humans or other living organisms and the effect the method will have on the ecosystem—how it may upset the ecologic balance. In 1986, the WHO advocated that the most basic, yet effective, approach is to improve sanitary conditions and practices to the extent that the conditions encouraging the multiplication of insects and rodents no longer exist (WHO, 1986).

### Nurse's Role

The community health nurse can contribute through awareness of the presence and possible health threat of rodents and insects. By remaining alert to the presence of rodents and insects in homes, schools, and communities, nurses can take measures to educate affected persons and notify proper authorities when corrective action is needed. They can assist this effort by surveying homes and neighborhoods for exposed rubbish or conditions that might attract insects and rodents. They can also promote preventive efforts through education and influencing policy makers.

Some of the simple changes families can make that will help to eliminate rodents and insects include the following:

- ◆ Ensure that screens are present on all open windows, and use screen doors.

- ◆ Wash dishes, pots, and pans after meals, and clean counter surfaces.
- ◆ Keep pet food off the floor; fill the pet dish when the pet eats, and do not leave it on the floor for extended periods.
- ◆ Keep foodstuffs that insects may infest, such as cereals, corn meal, and flour, in closed plastic containers.
- ◆ Ensure that doors and windows fit properly; use caulking if the outside can be seen through gaps in doors or windows.
- ◆ Eliminate food supplies for rodents and insects by keeping floors swept and vacuumed in rooms where people eat; preferably, eat only in the kitchen or dining room.
- ◆ Remove trash bags that include food scraps and food packaging from the home daily and place in garbage containers that are kept outside and have tight-fitting lids.

### Safety in the Home, Worksite, and Community

As we have seen, the environments of the home, workplace, and community at large significantly affect people's health. This section addresses six additional problems that affect people's safety: exposure to toxic chemicals, radiation exposure, injury hazards, noise pollution, and psychological hazards (Display 9.3).

#### Exposure to Toxic Chemicals

The number of natural and synthetic chemicals in the environment and the threats they pose to human and environmental health are overwhelming. Approximately 10 million chemical compounds were synthesized in laboratories in the 20th century (Yassi et al., 2001). Most chemicals are intermediates in the manufacture of end-products for human use. All chemicals are toxic to some degree, with the health risk being primarily a function of the severity of the toxicity and the extent of exposure. About 1,500 toxins constitute the greatest threat of hazardous exposures, but only some 450 have established threshold limit values and adequate toxicity testing. The *Household Products Database*, which is available to the public, links over 7,000 consumer brands to their health effects as described in the *Material Safety Data Sheets* (MSDS) provided by the manufacturers (NLM, 2007b). The number of new chemicals that come into use each year is of great concern, especially since many of them are essentially untested. Products originating from foreign sources, where consumer protection laws may be lax or nonexistent, are an ongoing threat. This section presents a general overview of the different categories of environmental chemicals, where they are found, the dangers they impose, and the community health nurse's role in forestalling or detecting those dangers.

Toxic chemicals include those that do not contain carbon, are not derived from living matter, are usually of mineral composition, and have an inherent capacity to cause injury to a living organism (Yassi et al., 2001). Inorganic toxic chemicals include halogens, corrosive materials, and metals. Substances such as zinc, iron, calcium, sodium, potassium, magnesium, and copper often play an important

#### DISPLAY 9.3

### TOXIC SUBSTANCES SCAVENGER HUNT

Do you know what toxic substances are in your community's air and water? You can find out by examining the Toxmap website. Other helpful sites may be found through the Centers for Disease Control & Prevention, the Environmental Protection Agency and local air resources boards or agencies. Go on a computer scavenger hunt and see what you can find:

- Look around your city or neighborhood. What are the most common environmental hazards? Find the ToxMap website and enter your zip code. For your city or area, which three companies have the highest amounts of emissions? Are there any VOCs (volatile organic compounds), metals, or polycyclic aromatic hydrocarbons listed for the top company?
- If you were an occupational health nurse, what safety measures would you want in place to respond to accidental exposures to these chemicals? What could you do for emergency first aid until assistance arrives?
- Search the web again to find the following information: What are the most deadly occupations? Which of the top three occupations are found in your area?
- Take another computer tour and learn more about air pollution. What is your estimated cancer risk from inhalation of air pollution? What other health problems arise from high levels of air pollution? Using the three Core Public Health Functions, state three things that a public health nurse can do to promote cleaner air and fewer health problems for clients.

U.S. National Library of Medicine—*Toxmap: Environmental Health e-Maps* <http://toxmap.nlm.nih.gov/toxmap/main/index.jsp>.

and healthful role in human physiology, but they become toxic if a person is exposed to large quantities. A toddler's accidental ingestion of several chewable vitamins with iron can cause mild gastrointestinal distress or, if many are ingested, devastating physiologic damage.

Lead is a toxic agent that is frequently found in occupational or industrial settings. Workers must be careful to avoid inhaling lead fumes or exposing their families to lead dust on their clothing. Lead, once widely used in paint and gasoline, can still be found in batteries and leaded gasoline sold in some parts of the world, mostly in developing countries. It is the top home environmental health hazard for children, with 310,000 children aged 1 to 5 years at risk for exposure (CDC, 2005). Although elevated blood lead levels (BLL) have been steadily and dramatically declining since the late 1970s, certain populations of children remain at high risk: minorities; children in low-income households; those exposed to lead-containing home remedies, cosmetics, and ceramics; children in contact with occupationally exposed adults; and those who live in older homes (EPA, 2007g). In 1997, there were 122,641 confirmed cases of elevated BLL (>10 µg/dL) in children under 6 years of age; by 2005, this number had dropped to 46,770 (CDC, 2007b).

Prenatal lead exposure is another concern. Even low-level exposure of pregnant women to lead has a dangerous cumulative effect leading to nerve damage, neurobehavioral problems, learning disabilities, and mental retardation in the child. It has also been linked to preterm birth, decreased gestational maturity, and reduced postnatal growth (CDC, 2007c). Display 9.4 shows some common sources of lead.

In occupational settings, workers have been exposed to lead since long before the Industrial Revolution, because lead was used for making pipes, pigments, and bullets. Workers in some occupations, such as smelters, have been exposed to high levels of lead, as have those exposed to leaded gasoline and lead-containing paints.

#### DISPLAY 9.4 WHERE LEAD IS FOUND

In general, the older your home, the more likely it has lead-based paint.

- **Paint.** Many homes built before 1978 have lead-based paint. The federal government banned lead-based paint from housing in 1978. Some states stopped its use even earlier. Lead can be found:
  - In homes in the city, country, or suburbs.
  - In apartments, single-family homes, and both private and public housing.
  - Inside and outside of the house.
- **In soil around a home.** Soil can pick up lead from exterior paint, or other sources such as past use of leaded gas in cars.
- **Household dust.** Dust can pick up lead from deteriorating lead-based paint or from soil tracked into a home.
- **Drinking water.** Your home might have plumbing with lead or lead solder. Call your local health department or water supplier to find out about testing your water. You cannot see, smell, or taste lead, and boiling your water will not get rid of lead. If you think your plumbing might have lead in it:
  - Use only cold water for drinking and cooking.
  - Run water for 15 to 30 seconds before drinking it, especially if you have not used your water for a few hours.
- **The job.** If you work with lead, you could bring it home on your hands or clothes. Shower and change clothes before coming home. Launder your work clothes separately from the rest of your family's clothes.
- **Old painted toys and furniture.**
- **Food and liquids** stored in lead crystal or lead-glazed pottery or porcelain.
- **Lead smelters** or other industries that release lead into the air.
- **Hobbies** that use lead, such as making pottery or stained glass, or refinishing furniture.
- **Folk remedies** that contain lead, such as *greta* and *azarcon* used to treat an upset stomach.

U.S. Environmental Protection Agency. Retrieved July 4, 2007, from <http://www.epa.gov/lead/pubs/leadinfo.htm#where>.

With new awareness of the dangers of lead exposure, most workplaces have instituted safeguards to protect workers from exposure. However, the accidental exposure of children to lead in the environment remains an important issue.

Community health nurses need to check with clients for possible exposure and to examine client homes for lead-based paint. Lead-based paint is now restricted in residential use, but any painted building that is more than 30 years old may still have lead paint. In particular, nurses can warn parents to keep their young children from eating paint chips from windowsills, walls, or furniture painted with lead-based paint; to keep them away from lead-infused dirt near roads; and to avoid dust and debris when older buildings are being torn down or renovated. The U.S. Department of Housing and Urban Development (HUD) *Lead-Safe Housing Rule*, enacted in 1999, has helped to reduce lead poisoning risk from paint in federally owned or subsidized housing (HUD, 2007).

Mercury is also highly toxic. It is used in many scientific instruments, electronic equipment, crop fungicides, and in the processing of dental fillings. Historically, mercury was used in goldsmithing, mirror-making, explosive detonators, and as an antiseptic and antifungal agent. Inorganic mercury can be changed through bacterial action in industrial processes to more toxic organic compounds, as in the bleach used for paper manufacturing. Toxic mercurials then escape into the environment and contaminate the food chain. In 1956, at Minamata Bay on the island of Kyushu, Japan, many people died and more were disabled with permanent neurologic impairment from eating mercury-contaminated seafood (Friis, 2007). In Iraq in 1971, hundreds of fatalities occurred among people who used methylmercury fungicide-treated seeds to make bread (Merson, Black, & Mills, 2004). The seeds had been supplied by USAID (U.S. Agency for International Development) for planting and were dyed red to indicate they shouldn't be eaten. Hungry farmers found that they could wash off the dye and make bread but not all the fungicide was removed. The end result was over 500 people dead and approximately 5,000 hospitalized.

Other harmful metals include aluminum, which recently was associated with certain mental disorders and has been found in high levels in the brain tissues of patients with Alzheimer disease. More research is needed to determine the role, if any, that aluminum exposure has in this debilitating disease. Chromium, nickel, and arsenic are other toxic compounds with severe health consequences from exposure (ATSDR, 2005).

Many toxic chemicals are by-products of the petroleum industry, including many alcohols, ethers, hydrocarbons (e.g., benzene), medicines, and plastics that contain carbon. Ingestion or exposure can cause cancer, liver and kidney disease, birth defects, and many other health problems. Pesticides for household and crop use have created major health hazards. Dichlorodiphenyltrichloroethane (DDT), a very dangerous chemical used for pest control, was banned in 1972 in the United States because of environmental and health concerns. However, it is still present in the environment and continues to be used in developing countries, thus posing a danger to their populations, but most especially to children (Friis, 2007).

Exposure to toxic chemicals can have far-reaching effects on humans. People may come in contact with these toxins in their homes through building materials, cleaning products, or

airborne dust. Another source is the workplace, where many different compounds are created and used each day. Toxic substances also may be transferred home from the workplace in motor vehicles and on clothing or shoes. In the greater community, pollutants in the air and food chain create further hazards. Toxic chemicals can cause illness when they are inhaled, come into contact with the skin (as in industrial accidents where chemicals are spilled), or are ingested (as when a child drinks from a liquid cleaning solvent bottle). Table 9.3 lists some common workplace carcinogens. The Occupational Safety and Health Administration (OSHA, 2006) standards require that information on toxic substances be made available in all workplaces that utilize chemical products. The regulations are extensive, but the essential components are:

- ◆ Industrial chemical manufacturers and importers are required to evaluate the hazards of the chemicals they produce or import.

- ◆ Manufacturers and importers must prepare labels and material safety data sheets (MSDSs) to convey the hazard information to their downstream customers.
- ◆ All employers with hazardous chemicals in their workplaces must display labels and MSDSs for their exposed workers, and train them to handle the chemicals appropriately.

Recognizing the key role that nurses play in environmental health, the *Environmental Health Nursing Initiative* was begun by ATSDR, with the goal to “make environmental health an integral component of nursing practice, education, and research” (ATSDR, 2007). The ATSDR notes that, in addition to protecting the health of all people, nurses also have the “credibility and access that enables them to provide scientifically sound information about environmental issues and toxic exposure.” A wide variety of educational tools and resources are available from the website at <http://www.atsdr.cdc.gov/EHN/>.

**TABLE 9.3 Occupational Carcinogens**

Carcinogen	Cancer Site	Examples of Exposed Occupations
4-Aminodiphenyl	Bladder	Dye manufacturing, rubber manufacturing
Auramine		
β-Naphthylamine		
Magenta		
Benzidine		
Arsenic	Skin, lung, liver	Metal smelting, arsenic pesticide production, metal alloy workers
Asbestos	Lung, mesothelium, gastrointestinal tract	Asbestos miners, insulators, shipyard workers
Benzene	Leukemia (blood-forming organs)	Petrochemical workers, chemists
Bischloromethyl ether (BCME)	Lung	Organic chemical synthesizers
Cadmium	Prostate	Cadmium alloy workers, welders
Chromium/chromates	Lung, nasal sinuses	Chromate producers, metal workers
Coke oven emissions	Lung, kidney	Coke oven workers
Foundry emissions	Lung	Foundry workers
Leather dust	Nasal cavity, nasal sinuses, bladder	Shoe manufacturing
Nickel	Lung, nasal passages	Nickel smelting, metal workers
Radiation (x-rays)	Leukemia (blood-forming organs), skin, breast, thyroid, bone	Radiologists, industrial radiographers, atomic energy workers
Radon gas	Lung	Uranium and feldspar miners
Soots, tars, and oil	Skin, lung, bladder, scrotum	Roofers, chimney sweepers, shale oil workers
Petroleum (aromatic hydrocarbons)		
Ultraviolet light	Skin	Outdoor workers
Vinyl chloride	Liver, brain, lung	Polyvinyl chloride synthesizers, rubber workers
Welding fumes	Lung	Welders
Wood dust	Nasal passages	Hardwood workers, furniture makers

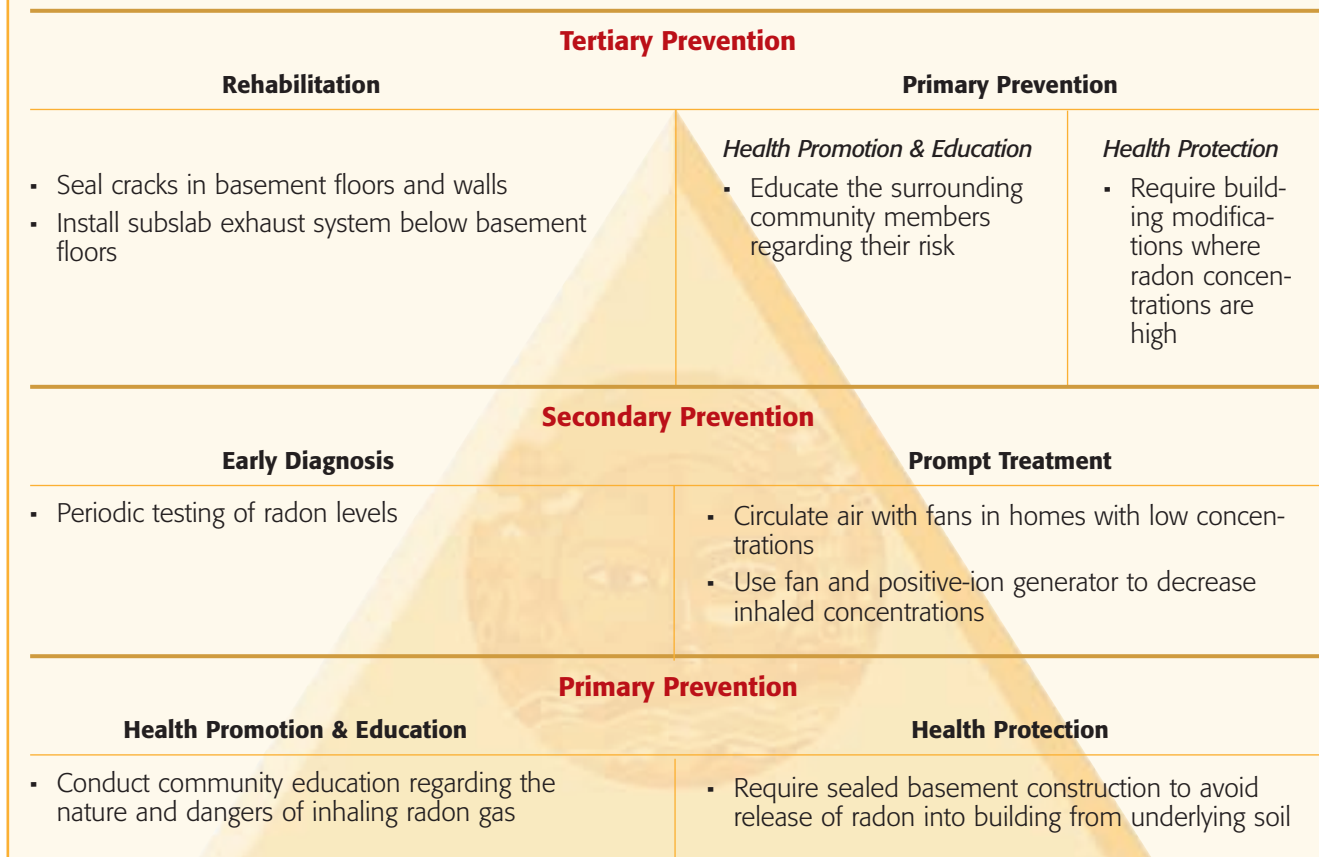

From Blumenthal, D., & Rutenber, J. (1994). *Introduction to environmental health*, (2nd ed). New York: Springer.

## LEVELS OF PREVENTION PYRAMID

**SITUATION:** Increase to at least 20% the proportion of homes in which homeowners/occupants have tested for radon concentrations (Baseline: 11% in 1994 from Healthy People 2010, USDHHS, 2000)

**GOAL:** Using the three levels of prevention, negative health conditions are avoided, promptly diagnosed and treated, and/or the fullest possible potential is restored.

### Exposure to Radiation

Radiation is technically defined as a process by which energy is propagated through space or matter. Natural radiation from the sun, soil, and minerals can be found in virtually all areas of the Earth's environment. The largest natural source of radiation exposure is airborne radon. Some radioactive substances produce particles, and others produce rays. Radiation in its manmade form has numerous beneficial uses in science and industry for lasers, radiographs (x-rays) that help in the diagnosis of disease, and the production of nuclear energy. It is found in many home electronic devices, such as television sets, smoke detectors, and microwave ovens (see Levels of Prevention Pyramid).

Regardless of its source, radiation is a threat to human health in the workplace and in the general environment. The extent of danger depends on the dose and type of radiation. For example, casualties among miners can be attributed to their prolonged and intense exposure to radioactive minerals such as uranium. Prolonged exposure can cause skin ulcers,

damage to cells, cancer, premature aging, kidney dysfunction, and genetic disorders in the children of those whose cells have been damaged.

A certain amount of natural radiation exposure from the sun is important for the production of vitamin D. However, intentional exposure by sunbathing, still a popular activity in many areas, must be tempered with the use of lotions with sunscreen. The current recommendations are that sunscreen products used have a sun protection factor (SPF) of at least 15. Debate has been ongoing since 1999 as to the value of SPF factors above 30; until resolution, many products advertise a SPF greatly exceeding 30. What remains clear is that sunscreen products must be reapplied frequently for continued protection, especially during and after swimming or activities that promote sweating. They should be used by people of all ages when exposed to the sun for more than 10 to 15 minutes in winter or summer. Sunscreen is more important at higher elevations and when participating in outdoor snow activities, such as skiing, because the snow reflects the sun's rays. An

## DISPLAY 9.5

## UV INDEX SCALE

**2 or less: Low**

A UV Index reading of 2 or less means low danger from the sun's UV rays for the average person:

- Wear sunglasses on bright days. In winter, reflection off snow can nearly double UV strength.
- If you burn easily, cover up and use sunscreen.

**3–5: Moderate**

A UV Index reading of 3 to 5 means moderate risk of harm from unprotected sun exposure.

- Take precautions, such as covering up, if you will be outside.
- Stay in shade near midday when the sun is strongest.

**6–7: High**

A UV Index reading of 6 to 7 means high risk of harm from unprotected sun exposure. Apply a sunscreen with a SPF of at least 15. Wear a wide-brim hat and sunglasses to protect your eyes.

- Protection against sunburn is needed.
- Reduce time in the sun between 10 AM and 4 PM.
- Cover up, wear a hat and sunglasses, and use sunscreen.

**8–10: Very High**

A UV Index reading of 8 to 10 means very high risk of harm from unprotected sun exposure. Minimize sun exposure during midday hours, from 10 AM to 4 PM. Protect yourself by liberally applying a sunscreen with an SPF of at least 15. Wear protective clothing and sunglasses to protect the eyes.

- Take extra precautions. Unprotected skin will be damaged and can burn quickly.
- Minimize sun exposure between 10 AM and 4 PM. Otherwise, seek shade, cover up, wear a hat and sunglasses, and use sunscreen.

**11+: Extreme**

A UV Index reading of 11 or higher means extreme risk of harm from unprotected sun exposure. Try to avoid sun exposure during midday hours, from 10 AM to 4 PM. Apply sunscreen with an SPF of at least 15 liberally every 2 hours.

- Take all precautions. Unprotected skin can burn in minutes. Beachgoers should know that white sand and other bright surfaces reflect UV and will increase UV exposure.
- Try to avoid sun exposure between 10 AM to 4 PM.
- Seek shade, cover up, wear a hat and sunglasses, and use sunscreen.

Adapted from: U.S. Environmental Protection Agency. Retrieved July 4, 2007, from <http://www.epa.gov/sunwise/uvindex2.html>.

easily understood public health advisory system, the UV Index, shows the risk level for that day and the steps that should be taken to reduce exposure (see Display 9.5).

A major area of concern centers on the problems associated with nuclear energy and nuclear weapons. The production of radioactive wastes, the threat of accidental exposure from unsafe reactors, and possible fallout from weapons testing generate real fears. These fears were confirmed by the nuclear reactor accidents at Three Mile Island and Chernobyl, which were discussed earlier in this chapter. Accidents of this type are uncommon, however, and the safe operation of nuclear power plants exposes communities to much less radiation than other sources, such as medical or natural radiation.

### Injury Hazards

When assessing a population's health risk, one environmental characteristic that must be considered is the community's level of physical safety. How likely is it that injuries will occur? This is a very important question when one considers that, in the United States, unintentional injuries kill more people during the first three decades of life than any other cause of death (National Center for Injury Prevention and Control [NCIPC], 2003). In 2003, a total of 109,277 Americans died from unintentional injuries (NCIPC, 2003). Groups at highest risk are the young, the elderly, the poor, minorities, and rural residents. Many of these deaths could have been prevented through community safety planning,

which can enhance the built environment to reduce accidents and injuries.

Not surprisingly, motor vehicle accidents were the leading cause of death in 2003 for those aged 4 to 34 years (Subramanian, 2006). In all age groups, more than 43,000 deaths resulted from vehicular accidents, and approximately 40% of all motor vehicle deaths are alcohol-related. The second-ranked cause of injury death is falls, followed by poisoning, drowning, and residential fires. Alcohol plays a major role in many of these injuries and subsequent deaths, particularly with motor vehicle crashes and drowning (USDHHS, 2000).

Community health nurses have a responsibility to assess situations for the threat of potential physical harm and to work with other professionals to design preventive measures. Safety education and primary prevention is a major role of the community health nurse. Because infants and children are particularly vulnerable to accidents, this teaching can begin one-on-one or in groups of pregnant women attending clinics or Women, Infants, and Children (WIC) appointments. The topics to be discussed are many but usually include anticipatory guidance to enhance infant safety, creating a child-proof home, and acquiring a car seat and using it properly. Topics and clients will change as the nurse branches out to preschools, schools, youth clubs, parent-teacher organizations, and other groups. The nurse may become a resource for others who do the teaching, and knowing where to find safety infor-

mation, brochures, and other “handouts” is important in information dissemination.

### Exposure to Noise Pollution

People in the United States are bombarded by noise from many sources. Noise has two definitions. One, related to its physical properties, defines noise as *a sound, generally random in nature, the spectrum of which does not exhibit clearly defined frequency components*. A simpler and more subjective definition is *any unwanted sound* (Behar, Chasin, & Cheesman, 2000). Household appliances, traffic, radios, machinery, and voices are typical noise sources. To a degree “noise” depends on the listener; a teen’s loud music choice may be a source of noise to his parents. Noise is measured three ways. First, noise is measured by magnitude, or *decibels*. A whisper may measure 10 to 20 decibels, and a fire engine siren may measure 80 to 100 decibels. Another way to measure is by the high and low tones of the noise, referred to as *frequency*. A male voice usually has a lower frequency than a female voice does, and a tuba is lower than a flute. A third factor is the *time history*, or the length of time one has been exposed to the noise.

Noise has been cited as a major environmental health problem. Prolonged exposure (months to years) to extremely loud noises, such as pneumatic drills or rock music, can cause temporary or permanent hearing loss (Behar et al., 2000). Other noises, perhaps occasional machinery noises at the workplace or residential exposure to airport traffic, can lead to general annoyance; headaches; sleep, speech, and task interference; alterations in emotions; stress; lowered body resistance to disease; ulcers; and aggravation of existing physical disorders. The effects vary in severity depending on the intensity and duration of the noises and the disposition of the people concerned. Ototoxic “refers to agents that can produce hearing loss” and may result from a combination of noise and workplace chemical exposures (Friis, 2007, p. 331).

Noise control comprises four methods. First, the source of the noise can be relocated (e.g., having the teen band practice in the garage instead of the family room) or replaced (e.g., fixing or replacing a broken toy or appliance). Another method is to do something about the path of the noise. A barrier, enclosure, or muffler may be effective. This is often seen along highways, where 8- to 10-foot high walls have been built between the highway traffic noises and housing developments. An automobile muffler serves a similar purpose of *muffling* the engine’s sound. A third method of control is to relocate the receiver. For instance, if parents are annoyed by the loudness and music choice of their teenager, they may want to go to another room in the house. Finally, the receiver can use hearing protectors such as ear plugs. For example, airline ground-crew members wear highly sophisticated hearing protectors.

Community responses to noise pollution take many forms. Community standards usually enforce noise abatement after 10 PM and before 8 AM, and police will respond if a neighbor complains about a loud neighborhood party. As highways creep into suburban neighborhoods, barriers are erected in the form of walls or noise-absorbing trees and shrubbery. Standards for the decibel levels of appliances and tools are set by manufacturers, following OSHA

standards. Packaging instructions indicate whether hearing protectors should be used when the tool or piece of equipment is in use.

Community health nurses can inform families of the damage or annoyance noises can inflict and help people quiet their environment. If community-generated noise comes from industry, the nurse can collaborate with health team members from the offending company and work to bring about positive changes that improve the relationship between the company and the community. In one low-income community during the 1950s, an aluminum factory created a loud, repetitive booming noise all day long that made it impossible for people in nearby housing to speak to each other within their homes without raising their voices or shouting. It was impossible to sit on a porch and hear someone nearby speak. OSHA did not exist at the time, and community attempts at changing the situation did not make an impact. It was not until the company’s manufacturing processes changed years later that the community felt relief. In the meantime, many families left the neighborhood as soon as they were able, leaving the housing choices near the factory for the uninformed.

### Exposure to Biologic Pollutants

Biologic pollutants or hazards include all of the forms of life, as well as the nonliving products they produce, that can cause adverse health effects. Some common indoor biologic pollutants include animal dander (minute scales from hair, feathers, or skin), dust mite and cockroach parts, fungi, molds, infectious agents (bacteria and viruses), plants, pollen, and a wide variety of toxins and allergens (Wigle, 2003).

Breathing indoor air contaminated with biologic pollutants can cause health problems or make existing health problems worse, especially among infants, young children (Wigle, 2003), the elderly, and those with chronic illnesses. The effects range from allergic symptoms (conjunctival inflammation, rhinitis, sneezing, nasal congestion, itching, dyspnea, coughing, wheezing, chest tightness, headache, and malaise) to infections and toxicity.

Home conditions that promote this type of pollution include dampness, which encourages the growth and build-up of biologic pollutants. It is estimated that 30% to 50% of all structures, mostly in warm, moist climates, have damp conditions. One especially concerning fungus is *Stachybotrys chartarum*, commonly referred to as *toxic mold*. *S. chartarum* is a greenish-black fungus that is being investigated in the deaths of infants in Cleveland, Ohio, and as the cause of other serious health problems in other areas of the United States. It is known to produce toxigenic spores, and it grows on high-cellulose materials such as fiberboard and gypsum board, which are commonly used in home construction. The EPA does not currently have evaluation or remediation guidelines to address this potential threat (EPA, 2007c).

There are particular items and areas in homes and personal environments where biologic pollutants are commonly found and where proper cleaning or care is especially important. These include:

- ◆ Humidifiers and dehumidifiers
- ◆ Bathrooms without vents or windows

- ◆ Kitchens without vents or windows
- ◆ Refrigerator drip pans
- ◆ Laundry rooms with an unvented dryer
- ◆ Unventilated attics
- ◆ Damp basement floors with carpeting
- ◆ Bedding
- ◆ Closets on outside walls
- ◆ Heating/air conditioning systems
- ◆ Bookshelves, curio cabinets, and other areas that accumulate dust
- ◆ Dog and cat bedding, litter boxes, bird cages, fish tanks, and so forth
- ◆ Areas with water damage (around windows, the roof, or the basement)
- ◆ In automobile ventilation systems where moisture pools after use of the air conditioner

The most important role of the community health nurse is to assess clients' homes for possible biologic pollutants and then to provide them with the information they need to correct or improve the situation. If clients are renting a house or apartment, and the dampness is caused by structural conditions or owner negligence, the nurse may act as an advocate for the clients to remedy the potentially hazardous situation. Display 9.6 includes a list of assessment questions the nurse should apply during home visits when clients may have been exposed to biologic pollutants.

### Psychological Hazards

A discussion of environmental health and safety would not be complete if it overlooked the psychological hazards that people must face in their environments. Environment plays a significant role in the mental health of a community. The psychological variables that affect people often lead to physiologic illnesses. Such elements as noise, overcrowding, traffic, inadequate housing, lack of privacy, unavailability of work, lack of natural beauty, and boredom can be detrimental to peoples' well-being.

Another psychological hazard is urban crowding. Early studies on crowding done by J. B. Calhoun demonstrated serious effects on behavior. When healthy, naturally clean laboratory mice were forced to live in overcrowded conditions, they experienced dramatic behavior changes. Gross unsanitary conditions led to aggressive behavior, attacks by strong mice on the weak, symptoms of regression and mental disturbance, mating decline, and neglect or cannibalization of weaker offspring. Although this is an extreme example, it perhaps provides some insight into the conditions of urban areas and the psychological stress that urban conditions can create (Nakamura, 1999).

The daily psychological stresses of the modern world are innumerable. Excessive stimulation comes from rapid societal changes created by new technology, an accelerated pace of living, increased work production demands, and other causes. All can create potential health hazards.

### Government's Role

The government plays an active role in promoting public safety. Standards and regulations have been set at the federal level regarding toxic chemicals, radiation exposure,

#### DISPLAY 9.6

#### ASSESSMENT QUESTIONS TO DETECT BIOLOGIC POLLUTANTS IN HOMES

- Does anyone in the family have frequent headaches, fevers, itchy watery eyes, a stuffy nose, dry throat, or a cough?
- Does anyone complain of feeling tired or dizzy all the time?
- Is anyone wheezing or having difficulties breathing on a regular basis?
- Did these symptoms appear after you moved to this home/apartment?
- Do the symptoms disappear when you go to school or work or go away on a trip, and return when you come back home?
- Have you (or your landlord or apartment manager) recently remodeled your home or done any energy conservation work, such as installing insulation, storm windows, or weather stripping?
- Does your home feel humid?
- Can you see moisture on the windows or on other surfaces, such as walls and ceilings?
- What is the usual temperature in your home? Is it very hot or cold?
- Have you recently had water damage?
- Do you have a basement? Is it wet or damp?
- Is there any obvious mold or mildew in the basement, closets, bathrooms?
- Does any part of your home have a musty or moldy odor?
- Is the air stale?
- Do you have pets? (Consider all—including fish, turtles, snakes.)
- Do you have house plants? Do they show signs of mold?
- Do you have air conditioners or humidifiers that have not been properly cared for or cleaned?
- Does your home have cockroaches or rodents?

Adapted from U.S. Consumer Product Safety Commission. (2007). *Biologic pollutants in your home* (CPSC Document #425). Bethesda, MD: Author. Retrieved July 5, 2007, from <http://www.cpsc.gov/CPSCPUB/PUBS/425.html>.

occupational safety practices, noise abatement, biologic hazards, and other safety issues. State and local governments seek to enforce business, industry, and community compliance with these standards. Health departments and other government agencies assist with monitoring of chemical use and production, as well as promotion of public education programs to alert people to the presence and potential dangers of toxic chemicals and exposure to radiation in the environment. Researchers are examining the biologic effects of chemicals and radiation. Those in medical and dental fields have developed simple safety procedures, such as having patients wear lead aprons during

radiographs and having technicians stand behind metal walls.

Because the government holds companies liable for the safety of their products, industry now invests considerable resources into researching and designing safe goods. Many products have been modified to make them safer, such as childproof caps on medication bottles, flame-retardant children's clothing, and seat belts and airbags in automobiles. Industries must also warn consumers if one of their products is inherently dangerous (e.g., toys with sharp edges or parts small enough to be ingested by toddlers). Bright-orange, frowning faces on bottles that contain harmful substances have helped to warn consumers and reduce the number of poisonings. Children learn to avoid poisonous plants and other potential hazards through school and community education efforts.

Community safety organizations, government agencies, and public health officials all play their part in assessing community safety and taking measures to prevent accidents. Organizations such as *Health Care Without Harm*, the *Natural Resources Defense Council*, as well as consumer advocates such as Ralph Nader, continue to serve as watchdogs for environmental safety. Federal and state legislation to enforce speed limits has helped to reduce the number of automobile crashes, and supervision of recreational and occupational areas has led to discovery of health hazards and promoted the development of safety programs. State-established boating safety regulations and the assignment of adequate lifeguards to monitor busy swimming beaches are measures that help to reduce the number of recreational accidents. Community surveys of intersections where multiple traffic crashes have occurred have led to installation of traffic signals and a reduction of crashes.

### **Nurse's Role**

It is difficult to monitor all the possible contacts a person or community may be experiencing with toxic chemicals, biologic agents, or radiation, but such monitoring is necessary in order to estimate health risks and establish correlations. Multiple exposures in small doses from many different sources may add up. Are clients' homes well ventilated? Is the burning of fossil fuels polluting the air with sulfur oxides? Does home, school, or worksite insulation contain asbestos? Are all household chemical agents stored in a childproof place? Is the home free of molds and other biologic hazards? Monitoring difficulties arise from the many opportunities for exposure to toxic chemicals, biological hazards, or radiation; cumulative exposure over time; and the fact that disease symptoms may not appear until years after exposure, when the agent may no longer be in the immediate environment. The best protection is to promote and monitor the safe use and disposal of chemical hazards, seek out and treat or remove biologic contaminants, and limit radiation exposure to prevent health problems from occurring.

Community health nurses can promote environmental safety and prevent injuries in many ways. Six target areas in which to concentrate preventive measures are highways, homes, worksites, schools, farms, and recreational sites. Working with the police, fire personnel,

social services, schools, drug rehabilitation counselors, and many other community groups, the nurse can help to develop programs focused on failed smoke detectors, unsafe playground equipment, and much more. In homes, nurses can encourage safe storage of toxic materials and removal of biologic hazards. Railings can be installed on stairways and in bathrooms used by elderly individuals. Gates at the tops of stairways and window guards can prevent falls by small children. Nonskid decals can be used in bathtubs to prevent slipping.

Safety education offers one of the most vital preventive measures. When people are made aware of possible dangers and unsafe areas, they can avoid injuring themselves. Local community programs to educate people on the dangers of driving while intoxicated, to instruct them on the proper handling of home machinery such as chain saws, or to encourage viewing community sponsored and professionally conducted fireworks during holiday celebrations rather than attempting to use them at home, can also help to reduce injuries. In the event that an injury does occur, public education about appropriate responsive actions can help to reduce the potential impact. Promotion of first aid and cardiopulmonary resuscitation (CPR) classes can be beneficial.

Community health nurses need to be aware of the effects noise can have on hearing health and overall well-being. This knowledge will help the nurse identify specific health problems caused by increased noise. Teaching employers, employees, teachers, and children about the potential harm of repeated loud noises in their environment (even the noise from a headset that is turned to a high decibel level) is essential.

It is necessary for community health nurses to be aware of psychological hazards in the environment, to recognize the potential they have for affecting both psychological and physiologic health, and to encourage stress reduction wherever possible (see From the Case Files). Some specific ways in which community health nurses can promote a psychologically healthy environment include active lobbying for neighborhood crime prevention, reduction of workplace stressors, and the development of educational and support programs to reduce lifestyle stressors.

## **STRATEGIES FOR NURSING ACTION IN ENVIRONMENTAL HEALTH**

Each of the preceding sections has discussed actions and given examples of ways in which the community health nurse can be involved in environmental health. To summarize, the nurse has a two-part challenge: to help protect the public's health from potential threats in the environment, and to help protect and promote the health of the environment itself, so that it can be life- and health-enhancing for its human inhabitants. The following strategies for collaboration and participation provide a summary of the nurse's role and can assist the nurse in addressing this two-part goal:

1. Learn about possible environmental health threats. The nurse has a responsibility to keep abreast of current environmental issues and to know the proper authorities to whom problems should be reported.

## From the Case Files

### Occupational Environmental Health and the Nurse's Role

#### Scenario

Metropolis Tool Company is a manufacturing plant that employs 1200 workers. Most of the employees work in assembly or data entry jobs. Recently, there have been increasing complaints of work-related stress, with employees citing pressure to perform and produce at higher levels as the root of the stress. You are an occupational health nurse working for the company.

It has come to your attention that there has been a significant increase in insurance claims for the following conditions:

- Stress-related migraine headaches
- Early pregnancy leave for women experiencing low maternal weight gain

Metropolis Tool Company has been in business for more than 29 years. Recently, competition in the manufacturing industry has increased, and the company's executives are looking for ways to cut expenses. Insurance premiums cost the company a considerable amount, and rates will increase if the number of claims continues to rise. Your employer recently became aware of the problems leading to increased utilization of disability benefits. He approached you and asked you to "fix" these problems in an expeditious manner.

Available assessment data that may be related to the problems include the following:

- The plant recently moved to rotating shifts and is now operating around the clock
- Staff layoffs are predicted within 6 months
- Increasing corporate competition has led to higher productivity standards and expectations

#### Questions

1. Discuss additional assessment data needed and how you will go about gathering these data.
2. Describe your role related to the issue of environmental health and safety.
3. Discuss interventions that your program may perform at the following levels of prevention:
  - Primary
  - Secondary
  - Tertiary
4. Your supervisor in your role of occupational health nurse is a company vice president. He is very knowledgeable about business but knows little about health issues. Where will you turn to obtain information to assist you in addressing the problems identified in this scenario?
5. How will you evaluate the effects of your interventions?
6. What issues does this scenario elicit regarding:
  - Fears and anxiety in this role.
  - Lack of immediate resources (supervisor)
  - Social justice
  - Building partnerships within your communities
  - Globalization of public health

2. Assess clients' environment and detect health hazards. Careful observation and an environmental checklist can assist in this assessment.
3. Plan collaboratively with citizens and other professionals to devise protective and preventive strategies. Remember that environmental health work is generally a team effort.
4. Assist with the implementation of programs to prevent health threats to clients and the environment.
5. Take action to correct situations in which health hazards exist. Nurses can use direct intervention (e.g., in an unsafe home situation), notify proper authorities, or publicly protest if corrective measures are beyond their sphere.
6. Educate consumers and assist them to practice preventive measures. Examples of preventive

measures include radon testing in homes and well-water testing in rural communities.

7. Take action to promote the development of policies and legislation that enhance consumer protection and promote a healthier environment.
8. Assist with and promote program evaluation to determine the effectiveness of environmental health efforts.
9. Apply environmentally related research findings and participate in nursing research.

### Summary

Environmental health is a discipline encompassing all of the elements of the environment that influence the health and well-being of its inhabitants. Public health workers, including

community health nurses, need to monitor and determine causal links between people and their environment with a concern as to how they may promote the health and well-being of both.

An ecologic perspective of environmental health is important to understand the human–environment relationship and how the health of one affects the health of the other. Prevention and strategic or long-range concerns are also important in considering environmental health, because what is done today may affect the health of many generations in the future.

Major global environmental concerns exist, such as overpopulation, ozone depletion and global warming, deforestation, desertification and wetlands destruction, energy depletion, air pollution, water pollution, contaminated food, waste disposal, insect and rodent control, biologic pollutants, safety (in the home, worksite, and community). Each has its own set of problems, concerns, and solutions.

Both public and private sectors are involved in regulating, monitoring, and preventing environmental health problems, and have accomplished much during the past 35 years. Much, however, is still left to be done, and new problems continue to develop. The community health nurse is an important member of the team of health professionals who promote and protect the reciprocal relationship between the environment and the public's health. The nurse can follow several important strategies to accomplish the two-part goal of protecting the public's health from environmental threats and promoting a healthy and health-enhancing environment. ■

problem? What evidence is provided in the article to substantiate the cause? Does the news coverage describe health effects? What population is at risk? Does the coverage provide adequate information for consumers to understand the problem and seek any needed assistance? What suggestions do you have for improving the article?

4. Design a list of items to include in a checklist for assessing clients' home, school, or worksite environments. Consider each of the environmental areas of concern described in this chapter and what potential health threats might be present in each area. Review this list with an environmental health expert for accuracy and completeness. Use the list as a teaching tool with two different sets of clients, and evaluate its effectiveness for assessment and diagnosis of environmentally related health hazards.
5. Identify an environmental health problem in your community or state. Become informed about this problem by talking with experts in the area, reading recent literature and research reports, and searching the Internet for information about the problem. Meet with a senator or congressperson who has been involved in legislation related to the problem, and learn what he or she plans to do about it. Summarize what you have learned, and present it in writing as a letter to the editor of your city newspaper.

### ACTIVITIES TO PROMOTE CRITICAL THINKING

1. You are planning a visit to a young family who live in an older home. You know that older homes may have radon, lead pipes and lead-based paint, asbestos insulation, and other safety, fire, and health threats, such as those from biologic pollutants. Using the nursing process, design a plan for (a) determining whether any of these threats are present, (b) deciding what actions should be taken if the dangers exist, (c) assisting the family in taking corrective action, and (d) evaluating successful removal of existing threats.
2. Data from the local health department show that, in the past year, five people from the same rural portion of the county died of cancer. What collaborative actions would be appropriate for you to take to determine whether an environmental relationship exists? What other members of the health team should be involved in the investigation? Write a letter to the mayor and the county commissioners to justify why nurses should be involved in this study.
3. Select an article from the mass media (e.g., newspaper, weekly news magazine) that deals with an "environmental health" problem. Analyze and critique the article by answering the following questions: What are the characteristics of the community involved? What appear to be the sources of the

## Communication, Collaboration, and Contracting

### LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Identify the seven basic parts of the communication process.
- ◆ Describe four barriers to effective communication in community health nursing and how to deal with them.
- ◆ Explain three sets of skills necessary for effective communication in community health nursing.
- ◆ Summarize the key issues related to health literacy.
- ◆ Explain the stages of group process.
- ◆ Differentiate between task roles and maintenance roles.
- ◆ Describe five characteristics of collaboration in community health.
- ◆ Compare the three phases common to the collaboration process.
- ◆ Identify four features of contracting in community health nursing.
- ◆ Discuss the value of contracting to both clients and community health nurses.
- ◆ Design an aggregate-level contract useful in community health nursing.

*“Think like a wise man but communicate in the language of the people.”*

 **Communication**, collaboration, and contracting are primary tools for community health nurses. They form the basis for effective relationships that contribute both to the prevention of illness and to the protection and promotion of aggregate health. To use these concepts skillfully in community health practice, it is important to understand their meaning and value. Because of its relationship to health promotion and disease prevention and management, health literacy is a concept that is becoming more important to health care providers, especially those in public settings. For the nurse accustomed to communicating one-on-one with clients, communication with aggregates, along with a wide range of professionals and lay community workers, requires new skills. Application of group process skills will facilitate work with both task and support groups. The computer, with its teleconferencing, telehealth, Internet and e-mail capabilities, as well as personal digital assistants, global positioning, and information systems, enriches communication and virtually brings the world into the home and work settings. Group work is a key component of community health nursing. Unlike ordinary social relationships, collaborative relationships are based on a team approach with shared responsibilities and mutual participation in establishing and carrying out goals. Clients and health care professionals enter into a working agreement, or contract, tailored to address specific client needs. The concept of contracting can further assist the collaborative process. This chapter examines these tools and discusses their integration into community health nursing practice.

## COMMUNICATION IN COMMUNITY HEALTH NURSING

Groups cannot exist without communication, nor can nurses practice without communication. These facts often are taken for granted, since most people spend most of their waking hours communicating: speaking, listening, reading, or writing. Yet, the quality of people's communication has far-reaching effects. Lack of effective communication can lead to misunderstanding, poor performance, interpersonal conflict, ineffective programs, weak public policy, medical mistakes, and many other undesirable outcomes (Arora, Johnson, Lovinger, Humphrey, & Meltzer, 2005; Kurtz, Silverman, & Draper, 2005; McKnight, Stetson, Bakken, et al., 2002). Effective communication is vital to all areas of nursing, and techniques can be used to improve communication (Boyle & Kochinda, 2004). To communicate, people must have, construct, or create shared realities and meanings. In other words, they must engage in an exchange that is both understood and meaningful. **Communication** involves transferring meaning and enhancing understanding.

Communication is the lifeblood of effective community health nursing practice. A recent study identified public health nurses' (PHNs) use of communication as a "core concept of client supervision," and found that important components included "building a trusting relationship, . . . creating a partnership and equality, . . . and . . . trying to act in the clients' best interest" (Tveiten & Severinsson, 2006, p. 235).

Communication provides a two-way flow of information that nourishes professional–client and professional–professional relationships. It also establishes the base of information on which health planning decisions are made and programs developed. For communication to take place, clients and professionals need to send and receive messages.

As participants in the communication process, community health nurses play both roles: sender and receiver. The nurse working with a group of abused women must learn to "read" the messages these women send. Similarly, as a member of a health planning team, the nurse must be able to elicit ideas as well as contribute to the planning process by speaking and acting in ways that communicate effectively.

Communication serves several functions in community health nursing. It provides information for decision-making at all levels of community health. From the choice of goals for a small client support group to health policy affecting a population at risk, decisions are enhanced through effective communication. Communication functions as a motivator by clarifying information, so that consensus is reached and the people involved can move forward with commitment to shared goals. Effective communication facilitates the expression of feelings and promotes closer working relationships. It also controls behavior by providing clear expectations and boundaries for group-member actions.

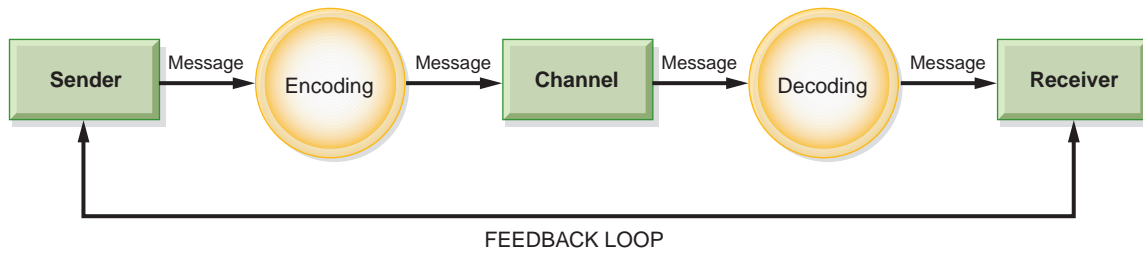

## The Communication Process

Communication occurs as a sequence of events or a process. The process consists of seven basic parts that work together to result in the transference and understanding of meaning. These parts are:

1. a message
2. a sender
3. a receiver
4. encoding
5. a channel
6. decoding
7. a feedback loop (Finkelman, 2006).

The first part of the communication process is a **message**, which is an expression of the purpose of communication. Without the message, there can be no communication. The next two parts include a sender and a receiver. The **sender** is the person (or persons) conveying a message, and the **receiver** is the person (or persons) to whom the message is directed and who is the intended recipient of the message. The fourth step is the act of **encoding**, which refers to the sender's conversion of the message into symbolic form. This involves how the sender translates the message to the receiver. It can be accomplished through verbal and/or nonverbal means. For example, a nurse teaching breathing techniques to a prenatal class may explain verbally while also demonstrating the correct procedures. The degree of the sender's success in encoding is influenced by the sender's communication skills, knowledge about the topic of the message, attitudes and feelings related to the message and the receiver, and the feelings, beliefs, and values held by the sender. The fifth part involves a **channel**, or the medium through which the sender conveys the message. The channel may be a written, spoken, or nonverbal expression. Examples include an e-mail stating a request, a report providing information, a written care plan, a verbal request for clarification, or a facial expression indicating confusion. Communication channels may be formal, such as a written grant proposal, or informal, such as a face-to-face verbal statement or an e-mail message.

Once the sender has conveyed a message through a channel, the receiver must translate the message into an understandable form, called **decoding**, which is the sixth

**FIGURE 10.1** The communication process (feedback loop).

part of the communication process. The receiver's ability to decode the message is influenced by knowledge of the topic, skills in reading and listening, attitudes, and sociocultural values. All communication involves perception and expectation. We interpret messages based upon prior experiences; either with the sender/receiver or with others who have influenced our lives (e.g., families, peers, bosses) (Finkelman, 2006). The seventh and final part is a **feedback loop**, which refers to the receiver's indication that the message has been understood (decoded) in the way that the sender intended (encoded). It requires feedback from the receiver to the sender, serving as a check on the success of the transference of meaning (Finkelman, 2006). Figure 10.1 portrays the seven components of the communication process.

### Communication Barriers

Community health nurses should be aware of the barriers that block effective communication. This section discusses four barriers that pose particular problems: selective perception, language barriers, filtering, and emotions (Robbins, 2003).

### Selective Perception

Receivers in the communication process interpret a message through their own perceptions, which are influenced by their own experience, interests, values, motivations, and expectations. They project this perceptual screen onto the communication process as they decode a message. They might distort or misinterpret the meaning from the sender's original intent. For example, the nurse may propose a class session on nutrition to a group of elderly persons, and the clients may translate that message to mean a focus on dieting for weight loss, which is not the intended meaning. Nurses can overcome this barrier by using the feedback loop to ask clients or others involved to voice their understanding of the message. In this case, the nurse could ask the elderly clients what the term *nutrition* means to them. This provides an opportunity for clarification and correction of misunderstandings, which is an essential step in the communication process and helps to prevent miscommunication that can lead to mistakes (see Perspectives: Student Voices).

### PERSPECTIVES STUDENT VOICES

#### The Case of the Misunderstood Directions

When I was in my junior year of nursing school, my grandfather began to have some intestinal problems. He thought at first it was just a little constipation, and he started drinking prune juice and added more fiber to his diet. The problem got worse, so he went to his family doctor and was told that he had a fecal impaction and needed to “take some enemas” before coming back to see the doctor who would then manually remove the fecal impaction. Because I had worked for this physician during the past two summers, he did not take a lot of time explaining the procedure to my grandfather. My grandfather is a very quiet man, a hard-working retired farmer who reads a lot and likes to listen to radio news and talk shows. The doctor told him to “take a couple of Fleets enemas, and then an oil retention enema” and to come back and see him in 2 days for removal of the fecal impaction. My grandfather had never before in his 79 years had an enema and didn't quite understand what he was supposed to do. Also, he was a bit embarrassed and didn't

ask me about it either. He lives alone, and bought the enemas at a local chain drugstore—also not asking for directions from the clerk there. When he returned for his appointment, the doctor asked him how it went with the enemas. My grandfather replied, “Well the little ones weren't so bad, but that big oily one was really hard to swallow.” You can imagine the doctor's reaction! My intelligent, confident grandfather had drunk the enemas! The doctor assumed that a man of his age, with a granddaughter in nursing school, would know what to do with enemas. He was sorely mistaken and very embarrassed! As was my grandfather, upon learning the correct administration of an enema. I was amazed that this could have happened and relieved that my grandfather didn't aspirate the oil retention enema. You always think that only poor, uneducated, or non-English speaking patients have problems like this, but that is not always the case. I learned that day how important it is to always have the patient explain their perception of your instructions back to you. It has come in handy in my community health nursing rotation, where many of my clients have real communication barriers. I always think about my grandfather, with all of his experience and knowledge, and remember that not everyone understands things the way you think you have explained them.

Rachel, age 34

## Language Barriers

People interpret the meaning of words differently, depending on many variables, such as age, education, cultural background, and primary spoken language. An adolescent understands the terms *sweet* and *tight* to mean that something is fashionable or desirable, whereas an 80-year-old woman might understand the terms to mean sugary and confining, respectively. In community health, nurses work with a wide range of clients and professionals whose disparate ages, education levels, and cultural backgrounds lead to different communication patterns. The use of scientific terminology or jargon by some health professionals can be confusing, as in the case of the Hmong refugee woman who was asked whether her son had experienced enuresis—a term she had never heard before. If the nurse had not used medical jargon, or had explained the term, or even asked the question using an illustrative example, the woman would have been able to more accurately answer the question. Instead of just nodding her head “yes”—meaning “I hear you,” the mother could have conveyed the correct message “no, my son does not wet the bed at night” (see From the Case Files). The use of unfamiliar terms can become a barrier to communication. Client differences in language and communication style must be taken into consideration during the communication process (Rubenfeld & Scheffer, 2006).

## Filtering Information

A third barrier to communication is filtering, which means manipulation of information by the sender to influence the receiver’s response. To gain favor with receivers, senders sometimes say what they believe receivers want to hear rather than the whole truth (Robbins, 2003). Clients sometimes use filtering during a needs assessment process, giving only partial or distorted information because they think this is what health professionals want to hear. Filtering can also affect PHNs. Cole (1990), in a classic work, notes that we have “filters” through which we view others—often influenced by culture and socioeconomic class or even gender—and these can lead to miscommunication. Cole’s premise is that dissimilar people actually view the world differently, thus confounding communication and leading to prejudice and stereotyping. Another intent of filtering is to slant information. Prepared minutes from a meeting or a department’s quarterly report can emphasize some points and omit or de-emphasize others, giving (sometimes unintentionally) false impressions that influence decision-making.

## Emotional Influence

How a person feels at the time a message is sent or received influences its meaning. Senders can distort messages and

## From the Case Files

### Mr. Sanchez Needs an Interpreter

I am in community health nursing now, but I work as an extern at our small, local county hospital helping out in the ER. A man came in one Saturday a month or so ago with a bad cut to his right hand from a push lawnmower—you know, the kind without a motor. Mr. Sanchez was trying to clean the grass from the blades and cut himself pretty badly. The ER doc asked him if he had received a tetanus shot recently, and he quickly nodded “yes.” He spoke a little English, but I could tell that he was having some trouble understanding some of our questions. His friend, who brought him to the ER, did not speak English at all. We couldn’t find an interpreter—they are always stretched so thin. None of us spoke Spanish. Anyway, we didn’t give him a tetanus booster—just cleaned his wound, closed it with stitches, bandaged it, and told him to keep it clean. He was given a prescription for an antibiotic medication. It was a busy night, and I didn’t think about it much. A few weeks later, Mr. Sanchez was back in the hospital because his wound had gotten infected and he had used a needle to drain some pus from his hand (he hadn’t gotten the prescription filled because he had no insurance and no money because he was off work now). Unfortunately, by poking around with the needle, he had provided a perfect, anaerobic place for tetanus to flourish. He now was in the ICU with full blown tetanus. I have never seen anything like this! He was on a ventilator and had to be “paralyzed,” so that we could get air into him. I had only read about opisthotonos—in which the body arches with only feet and head touching the bed because of a tetanic spasm—but now I was seeing it firsthand. This poor man was completely rigid, and we were trying to give him meds to relax him and permit the ventilator to work, but at the same time we were working to keep his blood pressure from dropping too low from the meds. Mr. Sanchez spent 30 agonizing days in ICU—all because he nodded “yes” to the doc’s question about the tetanus booster. In hindsight, he evidently just wanted to get out of the ER and didn’t truly understand the question. A \$5 tetanus booster could have prevented all of this misery and expense. (He had no insurance and was an illegal alien, so the county paid the bill.) We should have used an interpreter; should have insisted on it; should have waited until one was available. They are always in short supply—but I truly understand the importance of a translator now. I have some Spanish-speaking clients in my community health nursing rotation. I do my best to speak with them, but when I need to be sure that something is fully understood—I request that an interpreter accompany me on my home visits. I remember Mr. Sanchez and what happens when you don’t use an interpreter.

Amy, age 24

receivers can interpret messages incorrectly when emotions cloud their perception. Emotions can interfere with rational and objective reasoning, thus blocking communication. Nurses need to be aware of their own emotions as they send messages. To avoid misunderstandings, they also need to ascertain the emotional status of clients or health professionals with whom they are communicating. For example, it is important for community health nurses to remain calm and unruffled when dealing with families in crisis. Family communication may be angry, blaming, and confrontational because of a serious health crisis with a child, for instance. A PHN who responds with frustration, defensiveness, or anger only heightens the family's emotional reactions. A calm, firm, reassuring presence can go far in diffusing the situation and promoting clearer and more constructive communication. It is always helpful to be aware of the receiver's emotional status and help the receiver to identify it. You may say, "I sense that you are feeling upset about Joey's diagnosis. Are there any questions I can answer for you? How can I be of assistance?"

## Core Communication Skills

Overcoming the barriers to effective communication just described requires the development of sound communication skills. Community health nurses need to cultivate three sets of communication skills: sending skills, receiving skills, and interpersonal skills.

### Sending Skills

Sending skills enable nurses to transmit messages effectively. Through these skills, nurses convey information to clients and other persons. Two important considerations influence the clarity and effectiveness of message sending. First, the extent of the nurse's self-awareness affects the communication. Does the nurse feel anxious, angry, tired, impatient, or concerned? Does the nurse find certain individuals irritating or offensive? What motives and interests prompt the communication? Second, the nurse's awareness of the receiver influences the sending of messages. What do clients or the professionals with whom the nurse is interacting want or need? Is the message suited to their cultural background and level of understanding? Does the message have significance for them? How are receivers responding as the nurse sends the message?

Two main channels are used to send messages: nonverbal and verbal. **Nonverbal messages**, those conveyed without words, constitute a large portion of the messages transmitted in normal communication. People send messages nonverbally in many ways. Personal appearance, dress, posture, facial expression, gestures, and physical distance between sender and receiver all communicate messages. These nonverbal statements may enhance or discredit what someone says verbally (Robbins, 2003; Finkelman, 2006). Body language often speaks louder than words. Facial expressions convey acceptance or rejection, interest or boredom, anger or patience, fear or confidence. Gestures and bodily movements, such as clenched hands, crossed arms, tapping fingers, hands on hips, or a turned shoulder, all communicate messages. Eye contact, or lack of it, carries additional meaning—and may be culturally mediated. Tone of

voice and use of silence also send nonverbal messages. Accepting food in certain situations may communicate approval and the desire to be friendly. Nonverbal messages may have different cultural meanings or social interpretations (Spector, 2009). Nurse self-awareness and validation of meaning can save considerable misunderstanding.

**Verbal messages** are communicated ideas, attitudes, and feelings transmitted by speaking or writing. Nurses cannot assume that the intent of their words always is understood by clients or other professionals. Effective sending skills depend on asking for feedback to make certain that receivers have understood the verbal message's intent. Communication is more effective if speakers avoid using jargon that is unfamiliar to clients. Like all occupations, nursing has its own vocabulary, or jargon, that may not be understood by clients and that may make them feel ignorant or inferior. For example, the terms *critical pathways* or *case-management approach* may have little meaning to a community group. Nurses must make a special effort to avoid using jargon that is part of nursing's everyday speech. The basic rules for effective sending can be summarized in this manner:

1. Keep the message honest and uncomplicated.
2. Use as few words as possible to state it.
3. Ask for reactions (feedback) to make certain that the message is understood.

### Receiving Skills

Receiving skills are as important to communication as sending skills. They involve not only listening to what people say but also observing their behavior and nonverbal cues. They enable nurses to receive accurate and complete messages. If members of a seniors' exercise class agree to certain exercises but do not participate in them, they are sending a message. What message is their behavior sending? Were the proposed exercises too difficult? Did they misunderstand the nurse's instructions about how to perform the exercises? Are they resisting in other areas of the program? Effective receiving skills require attending to nonverbal as well as verbal messages and seeking feedback to understand their meaning.

An essential skill needed for receiving messages is **active listening** or reflective listening, which is the skill of assuming responsibility for and striving to understand the feelings and thoughts in a sender's message. Instead of expecting clients or others to help the nurse understand, the nurse should actively work to discover what clients mean. Understanding the message from the sender's perspective demands careful attention, which arises from a genuine interest in what the speaker has to say. Active listeners demonstrate their interest, perhaps by sitting forward, sustaining eye contact, nodding the head, and asking occasional questions for clarification (Fowler, 2006; Kar, Arcalay, & Alex, 2001). At times, **paraphrasing**, or repeating back to the sender what the receiver heard, is helpful in clarifying the sender's meaning. Summarizing your perceptions at the end of a home visit, for instance, helps to assure that the client's communication has been accurately interpreted. Active listening keeps us engaged; behaviors, such as daydreaming or pretending to be listening, block communication. Because we can listen to over 600 words a minute, but we can speak fewer than 200 words

a minute, it is important to focus and concentrate to stay engaged and keep your mind from wandering. Fowler (2006) suggests that you mentally repeat key words as your client speaks to you; this will help to reinforce your understanding and keep you from straying from the conversation. Also, the content and feeling of the sender's message may be overwhelming at times, and you can become preoccupied with formulating a response rather than listening actively. Nadig (2006) notes that we often listen to our own personal beliefs and values when clients are speaking, and make judgments about their messages. This interferes with effective communication; in these situations, paraphrasing can help you to stay focused. An example of the skill of paraphrasing follows:

*Client:* I don't think I can manage my elderly mother at home any longer. I know she never wanted to go to a nursing home, but with my job and the kids, caring for her is becoming impossible. My husband is so helpful, but I feel guilty burdening him. I'll be going against my mother's wishes if I place her somewhere, though.

*Nurse:* You sound like you are feeling frustrated caring for your mother and your family while maintaining a job, and you're not sure what is the best action to take.

Nurses also can listen actively by asking reflective questions that restate what clients or others have said to clarify the received meaning. Reflective questions have a twofold purpose: to show a sincere attempt to understand the senders' messages, and to make clear that the messages and the people who send them are important to the nurse. An example of a reflective question follows:

*Class members state:* Quitting smoking is impossible.  
*The nurse asks:* Do you feel you can't quit smoking?

Active listening helps to communicate acceptance and increase trust, especially when the listener refrains from making any negative judgments of the message or the way it is delivered. Clients may simply need to be "heard and acknowledged" before they can accept suggestions (Nadig, 2006, p. 12). A critical response to the client's message by the nurse cuts off communication. Many nurses note that "a curtain drops"—a visible change of expression takes place—when

the client *disengages* in response to a nurse's judgmental response. Active listening enables nurses to encourage clients to deliberate carefully and to exercise problem-solving skills; it avoids the pitfall of telling clients what to do. It is also a good initial response when your client seems hurt or angry, or is expressing dissatisfaction with you (Nadig, 2006). By asking reflective questions, the nurse continues to clarify the messages clients send. You can reflect back to clients their:

- ◆ Facts and information
- ◆ Thoughts and beliefs
- ◆ Feelings and emotions
- ◆ Wants, needs, motivations
- ◆ Hopes and expectations (Nadig, 2006).

### Interpersonal Skills

Effective communication in community health nursing also requires interpersonal skills. Three types of interpersonal skills build on sending and receiving skills but go beyond the mere exchange of messages. They are showing respect, empathizing, and developing trust and rapport.

#### Showing Respect

Showing respect means conveying the attitude that clients and others have importance, dignity, and worth—a concept basic to nursing practice (Harper, 2006). Community health nurses can express respect by treating clients' ideas and comments as valuable and worthy of attention. You can demonstrate an interest in wanting to understand the situation from the other person's point of view. We show respect by the manner in which we address people—for instance, by using the courtesy titles of "Mr." or "Mrs." until it is determined how the client wants to be addressed. On a more subtle level, the tone of voice the nurse uses can show respect or make people feel inferior and insignificant. Nonverbal cues and active listening can indicate to clients that you are fully engaged and interested in their issues. Clients, community members, and other professionals need to feel respected if they are to enter fully into the mutual exchange necessary for effective communication (Display 10.1).

#### DISPLAY 10.1

### HEALTH COMMUNICATION—ONE DISPARITY: LOW-LITERACY CLIENTS

Most poorly educated populations, those with the lowest literacy levels, have the highest mortality and morbidity. Changing demographics suggest that low literacy is an increasing problem among certain racial and ethnic groups, non-English-speaking populations, and persons older than 65 years of age, although the majority of people with low literacy are white native-born Americans (U. S. Department of Health and Human Services, 2000). Yet it has been well documented that most health information pamphlets, brochures, and other materials cannot be read or comprehended by low-literacy adults. Communication with these high-risk groups should be simplified and should include easy-to-read materials. At the same time, there is the danger of making the communication so

simple that the reader feels insulted. Low literacy does not necessarily mean low intelligence. How does the nurse find the right balance?

The goal of communication is to achieve understanding. If clients are to understand health communication—whether the messages are spoken or written—they must be given ample opportunity to provide feedback. Pamphlets and other written health information should be reviewed by their intended audiences before final printing and distribution. Proposed users should comment on the readability and acceptability of both text and graphics. With spoken communication, nurses should regularly solicit feedback to make certain that messages are understood.

## Empathizing

Empathizing is another important interpersonal skill. **Empathy** is the ability to communicate understanding and to vicariously experience the feelings and thoughts of others—a type of “emotional engagement” (Edelman & Mandel, 2006, p. 82). It is similar to the “moral value” of compassion (Von Dietze & Orb, 2000, p. 166) and involves “perspective-taking” (Lobchuk, 2006, p. 330). We show empathy by striving to put ourselves in our client’s shoes—by reflecting their feelings and expressing that message in the receiver’s language. The nurse should use the same terms and, if possible, the same tone of voice as the other person did. For example, you should assume a serious manner if the speaker seems serious. Empathy conveys the message, “This is the way it seems to me. Is that correct?” The nurse should keep validating the speaker’s true feelings to be certain that the message is being interpreted correctly. Empathy focuses attention on receivers and their feelings, thus reducing clients’ anxiety and defensiveness. It builds trust and a greater level of understanding, and shows that the nurse shares clients’ concerns and makes them feel that their contributions are valued (Edelman & Mandel, 2006; Finkelman, 2006).

## Developing Trust and Rapport

Developing trust is necessary for effective communication. Rapport—a warm, friendly, trusting relationship—develops when nurses are open, genuine, and demonstrate true concern for their clients. Building trust and rapport with clients is usually the first goal for community health nurses. Clients and others will not express their true feelings if they do not fully trust the nurse. Many times, clients say what they think the nurse wants to hear. They may agree to a plan of action simply because they do not want to displease the nurse, or they may hide their true feelings because they think that the nurse is eager for a decision. Agreeing with others, especially with people who are in powerful positions and from different cultures, is the polite and respectful thing to do in some cultures (Spector, 2009). The nurse who is unaware of this fact may interpret the client’s agreement as understanding, thus a “teachable moment” is lost.

Nurses develop trust in the communication process by being trustworthy—doing as they have promised, being reliable. We can also do this by showing that we truly accept others, that we believe in them as people. In a qualitative study by Falk-Rafael, clients of PHNs noted that a trusting relationship is developed when the PHN shows respect and enhances their dignity while “creating a safe environment” by being nonjudgmental and showing empathy (2001, p. 5). Trust generates trust; as the nurse shows confidence in clients and the other professionals with whom the nurse is communicating, they will respond in kind. Treating people as fully participating partners in the communication process means demonstrating that they are trustworthy and responsible. Trust also is developed through an open, honest, and patient approach with others. Candid discussion in a flexible timeframe encourages people to share their real feelings and to move at their own pace. We can model behaviors we want our clients to adopt. Clients appreciate nurses who are “authentic” and honest with them, who are “down to earth”

and admit when they don’t have all of the answers (Falk-Rafael, 2001, p. 5). We can promote trust by:

- ◆ Trusting our clients to do as they have committed.
- ◆ Clarifying expectations, anticipated behaviors, and boundaries of the nurse–client relationship.
- ◆ Demonstrating consistency.
- ◆ Being aware of attitudes and behaviors that do not promote trust (Gallant, Beaulieu, & Carnevale, 2002).

As trust develops, communication becomes more free-flowing and productive. When that occurs, you can become much more effective as a community health nurse and better able to assist your clients.

## Factors Influencing Communication

In a helping relationship, it is important for the community health nurse to demonstrate effective communication. It is important to project:

- ◆ Openness, genuineness, and self-awareness (ability to reflect on one’s strengths and weaknesses)
- ◆ Sensitivity, acceptance, concern, and respect for the client
- ◆ Knowledge, self-confidence, creativity, and empathy
- ◆ Ability to problem-solve and to confront when necessary (Edelman & Mandel, 2006, p. 87)

Effective communication, both sending and receiving, is strongly influenced by three factors: previous experiences, culture, and relationships.

Previous experiences of both sender and receiver influence their perceptions and the meanings they attach to messages. For example, adolescents who are having difficulty with parents’ authority may hear the nurse’s suggestion to “learn more about sexually transmitted diseases” as an authoritarian command or effort to exert control. Requests for clarification help to verify that messages are being received as intended.

The respective cultures of sender and receiver influence understanding and acceptance of messages. A nervous laugh, appropriate as an outlet in one culture, may appear rude and disrespectful to someone from another culture. Silence, which in Native American cultures indicates patience and thoughtfulness, may be interpreted as weakness or indifference to someone not familiar with these cultural practices. With many clients, the nurse must communicate cross-culturally, which requires patience and constant effort to ensure accurate and inoffensive messages (Williams, 2006; Spector, 2009).

## Health Literacy and Health Outcomes

**Health literacy** has been defined as “the ability to read, understand, and act on health information” (Andrus & Roth, 2002, p. 282). Nutbeam (2000) delineates three different levels of health literacy and their outcomes (Table 10.1). Comprehension of health information, either verbal or written, is important for clients in maintaining their health and the health of their families (Nielsen-Bohlman, 2004)—in fact, poor health literacy has been associated with poorer health status and increased health costs (Andrus & Roth, 2002).

**TABLE 10.1 Levels of Health Literacy**

Health Literacy Level	Outcome
Functional health literacy	Communication of factual information on health risks, health services and screenings; better compliance with prescribed actions
Interactive health literacy	Improved ability to independently act on knowledge and develop skills; increased motivation
Critical health literacy	Empowerment of individuals and communities; better resilience to economic and social problems; community action on economic and social determinants of health

Adapted from Nutbeam, D. (2000). Health literacy as a public health goal: A challenge for contemporary health education and communication strategies into the 21st century. *Health Promotion International*, 15(3), p. 266.

A recent study found that lower scores on a measure of functional health literacy were statistically correlated with poorer glycemic control and retinopathy in a group of type 2 diabetic patients (Schillinger, Grumbach, Piette, et al., 2002). In a study of 653 Medicare enrollees with chronic diseases, almost one-quarter of the participants tested had inadequate health literacy, and over 10% had only marginal skills in that area (Gazmararian, Williams, Peel, & Baker, 2003). Those patients with health literacy difficulties demonstrated significantly less understanding of their disease than those without health literacy problems—a fact that

could lead to greater complications and costs. Health literacy can also affect health promotion and disease prevention.

Another study found that low health literacy was a better predictor of cervical cancer knowledge than either education or ethnicity in a group of English-speaking ambulatory clinic patients (Lindau, Tomori, Lyons, et al., 2002). Over 40% of the women in this study were tested and found to have low health literacy. Understanding the purposes for receiving regular Papanicolaou (Pap) tests is a fundamental prerequisite to getting them—and the benefits of regular Pap testing are well documented.

Almost half of U.S. adults have been found to have deficits in regard to reading and math skills, and could be classified as having only basic literacy or a level below that—meaning that they can perform only simple everyday activities or have only the most simple and concrete skills (Andrus & Roth, 2002; National Assessment of Adult Literacy [NAAL], 2003). Health literacy goes beyond the basic definitions of literacy, however, and can include such things as cultural literacy and computer literacy, as well as scientific, media, and technological literacy (Kickbusch, 2001). *Healthy People 2010* defines health literacy as: “The capacity to obtain, interpret, and understand basic health information and services and the competence to use such information and services to enhance health” (USDHHS, Health Communication, 2006, ¶ 16).

Health literacy is characterized as critical to health promotion and disease prevention, and *Healthy People 2010* goals include improvement of health literacy and health communication for our population (Display 10.2). Health communication encompasses the concept of health literacy, but also incorporates health messages and campaigns, along with mass media and consumer health issues that are targeted to populations. Population health promotion is best achieved by health communication that uses “multiple communication channels . . . to reach specific audience segments with information that is

**DISPLAY 10.2 HEALTHY PEOPLE 2010: HEALTH LITERACY AND HEALTH COMMUNICATION**

These are only a portion of the *Healthy People 2010* objectives related to health literacy or health communication:

- 11-2. Improve the health literacy of persons with inadequate or marginal literacy skills.
- 11-3. Increase the proportion of health communication activities that include research and evaluation.
- 11-4. Increase the proportion of health-related World Wide Web sites that disclose information that can be used to assess the quality of the site.
- 11-5. Increase the number of centers for excellence that seek to advance the research and practice of health communication.
- 7-3. Increase the proportion of college and university students who receive information from their institution on each of the six priority health-risk behavior areas.
- 7-7. Increase the proportion of health care organizations that provide patient and family education.

- 7-8. Increase the proportion of patients who report that they are satisfied with the patient education they receive from their health care organization.
- 7-9. Increase the proportion of hospitals and managed care organizations that provide community disease prevention and health promotion activities that address the priority health needs identified by their community.
- 7-11. Increase the proportion of local health departments that have established culturally appropriate and linguistically competent community health promotion and disease prevention programs.
- 23-2. Increase the proportion of Federal, Tribe, State, and local health agencies that have made information available to the public in the past year on the Leading Health Indicators, Health Status Indicators, and Priority Data Needs.

From [www.healthypeople.gov/hpscripts/searchobjectives\\_FT.asp](http://www.healthypeople.gov/hpscripts/searchobjectives_FT.asp)

appropriate and relevant to them” (USDHHS, Health Communication, 2006, ¶ 5). More information on these topics can be found in Chapter 11.

Because much of community health nursing involves groups, the relationships among group members can significantly influence the effectiveness of communication. When many people are involved, group communication patterns can be complex, and interaction requires skill on the nurse’s part to elicit feedback from all members and to generate a common understanding among the group’s members.

## Communicating with Groups

An important aspect of communication in community health nursing involves working with groups of people. Community health nurses are regularly involved in committees, task forces, and other work-related groups. Nurses also work with aggregates in small groups—often teaching, gathering community assessment and evaluation data, and facilitating support groups. We need to understand how to organize groups and how groups function and develop over time, as well as techniques for facilitating group support and decision-making.

## Group Development

Think about the first time you walked into a nursing classroom—you didn’t know the teacher or any of the other students in your group. What were your feelings? What did you expect or need the teacher to do? How did your feelings and expectations about the students and teacher change by the end of the term? Changes in group dynamics over time are termed **group process**.

Groups may consist of organized workgroups or they may simply come together because of a common need or task. When a group of people first comes together, group members are often hesitant, quiet, and depend very much on the group leader or facilitator to give them structure and guidance (George Mason University Center for Service and Leadership [CSL], 2006). Members may feel awkward and need to be reassured. Acceptance is foremost in each group member’s mind. This first stage of group development is termed *forming* (see Display 10.3).

At this stage, the group leader’s task is to help the members become oriented to each other and the work or purpose at hand. Ice-breaker activities, to introduce members to each and move past the awkwardness and hesitancy, are often used at the first group meeting. Conflict and sensitive topics, or too much self-disclosure by leaders or group members, are to be avoided at this stage. Rather, it is important to set ground rules (e.g., no sharing personal information outside of support group) and define the scope of work and timeline for completion. A component of group process involves how members address the work of the group (task role) and the personal or relationship issues (maintenance role) derived from membership in the group (USDHHS Substance Abuse and Mental Health Services Administration [SAMHSA], 2006). In the first stage, task roles are the major focus, with maintenance roles emerging in later stages (see Task, Maintenance and Nonfunctional Roles, Display 10.4).

The next stage is called *storming*, because conflict and competition become more common as the group develops ideas about the task in a work group, or gets down to sharing more sensitive issues in a support group. Some conflict may not be readily apparent, as some members choose to be quiet and not express their feelings. It is important for the leader to make sure that all members have an opportunity to participate. Problem-solving is the goal of this stage, along with listening to others’ opinions. Modeling maintenance roles, by encouraging group members, asking for a quiet member to contribute to the group, and summarizing group feelings, is helpful in moving group members along in maintenance as well as task roles.

By the time group members begin to show signs of cohesiveness, they have moved on to the *norming* stage, and work begins to progress. Trust and openness are much more apparent, and there is a shared sense of “belonging” to the group. Creativity and shared ideas and opinions characterize this stage. Until this time, most groups function at the task level, but by this stage, maintenance activities are more apparent as members draw others in and constructively share feelings. The leader should continue to role model good maintenance behaviors to move the group along in its work.

The *performing* stage may not occur with all groups; it is characterized by the ability to work as a total group, in subgroups, or independently. This is considered the “most

### DISPLAY 10.3

### STAGES OF GROUP DEVELOPMENT

Forming	Group dependent on facilitator; anxiety high, need safe environment, structure, and avoid too much self-disclosure; agree on guidelines for group work/behavior; orient to task or purpose of group
Storming	Competition and conflict; need for structure; problem-solving; need to draw out quiet members; continue to clarify group task or purpose
Norming	Group now more cohesive and creative; acknowledge others’ contributions; shared leadership; trust increases; work moves along more quickly
Performing	Not reached by all groups; true interdependence—can work as group, or as individuals, and in subgroups; most productive; least reliant on facilitator
Adjourning	The termination phase; conclusion of activities and resolution of relationships; formal acknowledgement of group work

## DISPLAY 10.4

## TASK, MAINTENANCE, AND NONFUNCTIONAL ROLES IN GROUPS

**Task Roles:** Required in selecting and carrying out group tasks.

**Maintenance Roles:** Required in strengthening and maintaining group relationships and activities.

**Nonfunctional Roles:** Roles that harm the group and its work—often self-oriented behavior.

#### Task Role Behaviors

**Initiating Activity:** Proposing solutions; suggesting new ideas, new definitions of the problem, new approaches to the problem or new organization of material.

**Seeking Information:** Asking for clarification of suggestions; requesting additional information or facts.

**Seeking Opinions:** Looking for an expression of feeling about something from members; seeking clarification of values, suggestions or ideas.

**Giving Information:** Offering facts or generalizations; relating one's own experiences to the group problem to illustrate a point.

**Giving Opinions:** Stating an opinion or belief concerning a suggestion or suggestions; particularly concerning its value rather than its factual basis.

**Elaborating:** Clarifying, giving examples or developing meanings, trying to envision how a proposal might work if adopted.

**Coordinating:** Showing relationships among various ideas or suggestions, trying to pull ideas and suggestions together, trying to draw together activities of various subgroups or members.

**Summarizing:** Pulling together related ideas or suggestions; restating suggestions after the group has discussed them.

#### Maintenance Role Behaviors

**Encouraging:** Being friendly, warm, responsive to others, praising others and their ideas, agreeing with and accepting contributions of others.

**Gatekeeping:** Trying to make it possible for another member to make a contribution to the group by saying "We haven't heard anything from Jim yet," or suggesting limited talking time for everyone, so that all will have a chance to be heard.

**Standard Setting:** Expressing standards for the group to use in choosing its content or procedures or in evaluating its decisions; reminding the group to avoid decisions that conflict with group standards.

**Following:** Going along with decisions of the group; thoughtfully accepting ideas of others; serving as audience during group discussion.

**Expressing Group Feelings:** Summarizing what group feeling is sensed to be; describing reactions of the group to ideas or solutions.

#### Both Task and Maintenance Role Behaviors

**Evaluating:** Submitting group decisions or accomplishments to compare with group standards; measuring accomplishments against goals.

**Diagnosing:** Determining sources of difficulties; appropriate steps to take next; analyzing the main block to progress.

**Testing for Consensus:** Tentatively asking for group opinions in order to find out whether the group is nearing consensus on a decision; sending up trial balloons to test group opinions.

**Mediating:** Harmonizing, conciliating differences in points of view, suggesting compromise solutions.

**Relieving Tension:** Draining off negative feelings by jesting or pouring oil on troubled waters; putting a tense situation in a wider context.

#### Types of Nonfunctional Behaviors

**Being Aggressive:** Working for status by criticizing or blaming others; showing hostility toward the group or some individual; deflating egos or status of others.

**Blocking:** Interfering with the progress of the group by going off on a tangent; citing personal experiences unrelated to the problem; arguing too much on a point; rejecting ideas without consideration.

**Self-confessing:** Using the group as a sounding board; expressing personal, nongroup-oriented feelings or points of view.

**Competing:** Vying with others to produce the best idea, talk the most, play the most roles, gain favor with the leader.

**Seeking Sympathy:** Trying to induce other group members to be sympathetic to one's problems or misfortunes; deploring one's own situation, or disparaging one's own ideas to gain support.

**Special Pleading:** Introducing or supporting suggestions related to one's own pet concerns or philosophies, lobbying.

**Horsing Around:** Clowning, joking, mimicking, disrupting the work of the group.

**Seeking Recognition:** Attempting to call attention to one's self by loud or excessive talking, extreme ideas, unusual behavior.

**Withdrawal:** Acting indifferent or passive, using excessive formality, daydreaming, doodling, whispering to others, wandering off the subject.

productive" stage, and a true balance is achieved between task and maintenance functions (George Mason University CSL, 2006, ¶ 7). Group leaders are less involved with moving along the work of the group. Members now work together more smoothly and do not need a lot of direction from the facilitator.

When either work or support groups end, the final stage of development is termed *adjourning*. This is a withdrawal from both task and relationship activities. Group leaders may plan a small party or ceremony—something to formally commemorate the group's time together and help members successfully disengage (George Mason University CSL, 2006).

## Group Functions in Decision-Making

Groups, regardless of size, perform many functions. Four functions of particular relevance to group decision-making include:

1. *Group members share information.* In community health nursing, groups often include clients, health professionals, and community members who share their experience and expertise to arrive at solutions and decisions. Something one member says may spur others to think of more creative solutions or share similar problems (Nijstad & Stroebe, 2006).
2. *Groups are heterogeneous and present diverse views,* which enriches the number and types of alternatives in the problem-solving process. Group decisions are often better than individual ones because of the diversity of experiences and perspectives (Connery & Vohs, 2006).
3. *Groups influence their members' thinking* by broadening their perspectives and presenting new ways of thinking about the issues. This influencing function can improve the quality of group decision-making and reduce the likelihood of making serious mistakes in judgment (Nijstad & Stroebe, 2006).
4. *Groups progress toward consensus* or resolution by discussing a set of alternatives and arriving at solutions. Time pressures and the desire for completion help to move this process along. (Connery & Vohs, 2006).

## Techniques for Enhancing Group Decision-Making

As a member of many decision-making groups in the community, the community health nurse can facilitate the process through certain techniques. Robbins (2003) describes four useful strategies commonly used in community health settings: brainstorming, nominal group technique, Delphi technique, and electronic meetings.

### Brainstorming

**Brainstorming** is an idea-generating process that encourages group members to freely offer suggestions. When brainstorming, members sit around a table (if group size permits) and take turns presenting ideas. They are encouraged to be creative and “think out of the box”; no idea is too bizarre. Furthermore, no criticism or discussion is allowed until all ideas have been exhausted and recorded. This technique is helpful for generating creative possibilities and is most useful in the early stages of decision-making. Research has shown that brainstorming generates a large number of ideas, as well as a higher quality of ideas (Munoz, 2005).

### Nominal Group Technique

**Nominal group technique** is a group decision-making method in which ideas are pooled and discussed face-to-face after members initially think and write down their ideas independently. In this approach, members generally meet

together but first spend time silently writing down their ideas. Or, members may write down ideas and thoughts in advance of the meeting. Afterward, members take turns presenting one idea at a time to the group without discussion until all ideas have been recorded. Discussion then follows for clarifying and judging. Next, members independently and silently rank-order the ideas and read these rankings to the group. This allows the decisions to be narrowed down to the one with the highest aggregate ranking and facilitates earlier consensus. One example of the use of this technique led to the identification of health priorities among several rural districts in Tanzania, Africa. Input was gathered from lay people (e.g., religious leaders, community and youth leaders, elders). As was the case with health experts, the lay people identified malaria as the leading health concern, but noted that hunger, lack of water, and poverty were also issues that ranked high on the list of priorities needing to be addressed (Makundi, Manongi, Mushi, et al., 2005).

### Delphi Technique

The **Delphi technique** is a method of arriving at group consensus through a systematic pooling of individuals' judgments by using a written questionnaire and suggestions. Members do not need to be physically present to participate. The technique follows a series of steps:

1. The researcher identifies a problem or topic and designs a questionnaire to elicit responses from members (often a predetermined expert panel).
2. Members respond independently and anonymously and return the questionnaire.
3. The researcher compiles the information from the original questionnaire, then sends a “feedback report” and a revised questionnaire to the members (Anderson & McFarlane, 2004, p. 300).
4. Members offer new responses or solutions, based on the feedback report and earlier results, and return the questionnaires.
5. Steps 3 and 4 are repeated either for a preset number of times or as needed until consensus is reached.

This process is useful for polling experts who may be geographically distant from one another (Irvine, 2006). It also provides a way to reach a decision without group members unduly influencing each other. Its disadvantages are that it is time-consuming and can be expensive. By using e-mail, instead of “snail mail,” the Delphi technique provides practicality.

### Electronic Meetings

**Electronic meetings** provide a fourth group decision-making method. This method is often used in business settings and by government and voluntary health organizations. It applies nominal group technique combined with computer technology. Using meeting-productivity software, group members can access meeting agendas and pertinent information in a central location. Decisions are recorded and minutes of meetings are kept. Past minutes can be easily accessed, and timers can even be added to keep group members on task (Effective Meetings, 2006). This method

promotes greater honesty and speed. Experts claim that electronic meetings are significantly faster than face-to-face meetings, perhaps by as much as 50% (Robbins, 2003; Effective Meetings, 2006). Electronic meetings are becoming so common that resources about rules and parliamentary procedure have been specifically developed (National Association of Parliamentarians, 2006).

In community health, the availability of such technology may be limited in many settings. Nonetheless, computer-assisted decision-making is becoming increasingly useful and available. Computers are used with other group decision-making techniques for recording ideas and research findings, tabulating rankings, voting and election of officers in professional organizations, and conducting simulations.

### **Nursing Informatics**

**Nursing informatics** is a term for the collective technological sciences currently available to nurses in the health care delivery system for the delivery of nursing care. The classic definition of nursing informatics comes from Graves and Corcoran (1989, p. 227):

A combination of computer science, information science, and nursing science designed to assist in the management and processing of nursing data, information, and knowledge to support the practice of nursing and the delivery of nursing care.

Nursing informatics as a nursing specialty was approved in 1992 by the American Nurses Association. Specialty certification is awarded to nurses with a baccalaureate degree and either specialized education or practice in the field (Blais, Hayes, & Kozier, 2006). Graduate degrees in nursing informatics, including the Ph.D., can be found across the country. The computer is changing all aspects of health care. Educational efforts include online journals, workshops, courses, and conferences for professionals, and a vast amount of consumer-oriented health information can be found on the Web. The documentation process increasingly uses the computer, with paperless charting becoming commonplace. This technology is no longer used exclusively in acute care settings but in the community at clinics, with home health nurses, with advanced-practice nurses, and in PHN settings. Various practitioners use the computer to research diseases, treatment methodologies, and educational resources for clients, or to search for sites of clinical trials. Informatics can provide a framework for interdisciplinary study and research, thus enhancing individual and group decision-making.

In many community health settings, computer databases aid in tracking immunizations, and computerized charting and billing systems are commonly used. Community health nurses access computerized nursing information systems that assist with quality measurement and improvement (see Chapter 12), home visiting documentation according to protocols, documentation of all client contacts, time management, and work schedules. PHNs in four local health departments in Minnesota collaborated on a project to use “standardized nursing language” and create an “automated platform” for articulation of data and documentation of “client assessments, service delivery information, and client outcomes” (Monsen, Fitzsimmons,

Lescenski, Lytton, Schwichtenberg, & Martin, 2006, p. 152). Although there were barriers and frustrations when working across departments, the nurses felt that the project met its goals and improved the quality of nursing care. The technique of documenting everything on paper in handwriting is being replaced. Electronic health records make client information readily accessible (Ries & Moysa, 2005). The U.S. Department of Health and Human Services (USDHHS) is supporting the development of “prototypes for a Nationwide Health Information Network (NHIN)” (USDHHS, 2005, ¶ 1) that will standardize patient data and ensure ease of access by various providers while protecting privacy and security of patient records. Through its Consolidated Health Informatics initiative, the USDHHS Office of the National Coordinator for Health Information Technology (ONC) has begun to identify uniform standards among government agencies and a portfolio of 27 health domains (ONC, 2005). This work is in response to President George W. Bush’s directive for development of personal electronic health records. We may soon be able to swipe a card and access a patient’s health history and current health data (e.g., laboratory and x-ray results).

Computerized geographic information systems (GISs) are used to display, analyze, and manipulate spatial data. This allows community health and safety organizations to use three-dimensional graphics to locate and track diseases, toxic waste sites, ground water sources, and vehicle crashes on roads in a region, county, or census tract, and so on. With such information, community health and safety can be enhanced and traffic patterns can be altered to make roads safer; health care personnel resources can be redistributed based on disease distribution; and dumps and waste sites can be relocated to protect valuable ground water sources. In a survey, researchers from Pennsylvania and Tennessee found that GIS software is not often used to its full potential by public health professionals (Scotch, Parmanto, Gadd, & Sharma, 2006). Researchers used this advanced technology to map clusters of tuberculosis (TB) cases in Almora, India, and noted the potential for its use in TB surveillance (Tiwari, Adhikari, Tewari, & Kandpal, 2006).

Many of us are already familiar with personal digital assistants (PDAs) and enjoy the many features they provide. The use of PDAs is well established among physicians and medical students (Garrity & El Emam, 2006), and is growing among nursing students (Goldsworthy, Lawrence, & Goodman, 2006). Acute care nurses and nurse practitioners have found them to be helpful in managing complex patients, prescribing medications, and following complicated protocols (Taylor, 2005; Tilghman, Raley, & Conway, 2006).

However, PHNs may also benefit from the use of PDAs not only for calendaring appointments and keeping brief notes, but also for charting (Menachemi, Ettel, Brooks, & Simpson, 2006) and disease reporting. A case reporting system (RSVP) was developed jointly by University of Washington researchers and the Denver Public Health Department (Lober, Bliss, Dockrey, Davidson, & Karras, 2003). PDAs and wireless networks were used to collect data, notify the health department of reportable diseases (both routine and bioterrorism cases), and add cases to a reporting database, as well as access updated database files. A study in South Africa used PDAs and Bluetooth-linked global positioning system (GPS) receivers to assist in locating homes of

TB clients needing treatment followup (directly observed therapy [DOTS]). Because many people live in crowded areas with inadequate house numbering, and some live in “backyard shacks” or “informal settlements” without property numbers, it is often very difficult to locate clients for follow-up visits (Dwolatzky, Trengove, Struthers, McIntyre, & Martinson, 2006, ¶ 7). The researchers found that volunteers could locate homes more easily using the PDA/GPS systems versus aerial photographs.

The work of the community health nurse can be assisted as more technologies become available. Online chat rooms may be utilized for facilitating support groups; discussion boards can be used as a means of training for staff and students; and telehealth (the use of telecommunications and electronic information technologies to provide long-distance health care, professional and patient health education and public health administration) can be expanded to provide health care to medically underserved populations in remote areas (Copeland, 2002; Deering & Eichelberger, 2002; USDHHS Health Resources & Services Administration [HRSA], 2006).

## COLLABORATION AND PARTNERSHIPS IN COMMUNITY HEALTH NURSING

Interprofessional and interdisciplinary collaboration is an “essential element of quality health care” (Coeling & Cukr, 2000, p. 63). **Collaboration**, for community health nurses, means a purposeful interaction between nurses, clients, other professionals, and community members based on shared values, mutual participation, and joint effort. It involves building trust and confidence and is “more often voluntary,” with its roots “found in natural social skills developed by children through play” (Petersen, 2003, ¶ 1). These thoughts highlight two basic features of collaboration: it has a goal, and it involves several parties assisting one another to achieve that goal. The overriding purpose or goal of collaboration in community health practice is to benefit the public’s health. To that end, many players must work together—agencies, professionals, clients, and lay health workers. There are key strategies for establishing partnerships and collaboration with interprofessional team members (Allender, Carey, Castanon, et al., 1997):

- ◆ Think “outside the box” when looking for partners or collaborators.
- ◆ Partners must be part of the planning.
- ◆ Plans are *guides* toward a goal; stay flexible.
- ◆ When adding new partners, be prepared to re-plan.
- ◆ Maintain different levels of collaboration (different team members have more resources, come in later to the project, or leave the project earlier).
- ◆ Use consensus-building techniques that are creative and visual.
- ◆ Establish a shared vision, then share the plans and the leadership.

Like group process, collaboration among agencies or groups of people may occur in stages:

- ◆ **Competition.** Competing backgrounds, ideas, and motivations, and a search to find shared values, goals, and ethical principles

- ◆ **Networking/Communication.** Sharing information promotes development of trust and role clarity, and reduces miscommunication caused by stereotypical views of other disciplines, professions, or entities
- ◆ **Cooperation/Coordination.** More sharing of resources, less duplication, and formal communication through structure and agreements; more mutual respect
- ◆ **Coordination/Partnership.** Becoming more invested in the success of all partners, better able to manage and share resources; full support of agencies involved
- ◆ **Coalition.** Shared leadership and decision-making; resources benefit all members; sufficient power and authority to work collectively
- ◆ **Collaboration.** Shared mission and vision, open and trusting communication, strong relationships, sense of belonging, and shared accomplishment and goals (Petersen, 2003; Lewandowski & GlenMaye, 2002)

Addressing the needs of aggregates requires a variety of team players. Community health nursing practice draws on the expertise and assistance of numerous individuals. The list includes health planners and policy makers, epidemiologists, biostatisticians, community citizens, demographers, environmentalists, educators, politicians, housing experts, safety professionals, and industrial hygienists in addition to physicians, social workers, psychologists, physical therapists, dentists, and most of the other professionals involved in health services. Depending on the need to be addressed, community health nurses may work with many of these people on a single project. Furthermore, perhaps the most important team players are community clients—those populations and groups who are the targets of community health services. Clients’ cultural background, experience in collaboration and partnership building, perspectives, and expressions of need provide important information for the planning and delivery of services (Display 10.5). Their participation, either collectively or through representatives, ensures more comprehensive and accurate information as well as commitment to fully using the health programs designed for their benefit.

## Characteristics of Collaboration and Partnerships

To explore the meaning of collaboration in the context of community health nursing, this section examines five characteristics that distinguish collaboration from other types of interaction: shared goals, mutual participation, maximized resources, clear responsibilities, and set boundaries.

### Shared Goals

First, collaboration in community health nursing is goal directed. The nurse, clients, and others involved in the collaborative effort or partnership recognize specific reasons for entering into the relationship. For example, a lumber company with 150 employees seeks to develop a wellness program. The community health nurse, company employee representatives, a safety expert, an industrial hygienist, a health educator, an exercise therapist, a nutritionist, and a psychologist might work together to develop specific physical and

## DISPLAY 10.5

## CROSS-CULTURAL COLLABORATION GUIDELINES

1. Practice—we get better at cross-cultural collaboration when we practice it.
2. Do not use generalizations about other cultures to stereotype or oversimplify your ideas about another person or group.
3. Do not assume that there is only one right way (yours) to communicate. Keep questioning your assumptions about the “right way” to communicate.
4. Do not assume that breakdowns in communication occur because other people are on the wrong track. Search for ways to make communication work, rather than searching for who should receive the blame.
5. Listen actively and empathetically. Try to put yourself in the other person's shoes, especially when another person's ideas or perceptions are different from your own. Be willing to step outside your comfort zone.
6. Respect other opinions.
7. Stop, suspend judgment, and try to look at the situation as an outsider.
8. Be aware of power imbalances and the effects on communication.
9. Remember that cultural norms may not apply to the behavior of any particular individual. Start from where they are. Check your interpretations and ask for clarification.

From the National Institute for Dispute Resolution.

mental health goals. The team enters into the collaborative relationship with broad needs or purposes to be met and specific objectives to accomplish.

### **Mutual Participation**

Second, in community health nursing, collaboration involves mutual participation; all team members contribute and are mutually benefited (Leonard, Graham, & Bonacum, 2004). Collaboration involves a reciprocal exchange in which individual team players discuss their intended involvement and contribution, and it is important for all members of a team to feel equally valued—no hierarchies should exist. The lumber company representatives may outline assessed areas of need, such as back-strengthening exercises to facilitate lifting and reduce strain. The professionals, including the nurse involved in the collaboration, will offer their own specific ideas and expertise to design the wellness program. In interdisciplinary teams, physicians, nurses, lay community health workers, clients, outside agency personnel, and others must be able to effectively share ideas and frustrations on an equal, reciprocal basis.

### **Maximized Use of Resources**

A third characteristic of collaboration is that it maximizes the use of community resources. That is, the collaborative partnership is designed to draw on the expertise of those who are most knowledgeable and in the best positions to influence a favorable outcome. If the lumber company team has identified a need for health education materials, the nurse and other members of the collaborating team may explore health education resources through the local health department and within their own professions. In this age of dwindling resources, it is common for outside funding agencies to require proof of collaboration and coalitions in order to apply for grant or government funding.

### **Clear Responsibilities**

Fourth, the collaborating team members work in partnership and assume clearly defined responsibilities. As in a football

team, each member in the partnership plays a specific role with related tasks. The nurse may play a case-management or group leadership role, whereas others assume roles appropriate to their areas of expertise. Effective collaboration clearly designates what each member will do to accomplish the identified goals. The nurse, for example, might coordinate the planning effort for the lumber company wellness program and work with the health educator to develop classes on various topics. The psychologist might advise on a chemical dependency program, and the industrial hygienist would provide assistance with safety measures. Each member of the team develops an understanding of individual responsibilities based on realistic and honest expectations. This understanding comes through effective communication. The collaborating partners explore necessary resources, assess their capabilities, and determine their willingness to assume tasks.

### **Boundaries**

Fifth, collaboration in community health practice has set boundaries, with a beginning and an end that fall within the goals of the communication. An important part of defining collaboration is determining the conditions under which it occurs and when it will be terminated. The temporal boundaries sometimes are determined by progress toward the goal, sometimes by the number of team member contacts, and often by setting a time limit. The collaborating group might target 6 months as a completion date for the lumber company wellness program and establish a timeline with designated activities to reach the goal. Once the purpose for the collaboration has been accomplished, the group as a formal entity can be terminated.

In some settings, the partnership may desire to continue to work on other, mutually agreed upon activities. If so, the process begins again with different goals. Some partnerships are ongoing. For example, a university with a department of nursing might use a neighborhood community center for clinical experiences for the students. The community center has needs that may include health assessments and in-home health teaching among community members, flu shots given at the center for elders without

transportation, or health education classes for the adults in an English as a Second Language (ESL) class or for preschoolers in a Head Start program. The center and the university work in partnership so that, each semester, ongoing services are provided by the nursing students and coordinated by a faculty member or graduate nursing student in collaboration with the community center staff. Each partner wins. The students receive a rich educational experience, and the neighborhood center gets services they would otherwise do without. Within such a model, there are opportunities for students and volunteers. Students from other educational disciplines—social work, theater arts, physical therapy, early elementary education, and other areas—can be integrated into a center that serves people of all ages. Professionals (e.g., dentist, pediatrician) who are willing to volunteer (e.g., one-half or one day per week) enhance the services provided, as can lay volunteers, who can read to the children, answer the telephone, or participate in fund-raising. Any number of possibilities exist when people collaborate and work in partnership together.

### Fostering Client Participation

This chapter has stressed that communication and collaboration are based on mutual participation. The extent of clients' involvement in that participation varies, however, depending on their readiness and ability to participate (Chatterjee & Leonard, 2001). The client's level of wellness at the time of the initial professional–client encounter directly influences participation. Some people are not physically or emotionally well enough to assume an active role in the relationship. Women recently discharged from the hospital after a mastectomy, for example, have many physical and emotional adjustments with which to cope. Their families, too, must expend additional energies to provide needed support and to cope with the temporary loss of the woman's usual role in the family. They may find it difficult to engage actively in identifying their needs and goals at the start of the collaborative process. The nurse may have to take a stronger initial leadership role; however, the goals of collaboration are not abandoned. Gradually, as the client's wellness level improves or the client's family becomes more involved, the nurse can encourage more active participation. Developmentally disabled clients, or others who are cognitively impaired, may not have the full capacity for true collaboration.

Sometimes a client's previous experiences with health personnel limit participation in collaboration. Clients from poverty-stricken areas, those from different cultural backgrounds, or those with little education may need extensive encouragement to participate actively. Also, clients who were not previously encouraged to participate in decision-making by physicians, nurses, or other professionals may follow the pattern of a passive role and not truly collaborate. Unless the nurse persists in efforts to reduce the dependence of clients, the relationship can fall short of the therapeutic goals.

The nurse's own view of collaboration also influences the degree of client participation. Nurses who are accustomed to relating to clients in an adult-to-child manner restrict client involvement. If nurses see their position as more informed, and the client's position as one of complete ignorance and

need, a paternalistic relationship may develop. All clients have resources on which to build, and the community health nurse helps clients to discover these resources and use them to enhance collaboration and attain health goals.

Clients who initiate or seek service frequently are best able to assume an active participant role; examples include abused women seeking protection and elderly widowed persons seeking support. These clients have already demonstrated a sense of responsibility for their health by identifying a need and asking for assistance. They also are experts regarding their situation. This intimate knowledge of the problem makes the client an expert partner and a colleague in problem-solving. The nurse still must work carefully to build mutual participation and respond with concern and caring to foster continued interest and participation by clients.

### Structure of Collaborative Relationships

Effective collaboration occurs within a particular structure and sequence. During this process, the work of identifying and meeting the client's needs takes place. Because most collaborative and partner relationships are bound by time, the structure involves several phases: (1) a beginning phase when the team relationship is just being established; (2) a middle, working phase; and (3) a termination phase when the relationship ends.

The first phase is a period of establishing and defining the team relationship. All of the team members, including clients, are getting to know each other; they seek to establish communication patterns and develop trust. From these bases, they identify the clients' needs and determine the goals toward which they will work.

The second phase occurs when team members start working together to accomplish desired goals. Their work may include assessment and planning as well as implementation and evaluation. The cycle of the nursing process is repeated as needed during this working phase until goals are satisfactorily accomplished.

The third or termination phase occurs when the need for team members to work together has ended. When team members have grown close in the relationship, termination can be difficult. Termination should never occur abruptly or without participation. It often requires careful advance preparation to make certain that all parties understand when and why it is taking place. Termination helps to ensure a clear-cut end to the collaborative relationship. For example, a nurse, physician, social worker, psychologist, and nutritionist collaborated with a refugee group for almost 1 year. As the group's multiple needs declined, the professionals began to taper off their assistance. Two months before the relationship was ended, termination of the group was discussed. At first, client group members were frightened at the loss of group support, but slowly they took ownership and control, and with their newly acquired skills, they assumed more responsibility for their health needs.

### Barriers to Effective Collaboration

Communication barriers and miscommunication can inhibit effective collaboration. This is sometimes caused by misconceptions on the part of team members regarding the professional knowledge and motives of other team

members. Stereotypes and the perception of unequal power and authority granted to certain disciplines can sabotage the effectiveness of communication and true collaboration. Apprehension about sharing information with the team, inflexibility and uneasiness with the more fluid boundaries required in collaboration, and a failure to develop a common purpose and goals are all barriers for effective teamwork and collaboration. It is helpful for team members to share information about their respective disciplines and backgrounds, as well as personal expectations related to collaborative efforts. Structural factors, such as inadequate time, resources, and agency support, are also cited as barriers (Lewandowski & GlenMaye, 2002). Conflict is inevitable when dealing with groups of diverse individuals, but how that “dissent and disagreement” is handled is the key (Lewandowski & GlenMaye, 2002, p. 246). Open, honest communication must prevail. “Carefronting” has been described as a method of addressing and resolving conflict by confronting other professionals in a “caring, self-asserting, responsible manner” (Kupperschmidt, 2006, ¶ 4). It involves using “I” messages and “negotiating differences in clear, respectful, truthful ways” (¶ 2). It is more fruitful to focus on the issue or problem at hand in a safe environment where all members can voice their opinions openly, and not on personal determinations of who is right or wrong (Leonard, Graham, & Bonacum, 2004).

## CONTRACTING IN COMMUNITY HEALTH NURSING

**Contracting** means negotiating a working agreement between two or more parties in which they come to a shared understanding and mutually consent to the purposes and terms of the transaction. Some kinds of contracts are familiar, such as when a buyer signs a contract agreeing to pay a certain amount over a certain period of time to purchase an automobile. Paying tuition for an education involves a form of contracting: although no formal document is signed, students agree with an educational institution on a purpose (to obtain a degree), with the terms of the contract being regular tuition payments and regular learning opportunities over a specified period of time. For students in individual university courses, their syllabus is a contract. It spells out what is offered, what is expected, and what the outcomes may include. Sometimes, learning contracts are utilized within a course to further clarify roles and responsibilities, and students may “contract” for a grade—agree to do a specific number of assignments in exchange for a predetermined grade.

In contrast to legal contracts, which are written and legally binding, contracts in a collaborative relationship or a nurse–client alliance are flexible and changing, and are based on mutual understanding and trust. They are working agreements that may be renegotiated continuously between clients and health professionals. The flexibility built into nurse–client contracting makes it a valuable tool for community health nurses.

The same format is followed with clients who are receiving home health care services. The contract that develops from the partnership between client and home health care nurse often is referred to as a **critical pathway**. It consists of the written plans for client care with a timetable. This represents a more formal type of contracting:

it is typically a fiscally driven and agency-required tool designed to document standards and quality of care while reducing costs (see Chapters 12 and 32).

## Characteristics of Contracting

The concept of contracting, as used in the collaborative relationship, incorporates four distinctive characteristics: partnership and mutuality, commitment, format, and negotiation.

### Partnership and Mutuality

All aspects of contracting involve shared participation and agreement between team members; they become partners in the relationship. There is also a mutuality to the nurse–client relationship: if we were to document nurse–client collaboration on a continuum, paternalism would be at one extreme and autonomy at the other. Mutuality becomes the midpoint, balance, or ideal of these two extreme positions. For example, a parenting group of 15 couples requested community health nursing involvement. The group entered into a mutual partnership with the nurse and came to an agreement on what they needed and what the nurse could provide. Together, they developed goals, outlined methods to meet those goals, explored resources to help achieve them, defined the time limits for the contract, and outlined their separate responsibilities. The contract involved reciprocal negotiation and shared evaluation. A partnership with mutuality means that all parties are responsible for setting up and carrying out the terms of the agreement within a dynamic balance. Display 10.6 shows an individual service plan, which includes a contract, that is used by one community health nursing program in a California county health department with clients in their Perinatal Outreach Education program.

### Commitment

Second, every contract implies a commitment. The involved parties make a decision that binds them to fulfilling the purpose of the contract. In community health collaboration, contracting does not mean making a binding agreement in the legal sense; rather, it is a pledge of trust and dedication. Accompanying that sense of dedication is a strong motivation to see the contract through to completion. All parties feel responsible for keeping promises; all want to achieve the intended outcomes. When the nurse and the parenting group identified their separate tasks, they committed themselves: “Yes, we will do thus and so.”

### Format

Format, the third distinctive feature of contracting, involves outlining the specific terms of the relationship. Clients and professionals gain a clear idea of the purpose of the relationship, their respective responsibilities, and the specific limits within which they will work. Expectations are clarified for all parties involved. The format of contracting provides the framework for collaboration. Once the terms of the contract have been spelled out, there is no question about what has to be done, who is to do it, or within what timeframe it is to be accomplished. This format helps to avoid the difficulty of terminating long-term relationships and shifts health care responsibilities from the professionals to the individual or

## DISPLAY 10.6

## CLIENT SERVICE PLAN WITH CONTRACT

**Madera County Public Health Department**  
**Public Health Nursing: Client Individual Service Plan**

Client Name: Angelica Luz-SmithClient Signature: Angelica Luz-SmithCase Manager: J. Allender, RN, PHNStart Date: 6-02-10

Date: <u>6-02-10</u> Strengths Identified: <i>Desires to have a healthy baby</i> Problems/Risks/ Concerns Identified: <i>Doesn't like vegetables</i> <i>Doesn't like many fruits</i>	Client Goal: 1. Eat 5 fruits + vegetables daily A. Start with 1—2 fruits + 1—2 vegetables/day B. Try new ones (use list provided) at least 1/week (May use cheese and/or ranch dressing)	Case Manager: Teaching/Counseling/ Referral —value of fruits + v <sup>e</sup> gs —nutrients not available in any “vitamin” —reviewed v <sup>e</sup> gs—client likes corn, canned green beans, V-8 juice —reviewed fruits—client likes apples, bananas + strawberries —CI will try peas + carrots + pears	Follow-up/Reassessment Date: <u>6-30-10</u> Outcome/Evaluation —Client eating 4 v <sup>e</sup> gs/day on 24 hr dietary recall —Client eating 1 fruit/day (banana) Teaching- —reviewed fruits in season —client will try a fresh peach or grapes each day	Follow-up/Reassessment Date: _____ Outcome/Evaluation
Date: _____ Strengths Identified: Problems/Risks/ Concerns Identified:	Client Goal:	Case Manager: Teaching/Counseling/ Referral	Follow-up/Reassessment Date: _____ Outcome/Evaluation	Follow-up/Reassessment Date: _____ Outcome/Evaluation

group. At times, having something in writing helps the client ‘legitimize’ the nurse–client interaction. The goals and specific objectives are visualized and can be referred to and followed by all parties, as seen in Display 10.6.

### Negotiation

Finally, contracting always involves negotiation. The nurse and other team members propose to accept certain responsibilities and then ask whether the clients agree. The nurse might ask, “What do you feel you can do to achieve this goal?” A period of give-and-take then occurs in which ideas are discussed and conclusions and consensus are reached—no coercion should be involved. Team members may find over time that terms or goals on which they had agreed need modification. Perhaps clients have assumed more responsibility than they can realistically handle at this time and need to redefine their specific responsibilities. Perhaps the nurse feels a need to involve another professional in the collaborative process. The importance of effective interpersonal

communication between clients and professionals to keep contracts updated is emphasized. Negotiation during contracting allows for changes that facilitate the ultimate achievement of goals. It provides built-in flexibility and encourages ongoing communication among all team members. Negotiation gives contracting a dynamic quality. Also, we need to remember that, although we may be experts in community health nursing and feel that we know best what is needed for our clients, they know more about their life circumstances and how health and illness impact them (Mayor, 2006). Mutual respect and regard are necessary before effective contracting can take place.

### Value of Contracting

The value of contracting has been demonstrated in many settings and disciplines. Contracts have been used for many years in psychiatric and other nursing settings to promote client self-respect, problem-solving skills, autonomy, and motivation. Other disciplines, such as social work, have long

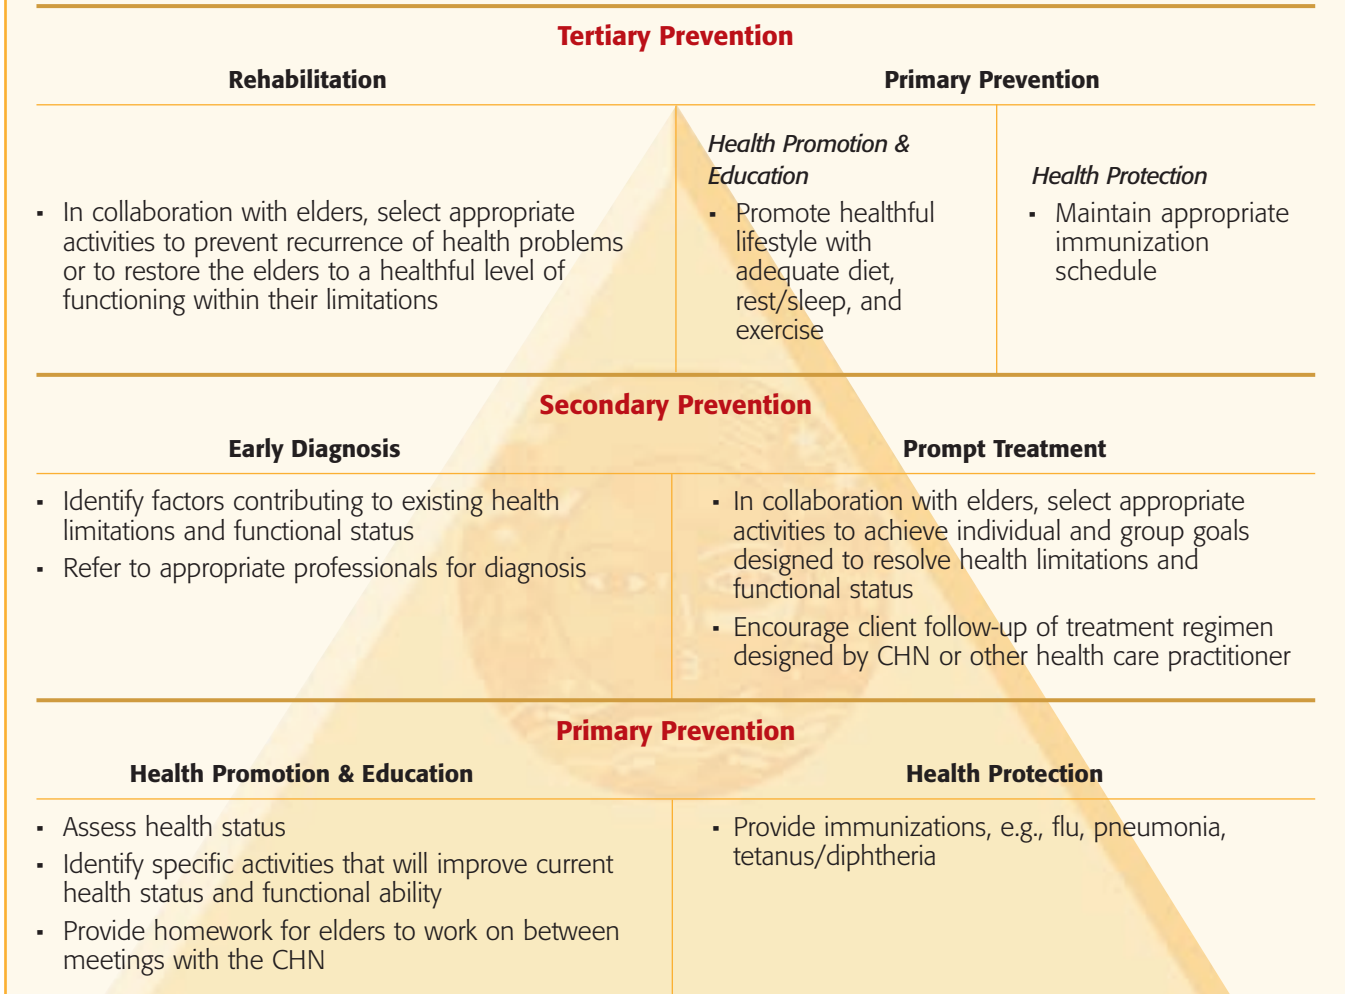

## LEVELS OF PREVENTION PYRAMID

**SITUATION:** A population of elderly clients, interacting with a community health nurse on a monthly basis at a senior center health clinic, will experience healthful living to the fullest extent of their ability.

**GOAL:** Using the three levels of prevention, negative health conditions are avoided, promptly diagnosed and treated, and/or the fullest possible potential is restored.

used contracting as a tool in helping to enhance realistic planning and emphasize partnership (Madden, 2003). Educational contracts between students and instructors have proved valuable for facilitating learning (Chan & Chien, 2000; Donovan, 2001; Waddell & Stephens, 2000). In the Levels of Prevention Pyramid, the three levels of prevention are used to provide a framework of care for elderly clients in which contracting may be useful.

Community health nursing also has used the concept of contracting for many years. Without always labeling it as contracting, community health nurses have used these techniques with clients who, for example, want to lose weight. In this case, the contract involves mutual agreement on certain exercise and eating patterns for clients and teaching and support responsibilities for the nurse. Often, it has set a time limit,

such as 6 months, within which to achieve the intended weight loss. In each case, a partnership is developed, with agreement about the purpose of the relationship and the conditions under which it will be carried out. Nurses and clients are, in effect, contracting even though they may see it simply as setting goals with clients, and no written documentation is developed.

As more nurses seek to promote client autonomy and self-care, the wide applicability of contracting to nursing practice is being increasingly recognized (Buelow & Range, 2001). Community health nurses have provided case management for HIV/AIDS clients, care for infants receiving total parenteral nutrition, worked with outpatients receiving chemotherapy, and collaborated with prenatal groups, postpartum mothers, and home health clients using various forms of contracting with the clients.

The advantages of contracting in community health nursing are summarized as follows:

1. It involves clients in promoting their own health.
2. It motivates clients to perform necessary tasks.
3. It focuses on clients' unique needs, regardless of aggregate size.
4. It increases the possibility of achieving health goals identified by collaborating team members.
5. It enhances all team members' problem-solving skills.
6. It fosters client participation in the decision-making process.
7. It promotes clients' autonomy and self-esteem as they learn self-care.
8. It makes nursing service more efficient and cost-effective.

### Potential Problems with Contracting

Emphasis on contracting as a method rather than a concept can create problems. If a client has experienced contracts only in a business setting, it is possible to carry the stereotype of a cold, formal arrangement into the nursing practice setting. Some nurses fear that asking clients to negotiate a contract will place clients under stress, impede the development of trust, and negatively influence the relationship. Others have found that some clients prefer to have the nurse make decisions for them and are not ready to enter into any kind of negotiation. These problems in contracting can be overcome by understanding the true concept of contracting. Contracting is not a panacea, however. Some clients cannot fully participate in a collaborative relationship. Developmentally delayed clients and those with serious mental or cognitive impairments (e.g., mental illness, dementia) may be unable to fully participate in the nurse–client contract.

### Process of Contracting

Contracting applies the basic principles of adult education: self-direction, mutual negotiation, and mutual evaluation. It need not be a formal, written, or complex negotiation; it may be formal or informal, written or verbal, simple or detailed, and signed or unsigned by client and nurse. It should be adapted to the particular client's abilities to assess, plan, implement, and evaluate, which may vary greatly from situation to situation (Friedman, Bowden, & Jones, 2003). The tool shown in Display 10.6 seeks input from the client. The client's goals are mutually set, and the goals are spelled out. Initial interventions are dated, as are follow-up and reassessment visits. In addition, there is a place for a continuing assessment of outcomes and for evaluation on future dates. Like all nursing tools, contracting enhances client health only if it is adapted to each particular set of client needs and abilities.

Contracting follows a sequence of steps. As a working agreement, it depends on knowing what clients want, agreeing on goals, identifying methods to achieve these

goals, knowing the resources that collaborating members bring to the relationship, using appropriate outside resources, setting limits, deciding on responsibilities, and providing for periodic reviews. Each of these tasks requires discussion among members of the contractual group. The tasks are incorporated into the contracting process and can be described in eight phases that follow the nursing process:

#### Assessment

1. *Explore needs:* Assess clients' health and needs: done by clients, nurse, and other relevant persons

#### Nursing Diagnosis/Goal Setting

2. *Establish goals:* Discussion followed by agreement among contracting members on goals and objectives

#### Plan/Intervention

3. *Explore resources:* Define what each member has to offer and can expect from the others; identify appropriate resources and agencies
4. *Develop a plan:* Identify methods, activities, and a timeline for achieving the stated goals
5. *Divide responsibilities:* Negotiate the activities for which each member will be responsible
6. *Agree on time frame:* Setting limits for the contract in terms of length of time or number of meetings

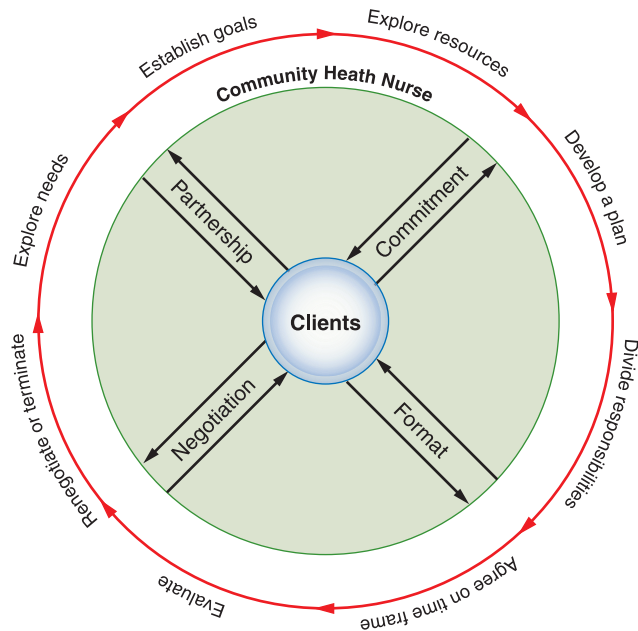

#### Evaluation

7. *Evaluation:* Formative and summative assessments of progress toward goals occur at agreed-on intervals
8. *Renegotiation or termination:* Agree to modify, renegotiate, or terminate the contract

As community health nurses use this process to negotiate a contract, they must adapt it to each situation. The sequence of phases may change, and some steps may overlap. Nevertheless, the basic elements remain important considerations for successful contracting (Fig. 10.2).

### Levels of Contracting

Community health nurses use contracts at levels ranging from formal to informal. The degree of formality depends on the demands of the situation. To fund a community health program for preventing child abuse, for example, a formal contract in the form of a written grant proposal may be needed. To conduct a wide-scale needs assessment of a homeless population, the services of an epidemiologist and statistician may require a formal contract to clarify roles and expectations. **Formal contracting** involves all parties' negotiating a written contract by mutual agreement, signing the agreement, and sometimes having it witnessed or notarized. This level of contract has been used with mental health or substance-abusing clients, where the seriousness of the working agreement and the need to actively involve the client are important aspects of therapy.

**FIGURE 10.2** The concept and process of contracting. Contracting is based on four distinctive features, shown here as spokes that support a wheel. These features form the basis for a reciprocal relationship among clients, nurse, and other persons. This relationship is not static; it is a dynamic process that moves through phases, represented here as the outer rim of the wheel. The process moves forward, focused on meeting clients' needs, and enables the collaborating group to facilitate ultimate achievement of clients' goals.

Some situations best lend themselves to a modified and less formal use of contracting, in which the nursing plan becomes the written contract. For example, a school nurse forms a support group for pregnant adolescents. The nurse uses modified contracting by discussing with the girls the purpose of the group and the number of sessions needed and obtaining their agreement to attend all sessions.

**Informal contracting** involves some form of verbal agreement about relatively clear-cut purposes and tasks. A client group may agree to prioritize their list of needs, the nurse may agree to conduct health teaching sessions, the social worker may agree to obtain informational materials, and so on. Sometimes, nurses use contracting informally without realizing it. They conclude a session with clients by agreeing with them about the purpose and time of the next meeting. Conscious use of contracting, however, is a more effective way to provide structure for the relationship and foster client involvement, regardless of the level at which it is applied.

The level of contracting also may change during the development of communication and collaboration. Clients often need education about their options. Initially, they may have difficulty in identifying needs and making choices. The professional team can work to promote clients' self-confidence and help them to assume increasing responsibility for their own health. Through these efforts, contracting becomes a consciously recognized part

of the relationship, and clients become fully participating partners.

## Summary

Communication and collaboration are important tools for community health nurses to promote aggregate health. Communication involves the transfer and understanding of meaning between individuals. The communication process comprises seven parts: a message, a sender, a receiver, encoding, a channel, decoding, and a feedback loop. Barriers to effective communication include selective perception, language barriers, clients filtering out parts of the message, and emotional influence. Core skills essential to effective communication in community health nursing include sending skills, which allow the nurse to transmit messages effectively; receiving skills, which allow the nurse to receive accurate and complete messages; and interpersonal skills, which allow the nurse to interact and respond to the messages from clients. These skills include special techniques of active listening, the ability to show respect regardless of the message (whether positive or negative), the ability to empathize with clients' thoughts and feelings, and the ability to develop trust. Many factors can influence the quality of communication, such as negative previous experience, cultural influence, and relationships among the people involved. The community health nurse must consider all of these factors when trying to foster good communication.

In community health, nurses frequently need to promote communication in groups and in-group decision-making. Decisions made by groups have many advantages, including sharing of members' experience and expertise, diversity of opinions, potential for broadening members' perspectives, and a focus on arriving at consensus solutions. Several methods of enhancing group decision-making are available, including brainstorming, nominal group technique, Delphi technique, and electronic meetings. Nursing informatics, encompassing all of the computer-generated tools created to enhance communication, is changing the form of communication in community health nursing, as it has in the acute care setting.

Collaboration and partnership building is a purposeful interaction among the nurse, clients, community members, and other professionals based on mutual participation and joint effort. It is characterized by shared goals, mutual participation, maximized use of resources, clear responsibilities, and set boundaries. Clients play an important role in the collaborative relationship.

Contracting is a helpful tool in promoting clients' participation, independence, and motivation. It is used at all levels in community health nursing to promote partnership in the collaborative process, to encourage commitment to health goals, and to ensure a format and a means for negotiation among the collaborating group. Contracts can be formal or informal, written or verbal, simple or complex. The nurse must know the needs and abilities of clients and must tailor the type of contracting to best suit the client's particular situation. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Discuss how you would handle the communication barrier of selective perception with a group of clients.
2. Practice active listening with a colleague and analyze the factors that interfered with your total concentration. Identify three actions to take to improve your active listening and apply them during the next week, keeping a log of your progress. Think of a patient you have worked with who may have low health literacy. What kinds of things can you do to help them better communicate with their physician and other health professionals? Why is good health literacy important not only for the patient as an individual, but for the community and society as a whole?
3. Use nominal group technique with a group of classmates to arrive at a rank-ordering of barriers to cross-cultural communication. What did you learn about arriving at a quality decision in the process?
4. Attend an open meeting (e.g., student body council, school board, city council) and watch for task and maintenance roles among the members. Are any members displaying nonfunctional role behaviors? Can you recognize task, maintenance, and nonfunctional role behaviors in some of the student groups in which you participate?
5. Organize a group of classmates to represent a group of clients, professionals, and community members who are collaborating to address the needs of an inner-city homeless population. Analyze how well you integrated the five characteristics of collaboration into your activity.
6. Explain the concept of contracting as it applies to aggregates. Discuss its four distinctive characteristics and the advantages that contracting offers to the community health nurse.
7. Develop a hypothetical contract with a group of elderly widows who need support and outlets to alleviate their loneliness. What other community members and professionals might be helpful as part of a collaborative team to address the widows' needs?
8. Become a good listener. This exercise asks you to list your closest friends, relatives, school peers, and work associates. Rank them on a scale of 1 to 10, with 1 meaning always fascinating and 10 meaning boring. If you find that you've labeled most as boring, you probably have one of two problems: you are either socializing and working with the wrong people, or you are a poor listener. The likelihood is the latter. To improve listening skills, compliment people and encourage them; this increases the chance that they will continue conversing with

you, and it is a valuable skill in both your personal and professional life.

9. Experiment in communication. The activity described in Display 10.7 can be used with your peers or as part of a group teaching project on communication with elementary or high school students.

### DISPLAY 10.7

## EXPERIMENT IN COMMUNICATION

### Purpose

The experiment will demonstrate the differences between one-way and two-way communication and demonstrate the advantages of the latter.

### Setting

The experiment can be conducted in the classroom with any size group. Each person will need paper and pencil.

### Procedure

Have the group members select one person who everyone believes can communicate clearly and effectively to be the "sender." Place this person so that he or she is out of sight but can be clearly heard by the rest of the group (the "receivers"). The sender is to describe a diagram, and the receivers are to draw it. The sender should explain the diagram with the intention that the receivers will be able to recreate it exactly, without any further communication with the sender or with other group members. Time the exercise. When the receivers are finished, rank the accuracy of their drawings by placing them on a Likert scale (a 10-point scale, with 1 as Least Accurate to 10 as Most Accurate). Ask receivers how they felt and how the sender probably felt. Ask the sender how she or he felt.

Next, begin the two-way communication demonstration by allowing the sender to remain in sight of the group as he or she explains a second diagram and the receivers draw it. Allow the receivers to ask questions. The sender may reply, but may not use gestures. Record the time required and rank the drawings for accuracy. Discuss how the receivers felt and how the sender probably felt. Ask the sender how she or he felt this time.

### Analysis

Compare your findings with the following statements:

1. Two-way communication takes longer.
2. Two-way communication results in greater accuracy among the drawings.
3. In one-way communication, the sender often feels relatively confident; the receiver, uncertain or frustrated.
4. In two-way communication, the sender may feel frustrated or angry; the receiver relatively confident.

# Health Promotion: Achieving Change Through Education

## LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Explain the three stages of change.
- ◆ Identify three planned-change strategies.
- ◆ Summarize six principles for effecting change in community health.
- ◆ Describe the community health nurse's role as educator in promoting health and preventing or postponing morbidity.
- ◆ Identify educational activities for the nurse to use that are appropriate for each of the three domains of learning.
- ◆ Select learning theories that are applicable to an individual, family, or aggregate client.
- ◆ Identify health-teaching models for use when planning health education activities.
- ◆ Select teaching methods and materials that facilitate learning for clients at different developmental levels.
- ◆ Develop teaching plans focusing on primary, secondary, and tertiary levels of prevention for clients of all ages.
- ◆ Identify teaching strategies for the community health nurse to use when encountering clients with special learning needs.

*“As I see it, every day you do one of two things: build health or produce disease in yourself.”*

—Adelle Davis

## KEY TERMS

Accommodation  
Adaptation  
Affective domain  
Anticipatory guidance  
Assimilation  
Change  
Cognitive domain  
Empiric-rational change strategy  
Evolutionary change  
Force field theory  
Gestalt-field  
Health Promotion  
Learning  
Normative-reeducative change strategy  
Operationalize  
Planned change  
Power-coercive change strategy  
Psychomotor domain  
Revolutionary change  
Stages of change  
Teaching

 **Think** of a time when you were so influenced by a teacher that you stopped an unhealthy habit, altered a long-held belief, or embarked on a new endeavor. What precisely was it that motivated the change? Was it simply the content of the teaching, or was it how the teacher presented the content? What is good teaching, and why is it so important to community health nursing?

Teaching has been a critical part of the community health nurse's role since the origins of the profession, and it frequently is the primary role or function. Community health nurses develop partnerships with clients to achieve behavior changes that promote, maintain, or restore health. This partnership focuses on self-care—the ability to effectively advocate and manage a person's own health. The rationale for health teaching is to equip people with the knowledge, attitudes, and practices that will allow them to live the fullest possible life for the greatest length of time. The goals of *Healthy People 2010* emphasize not only health status and longevity but also the quality of our lives, emphasizing that even the

later years should be full of vigor (U.S. Department of Health and Human Services [USDHHS], 2000). Table 11.1 provides a list of *Healthy People 2010* objectives for educational, community-based programs.

When the community health nurse identifies a need that is best met through health education, the nurse is faced with a series of questions: How can I teach effectively? What content should I cover? What method of presentation will communicate most effectively? What resources can I use as teaching tools? How do I know when the client has grasped the information or mastered the skills? How do I help clients with special learning needs? The nurse must understand what makes teaching effective, how teaching skills are acquired, and how mastery is measured. The nurse might also need to consider why some individuals adopt new health practices and others do not. This chapter addresses these questions and discusses teaching as a basic intervention tool in community health nursing practice. For health education to be effective, awareness of the underlying principles of behavior change is

**TABLE 11.1** *Healthy People 2010 Objectives for Educational and Community-Based Programs*

	Objective	2010 Goals	Baseline
7.1	High school completion	Increase the high school completion rate to at least 90%.	85%
7.2	School health education	Increase to at least 70% the proportion of middle/junior high and senior high schools that require 1 school year of health education.	28%
7.3	Undergraduate health risk behavior information	Increase to at least 25% the proportion of undergraduate students attending postsecondary institutions who receive information from their college or university on all six priority health risk behavior areas—behaviors that cause unintentional and intentional injuries, tobacco use, alcohol and other drug use, sexual behavior, dietary patterns that cause disease, and inadequate physical activity.	6%
7.4	School nurse-to-student ratio	Increase to at least 50% the proportion of the middle/junior and senior high schools that have a nurse-to-student ratio of at least 1:750.	28%
7.5	Work site health-promotion programs	Increase to 75% the proportion of work sites (with more than 50 employees) that offer a comprehensive health-promotion program to their employees.	33–50%
7.6	Participation in employer-sponsored health-promotion activities	Increase to at least 75% the proportion of all employees (over age 18) who participate in employer-sponsored health-promotion activities.	61%
7.8	Patient satisfaction with health care provider communication	This objective is developmental: increase the proportion of patients who report that they are satisfied with the patient education they receive from their health care organization.	—
7.10	Community-based health promotion	This objective is developmental: increase the proportion of tribal and local health service areas or jurisdictions that have established a community health promotion program that addresses multiple <i>Healthy People 2010</i> focus areas.	—
7.11	Culturally appropriate community health-promotion programs	Increase the proportion of local health departments to at least 50% that have established culturally appropriate and linguistically competent community health-promotion and disease-prevention programs for racial and ethnic minority populations.	13–27%
7.12	Elderly participation in community health promotion	Increase to at least 90% the proportion of people age 65 and older who have participated during the preceding year in at least one organized health-promotion program.	12%

U.S. Department of Health and Human Services (USDHHS). (2000). *Healthy people 2010: Understanding and Improving Health* (2nd ed.). Washington, DC: U.S. Government Printing Office.

vital. The community health nurse should consider what motivates people to adopt new behaviors and what factors may inhibit or prevent that change. By understanding the principles of teaching and behavior change, the community health nurse can work toward the ultimate goal of health promotion for individuals, families, groups, and communities.

## HEALTH PROMOTION THROUGH CHANGE

**Health promotion** has been defined as “behavior motivated by the desire to increase well-being and actualize human health potential” (Pender, Murdaugh, & Parsons, 2006, p.7). Another term often confused with health promotion is *disease prevention* (or *health protection*), which is “behavior motivated by a desire to actively avoid illness, detect it early, or maintain functioning within the constraints of illness” (Pender et al., p. 7). These two terms, so often used interchangeably, are clearly both important aspects of health education efforts, yet they imply a decidedly different motivation. For the community health nurse, both terms are aligned to practice at the primary level of prevention. The Levels of Prevention Pyramid at the end of this chapter describes educational activities within both of these approaches in relation to primary prevention. For instance, a community health nurse may plan an educational program for community-dwelling older adults to learn about the need for a balanced diet, rich in fruits and vegetables. This would be an example of a health promotion focus, since there is no clear disease or condition at issue. As the nurse continues to work with these individuals, he learns that several clients have had recent falls. Fortunately, none of the falls was serious, yet the nurse recognizes the need to discuss foods that will help reduce bone loss and promote healthy bone growth. To protect the clients’ health, the nurse provides information on a variety of foods rich in calcium and explains the need for adequate vitamin D. This effort would be still primary prevention, but with the purpose of health protection.

For the community health nurse, teaching is the primary means to influence health at all levels, primary, secondary, and tertiary. But consider the community health nurse’s educational program just described: He has provided a well-developed educational program that was well received by the participants. They listened attentively, took the nurse’s well-prepared handouts home, and even promised to add more fruits, vegetables, and calcium-rich foods to their diet. A few weeks later, in another educational program, the nurse learns from the participants that they have not altered their dietary patterns in the slightest. This is an example of how understanding the principles of behavior change may have provided guidance to this nurse in planning a more effective program, with greater prospects for success.

## The Nature of Change

To be a community health nurse is to be a health educator with the goal of effecting change in people’s behaviors. When nurses suggest that families adopt healthier communication patterns, they are asking them to change. Teaching parenting skills to teenagers is introducing a change. Promoting a community’s self-determination in choosing a safer environment requires that the individuals involved must change. Therefore, it becomes imperative for community health nurses to understand the nature of change, how

### DISPLAY 11.1

## CHANGING BEHAVIOR

- People decide to change for lots of different reasons.
- People try and fail several times before they successfully change habits.
- Working at some changes can be life-long.
- Most people change on their own; they don’t need special programs.
- What works for one person may not help another.

Adapted from Center for the Advancement of Health. (2006). *What we know about changing behavior*. Retrieved June 13, 2008 from <http://www.cfah.org/about/whatweknow.cfm>.

people respond to it, and how to effect change for improved community health (see Display 11.1).

## Definitions and Types of Change

**Change** is “any planned or unplanned alteration of the status quo in an organism, situation, or process” (Lippitt, 1973, p. 37). This classic definition explains that change may occur either by design or by default. Over the years, various theorists have contributed to understanding the nature of change. From a systems perspective, change means that things are out of balance or the system’s equilibrium is upset (Roussel, Swansburg, & Swansburg, 2006; Rowitz, 2006). For instance, when a community is devastated by a flood, its normal functioning is thrown off balance. Adjustments are required; new patterns of behavior become necessary.

Other classic theorists have explained change as the process of adopting an innovation (Spradley & McCurdy, 1994). Something different, such as an organization-wide smoke-free policy, is introduced; change occurs when the innovation is accepted, tried, and integrated into daily practice. Some have explained change in terms of its effect on behavior—change requires adjustment in thinking and behavior, and people’s responses to change vary according to their perceptions of it. Change threatens the security that people feel when following established and familiar patterns (Cherry & Jacob, 2005). It generally requires adopting new roles. Change is disruptive. The way people respond to change depends partly on the type of change. The change process can be described as sudden or drastic (revolutionary) or gradual over time (evolutionary).

**Evolutionary change** is change that is gradual and requires adjustment on an incremental basis. It modifies rather than replaces a current way of operating. Some examples of evolutionary change include becoming parents, gradually cutting back on the number of cigarettes smoked each day, and losing weight by eliminating desserts and snacks. Because it is gradual, this kind of change does not require radical shifts in goals or values. For the most part, people resist discarding their own ideas. Accepting another’s idea can reduce their self-esteem and is resisted. Gradual change may “ease the pain” that change brings to some individuals. Sometimes this type of change may be viewed as *reform*.

**Revolutionary change**, in contrast, is a more rapid, drastic, and threatening type of change that may completely upset the balance of a system. It involves different goals and perhaps radically new patterns of behavior. Sudden unemployment, stopping smoking overnight, losing the town's football team in a plane accident, suddenly removing children from abusive parents, or suddenly replacing human workers with computers are examples of revolutionary changes. In each instance, the people affected have little or no advance warning and little or no time to prepare. High levels of emotional, mental, and sometimes physical energy and rapid behavior change are required to adapt to revolutionary change. If the demands are too great, some may experience defense mechanisms such as incapacitation, resistance, or denial of the new situation.

The impact of a proposed change on a system clearly depends on the degree of the change's evolutionary or revolutionary qualities, a factor to be considered in planning for change. Some situations lend themselves better to one kind of change than another. A community in need of improved facilities for the handicapped (e.g., ramps, wider doors) can introduce this change on an evolutionary, incremental basis, whereas a community that is involved in an unsafe, intolerable, or life-threatening situation, such as a flood or serious influenza epidemic, may require revolutionary change.

### Stages of Change

The phrase **stages of change** refers to the three sequential steps leading to change: unfreezing (when desire for change develops), changing (when new ideas are accepted and tried out), and refreezing (when the change is integrated and stabilized in practice). These stages were first described by Kurt Lewin in the 1940s and early 1950s, and they have become a cornerstone for understanding the change process in more recent years (Lewin, 1947, 1951; Lippitt, Watson, & Westley, 1958).

#### Unfreezing

The first stage, unfreezing, occurs when a developing need for change causes disequilibrium in the system. A system in disequilibrium is more vulnerable to change. People are motivated to change either intrinsically or by some external force. People have a sense of dissatisfaction; they feel a void that they would like to fill. The unfreezing stage involves initiating the change.

Unfreezing may occur spontaneously: A family requests help in solving a problem with alcoholism, a group seeks assistance in adjusting to retirement, a community desires a solution to noise pollution. However, the nurse as change agent may need to initiate the unfreezing stage by attempting to motivate clients, through education or other strategies, to see the need for change.

#### Changing/Moving

The second stage of the change process, changing or moving, occurs when people examine, accept, and try the innovation. For instance, this is the period when participants in a prenatal class are learning exercises or when elderly clients in a senior citizens' center are discussing and trying ways to make their apartments safe from accidents. During the changing stage,

people experience a series of attitude transformations, ranging from early questioning of the innovation's worth, to full acceptance and commitment, to accomplishing the change. The change agent's role during this moving stage is to help clients see the value of the change, encourage them to try it out, and assist them in adopting it (Cherry & Jacob, 2005).

#### Refreezing

The third and final stage in the change process, refreezing, occurs when change is established as an accepted and permanent part of the system. The rest of the system has adapted to it. Because it is no longer viewed as disruptive, threatening, or new, people no longer feel resistant to it. As the change is integrated, the system becomes refrozen and stabilized. It is evident that refreezing has occurred when weight-loss clients, for example, are routinely following their diets and losing weight, or when senior citizens are using grab bars in their bathrooms and have removed scatter rugs from their homes, or when a community has erected stop signs and established crosswalks at dangerous intersections.

Refreezing involves integrating or internalizing the change into the system and then maintaining it. Because a change has been accepted and tried does not guarantee that it will last. Often, there is a tendency for old patterns and habits to return. Consequently, the change agent must take special measures to ensure maintenance of the new behavior. A later section discusses ways to stabilize change.

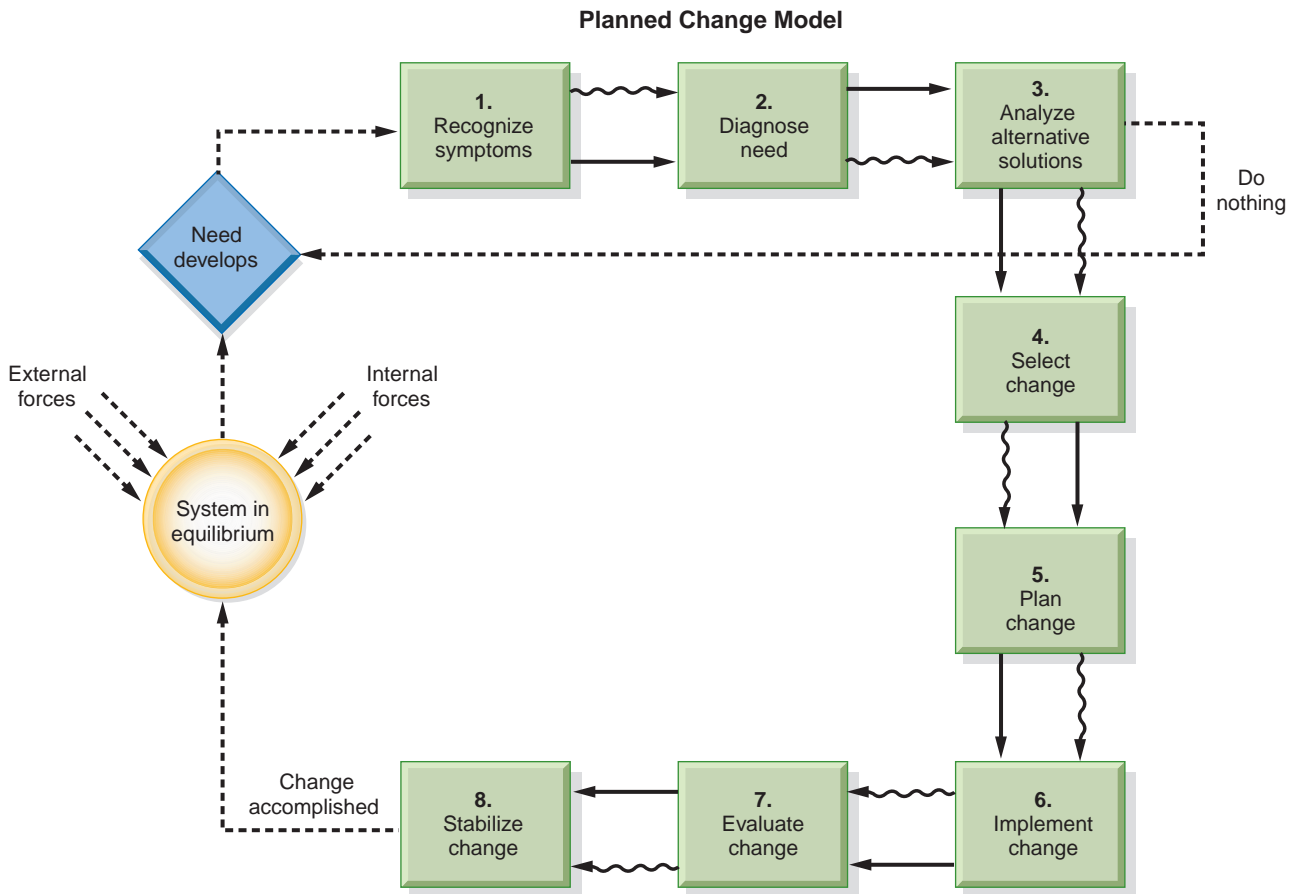

### Planned/Managed Change

Leaders in community health nursing have been change agents for decades. They have planned and managed change in a variety of systems. **Planned change** is a purposeful, designed effort to effect improvement in a system with the assistance of a change agent (Spradley, 1980). Planned change, also known as managed change (Roussel, et al. 2006), is crucial to the development of successful community health nursing programs. The following characteristics of planned change are key to its success:

- The change is purposeful and intentional:* There are specific reasons or goals prompting the change. These goals give the change effort a unifying focus and a specific target. Unplanned change occurs haphazardly, and its outcomes are unpredictable.
- The change is by design, not by default:* Thorough, systematic planning provides structure for the change process and a map to follow toward a planned destination.

*Planned change in community health aims at improvement:* That is, it seeks to better the current situation, to promote a higher level of efficiency, safety, or health enhancement. Planned change aims to facilitate growth and positive improvements. Plans to provide shelter and health care for a homeless population, for example, are designed to improve this group's well-being.

*Planned change is accomplished through an influencing agent:* The change agent is a catalyst in developing and carrying out the design; the change agent's role is a leadership role; often as an educator.

**FIGURE 11.1** Planned change model. The planned change process begins when one recognizes a need. When the change agent fails to respond to a need for change, the need continues and may escalate. Client system (those involved and affected by the change) and change agent must work together throughout the entire planned change process. Their respective roles vary depending on the situation and the players' abilities, but no planned change is truly effective without utilization of this collaborative relationship. The client system (*wavy arrow*), which may be an entire community, will fluctuate in its involvement with the change process. The change agent (*straight arrow*), as a good leader, analyzes the situation thoroughly, plans carefully, and sets a steady course for effecting the change.

### Planned Change Process

The planned change process involves a systematic sequence of activities that follows the nursing process. Following its eight basic steps leads to the successful management of change: (1) recognize symptoms, (2) diagnose need, (3) analyze alternative solutions, (4) select a change, (5) plan the change, (6) implement the change, (7) evaluate the change, and (8) stabilize the change (Spradley, 1980). Figure 11.1 shows how forces acting on a system create a need for change using the planned-change model.

#### Step 1: Recognize (Assess) Symptoms

The first step in managing change is to recognize and assess the symptoms that indicate a need for change. This step requires gathering and examining the presenting evidence, not diagnosing or jumping ahead to treatment. For instance, assume that a group of clients shows interest in receiving help with parenting skills. The nurse cannot assume that these clients feel inadequate in the parent role, nor can the nurse

assume that they lack information about parenting or are having difficulty with their children. The nurse must assess the specific needs to discover that some of the parents have trouble talking to their teenagers, others wonder whether their children's behavior is normal, a few question how strictly they should set limits, and still others are not certain about how to handle punishment. These symptoms are pieces of evidence that will assist diagnosis in the next step. This first step is an assessment phase. Before moving on, however, change agents need to ask themselves what their motives are for pursuing this change. Inappropriate motives on the change agent's part, such as wanting to feel needed, can cloud judgment and interfere with effective management of change.

#### Step 2: Diagnose Need

Diagnosis involves analyzing the symptoms and reaching a conclusion about what needs changing. First, describe the situation as it is now (the real) and compare it with the way it should be (the ideal). For example, loud arguing and conflict may be normal and functional behavior for an adolescent

support group. There is no discrepancy between the real and the ideal and, therefore, no need for change within the group. If, however, a discrepancy exists between the real and the ideal, then a need exists and a change effort is justified (Hersey, Blanchard, & Johnson, 2008). For example, the community health nurse, in talking with a group of parents, hears the following comment: “I’m not sure how much freedom to allow Karen. She came in late twice last week and I’m not sure how to punish her.” Clearly, the nurse notices a discrepancy between this family’s present and ideal situations; hence, a need exists.

The next step is to determine the nature and cause of the need. Gathering data by questioning clients, checking the literature, or seeking consultation is important for making a more accurate diagnosis. The parents should be questioned in more detail about the difficulties that they are having with their children. The nurse asks questions such as the following: How do they feel about being parents? What are the most difficult aspects of parenting for them? Have they read any books or used any other resources to help them in their parenting activities? To whom do they talk about parenting problems? When they have a problem raising their children, how do they usually solve it? Secondary data should be obtained by checking the literature to determine the most effective approaches to solving parenting problems or by consulting an expert on family life to get ideas about what this group of parents might need. The parents also should be asked directly what information they desire or need. Conclusions should be drawn about the specific changes needed for these parents. Unless the diagnosis is made accurately, the entire change effort may address the wrong problem. Also, the client system should help the nurse to diagnose their problem; the nurse should ask the parents what it is that they want and need.

These findings should be formulated into a single, diagnostic statement that also includes the problem’s cause. After data collection, the nurse discovers that the parents are insecure in their parenting roles, partially because of lack of knowledge about how to carry out parental responsibilities, but primarily because they lack a supportive reference group. Most of them live some distance from relatives or no longer maintain close ties with them. The diagnosis for these parents is insecurity in the parenting role resulting from a lack of support and knowledge.

### Step 3: Analyze Alternative Solutions

Once the diagnosis and its cause are determined, it is time to identify solutions or alternative directions to follow. Brainstorming is helpful here, and the client system should be involved as much as possible in the process. Reviewing the literature is helpful at this point to suggest solutions tried by others. Make a list of all reasonable, broad alternatives and then analyze them thoroughly to determine the advantages, disadvantages, possible consequences, and risks involved in each. For the parents, general alternatives might be considered, such as family counseling, a support group, or education in family life. Each of these alternatives includes some advantages and disadvantages toward meeting the parents’ need for confidence in their roles.

Next, each alternative should be analyzed. For example, the counseling solution could provide insight and aware-

ness into family behavior. It would give family members opportunities to express feelings and gain understanding of how other family members feel. However, it would not provide a frame of reference that the clients could use to compare their own parenting behaviors with other acceptable ones, nor would it provide adult peer support for the parents. The consequences of this alternative most likely would be to promote parents’ self-understanding and better family communication. Risks would include the possibility that children, especially teenagers, might not be willing to participate and that parents might not gain self-confidence in their roles. Each alternative should be examined to determine its usefulness and feasibility, again literature and other resources (e.g., consultants) can be used to learn the best ways to meet the parents’ need for change.

### Step 4: Select a Change

After all alternatives have been carefully analyzed, the best solution must be selected. The parents favor the idea that the best solution is a parenting support group. The risks involved in the choice of change should be reexamined, such as whether this action might be too costly in terms of time, money, or potential for failure. Ways to reduce these risks might be explored.

To know what the change is aiming to accomplish, a clearly stated goal should be formulated. For this parenting group, the mutually agreed-on goal is to provide a supportive, reinforcing climate while increasing members’ parenting skills.

### Step 5: Plan the Change

Step 5 is at the heart of planned change, because at this stage, the change agent and client system together prepare the design, or blueprint, that guides the change action. In steps 1 through 4, data are gathered, a diagnosis is made, resources are assessed, and a goal is established—all preparatory actions for planning the change. The plan tells the change agent and the client system how to meet that goal. Preferably, they develop the plan together.

The nurse talks with the parents about ways to meet their goal, considering such possibilities as weekly discussion groups on selected topics, monthly meetings with an informed speaker, or reading books and articles on parenting and holding regular sessions to discuss their application. After analysis and discussion, the group decides to meet one evening a month, rotating the location among members’ homes. Group sessions will include a variety of approaches: a speaker will be invited every 4 months, a book or article discussion will be held quarterly, and the remaining meetings will be spent on topics of the group’s choice. All sessions will provide opportunities for parents to discuss their concerns or problems. The nurse and the group design this plan around a set of objectives.

The most important activity in planning is to have clear, specific objectives. These should be measurable and, preferably, stated as outcomes. For example, the following objective is measurable and describes an outcome: “By the end of the second session, each parent in the group will have participated in the discussion at least once.” It is helpful to prepare a list of activities to help accomplish each objective

and to develop a time plan. It also is important to assess the potential costs in terms of time, money, materials, and the number of people needed and to determine the resources available. Then the evaluation plan is designed, and a list of ways to stabilize (refreeze) the change is made.

During planning, it is useful to perform a *force field analysis* (Hersey, Blanchard, & Johnson, 2008), a technique developed by Kurt Lewin for examining all positive (driving) and negative (restraining) forces that are influencing a change situation. **Force field theory** describes driving forces, which favor change, and restraining forces, which decrease or discourage change. Examples of driving forces include clients' desire to be healthier, to be more productive, or to have a safer environment. Examples of restraining forces include apathy, habits, fear of something new, perceived loss of power, low self-esteem, insecurity, and hostility (Roussel, Swansburg, & Swansburg, 2006). When the strength of the driving forces is equal to the strength of the restraining forces, equilibrium exists. To introduce a change and move the client system to a higher level of health, that balance must be altered. The change agent either increases the driving forces, decreases the restraining forces, or both. The change agent uses force field analysis to study both sets of forces and to develop strategies to influence the forces in favor of the change (Fig. 11.2).

The procedure for conducting a force field analysis follows a few simple steps. The change agent may perform the analysis alone but preferably consults with clients and a change-planning resource group such as community health colleagues. The steps for conducting force field analysis are as follows:

1. Brainstorm to produce a list of all driving and restraining forces. (For the parenting group, one driving force is the parents' desire to be more suc-

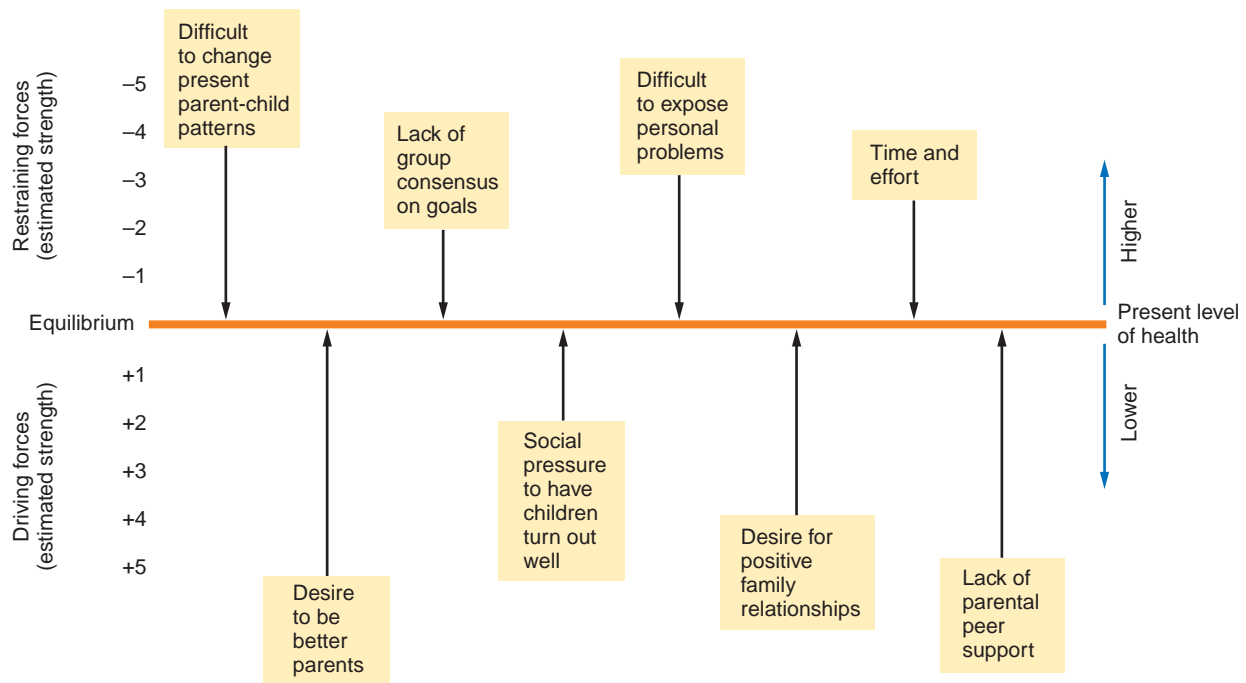

cessful parents; a restraining force might be lack of group agreement on discussion topics.)

2. Estimate the strength of each force.
3. Plot the forces on a chart such as the one shown in Figure 11.2.
4. Note the most important forces, then research and analyze them.
5. List and document possible responses or actions that might strengthen each important driving force or weaken each important restraining force.

Finally, as a consideration in planning the change and in analyzing the driving and restraining forces, the change agent studies the social network and interactions within the system involved in the change. The change agent needs to be aware of formal and informal leaders, cliques within larger groups, influential persons, and all other social network influences on the change process. For instance, one nurse attempting to improve the infant-feeding practices among a group of young southeast Asian mothers failed to consider the strong cultural influence of the infants' grandmothers living nearby. The older women had strong opinions based on long-held cultural traditions about what infants were to eat and how they were to be fed. To ignore their influence could cause the proposed change to fail; involving the grandmothers could be a way of turning their influence into a driving force for the change.

### Step 6: Implement the Change

The implementation step involves enacting the change plan. Because the objectives and activities have been clearly defined in previous steps, the change agent and client system know what needs to be done and how to begin the process.

**FIGURE 11.2** Analysis of restraining and driving forces.

For example, the parenting group and their nurse/change agent begin group discussions meeting every Tuesday evening at a local school.

At the start of implementation, be certain that all persons concerned clearly understand and are prepared for the change. When working with an aggregate, for example, the nurse may do most of the planning with a few key members. The nurse must be sure that each member who will be affected by the proposed change understands (a) what to expect, (b) the meaning of the change, and (c) what will be required of them in adapting to it. An unprepared client system, especially in a large group or organization, may bring disaster (Tiffany & Lutjens, 1998). No matter how well a change effort is planned, people who are unprepared for it may resist it strongly and render it useless.

When implementing change that will affect a large group of people, such as introduction of a mass screening or immunization program, it is helpful to do a *pilot study*. The pilot study is done to test the change on a small scale, iron out problems, and revise the change before implementing it in the larger system. One advantage of a pilot study is that it demonstrates the change to the client system on a small scale, which is less threatening, so that clients are more receptive. It gives people time to adjust their thinking and to discover that the change will not disrupt their lives too much or require drastic adaptations.

### Step 7: Evaluate the Change

The success of step 7 depends on how well the change is planned. Well-written objectives with specific criteria for their measurement make the evaluation step simpler. However, evaluation does not end with saying whether the objectives were met. Each objective requires analysis: Was it met? What evidence (documentation) shows that it was met? Was it accomplished using the best means possible, or would another method have been better? The objective for the parenting group stated that each member should enter into the discussion by the end of the second session. Although this objective could easily be evaluated by the nurse leader, the objective could have been improved by more a specific description of how this participation would occur. A better method to achieve this objective would have been to suggest that more active group members could solicit ideas from those who did not have an opportunity to speak. This would facilitate more group participation, rather than having the nurse educator call on nontalkers to speak. Finally, considering the evaluation, the change agent makes needed modifications in the change before stabilization.

### Step 8: Stabilize the Change

The final step in the planned change process requires taking measures to reinforce and maintain the change. A well-developed change plan includes a design for stabilization. The change agent actively encourages continued use of the innovation by establishing two-way communication. In this way, future resistance can be overcome, and the client's full commitment to the change can be maintained. Stabilization occurs by soliciting reactions from the client system. Do the clients perceive any potential problems? Do they have doubts? Reinforcing the desired behavior and following up on the change as long as necessary will help to ensure its permanence.

Alcoholics Anonymous, for example, stabilizes the change to nondrinking by providing a regular support group that reinforces the nondrinking pattern. The group rewards compliance with praise and replaces drinking with other satisfying experiences, such as social acceptance, to keep the alcoholic from returning to the old behavior. In the example of the parenting group, the nurse stabilizes changed behaviors by focusing on the group's increased confidence in their parenting roles and emphasizing the increased success in coping with their children. The group decides to reward successes by giving a "Parent of the Month" plaque to the member who demonstrates the most growth in parenting skills, and they agree to nominate one member as "Parent of the Year" in the community newspaper contest. After stabilization occurs and the system achieves a new equilibrium, the change agent–client system relationship can be terminated for this specific change effort.

## Applying Planned Change to Larger Aggregates

We have viewed the planned-change process primarily in the context of introducing change to smaller aggregates. Community health nurses also use these eight steps when managing change at organization, population group, community, and larger aggregate levels. For example, a nurse may suspect that there is a widespread lack of confidence among young parents. This hypothesis could be tested through a survey using a mailed questionnaire to determine parenting needs among the entire community's population of young parents. If symptoms are present (step 1), the nurse, in collaboration with health department personnel or other appropriate professionals, could analyze the symptoms and reach a diagnosis (step 2), perhaps that many young parents in the community are lacking in confidence and knowledge of parenting skills. Several approaches to meeting this need could be considered, such as instituting a parenting center in the community with satellite clinics, organizing churches or clubs to sponsor parenting support groups, or working through the community college system to hold workshops and classes on parenting skills (step 3). The most feasible and useful alternative could be selected (step 4), and a parenting program for the community could be planned (step 5) and implemented (step 6). The nurse, with parents and other professionals involved, then would evaluate the outcomes (step 7) and make necessary adjustments in the parenting program before finally stabilizing it (step 8), making certain that this change, undertaken to meet a population group need, remains an established and effectively functioning service.

## Planned-Change Strategies

Here we focus on the three major change strategies: (1) empiric-rational, (2) normative-reeducative, and (3) power-coercive. In a given situation, the change agent may use one or a combination of these strategies to effect a change.

### Empiric-Rational Change Strategies

**Empiric-rational change strategies** are used to effect change based on the assumption that people are rational

and, when presented with empiric information, will adopt new practices that appear to be in their best interest. To use this approach, which is common in community health, new information is offered to people. For instance, most family planning programs use empiric-rational strategies. Clients are given basic information (communication-related strategy) on reproductive anatomy and physiology, and they are told about the benefits of contraception with an explanation of a variety of family planning methods. Health workers hope that once clients have this information, they will adopt some method of family planning. Some clients respond well to this approach, and others do not. The difference lies in client ability and interest in self-help. The nurse/change agent uses empiric-rational strategies with clients who can assume a relatively high degree of responsibility for their own health.

### Normative-Reeducative Change Strategies

**Normative-reeducative change strategies** are used to influence change that not only presents new information but also directly influences people's attitudes and behaviors through persuasion. It is a sociocultural reeducation. This approach assumes that people's attitudes and practices are determined by sociocultural norms and that they need more than presentation of information to change behavior. This approach strengthens client self-understanding, self-control, and commitment to new patterns through direct urging and influence. For example, a health education program that aims to increase safety practices in an industrial setting not only provides safety information, such as posters and warning signs, but also uses persuasive tactics, such as individual rewards for safe practices, division recognition for minimum number of accidents, or discipline for noncompliance. Nurses use normative-reeducative strategies with clients who have a measure of self-care skill but at the same time need external assistance to effect lasting behavioral change. This type of client is found in teaching, counseling, and therapy situations.

### Power-Coercive Change Strategies

**Power-coercive change strategies** use coercion based on fear to effect change. Change agents may derive power from the law (e.g., health regulations, administrative policies), from position (e.g., political, social, or managerial), from a group (social, work, or professional), or from personal power (e.g., personal charisma, competence, respect of followers). They use this power to coerce change; the result is forced compliance on the part of the client system. Some situations, particularly those that are life-threatening, may require power-coercive strategies. In community health practice, power-coercive strategies may be used with people who cannot help themselves or in situations that threaten individuals' safety or the public's health. An example is the stringent enforcement of infection control policies regarding the treatment of contaminated objects such as used needles and the safe disposal of infectious wastes. In another example, if officials find a restaurant to be in violation of health codes, they will either force compliance with the code or close the restaurant. Occasionally, clients cannot exercise responsibility because of temporary or permanent physical or psycho-

logical incapacitation; examples may include mentally ill individuals, abusive parents, or developmentally disabled persons. In such cases, the nurse may need to use the power of the law to effect changes that are in clients' best interests. Although power-coercive strategies are appropriate in some situations, they should be used with caution because they can rob people of opportunities to grow in autonomy and capacity for self-care.

Planned-change strategies may be combined; for instance, a normative-reeducative approach might have a power-coercive backup. This combination is evident in programs that educate and persuade groups of people to be immunized against an impending epidemic or to keep their garbage contained to avoid insect and rodent infestation. Behind this normative-reeducative strategy is an implied coercive threat of official disapproval, or worse, if the clients are noncompliant.

The effectiveness of a change strategy, then, varies with each situation and particularly with the degree of client capacity for self-care. The community health nurse, as a change agent must adapt strategies to fit each change situation. It is important to remember that "the central issue in change is not just strategy, structure, culture, or systems change, but how people see the proposed change and how it affects their feelings about the changes proposed" (Rowitz, 2006, p. 437).

### *Principles for Effecting Positive Change*

Community health nurses introduce change every day that they practice. Every effort to solve a problem, prevent another problem from occurring, meet a potential community need, or promote people's optimal health requires changes. For these changes to be truly successful, so that desired outcomes are reached, they must be managed well. The following six principles provide guidelines for effecting positive change: (1) principle of participation, (2) principle of resistance to change, (3) principle of proper timing, (4) principle of interdependence, (5) principle of flexibility, and (6) principle of self-understanding.

#### Principle of Participation

Persons affected by a proposed change should participate as much as possible in every step of the planned change process (Cherry & Jacobs, 2005). This involvement is important for several reasons. Collaboration with those who have a vested interest in the change can produce a wealth of ideas and insights that can greatly improve the change plan. Furthermore, such participation can help remove obstacles and reduce resistance. Participation ensures a greater likelihood that the change will be accepted and maintained. One nurse, for instance, when planning with a school's parent-teacher association for a drug education program, involved students as well as teachers and parents. As a result, the nurse secured all this group's support and cooperation, gained many helpful suggestions that had not been previously considered, and discovered that students were more responsive to the program because the change plan was specifically tailored to their needs.

## Principle of Resistance to Change

Because all systems instinctively preserve the status quo, the change agent can expect people to resist change (Cherry & Jacob, 2005). The homeostatic mechanism operating in any system seeks to maintain equilibrium; change poses a threat to that stability and security. Furthermore, all systems experience inertia; that is, they resist beginning movement. People do not undertake a change until they are convinced of its worth. Resistance may also come from a conflict over goals and methods or from misunderstanding about what the change will mean and require. Involving people in the planned change process, as discussed in the previous section, is one way to overcome resistance. Another way is establishing and maintaining open lines of communication to make ideas clearly understood and to resolve disagreements quickly. The nurse must prepare clients thoroughly for the change, provide support and patience during the change process, and encourage response and expression of feelings (Tiffany & Lutjens, 1998).

## Principle of Proper Timing

Sometimes a change, even a well-designed and much-needed one, should be postponed because it is not the right time to introduce it. For example, perhaps the client system is experiencing too many other changes to handle the stress of this one. Other projects or activities in which the client system is currently engaged may compete for energy and other resources, depleting the energy and resources needed to make the proposed change successful. For example, in November, some middle-aged women, eager to start a book club that focused on discussion of preparing for midlife changes (including menopause, “empty-nest” syndrome, and planning for retirement), had to postpone the project because the holidays were approaching. Shopping, entertaining, and vacations made it impossible to give the kind of time and energy needed to make the book club effective.

Proper timing is as important to a planned change as well-timed seed planting is to a good harvest. The change idea must be appropriate, the change recipient prepared, the climate right, and the resources available before the change can be fostered to grow into full maturity and usefulness.

## Principle of Interdependence

Every system has many subsystems that are intricately related to and interdependent on one another. A change in one part of a system affects its other parts, and a change in one system may affect other systems. For example, a county community nursing agency made a change in its use of home health aides. Because many homebound clients needed more care than the agency staff could provide, the agency contracted with a private home-care service for extra home health aides. These paraprofessionals worked in the homes of agency clients, supplementing the care given by agency staff. The private company preferred to supervise its own aides, whereas the county agency had a policy of using community health nurses to supervise aides. The county agency was legally responsible and professionally accountable for the quality of care given to clients. The private company wanted to retain control of its workers. The matter was

resolved by contracting with a different private service that would accept the county agency’s supervision. The change, however, had affected the roles of nurses and aides within the system, as well as the relationships between the two systems.

This principle of interdependence reminds the nurse that change does not take place in a vacuum. When workers learn new health and safety practices associated with their jobs, their relationships with one another, and their bosses, their overall productivity in the organization may easily be affected. One must anticipate and prepare for the impact of the proposed change on the clients involved, other persons, departments, organizations, or even geographic areas.

## Principle of Flexibility

Unexpected events can occur in every situation. This fifth principle—flexibility—emphasizes two points. First, the nurse needs to be able to adapt to unexpected events and make the most of them. Perseverance and flexibility are the marks of a creative change manager (Clampitt & DeKoch, 2001; Roussel et al., 2006). One community health nurse had tried unsuccessfully to contact a young mother who was reportedly abusing her 2-year-old son. After several phone calls and visits to an empty house, the nurse finally found the mother and son at home with a neighbor who insisted on staying for the entire visit. At first, the nurse was irritated by the neighbor’s presence and viewed it as interfering with the goal of getting to know the mother and child. When the nurse realized that the neighbor’s presence offered an opportunity to learn more about the situation through the neighbor’s input, the nurse viewed it as an opportunity to influence another client as well. She asked whether the neighbor had children, and began to include both women in the discussion, explaining what could be offered in terms of health teaching and support. This nurse was flexible in her approach to this situation.

The second point to remember about flexibility is that a good change planner anticipates possible blocks or problems by preparing strategies and alternative plans. During step 3 of the planned change process, it is helpful to rank the alternative solutions considered. Then, if the first choice does not work out for some reason, an alternative is ready to be put into action. Flexibility involves a willingness to consider a variety of options and suggestions from many sources (Clampitt & DeKoch, 2001).

## Principle of Self-Understanding

Self-understanding is essential for an effective change agent (Hersey, Blanchard, & Johnson, 2008). The community nurse (as change agent) should be able to clearly define his role and learn how others define it. It is important to understand one’s values and motives in relation to each change that one might ask people to make. Nurses also should understand their own personality traits, so that they can capitalize on or alter them to be more effective change agents. Understanding oneself is crucial to learning to make use of one’s best qualities and skills to effect change.

Change is inevitable. It can be seen as the “process of moving from what has become an obsolete present into a revitalized present with an eye on the future . . . the old

rules do not seem to be working anymore, and new rules and procedures need to be developed for the changing context in which we live today” (Rowitz, 2006, p. 431). Understanding the principles of planned change can assist the community health nurse in guiding individuals, families, and communities toward achieving the highest level of health.

## CHANGE THROUGH HEALTH EDUCATION

Early in this chapter, you were introduced to one definition of health promotion, with a clear focus on individual and aggregate behavior (Pender et al., 2006). Consider another definition: “any combination of educational, organizational, environmental, and economic supports for behavior and conditions of living that are conducive to health” (Ottoson & Green, 2008, p. 614). This definition points out the need for a system-wide approach to promoting healthy behaviors, one that includes education. For the community health nurse, health education is a foundation of practice. Whether the nurse is providing one-on-one education to a new mother about the benefits of breast-feeding or briefing county officials on the need to maintain breast-feeding support centers, educational techniques are being used to promote health in the community. Knowledge of educational theories and teaching methods can assist the nurse to frame these “health messages” for the greatest impact and chance of success.

**Teaching** is a specialized communication process in which desired behavior changes are achieved. The goal of all teaching is learning. Learning is thought to mean gaining knowledge, comprehension, or mastery. These are nebulous terms, and a more acceptable definition suggests that **learning** is a process of assimilating new information that promotes a permanent change in behavior. All people have been presented with information that was not interesting, relevant to their needs, or comprehensible. In such situations, learning is difficult, if not impossible. The nurse as teacher seeks to transmit information in such a way that the client demonstrates a relatively permanent change in behavior. After learning, clients are capable of doing something that they could not do before learning took place. Effective teaching is a cause; learning becomes the effect. To teach effectively, especially in the community where teaching is the focus of care, nurses need to understand the various domains of learning and related learning theories.

## DOMAINS OF LEARNING

Learning occurs in several realms or domains: cognitive, affective, and psychomotor. Understanding of the differences among the domains and of the related roles of the nurse provides the background necessary to teach effectively.

### Cognitive Domain

The **cognitive domain** of learning involves the mind and thinking processes. When the meaning and relationship of a series of facts is grasped, cognitive learning is experienced. The cognitive domain deals with the recall or recognition of knowledge and the development of intellectual abilities and skills (Bloom, 1956). There are six

major levels in the cognitive domain (Gronlund, 1970; Gronlund & Linn, 1990): knowledge, comprehension, application, analysis, synthesis, and evaluation. To **operationalize** these levels (i.e., put these ideas or concepts into words that can be used), verbs are used. As the goal of the learning or behavioral objective changes, so do the verbs, indicating the learning to be accomplished within that particular level of the cognitive domain. Notice that the objectives at the beginning of each chapter in this text follow this format, using a variety of verbs to indicate the expected level of learning. A representative sample of behavioral objectives focusing on nutrition and appropriate cognitive-level verbs is included in the discussion of each level.

### Knowledge

Knowledge, the lowest level of learning according to Bloom’s taxonomy (1956), involves recall. If students remember material previously learned, they have acquired knowledge. This level may be used with clients who are unable to understand underlying reasons or rationales, such as young children or people who have had strokes. Stroke clients may need to remember that medication should be taken daily, that regular exercise restores function, and that drinking alcohol should be avoided, although they may not grasp the reasons behind these measures. Five-year-olds may need to identify healthful foods rather than understand why they are nutritious.

A knowledge-level behavioral objective might be, “The client can *recall* the names of six fruits to eat as nutritious snacks.” Other knowledge-level verbs include *define*, *repeat*, *list*, and *name*.

### Comprehension

The second level of cognitive learning, comprehension, combines remembering with understanding. Teaching aims at instilling at least a minimal understanding. Nurses want clients to grasp the meaning and to recognize the importance of suggested health behaviors.

An example of a comprehension-level behavioral objective might be, “The pregnant client will *describe* a well-balanced diet during pregnancy.” Other appropriate verbs at the comprehension level include *discuss*, *explain*, *identify*, *tell*, and *report*.

### Application

Application is the third level of cognitive learning, in which the learner can not only understand material but also apply it to new situations. Application approaches the possibility of self-care when clients use their knowledge to improve their own health. The test of application is a transfer of understanding into practice. Therefore, to encourage application, the nurse can design teaching plans that provide clients with knowledge that can be put into practice. In the home setting, a nurse may suggest that a diabetic client write down glucometer readings to show the nurse at the next visit. A school nurse could ask adolescents in a weight-loss group to keep a diet record for a week, draw up a diet plan, and share this plan with the

group at the next meeting. In contrast, the construction worker who understands on-the-job hazards but seldom wears a protective hat in the work area has yet to transfer knowledge and comprehension into practice or application.

An example of an application-level behavioral objective might be, “The client will *practice* eating well-balanced meals at least two times a day.” Other verbs at this level include *apply*, *use*, *demonstrate*, and *illustrate*.

### Analysis

The fourth level of cognitive learning is analysis; at this level, the learner breaks down material into parts, distinguishes between elements, and understands the relationships among the parts. This level of learning becomes a preliminary step toward problem-solving. The learner carefully scrutinizes all of the variables or elements and their relationships to each other to explain the situation. A family that studies its own communication patterns to identify sources of conflict is using analysis. A mother analyzes when she seeks to determine the cause of an infant’s crying. After viewing the total situation, she breaks it down into variables such as hunger, pain, overstimulation, loneliness, type of crying, and intensity of crying. She examines these parts and draws conclusions about their relationships. In health teaching, community health nurses foster clients’ analytic skills by (a) demonstrating how to isolate the parts in a situation, and (b) encouraging the clients to consider the relationships among the parts and to draw conclusions from their thinking.

An analysis-level behavioral objective for senior citizens trying to learn more about low-fat foods might be, “The seniors should be able to *compare* the fat content in a variety of packaged foods.” Other verbs at the analysis level include *differentiate*, *contrast*, *debate*, *question*, and *examine*.

### Synthesis

Synthesis, the fifth level of cognitive learning, is the ability not only to break down and understand the elements of a situation, but also to form elements into a new whole. Synthesis combines all of the earlier levels of cognitive learning to culminate in the production of a unique plan or solution. Clients who achieve learning at this level not only analyze their problems but also find solutions for them. For example, a nurse may assist mental health clients in a therapy group to examine their frequent depression and then to generate their own plan for alleviating it. A young couple who want to toilet train their 2-year-old child may learn the physiologic and psychological dimensions of toilet training, analyze their own situation, and then develop strategies (their own plan) for training the child. Nurses facilitate synthesis by assisting and encouraging clients to develop their own solutions with specific plans. After a problem is identified, the client should be asked, “What are some possible causes? Do you see anything that has been overlooked about the problem?” If the client asks for a solution, the nurse should encourage synthesis by asking, “What are some possible solutions to this problem that you might carry out?”

An example of a synthesis-level behavioral objective for a client on a sodium-restricted diet might be, “The client will be able to *prepare* an enjoyable meal using low-sodium foods.” Other verbs at this level include *compose*, *design*, *formulate*, *create*, and *organize*.

### Evaluation

The highest level of cognitive learning is evaluation: at this level, the learner judges the usefulness of new material compared with a stated purpose or specific criteria (Gronlund & Linn, 1990). Clients can learn to judge their own health behavior by comparing it with standards established by others—such as complete abstinence from smoking, maintenance of normal weight, or exercising three times a week. Alternatively, clients may establish their own criteria. For example, a parent support group might design activities to enhance parent–child communication, then judge their performance by using their desired outcomes as evaluation criteria. When nurses aim for this level of client learning, they have made self-care a concrete objective. Evaluation, because it goes beyond attempts at problem-solving, enables the client to judge the adequacy of solutions, to critique lifestyle and health-related behaviors, and to anticipate needed improvements.

An example of a behavioral objective at the evaluation level might be, “The clients in a nutrition class will be able to *measure* the cholesterol content in one portion of the low-cholesterol dish they brought to share.” Other verbs at this level include *judge*, *rate*, *choose*, and *estimate*.

### How to Measure Cognitive Learning

Cognitive learning at any of the levels described can be measured easily in terms of learner behaviors. Nurses know, for instance, that clients have achieved teaching objectives for the application of knowledge if their behavior demonstrates actual use of the information taught. Client roles in cognitive learning range from relatively passive (at the knowledge level) to active (at the evaluation level). Conversely, as clients become more active, the nurse’s role becomes less directive. Notice that not all clients need to be brought through all levels of cognitive learning, nor does every client need to reach the evaluation level for each aspect of care. For some clients and situations, comprehension is an adequate and effective level; for others, the nurse should focus on the application level as the level of achievement. Table 11.2 illustrates client and nurse behaviors for each cognitive level.

### Affective Domain

The **affective domain** in which learning occurs involves emotion, feeling, or *affect*. This kind of learning deals with changes in interest, attitudes, and values (Bloom, 1956). Here, nurses face the task of trying to influence what clients value and feel. Nurses want clients to develop an ability to accept ideas that promote healthier behavior patterns, even if those ideas conflict with the clients’ own values.

Attitudes and values are learned. They develop gradually, as the way an individual feels and responds is molded

**TABLE 11.2 Cognitive Learning: Case Study in Controlling Diabetes**

Level	Illustrative Client Behavior	Illustrative Nurse Behavior
Knowledge (recalls, knows)	States that insulin, if taken, will control own diabetes	Provides information
Comprehension (understands)	Describes insulin action and purpose	Explains information
Application (uses learning)	Adjusts insulin dosage daily to maintain proper blood sugar level	Suggests how to use learning
Analysis (examines, explains)	Discusses relationships between insulin, diet, activity, and diabetic control	Demonstrates and encourages analysis
Synthesis (integrates with other learning, generates new ideas)	Develops a plan, incorporating above learning, for controlling own diabetes	Promotes client formulation of own plan
Evaluation (judges according to a standard)	Compares degree of diabetic control (outcomes) with desired control (objectives)	Facilitates evaluation

by family, peers, experiences, and cultural influences (Hollinger, 2005). These feelings and responses are the result of imitation and conditioning. In this way, clients acquire their health-related beliefs and practices. Because attitudes and values become part of the person, they are difficult to change unless the nurse is aware of how they develop.

Affective learning occurs on several levels as learners respond with varying degrees of involvement and commitment. At the first level, learners are simply receptive; they are willing to listen, to show awareness, and to be attentive. The nurse aims at acquiring and focusing learners' attention (Gronlund & Linn, 1990). This limited goal may be all that clients are ready for during the early stages of the nurse–client relationship.

At the second level, learners become active participants by responding to the information in some way. Examples are a willingness to read educational material, to participate in discussions, to complete assignments (e.g., keeping a diet record), or to voluntarily seek out more information.

At the third level, learners attach value to the information. Valuing ranges from simple acceptance through appreciation to commitment. For example, a nurse taught members of a therapy group several principles concerning group effectiveness. An explanation of the importance of a democratic group process and ways to improve group skills was given. Members showed acceptance when they acknowledged the importance of these ideas. They showed appreciation of the ideas by starting to practice them. Commitment came when they assumed responsibility for having their group function well.

The final level of affective learning occurs when learners internalize an idea or value. The value system now controls learner behavior. Consistent practice is a crucial test at this level. Clients who know and respect the value of exercise but only occasionally play tennis or go for a walk have not internalized the value. Even several weeks of enthusiastic jogging is not evidence of an internalized value. If the jogging continues for 6 months, 12 months, or longer, learning may have been internalized.

Affective learning often is difficult to measure (Rankin, Stallings, & London, 2005). This elusiveness may influence community health nurses to concentrate their efforts on cognitive learning goals instead. Yet, client attitudes and values have a major effect on the outcome of cognitive learning—desired behavioral changes. Therefore, both cognitive and affective domains must remain linked in teaching, otherwise, results quickly fade.

Attitudes and values can change in the same way that they were first learned, that is, through imitation and conditioning (Redman, 2001). Role models, particularly individuals from the client's peer group who practice the desired health behaviors, can be a strong influence. Support groups, such as mastectomy clubs or chemical dependency support groups, can have a powerful role-model effect. Frequently, the nurse is viewed as a role model by clients; for this reason, nurses should be careful to demonstrate healthy behaviors.

Attitudes often change when the nurse provides clients with a satisfying experience during the learning process. The nurse who recognizes clients' participation in a group, praises them for completing assignments, or commends them for sticking to diet plans will have more success than the nurse who only criticizes failures. Another point to remember is that clients can develop a close relationship with the nurse during the teaching–learning process. When this occurs, some limited sharing of the nurse's experiences in managing personal health issues may be appropriate to let clients know that the nurse, too, is human. This can be an effective addition to teaching strategies if it feels comfortable and is used wisely. Table 11.3 shows client and nurse behaviors for each level of affective learning.

To influence affective learning requires patience. Values and attitudes seldom change overnight. Remember that other forces continue to reinforce former values. For example, a middle-aged housewife may want to pursue a career for self-fulfillment, but she might not do so because she has children in high school and feels that their needs come first. A young man who can verbalize to the nurse the importance of safe sex may be uncomfortable discussing the subject with his partner, thus jeopardizing his compliance with the nurse's instruction.

TABLE 11.3 Affective Learning: Case Study in Family Planning

Level	Illustrative Client Behavior	Illustrative Nurse Behavior
Receptive (listens, pays attention)	Attentive to family planning instruction	Directs client's attention
Responsive (participates reacts)	Discusses pros and cons of various methods	Encourages client involvement
Valuing (accepts, appreciates, commits)	Selects a method for use	Respects client's right to decide
Internal consistency (organizes values to fit together)	Understands and accepts responsibility for planning for desired number of children	Brings client into contact with role models
Adoption (incorporates new values into lifestyle)	Consistently practices birth control	Positively reinforces healthy behaviors

## Psychomotor Domain

The **psychomotor domain** includes visible, demonstrable performance skills that require some kind of neuromuscular coordination. Clients in the community need to learn skills such as infant bathing, temperature taking, breast or testicular self-examination, prenatal breathing exercises, range-of-motion exercises, catheter irrigation, walking with crutches, and how to change dressings.

For psychomotor learning to take place, three conditions must be met: (1) learners must be capable of the skill, (2) learners must have a sensory image of how to perform the skill, and (3) learners must practice the skill.

The nurse must be certain that the client is physically, intellectually, and emotionally capable of performing the skill. An elderly diabetic man with tremulous hands and fading vision should not be expected to give his own insulin injections; it could frustrate and harm him. An accessible person who is more physically capable should be enlisted and taught the skill. Clients' intellectual and emotional capabilities also influence their capacity to learn motor skills. It may be inappropriate to expect persons of limited intelligence to learn complex skills. The degree of complexity should match the learners' level of functioning. However, educational level should not be equated with intelligence. Many clients have had limited formal schooling but are able to learn complex skills for themselves or as caregivers after thorough instruction. Developmental stage is another point to consider in determining whether it is appropriate to teach a particular skill. For example, most children can put on some article of clothing at 2 years of age but are not ready to learn to fasten buttons until well past their third birthday.

Learners also must have a sensory image of how to perform the skill through sight, hearing, touch, and sometimes taste or smell. This sensory image is gained by demonstration. To teach clients motor skills effectively, the nurse has to provide them with an adequate sensory image. The nurse must demonstrate and explain slowly, one point at a time, and sometimes repeatedly, until clients understand the proper sequence or combination of actions necessary to carry out the skill.

The third necessary condition for psychomotor learning is practice. After acquiring a sensory image, clients can start to perform the skill. Mastery comes over time as clients repeat the task until it is smooth, coordinated, and unhesitating. During this process, the nurse should be available to provide guidance and encouragement. In the early stages of practice, the nurse may need to use hands-on guidance to give clients a sense of how the performance should feel. When clients give return demonstrations, the nurse can make suggestions, give encouragement, and thereby maximize the learning. For example, a nurse demonstrates passive range-of-motion exercises on a client's wife to show her how the exercises should feel (giving her a sensory image). The wife then learns to perform the exercises on her husband. During practice, feedback from the nurse enables the wife to know whether the skill is being performed correctly.

The psychomotor domain, like the cognitive and affective domains, ranges from simple to complex levels of functioning. It is necessary to exercise judgment in assessing a client's ability to perform a skill. Even clients with limited ability often can move to higher levels once they have mastered simple skills. Nurse behavior that influences psychomotor learning is shown in Table 11.4.

TABLE 11.4 Nurse Behaviors in Psychomotor Learning

The Nurse	Provides Sensory Image	Encourages Practice
Determines capability: Assesses client's physical, intellectual, and emotional ability	Demonstrates and explains	Uses guidance and positive reinforcement

## LEARNING THEORIES

A *learning theory* is a systematic and integrated look into the nature of the process whereby people relate to their surroundings in such ways as to enhance their ability to use both themselves and their surroundings more effectively. Each nurse has and uses a particular theory of learning, whether consciously or unconsciously, and that theory, in turn, dictates his way of teaching. It is useful to discover what each nurse's learning theory is and how it affects his role as health educator.

Some of the learning theories developed by educational psychologists in the 20th century remain influential. They are grouped into four categories: behavioral, cognitive, social, and humanistic. Recently, the adult learning theory of Malcolm Knowles (1980, 1984, 1989) has influenced client teaching. A brief examination of these categories and the specific theories of each follows.

### Behavioral Learning Theories

Behavioral theory (also known as stimulus-response or conditioning theory) approaches the study of learning by focusing on behaviors that can be observed, measured, and changed. Developed early in the 20th century, behavioral theory work is associated primarily with three famous names: Ivan Pavlov (1957), Edward Thorndike (1932, 1969), and B. F. Skinner (1974, 1987). To a behaviorist, learning is a behavioral change—a response to certain stimuli. Therefore, the behavioristic teacher seeks to significantly change learners' behaviors through a series of selected stimuli.

The stimulus-response “bond” theory proposes that, with conditioning, certain causes (stimuli) evoke certain effects (responses). The teacher promotes acquisition of the desired stimulus-response connections so that transfer of learning can occur in another situation having the same stimulus-response elements. Pavlov's early work with stimulus-response and involuntary reflex actions is the best-known application of this theory. Pavlov conditioned a dog to anticipate food by ringing a bell at feeding time. Initially, the dog would salivate as the food was brought to the cage. However, after time, the dog would salivate at hearing the bell, before seeing or smelling the food.

Two other behavioral theories are conditioning with no reinforcement (Thorndike) and conditioning through reinforcement (Skinner). No-reinforcement theorists focus on the learner's innate reflexive drives to accomplish the desired response after conditioning, such as when the nurse repeatedly

emphasizes to a group of pregnant women that their prenatal classes promote a positive delivery experience and healthy newborns. In contrast, the reinforcement theorists use successive, systematic changes in the learner's environment to enhance the probability of desired responses. For example, a school nurse might give rewards (balloons, coloring books, crayons) to children who attend each class on safety.

### Cognitive Learning Theories

Jean Piaget is the most widely known cognitive theorist. His theory of cognitive development contributed to the theories of Kohlberg (moral development) and Fowler (development of faith). Piaget (1966, 1970) believed that cognitive development is an orderly, sequential, and interactive process in which a variety of new experiences must exist before intellectual abilities can develop. His work with children led him to develop five phases of cognitive development, from birth to 15 years of age (Table 11.5).

Each stage signifies a transformation from the previous one, and a child must move through each stage sequentially. The three abilities of **assimilation** (reacting to new situations by using skills already possessed), **accommodation** (being sufficiently mature so that previously unsolved problems can now be solved), and **adaptation** (the ability to cope with the demands of the environment) are used to make the transformation. Nurses must understand their audience's learning stage to ascertain how to approach teaching for that developmental stage. The nurse can see how the use of puppets with 3-year-olds may be a beneficial addition to a presentation on safety, whereas a group of young teens with diabetes may respond to information on the consequences of taking or not taking their insulin.

The **Gestalt-field** family of cognitive theories assumes that people are neither good nor bad—they simply interact with their environment, and their learning is related to perception (Wertheimer, 1945/1959, 1980). A principal assumption of this approach is that “each person perceives, interprets, and responds to any situation in his or her own way” (Braungart, & Braungart, 2008, p. 61).

The first Gestalt-field theory, called *insight theory*, regards learning as a process in which the learner develops new insights or changes old ones. Learners sense their way intuitively and intelligently through problems. However, the “insight” is useful only if the learner understands its significance. For example, Lana dropped out of high school after the birth of her daughter; after attending a career planning class offered by a community health nurse, she realizes that

**TABLE 11.5 Piaget's Five Phases of Cognitive Development**

Age	Stage	Behavior
Birth to 2 yr	Sensorimotor stage	The child moves focus from self to the environment (rituals are important).
2–4 yr	Preconceptual stage	Language development is rapid and everything is related to “me.”
4–7 yr	Intuitive thought stage	Egocentric thinking diminishes, and words are used to express thoughts.
7–11 yr	Concrete operations stage	Child can solve concrete problems and recognize others' viewpoints.
11–15 yr	Formal operations stage	Child uses rational thinking and can develop ideas from general principles (deductive reasoning) and apply them to future situations.

she has limited job skills and that if she knew how to use a computer she could get a better job. This learner understood the significance of her insight.

The second theory, *goal-insight*, is similar to the insight theory but goes beyond intuitive hunches to tested insights. Teachers subscribing to this theory promote insightful learning but assist learners in developing higher-quality insights. For example, Lana takes a beginning and then an advanced computer class and is offered a higher-paying job. The community health nurse discusses Lana's successes with her, asks Lana whether she ever thought about going to college, and mentions the added benefits of college-level course work. Lana reflects on this for a while and begins to think about completing the requirements to go to junior college, because if she had an associate degree she could be promoted to supervisor.

In the third theory, *cognitive-field theory*, the learner is seen as purposive and problem-centered. Teachers seek to help learners gain new insights and restructure their lives accordingly. For example, Lana confers with the community health nurse about her choices and has changed her thinking about herself so much that she is planning to get an apartment in a neighborhood that is better for her child, and she may continue taking classes "for the fun of it" after she completes her degree in a few months.

## Social Learning Theories

The aim of social learning theory is to explain behavior and facilitate learning. An important social theorist, Bandura (1977, 1986), pointed out that apparent but not real relationships often are dysfunctional, producing undesirable or inappropriate behavior. He described three ways that dysfunctional beliefs develop:

1. In *coincidental association*, outcomes typically are preceded by numerous events, and the client selects the wrong events as predictors of an outcome. For example, Juanita had a negative experience with a man who wore a hearing aid. Afterward, all of her experiences with men who wore hearing aids were negative. She reached the conclusion that all men who wear hearing aids were undesirable. This client's beliefs became a self-fulfilling prophecy.
2. In *inappropriate generalization*, one negative experience provokes negative feelings for future experiences. For example, Shauna had a purse snatched by a teenager and generalized that all teenagers are bad. Three-year-old Ryan accidentally drank some spoiled milk. He generalized that milk tastes bad and now refuses to drink it.
3. In *perceived self-inefficacy*, "Persons who judge themselves as lacking coping capabilities, whether the self-appraisal is objectively warranted or not, will perceive all kinds of dangers in situations and exaggerate their potential harmfulness" (Bandura, 1986, p. 220). For example, an older client, William, tells the community health nurse about two missing Social Security checks, but he refuses to take a bus to the post office. He states that he does not know what to say to the postal clerk and has read about senior citizens getting mugged on buses. He refused to follow up on his lost income.

Social learning theory focuses on the learners. They are benefitted by role models, building self-confidence, persuasion, and personal mastery. Self-efficacy can lead to the desired behaviors and outcomes. Juanita may begin to separate her negative experiences with men from their hearing disabilities after attending a class on building self-esteem suggested by the nurse. Through some positive experiences with teenagers organized by the nurse, Shauna may learn that not all teenagers are bad. The nurse can suggest to Ryan's mother that he may be persuaded to drink chocolate milk. She then can slowly reintroduce plain milk. William might find the courage and self-confidence to solve future problems after the nurse introduces him to another gentleman in the apartment complex who feels confident in the neighborhood.

## Humanistic Learning Theories

Humanistic theories assume that people possess a natural tendency to learn and that learning flourishes in an encouraging environment. Two of the best-known humanists are Abraham Maslow and Carl Rogers. Abraham Maslow developed the classic hierarchy of human needs in the 1940s. It suggests that a person's first needs are physiologic (e.g., air, food, water). Once these needs are met, people work to fulfill safety and security needs. Next is the need for love and a sense of belonging; then come self-esteem needs (positive feelings of self-worth). Only after these needs are met do people work toward self-actualization or "becoming all that we can be" (Maslow, 1970).

In community health nursing, the clients' needs must be considered when planning health education programs. For example, it would be difficult for a group of young mothers to concentrate on learning about proper infant nutrition if they are worried about their babies crying in the next room or about an abusive partner who doesn't want them out of the house. Their need to care for their children (need for love and belonging) or for their personal well-being (security and safety) would be greater than the need to learn about future health considerations (self-esteem, self-actualization). Likewise, it is impossible for learning to take place if a room is so warm that the participants are falling asleep (i.e., physiologic needs are not being met).

Carl Rogers developed the client-centered counseling approach that has long been important in psychotherapy. He believed the role of the therapist should be nondirective and accepting, and proposed approaching clients in a warm, positive, and empathetic manner to get in touch with their feelings and thoughts. Rogers soon applied his beliefs to education, suggesting that the learning environment be learner-centered (1969, 1989). The outcome of a learner-centered educational environment is that students become more self-directed and guide their own learning. Rogers believed that the learner is the person most capable of deciding how to find the solutions to problems. The client identifies the problem and, given time and space, can find a way through the problem to a solution. The nurse acts as a facilitator in this learning process, as for example, when a 55-year-old man wants to quit smoking after a prolonged upper respiratory tract infection, aggravated by his habit, and comes to a stop-smoking class conducted by a nurse in the county health department.

## DISPLAY 11.2

## CHARACTERISTICS AND IMPLICATIONS FOR KNOWLES' ADULT LEARNING THEORY

### Characteristics

#### *Self-Concept*

Adult learners are self-directed.

#### *Experience*

Adults have a lifetime of experience and define self in terms of this experience.

#### *Readiness to Learn*

Learning is focused on social and occupational roles.

#### *Need to Learn*

Adults have a problem-centered time perspective.

### Learning Implications

Openness and respect between teacher and learner.  
The learner plans and carries out own learning activities.  
Learner evaluates own progress toward self-chosen goals.

Teaching methods focus on experiential activities.  
Discovering how to learn from experience is key to self-actualization.  
Mistakes are opportunities for learning.

Experiential learning opportunities focus on requirements for occupational and social roles.  
Learning peaks when there is a need to know.  
Adults can best assess own readiness to learn and teachable moments.

Teaching needs to be problem-centered rather than theoretically oriented.  
Teacher needs to teach what the learners need to learn.  
Learners need to apply and try out learning quickly.

## Knowles' Adult Learning Theory

In the last 20 to 30 years, a variety of techniques have been developed to help adults learn. One of the main discoveries is that adults as learners are different from children. They do not learn differently, but rather are a different kind of learner. Knowles (1984) suggested that there are four characteristics of adult learners, and these characteristics have implications for adult learning. Adults are self-directed in their learning; they have a lifetime of experience to draw on when learning; their readiness to learn is focused on requirements for their personal and occupational roles; and adults have a problem-centered time perspective, in that the learners have a need to learn so that it can be applied and tried out quickly. Display 11.2 describes the characteristics of adult learners and implications for nurses working with adults in more detail.

## HEALTH TEACHING MODELS

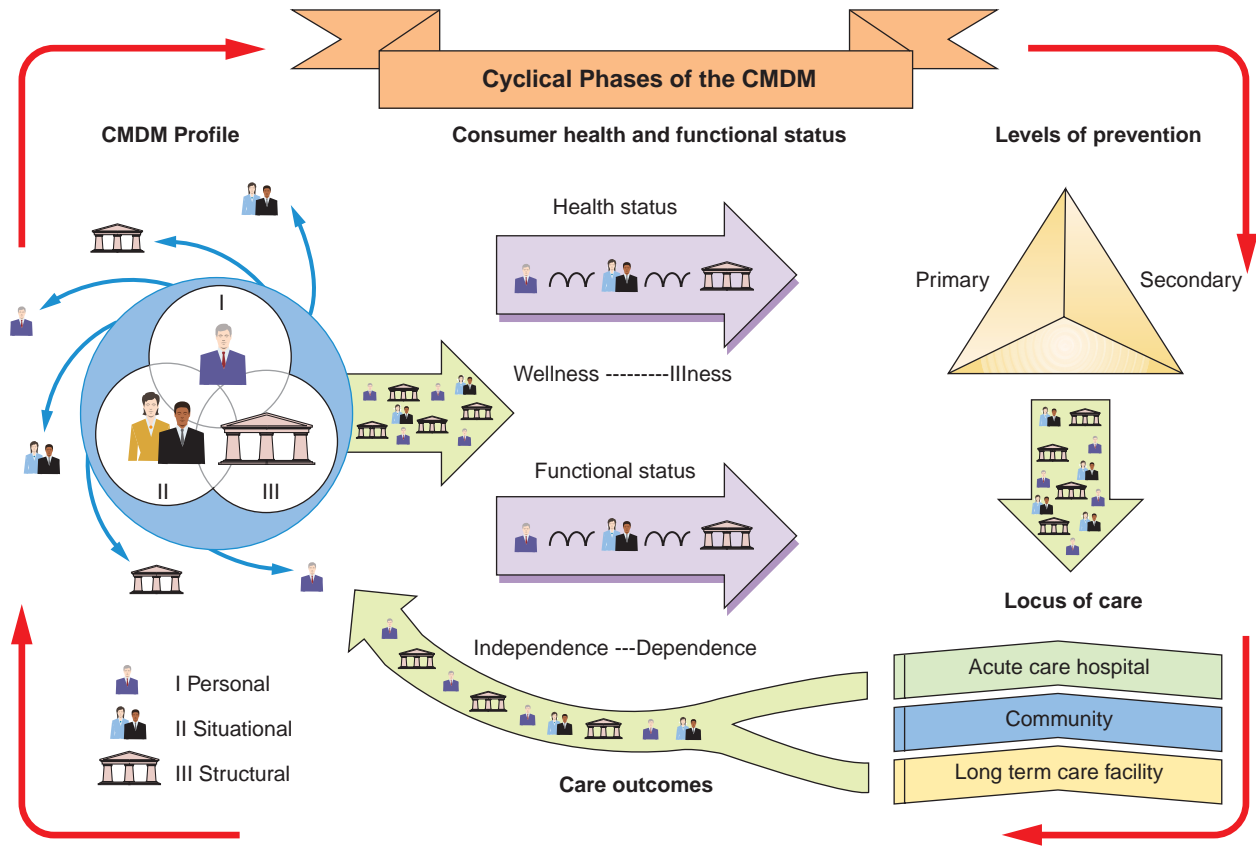

Theories on learning provide a general understanding of how people learn. In addition, various health teaching models specifically focus on explaining individual health experiences, behaviors, and actions. These models fit with the learning theories to give nurses a more accurate picture of the client and the clients' learning needs. Five useful models are described here: the Clutterbuck Minimum Data Matrix (CMDM), the Health Belief Model (HBM), Pender's Health Promotion Model (revised) (HPM), and the PRECEDE and PROCEED models.

## The Clutterbuck Minimum Data Matrix

The Clutterbuck Minimum Data Matrix (CMDM) generates a comprehensive base of client information. This information is prerequisite to the in-depth level of critical analysis and synthesis needed to produce quality health care outcomes in the 21st century. It assumes an interdisciplinary perspective and educates the nurse to recognize and incorporate client diversity into care. In teaching, it assists the nurse in conceptualizing clients beyond the institutional, individual, and biomedical perspectives (Clutterbuck & Cherry, 1998). The model helps the nurse to discern the life circumstances or chain of events that have jeopardized a client's health (Fig. 11.3).

The model comprises a set of empiric variables that are "known to influence consumer health status, behavior, and outcomes" (Clutterbuck & Cherry, 1998, p. 386). For example, in the personal variables dimension are items such as age, ethnicity, level of education, and self-care practices. These variables are distributed across three dimensions: personal, situational, and structural. Information generated by the CMDM creates a more comprehensive profile than information gathered in the traditional biomedical health care system. This information, such as client health beliefs and practices and a broad range of personal factors, can be instrumental in helping the nurse design and implement health education programs to promote positive changes in clients' health. Although community health nurses have a long tradition of considering the client holistically, this matrix helps the nurse visualize the complexity of factors

**FIGURE 11.3** The Clutterbuck Minimum Data Matrix, a tool to promote health education.

influencing clients' health. It helps to identify and challenge assumptions, recognize the importance of context, imagine and explore alternatives, and use reflective skepticism. When the nurse approaches individuals, families, and groups prepared with complete information, all of the caregiving—especially the appropriateness and effectiveness of the teaching—is enhanced.

This model has been found to be particularly useful in helping undergraduate nursing students to differentiate between individual- and population-focused practice (Dalton, 2008; Dalton & Clutterbuck, in press). The model provides an “opportunity for critical analysis of the multiple variables that affect health and the provision of health care” (Dalton, 2008) and can be used in a wide variety of community settings (e.g., elementary schools, homeless shelters, home care settings, home visiting programs for new mothers and their infants, and community senior service centers). An expected student outcome of the use of this particular model is an enhanced awareness of the need for advocating for social change in the communities served. In addition, health promotion and learning needs of the target populations can be more easily identified with this approach.

### The Health Belief Model

This section and the next describe two closely associated health models. The HBM, which was developed by social

psychologists and brought to the attention of health care professionals by Rosenstock (1966), has undergone much empiric testing. The HBM is useful for explaining the behaviors and actions taken by people to prevent illness and injury. It postulates that readiness to act on behalf of a person's own health is predicated on the following (Strecher & Rosenstock, 1997):

- Perceived susceptibility to the condition in question
- Perceived seriousness of the condition in question
- Perceived benefits to taking action
- Barriers to taking action
- Cues to action, such as knowledge that someone else has the condition or attention from the media
- Self-efficacy—the ability to take action to achieve the desired outcome.

For example, using concepts from this model, researchers looked at beliefs about the ability to control diabetes and beliefs about the degree to which family members supported a targeted Mexican American population in following their diabetes treatment regimen (Brown, Becker, Garcia, Barton, & Hanis, 2002). Unable to find many tools to measure diabetes-related health beliefs, the researchers took ideas from some older tools and designed a culturally sensitive education and group support intervention (Brown & Hanis, 1999). They realized how influential health beliefs are in managing one's health, whether in promoting or improving

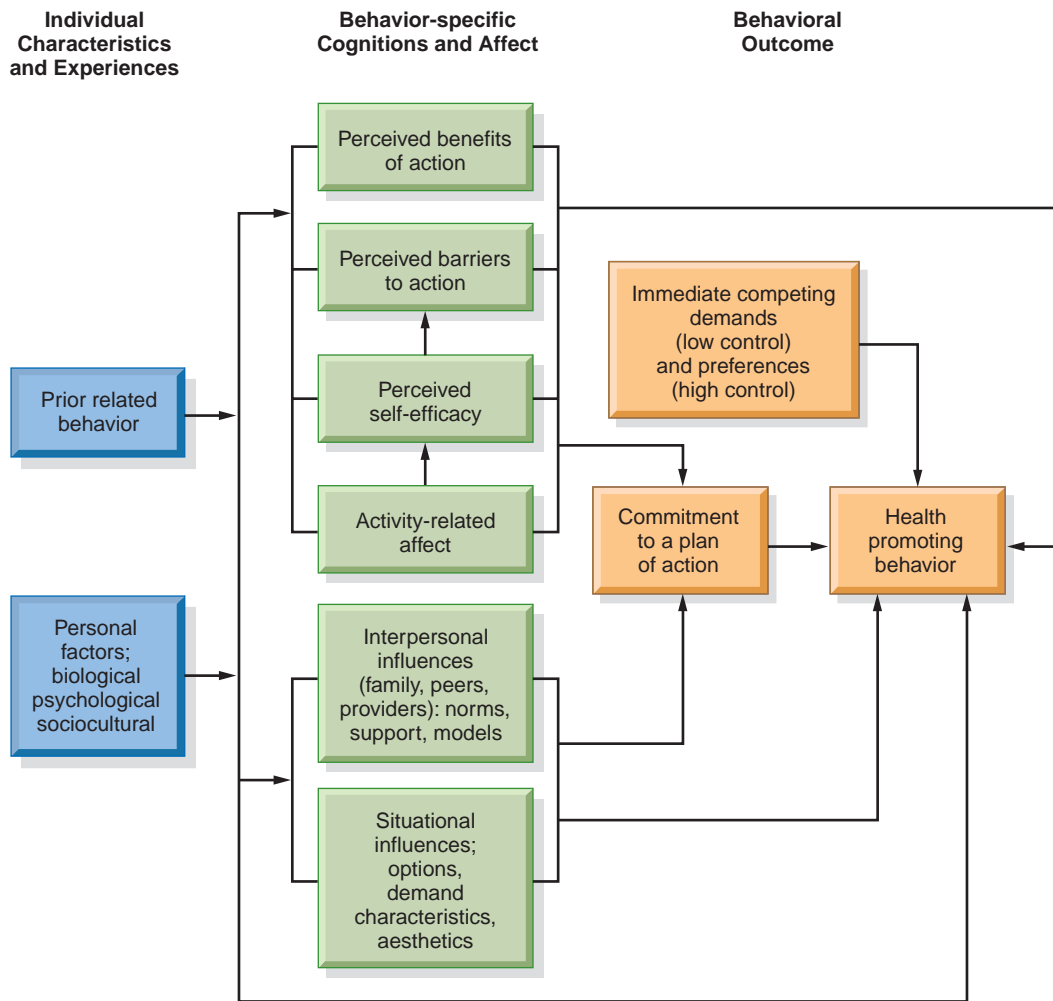

health or in trying to control a disease. Facing similar challenges, researchers in Turkey developed a 33-item health belief model scale for use with diabetic patients in their country (Kartal & Ozsoy, 2007). Building on the work of Schwab, Meyer, and Merrell (1994) with Mexican Americans and Tan’s (2004) work with Chinese individuals, they studied the validity and reliability of the tool with 352 patients with type 2 diabetes mellitus. Their findings supported the use of this tool with this population and noted that it could provide a means to test the effectiveness of intervention strategies. Community health nurses may find the use of the HBM (and variations) to be helpful in assessing the health behaviors and beliefs of culturally diverse populations.

### Pender’s Health Promotion Model

First published by Pender in the early 1980s, the HPM was envisioned as a framework for exploring health-related behaviors within a nursing and behavioral science context (1996). Reflecting the growing body of literature relevant to the HPM, Pender revised the model to reflect a number of major theoretical changes. Consistent with the original, the revised

model is derived from social cognitive theory and expectancy-value theory. The revised HPM includes three general areas of concern to health-promoting behavior: *Individual characteristics and experiences* are seen to interact with *behavior-specific cognitions and affect* to influence specific *behavioral outcomes* (Pender, Murdaugh, & Parsons, 2006). The revised HPM modifies the HBM and focuses on predicting behaviors that influence health promotion. In addition, the HPM includes the variable of interpersonal influence of others, including family and health professionals.

Being able to predict health promotion behaviors enhances the community health nurse’s ability to work with clients. Awareness of their characteristics, experiences, comprehension of their health-related issues, perceived barriers, self-efficacy, support (or lack of it) from significant others, and commitment provides the nurse with a picture that clarifies the client–nurse role and gives direction for action-taking. “The HPM is a competence- or approach-oriented model . . . [and] does not include ‘fear’ or ‘threat’ as a source of motivation for health behavior” (Pender, et al., 2006, p. 48). The HPM (Fig. 11.4) is based on the theoretical propositions found in Display 11.3.

**FIGURE 11.4** Health Promotion Model. From Pender, N.J., Murdaugh, C.L., & Parsons, M.A. (2006). *Health promotion in nursing practice*, 5th ed. Upper Saddle River, NJ: Pearson Education, Inc., p. 50, with permission.

## DISPLAY 11.3

## THEORETICAL PROPOSITIONS OF THE HEALTH PROMOTION MODEL

1. Inherited and acquired characteristics along with prior behavior influence beliefs, affect, and health-promoting behavior.
2. People engage in behaviors from which they anticipate deriving personally valued benefits.
3. Perceived barriers can constrain action to change behavior and the behavior itself.
4. Perceived self-efficacy to embrace a given behavior increases the likelihood to commit to action and implementing the behavior.
5. Greater perceived self-efficacy results in fewer perceived barriers.
6. Positive affect toward a behavior results in greater perceived self-efficacy, which can result in increased positive affect.
7. When positive affect is associated with a behavior, commitment and action are increased.
8. People are more likely to commit to and participate in health-promoting behaviors when significant others model the behavior, expect it, and provide assistance and support for the behavior.
9. Others—family members, peers, and health care providers—are important sources of influence that can positively or negatively influence commitment to and implementation of health-promoting behavior.
10. Situational influences can positively or negatively influence commitment to and implementation of health-promoting behavior.
11. The greater the commitment to a behavior change, the more likely the change will be maintained over time.
12. Distracting demands over which the person has little control may affect commitment to a behavior change.
13. Commitment to a behavior change is less likely to be maintained when other actions are more attractive and preferred.
14. People can modify the interpersonal and physical environments to create incentives for behavior changes.

Adapted from Pender, N.J., Murdaugh, C.L., & Parsons, M.A. (2006). *Health promotion in nursing practice* (5th ed.). Upper Saddle River, NJ: Pearson Education, Inc.

Using these propositions, researchers explored clients' health behaviors in many studies conducted in the 1980s, 1990s, and into the 21st century. Examples of some of the most recent uses of the model include surveying health-promoting behavior among low-income elderly Korean women (Shin, Kang, Park, Cho, & Heitkemper, 2008), and surveying health promotion in adolescents (Srof & Velsor-Friedrich, 2006), in older Iranian adults (Morowatisharifabad et al., 2006), and low-income pregnant minority women (Esperat, Feng, Zhang, & Owen, 2007). The model was even used in a pilot study of farm accidents in children (Conway, McClune, & Nosel, 2007).

### The PRECEDE and PROCEED Models

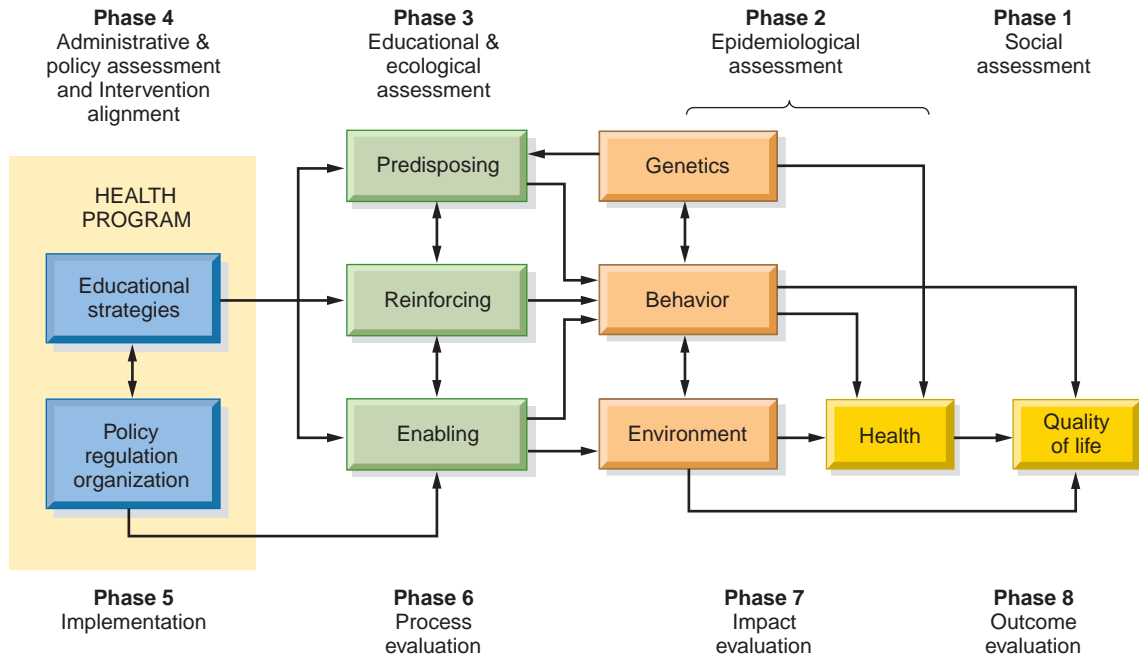

First published by Green in 1974, the PRECEDE model was developed for educational diagnosis. The acronym PRECEDE has been slightly revised from the original to stand for *P*redisposing, *R*einforcing, and *E*nabling Constructs in *E*ducational/*E*cological *D*iagnosis and *E*valuation (Green & Kreuter, 2005).

The PROCEED model (1991) works in tandem with the PRECEDE model as the community health nurse proceeds to plan, implement, and evaluate health education programs. This acronym stands for *P*olicy, *R*egulatory, and *O*rganizational Constructs for *E*ducational and *E*nvironmental *D*evelopment. The entire PRECEDE-PROCEED model includes eight phases in the formulation and evaluation of health educational programs. The first five of these phases are included in the PRECEDE

portion of the model and include: (1) social, (2) epidemiologic, and (3) education/ecological assessments, followed by (4) administrative and policy assessment and intervention alignment, and (5) implementation. The PROCEED model is emphasized in the last three phases: (1) process evaluation, (2) impact evaluation, and (3) outcome evaluation.

A hallmark of the PRECEDE-PROCEED model is the emphasis on the desired outcome. The model both begins and ends with *quality of life*, which includes “subjectively defined problems and priorities of individuals and communities” (Green, & Kreuter, 2005, p. 11). The emphasis on what the individual or community perceives as the problem, not what the professional believes it to be, is crucial. Outcome evaluation is logically linked back to that same individual or community in assessing achievement of the desired change.

The steps in this model are similar to those of the nursing process. Because of this familiarity, the model has become a useful tool for nurses teaching in the community. The nurse builds on the assessment formulated from the PRECEDE model, determines the best interventions, and then proceeds to evaluate the outcome of those interventions. The emphasis on the perceived needs of the individual or community as the starting point for all community efforts is consistent with community health nursing practice. The model reminds us of the importance of an organized approach to health educational programs, one that begins and ends with the “experts”—the individuals, families, and communities we hope to help through our efforts. The PRECEDE-PROCEED model can be seen in Figure 11.5.

**FIGURE 11.5** The PRECEDE-PROCEED model. From Green, L.W., & Kreuter, M.W. (2005). *Health program planning: An educational and ecological approach*, 4th ed., p.10. New York: McGraw-Hill, with permission.

## TEACHING AT THREE LEVELS OF PREVENTION

Nurses should develop teaching programs that coincide with the level of prevention needed by the client. The three levels of primary, secondary, and tertiary prevention are demonstrated in the Levels of Prevention Pyramid for nurses who teach clients, families, aggregates, or populations.

Ideally, the community health nurse focuses teaching at the primary level. If nurses were able to reach more people at this level, it would help to diminish years of morbidity and limit subsequent infirmity. Many people experience disabilities that could have been prevented if primary prevention behaviors had been incorporated into their daily activities.

Because the primary level of prevention is not possible in all cases, a significant share of the nurse's time is spent teaching at the secondary or tertiary level. An example is an 88-year-old woman with a fractured hip who has returned home after 3 weeks of physical therapy at a skilled nursing facility. The nurse assesses the client's environment, gait, functional limitations, safety, and adherence to medication, and initiates needed referrals. The teaching focuses on rehabilitation and prevention of a secondary problem that may affect the healing process and the client's health and safety in general.

## EFFECTIVE TEACHING

Teaching is an art. It was described in the classic book *The Educational Imagination* by E.W. Eisner (1985). Teaching can be performed with such skill and grace that the client becomes part of a well-orchestrated event, with learning as

the natural outcome. Instead of relying on prescribed teaching methods, the skillful nurse can make judgments based largely on client qualities, situations, and needs that guide the experience to fruition. The desired changes emerge in the course of the interaction rather than at a level conceived before the teaching. Before the community health nurse can reach this level of artistry, there is much to learn about being an effective teacher.

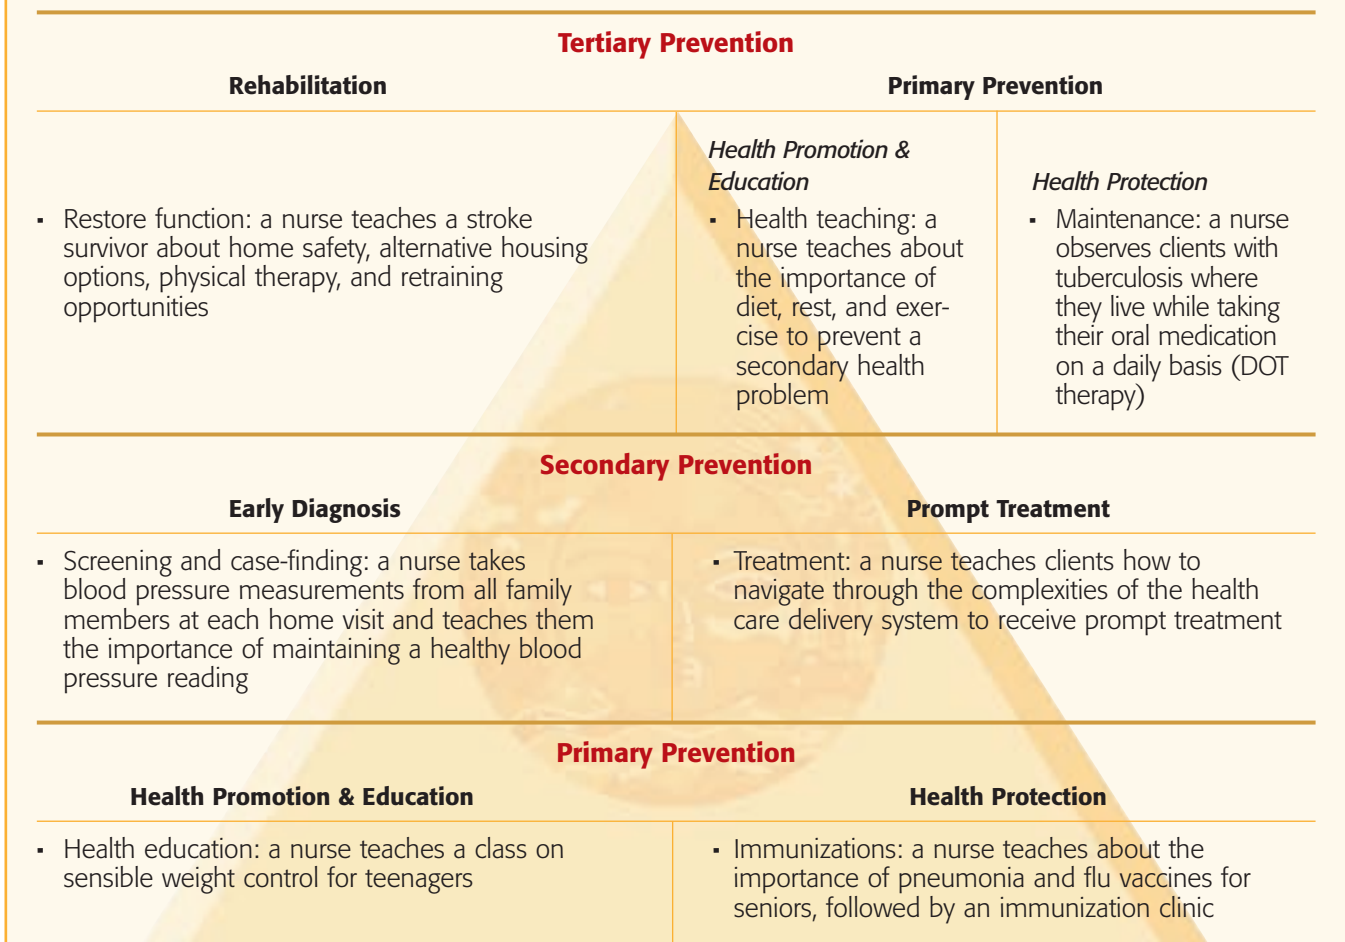

## Teaching-Learning Principles

Teaching lies at one end of a continuum. At the other end is learning. Without learning, teaching becomes useless in the same way that communication does not occur unless a message is both sent and received. Both the teacher and the learner have responsibilities on that continuum. Learners must take responsibility for their own learning (Braungart & Braungart, 2008). Teachers obstruct that process if they assume complete responsibility for bringing about changed behavior. Clients can be directed toward health knowledge, but they will not learn unless they have the desire to learn. Teaching, then, becomes a matter of facilitating both the desire and the best conditions for satisfying it. Teaching in community health nursing means to influence, motivate, and act as a catalyst in the learning process. Nurses bring information and learners together and stimulate a reaction that leads to a change (Rankin et al., 2005). Nurses facilitate learning when they make it as easy as possible for clients to change. To do this, the nurse needs to understand the basic principles underlying the art and science of the teaching-learning process and the use of appropriate materials to influence learning (Table 11.6).

## LEVELS OF PREVENTION PYRAMID

**SITUATION:** Several examples of teaching at three levels of prevention.

**GOAL:** Using the three levels of prevention, negative health conditions are avoided, or promptly diagnosed and treated, and the fullest possible potential is restored.

**TABLE 11.6 Seven Principles for Maximizing the Teaching-Learning Process**

Teaching Principles	Learning Principles
1. Adapt teaching to clients' level of readiness.	1. The learning process makes use of clients' experience and is geared to their level of understanding.
2. Determine clients' perceptions about the subject matter before and during teaching.	2. Clients are given the opportunity to provide frequent feedback on their understanding of the material taught.
3. Create an environment that is conducive to learning.	3. The environment for learning is physically comfortable; offers an atmosphere of mutual helpfulness, trust, respect, and acceptance; and allows for free expression of ideas.
4. Involve clients throughout the learning process.	4. Clients actively participate. They assess needs, establish goals, and evaluate their learning progress.
5. Make subject matter relevant to clients' interest and use.	5. Clients feel motivated to interest and learn.
6. Ensure client satisfaction during the teaching-learning process.	6. Clients sense progress toward their goals.
7. Provide opportunities for clients to apply material taught.	7. Clients integrate the learning through application.

Adapted from Knowles, M. (1980). *The modern practice of adult education. Androgogy versus pedagogy* (2nd ed.). Chicago: Follett.

### Client Readiness

Clients' readiness to learn influences teaching effectiveness (Kitchie, 2008; Rankin et al., 2005). Four facets of client readiness have been identified (Kitchie) and must be assessed by the nurse: (1) physical readiness, which deals with ability, complexity of the task, environment, health status, and gender; (2) emotional readiness, which deals with the state of receptivity to learning; (3) experiential readiness, which reflects the learner's past experiences with learning; and (4) knowledge readiness, which encompasses the learner's knowledge and understanding. For instance, one community health nurse found that a young primipara was not ready for prenatal teaching on fetal growth and development. She had strong fears, the nurse discovered, that "losing her figure" would make her sexually unattractive to her partner. Until these anxieties had subsided, the teaching would remain ineffective. Clients' needs, interests, motivation, stress, and concerns determine their readiness for learning.

Another factor that influences readiness is educational background. If a group of women who never completed grade school meet to learn how to care for a sick person in the home, material should be presented simply, factually, and in terms that they understand. To discuss complex concepts of health, illness, and scientific research would be above their level of readiness. However, increasingly complex concepts can be introduced as the nurse works with the women and assesses their readiness to assimilate advanced concepts.

Maturational level also affects readiness. An adolescent mother who is still working on the normal developmental tasks of her age group, such as seeking independence or selecting a career path, may not be ready to learn parenting skills. Readiness of the client determines the amount of material presented in each teaching session. The pace or speed with which information is presented must be manageable. A moderate amount of anxiety often increases client receptivity to learning; however, high or low levels of anxiety can have the opposite effect.

### Client Perceptions

Clients' perceptions also affect their learning, serving as a screening device through which all new information must pass. Individual perceptions help people interpret and attach meaning to things. A wide range of variables affects human perception. These variables include values, past experiences, culture, religion, personality, developmental stage, educational and economic level, surrounding social forces, and the physical environment. One client may view the experience of parenting as a positive, growth-producing relationship; another may see it as a conflict-ridden, unhappy experience to avoid. Each kind of perception has a different consequence for teaching and learning. In another example, the nurse working with adolescents to educate them about the dangers of substance abuse should understand that adolescents seeking independence need to feel that they have options and choices and do not want to be told what to do.

Frequently, clients use selective perception. They screen out some statements and pay attention to those that fit

their values or personal desires. For example, a nurse is teaching a client about the various risk factors in coronary disease; the individual screens out the need to quit smoking and lose weight, paying attention only to factors that would not require a drastic change in lifestyle. Nurses must know their clients, understand their backgrounds and values, and learn about their perceptions before health teaching can influence their behavior.

### Educational Environment

The setting in which the educational endeavor takes place has a significant impact on learning (Kitchie, 2008). Students probably have had the experience of sitting in a cold room and trying to concentrate during a lecture or of being distracted by noise, heat, or uncomfortable seating. Physical conditions such as ventilation, lighting, decor, room temperature, view of the speaker, and whispering must be controlled to provide the environment most conducive to learning.

Equally important for learning is an atmosphere of mutual respect and trust. The nurse needs to convey this attitude both verbally and nonverbally. The way the nurse addresses clients, shows courtesies, and gives recognition makes a considerable difference in establishing clients' respect and trust. Both nurse and clients need to be mutually helpful and considerate of one another's needs and interests. All participants in the educational experience should feel free to express ideas, should know that their views will be heard, and should feel accepted despite differences of opinion and perspective. According to Knowles, this requires that the nurse refrain from seeming judgmental or inducing competitiveness among learners. Knowles adds that the teachers should share their own feelings and knowledge "as a co-learner in the spirit of inquiry" (1980, p. 58).

### Client Participation

The degree of participation in the educational process directly influences the amount of learning. One nurse discovered this principle while working with a group of clients who were nearing retirement. After talking to them about the changes they would face and receiving little response, the nurse shifted to a different method of teaching. Pamphlets on Social Security benefits were distributed, and everyone was asked to read them during the week and come the next week with questions generated by the pamphlets. This strategy prompted the group to slowly begin to participate in their own learning.

When the nurse works with clients in a learning context, one of the first questions to discuss is, What does the client want to learn? As Carl Rogers (1969, p. 159) stated:

Learning is facilitated when the student participates responsibly in the learning process. When he chooses his own directions, helps to discover his own learning resources, formulates his own problems, decides his own course of action, lives with consequences of each of these choices, then significant learning is maximized.

The amount of learning is directly proportional to the learners' involvement. In another example, a group of senior

citizens attended a class on nutrition and aging, yet made few changes in eating patterns. It was not until the members became actively involved in the class, encouraged by the nurse to present problems and solutions for food purchasing and preparation on limited budgets, that any significant behavioral changes occurred.

Contracting, in which the client participates in the process as a partner to determine goals, content, and time for learning, can contribute to client learning (see Chapter 10). Contracting in the context of teaching assists clients to develop a sense of accountability for their own learning (Rankin et al., 2005).

### **Subject Relevance**

Subject matter that is relevant to the client is learned more readily and retained longer than information that is not meaningful (Lorig, 2000). Learners gain the most from subject matter that is immediately useful to their own purposes. This is particularly true for adult learners, who have more life experiences that can be related to learning and who tend to see the immediate relevance of the material taught (Knowles, 1980).

Consider two middle-management men taking a physical fitness course offered by their employer. One, the father of a Boy Scout, has agreed to co-lead his son's troop on a 2-week backpacking trip in the mountains. He wants to get in shape. The second man is taking the course because it is required by the company. Its only relevance to his own purposes is that it prevents incurring the disfavor of his boss. There is little question about which man will learn and retain the most. The course has considerable relevance and meaning to the first man and little to the second.

Relevance also influences the speed of learning. Diabetic clients who must give themselves daily injections of insulin to live, learn that skill quickly. When clients see considerable relevance in the learning, they accomplish it with speed. According to Rogers (1969), 65% to 85% of the time allotted for learning various subjects could be deleted if learners perceived the material to be related to their own purposes. This is seen in the short period of time that it takes for families to learn the skills needed to provide home care for a family member in need (Baltazar, Ibe, & Allender, 1999).

When the subject matter is relevant to the learner, more knowledge is retained. On seeing the usefulness of the material, the learner develops a strong motivation to acquire and use it, and he is less likely to forget it. Even in instances when a previously learned motor skill has not been used for years, it often is quickly recaptured when it is needed.

### **Client Satisfaction**

To maintain motivation and increase self-direction, clients must derive satisfaction from learning (Lorig, 2000). Learners need to feel a sense of steady progress in the learning process. Obstacles, frustrations, and failures along the way discourage and impede learning. Many clients who have had strokes and who have potential for rehabilitation give up trying to regain speech or move paralyzed limbs because they become frustrated, discouraged,

and dissatisfied. On the other hand, clients who experience satisfaction and progress in their speech and muscle retraining maintain their motivation and work on exercises without prompting (Diamantopoulos, 1999). Nurses can promote client satisfaction through support and encouragement.

Realistic goals contribute to learner satisfaction. Objectives should be set within the learner's ability, thereby avoiding the frustration resulting from a task that is too difficult and the loss of interest resulting from one that is too easy. Setting objectives requires agreement on goals, periodic reviews, and revision of goals if they become too easy or too difficult. Nurses further promote clients' learning satisfaction by designing tasks with rewards. One school nurse led a class for obese adolescents, and together they set the goal of a weekly 2-lb weight loss. The nurse helped the group to design a plan that included counting calories, reducing fat in their diets, increasing physical activity, and a buddy system to bring about behavior change. As members in the group achieved monthly goals, they were encouraged to reward themselves with a pair of earrings, new nail polish, or a special outing as a group. These students found this learning experience satisfying because goals were attainable, and their progress was rewarded. Instead of competing with one another, the group members set out to help each member achieve the goal. As a result, most kept the weight off after the class finished.

### **Client Application**

Learning is reinforced through application (Lorig, 2000). Learners need as many opportunities as possible to apply the learning in daily life. If such opportunities arise during the teaching-learning process, clients can try out new knowledge and skills under supervision. Learners are given an opportunity to begin integrating the learning into their daily lives at a time when the teacher is there to help reinforce that pattern. Take a prenatal class as an example. The learning begins with explanations of proper diet, exercise, breathing techniques, hygiene, and avoidance of alcohol and tobacco. More learning occurs as the group members discuss these issues and apply them intellectually, exploring ways to practice them at home. Additional reinforcement comes by demonstrating how to do these activities. Sample diets, demonstrations of exercises, posters, pamphlets, or models may be used. The group can begin application in the classroom by making diet plans, exercising, role-playing parenting behavior, or engaging in group problem-solving. The members then can be encouraged to apply these activities on a daily basis at home and to share their results with the group at future sessions.

Frequent use of newly acquired information fosters transfer of learning to other situations. The major goal of illness prevention and health promotion depends on such a transfer. For instance, mothers who learn and practice a well-balanced diet that is free of non-nutritious snacks can be encouraged to offer more nourishing foods to other family members. A family that practices asepsis and good hand-washing techniques when caring for a family member's post-surgical wound can learn to transfer this same principle to prevention of infection in daily living.

## Teaching Process

The process of teaching in community health nursing follows steps similar to those of the nursing process:

1. *Interaction*: Establish basic communication patterns between clients and nurse.
2. *Assessment and diagnosis*: Determine clients' present status and identify clients' need for teaching (keeping in mind that clients should determine their own needs).
3. *Setting goals and objectives*: Analyze needed changes and prepare objectives that describe the desired learning outcomes.
4. *Planning*: Design a plan for the learning experience that meets the mutually developed objectives; include content to be covered, sequence of topics, best conditions for learning (place, type of environment), methods, and materials (e.g., visual aids, exercises). A written plan is best; it may be part of the written nursing care plan.
5. *Teaching*: Implement the learning experience by carrying out the planned activities.
6. *Evaluation*: Determine whether learning objectives were met and if not, why not. Evaluation measures progress toward goals, effectiveness of chosen teaching methods, or future learning needs.

### Interaction

Reciprocal communication must occur between nurse and client. It is essential in the nurse–client relationship and requisite to effective use of the nursing process. Community health nurses need to develop good questioning techniques and listening skills to determine clients' learning needs and levels of readiness.

### Assessment and Diagnosis

Identifying clients' learning needs presents a challenge to the nurse. Too often, teaching occurs based on the nurse's assumption of what the learner needs to know. In client education, nurses have a responsibility to tailor their teaching to clients' real and perceived needs. Knowles (1980, 1984, 1989) described educational needs as gaps between what people know and what they need to know to function effectively. He related that the potential learners, the sponsoring organization, and the community all help to determine the needs to be addressed in the teaching–learning situation.

Assessing educational needs may be accomplished in several ways. The nurse can use surveys, interviews, open forums, or task forces that include representative clients as members. The principle to remember is that clients should be involved in identifying what they want to learn. When a “need” to learn something, such as the importance of immunizing children, is identified by the nurse rather than by clients, the nurse may need to “sell” clients on the importance of the topic. Nurses need to use approaches that assist clients toward their own awareness of the need.

## Setting Goals and Objectives

Once a need has been clearly identified, the nurse and clients can establish mutually agreed-on goals and objectives. *Goals* are broad statements of intent, and *objectives* are more specific descriptions of intended outcome (Mager, 1975). Sometimes, in a teaching situation, an objective may be broken down into short- and long-term goals. For example, the nurse may have identified a group's desire to stop smoking. The need and teaching goals might be stated as follows:

*Need*: A group of smokers wish to end their addiction to nicotine.

*Short-term goal*: All members of the group will stop smoking within 1 month.

*Long-term goal*: Ninety percent of group members will remain tobacco-free for 6 months.

Objectives should be stated in measurable behavioral terms, using a grammatical structure that contains a subject, verb, condition/criterion, and time frame. That is, each objective should include a single idea that describes an outcome that can be measured within a certain time frame. To accomplish the short- and long-term goals of smoking cessation, educational objectives are developed from the levels of cognitive learning covered earlier in this chapter. Each behavioral objective is stated in measurable terms and includes a verb that coincides with one of the six levels within the cognitive domain (Display 11.4). Objectives might appear as follows:

At the end of the program all clients should be able to:

1. *List* three reasons why smoking is unhealthy.
2. *Identify* at least two factors that influenced their smoking habit.
3. *Apply* a series of action steps leading to smoking cessation within 1 month.
4. *Examine* the steps as they contribute to living tobacco-free in the first 3 months.
5. *Design* a way to live a fulfilled, tobacco-free life.
6. *Evaluate* successful strategies to remain tobacco-free for 6 months.

Each of these objectives (a) refers to a subject; (b) can be readily measured, because each describes a specific outcome, condition, criterion, or expected behavior; (c) uses a verb for stating cognitive outcomes; and (d) includes a specific time frame. Well-written objectives meet these four criteria and enhance evaluation of the success of the educational effort.

### Planning

Teaching preparation and the planning of it are all-important (Bastable & Doody, 2008). Although nurses teach individuals and families informally, it is generally best to have a written plan when teaching. The formalization of creating a written plan provides a framework within which the nurse can function securely, knowing that the topic is well thought out and presented and individualized for a specific client group. This plan should include the following eight items: (1) purpose; (2) statement of the overall goal; (3) list of objectives; (4) outline of the related

content; (5) instructional methods; (6) time allotted for the teaching of each objective; (7) instructional resources; and (8) evaluation methods and criteria (Bastable & Doody).

### Teaching

The class, seminar, workshop, or small-group teaching should be conducted according to the plan described earlier. Even with one-on-one teaching, these eight steps should be planned in advance, because each client has a different cultural background, education, intellectual level, and learning need. Use of a variety of teaching methods addresses the unique needs of learners and makes the teaching interesting. Include and combine such methods as lectures, discussions, role-playing, demonstrations, and videos (see Teaching Methods and Materials).

If necessary, assignments can be made, such as readings, presentations, journaling, practice experiences, or return demonstrations can be designed to reinforce and synthesize the learning. The teaching methods used and activities selected are important parts of the teaching plan. The teacher will find that a well-designed plan enhances the smoothness and effectiveness of the teaching situation. Problems in teaching often can be related to a poorly developed plan.

### Evaluation

The final step of evaluation is critical in the teaching–learning process. According to Tyler (1949, p. 106), “evaluation is the process for determining the degree to which changes in behavior are actually taking place.” At this point, the nurse determines whether the goals and objectives for the educational experience have been met and, if not, why not. Clear, measurable objectives facilitate evaluation.

If objectives have not been met or have been met only partially, this too requires attention. The nurse should explore this outcome with his clients to determine what factors hindered their success and what actions might be helpful. Partially met objectives give the nurse a place to begin with the group at follow-up sessions and should not be considered a failure.

### Teaching Methods and Materials

Teaching occurs on many levels and incorporates various types of activities. It can be formal or informal, planned or unplanned. Formal presentations, such as group lectures, usually are planned and fairly structured. Some teaching is less formal but still planned and relatively structured, as in group discussions in which questions stimulate the exploration of ideas and guide thinking. Informal levels of teaching, such as counseling or **anticipatory guidance** (in which the client is assisted in preparing for a future role or developmental stage), require the teacher to be prepared, but there is no defined plan of presentation. Perhaps the nurse uses a pamphlet or agency protocol steps as a guide. All nurses use one or a combination of methods and a variety of materials to facilitate the teaching–learning process. However, nurses need to expand their repertoire of teaching methods and avoid relying on only one or two methods. Generating a variety of teaching methods stimulates creative thinking. Nurses use knowledge from physiology, pathology, sociology, and psychology in their practice, and, when teaching, nurses can benefit from using concepts, principles, and teaching methods derived from education, especially adult education. This chapter closes by discussing four commonly used teaching methods (lecture, discussion, demonstration, and role playing), teaching materials for enhanced learning, and how to effectively teach the client with special learning needs.

## Lecture

The community health nurse sometimes presents information to a large group, such as a local parent–teacher association, a women’s club, or a county board of commissioners. Under such circumstances, the lecture method, a formal kind of presentation, may be the most efficient way to communicate general health information. However, lecturers tend to create a passive learning environment for the audience unless strategies are devised to involve the learners. Many individuals are visual rather than auditory learners. To capture their attention, slides, overhead projections, computer-generated slide presentations, or videotapes can supplement the lecture. Allowing time for questions and discussion after a lecture also actively involves learners. This method is best used with adults, but even they have a limited attention span, and a break at least midway through a presentation of 1 hour or longer will be appreciated. Distributing printed material that highlights and summarizes the content shared, or supplements it, also reinforces important points.

## Discussion

Two-way communication is an important feature of the learning process. Learners need an opportunity to raise questions, make comments, reason out loud, and receive feedback to develop understanding. When discussion is used in conjunction with other teaching methods, such as demonstration, lecture, and role playing, it improves their effectiveness. In group teaching, discussion enables clients to learn from one another as well as from the nurse. The nurse must exercise leadership in controlling and guiding the discussion so that learning opportunities are maximized and objectives are met. Discussions that are organized around specific questions or topics are most fruitful.

## Demonstration

The demonstration method often is used for teaching psychomotor skills and is best accompanied by explanation and discussion, with time set aside for return demonstration by the client or caregiver. It gives clients a clear sensory image of how to perform the skill. Because a demonstration should be within easy visual and auditory range of learners, it is best to demonstrate in front of small groups or a single client. Use the same kind of equipment that clients will use, show exactly how the skill should be performed, and provide learners with ample opportunity to practice until the skill is perfected.

This is an ideal method to use in a client’s home as well as in groups. The materials and supplies that the client will use when unaided by the nurse should be used in the demonstration. This might be the time when the nurse uses improvising skills. Helping families figure out ways to accomplish goals with materials found at home often becomes the hallmark of an experienced community health nurse. The new mother learns how to bathe her baby safely in the kitchen sink. The nurse assists several low-income parents in using household items to make inexpensive toys (e.g., mobiles from plastic coat hangers, string, and pictures from a magazine; bean bags using dry beans and scraps of fabric). The husband learns how to change dressings over his wife’s central venous line site using sterile technique while conserving

supplies purchased on their fixed income. Each activity takes a different type of psychomotor skill and ingenuity on the part of the nurse.

## Role-playing

At times, having clients assume and act out roles maximizes learning. A parenting group, for example, found it helpful to place themselves in the role of their children; their feelings about various ways to respond became more apparent. Reversing roles can effectively teach spouses in conflict better ways to communicate. To prevent role-playing from becoming a game with little learning, plan the proposed drama with clear objectives in mind. What behavioral outcomes should be achieved? Define the context (the “stage”) clearly, so that everyone shares in the situation. Then define each role ahead of time, making sure that participants understand their performance roles. Emphasize that no wrong or right performance exists, and that participants should behave the way people behave in everyday life. Avoid having people play themselves, because it can embarrass them and make it difficult for them to achieve objectivity. After the drama has concluded, elicit discussion with carefully prepared questions. This technique can be used with staff, co-workers, young children, teenagers, and adults. However, it can be a risk-taking experience for some people, and they may be reluctant to participate. The nurse should use judgment, begin with volunteers, and avoid pushing this technique on unwilling or nonreceptive people. Build up to full participation.

## Teaching Materials

Many different kinds of teaching materials are available to the nurse. They often are used in combination and are useful during the teaching process. Visual images—such as PowerPoint presentations, pictures, slides, posters, chalkboards, flannel boards, DVDs, bulletin boards, flash cards, pamphlets, flyers, charts, and gestures—can enhance most learning. Some tools, such as tapes and compact disks, provide an auditory stimulus as well. Americans readily learn from television; it appeals to vision and hearing senses and more or less grabs attention. Learning of both positive and negative health behaviors through television can be more effective and efficient than traditional teaching methods. Other tools, such as anatomic models and improvised or purchased equipment, provide clients with both visual and tactile learning experiences. Still others, such as interactive computer games or instruction, actively involve the learners.

The choice of teaching materials varies with the clients’ interests and abilities and the resources available. Teaching often occurs in casual conversations, spontaneously in situations in which clients raise unexpected questions, or when a crisis arises. In these instances, nurses draw on their background of knowledge and exercise professional judgment in their selection of content, methods, and materials.

Several different types of printed educational support materials are available, such as pamphlets, brochures, booklets, flyers, and informational sheets. Each should be evaluated for its appropriateness and effectiveness with particular individuals, families, or groups. Many come from state and local official sources. Nurses can create their own handouts by using the Internet and a computer, customizing them to

the needs of individual clients. The Internet has vast health resources that can be combined with the desktop publishing capabilities of the nurse's computer to create one-of-a-kind materials for clients. The nurse can get educational information from state, federal, and international health agencies such as state health departments, the U.S. Food and Drug Administration (FDA), the Centers for Disease Control and Prevention (CDC), the National Institutes of Health (NIH), and the World Health Organization (WHO). Other materials come from nonprofit national agencies such as the American Diabetes Association (ADA), the March of Dimes, the American Association for Retired Persons (AARP), and the American Heart Association (AHA). Materials from these sources can be acquired in large quantity for free or at a nominal cost to the nurse or agency. Major manufacturers of infant formulas, foods, diapers, and toys are good sources for literature on growth and development, safety, and caring for infants and children. Pharmaceutical companies develop educational materials for the public, as do the manufacturers of in-home supplies and equipment. Usually, these are excellent sources of information for families or groups; however, the nurse needs to assess the material for appropriateness. Also, be sure that the commercial message in the literature does not outweigh the educational impact, thus making it misleading or confusing to the client.

Factors to be considered with all educational literature include the material's content, complexity, and reading level. There are several ways to assess the readability of the printed word. One easy way is to use the Fog Index. It is a rough way of determining the years of schooling needed to understand printed material. It works by analyzing words and sentence

length. The higher the Fog Index, the more difficult the reading level. A Fog Index of 6 is a sixth-grade reading level, and 11 is the junior year in high school (Bastable, 2008). Fortunately, most word processing programs now include a feature to allow assessment of the reading level in text. Another very common tool is the Fleish Reading Ease program, which evaluates the material on a 100-point scale, with 90 to 100 being rated as very easy to read, and 60 to 70 as the standard; a rating of under 59 indicates a more difficult level (Bastable, 2008). Similar to the Fog Index, the Flesch-Kincaid Grade Level readability score rates the material in terms of typical grade level; a score of 8 would indicate that an 8th grade student should be able to read and understand the material. For most health promotion materials, a reading level of 6th grade is normally sufficient (Doak, Doak, & Root, 1996). The nurse should always consider the population when selecting a reading level, as many individuals cannot understand materials at that high a grade level. (For a related discussion on a research project that studied how reading levels affect understanding and behavior, see the Evidence-based Practice box.)

Culturally appropriate health education materials must be acquired or developed for the predominant cultural and linguistic minority populations taught by the nurse. Developing printed materials is an important first step, but the development of video, audio, and public service announcements in community-appropriate languages is also necessary. When translating printed materials from English into another language, it is strongly suggested that a separate translator, "back-translate" the materials. This added step helps assure that the meaning from the original has not been distorted or lost in the translation. Essentially one person or

## EVIDENCE-BASED PRACTICE

Advance directives allow individuals to legally express their end-of-life wishes. These forms are typically written at the 12th grade reading level (or higher) and are often difficult to understand, especially for those with limited literacy skills. In a study involving over 200 English- and Spanish-speaking individuals, aged 50 years and older, researchers sought to determine if a redesigned advance directive form would be more useful, especially for individuals with limited literacy skills. The redesigned form was written at the 5th grade level. The researchers cited the relatively low rate of completion of advance directives, especially among disadvantaged populations, as impetus for this study. Approximately 40% of the study participants had limited literacy skills.

Results from this study demonstrated that the redesigned form was more acceptable and useful when compared to the typical form. Of particular importance was that 19% of the participants assigned the redesigned form had completed it at 6 months, as compared to the only 8% of completed forms using the standard format. The researchers suggest that these findings support the

redesign of advance directive forms that can meet the literacy needs of most adults.

### Nursing Implications

The community health nurse is often in a position to inform individuals about end-of-life decisions and the need for preparing advance directives well in advance of life-threatening illness or injury. Typical advance directive forms are often difficult to understand and may not be in the native language of the individual. This study points out the need for a variety of forms that can be used with individuals with either limited literacy or language needs. The forms should be both easily understood by the client and be clear to the care provider or hospital should the need arise for these documents. Increased use of advance directives may be achieved with options addressing the needs of particular individuals.

Sudore, R.L., Landefeld, C.S., Barnes, D.E., Linquist, K., Williams, B.A., Brody, R., et al. (2007). An advance directive redesigned to meet the literacy level of most adults: A randomized trial. *Patient Education and Counseling*, 69, 165–195.

group translates the material and another individual or group translates it back into English. This can add time and cost to the project, but it may prevent inaccuracies in the final material.

Finally, nurses teach by example. Actions speak louder than words. If a nurse teaches the importance of washing hands to reduce disease transmission and then begins a newborn assessment without hand-washing, the message of observed actions carries more impact than the words. Nurses who exhibit healthy practices use themselves as teaching tools and serve as role models as well as health teachers.

### **Clients with Special Learning Needs**

At times, the nurse experiences a challenging teaching situation with an individual, family, or group. These challenges may involve clients who have cultural or language differences, hearing impairments, developmental delays, memory losses, visual perception distortions, problems with fine or gross motor skills, distracting personality characteristics, or demonstrations of stress or emotions. Regardless of the situation, the nurse will feel most comfortable and confident if he is prepared to deal with these situations before they are experienced.

Before beginning to teach a client, family, or aggregate, thorough preparation is important for successful learning to occur. This includes finding out whether it is possible to teach in English or whether other modifications are needed as the teaching plan is being developed. Nurses should never assume anything, including the primary language spoken by clients, their visual or hearing ability, or their capacity to understand. When teaching unfamiliar groups, the nurse can obtain information regarding the interests and abilities of the members from a center manager, caretaker, or program director. These human resources are invaluable in planning any teaching when English may be a second language or when other barriers exist that may impede success if they are not known by the nurse. The phases of the nursing process continue to guide the nurse as a teacher.

Another difficulty that can arise is unexpected behavior from a client who disrupts the group process. The client may monopolize the discussion, answer questions asked of others, burst out with personal experiences that have no relevance to the topic, become irate at the comments of others, or sit silently and never speak. This can be unnerving to even the most experienced nurse. Any behavior that has the potential to distract the other learners must be diffused by the nurse. This is accomplished by caringly giving the recognition sought by the person while also setting limits.

### **Summary**

The purpose of health education is to effect change, which alters the equilibrium in a system. Change may occur gradually, with time for people involved to adjust, or it may occur in a drastic fashion, such as in a crisis or natural disaster. Change occurs in three stages: *unfreezing* when the system is ready for change, *changing* when the innovation is implemented, and *refreezing* when the change is stabilized.

Planned or managed change is a purposeful, designed effort to effect improvement in a system with the help of a change agent. It involves a process of eight steps, similar to the nursing process, which nurses can use to create change. These

steps include assessing symptoms, diagnosing need, analyzing alternative solutions, selecting a change, planning the change, implementing the change, evaluating the change, and stabilizing the change. During planned change, the nurse can use one or a combination of several change strategies. However, the three major change strategies—a rational approach of providing information to influence people to change, an educative approach of combining new information with persuasion to effect change, and a coercive approach of enforcing compliance—are encompassing strategies. Several important principles serve as guidelines for community health nurses to effect change. They include involving all persons affected by the change, introducing change in a timely fashion, considering the impact of the change on other systems, being flexible, and understanding oneself and one's own qualities, which can be groomed to provide the most effective leadership.

Much of community health nursing practice involves teaching. More than simply giving health information to clients, the purpose of teaching is to change client behavior to healthier practices. If these practices are internalized and implemented regularly, years of morbidity and premature mortality can be avoided, thus contributing to the quality and length of the human lifespan. *Healthy People 2010* focuses on teaching to improve the quality of life.

Understanding the nature of learning contributes to the effectiveness of teaching in community health. Learning occurs in three domains: cognitive, affective, and psychomotor. The cognitive domain refers to learning that takes place intellectually. It ranges in levels of learner functioning from simple recall to complex evaluation. As learners move up the scale of cognitive learning, they become more self-directed; the nurse then assumes a more facilitative role.

Affective learning involves the changing of attitudes and values. Learners may experience several levels of affective involvement, from simple listening to adopting the new value. Again, as the client increases involvement, the nurse becomes less directive.

Psychomotor learning involves the acquisition of motor skills. Clients who learn psychomotor skills must meet three conditions: they must be capable of the skill, they must develop a sensory image of the skill, and they must practice the skill.

Learning theories can be grouped into four broad categories: (1) behaviorist theories, which view learning as a behavioral change accomplished through stimulus-response or conditioning; (2) cognitive learning theories, which seek to influence learners' understanding of problems and situations through promoting their insights; (3) social learning theories, which explain dysfunctional behavior and facilitate learning; and (4) humanistic theories, which assume that people have a natural tendency to learn and that learning flourishes in an encouraging environment. Knowles' adult learning theory provides a framework for understanding adult characteristics and appropriate teaching interventions.

Health teaching models work together with the learning theories to give nurses a more accurate picture of the client and the client's learning needs. Five models were explored in this chapter. The CMDM is designed as a teaching mechanism to create a comprehensive base of client information that enhances all care, including client teaching. The HBM is useful in explaining the behaviors that are triggered by people with an interest in preventing diseases, and the revised

HPM modifies the HBM and focuses on predicting behaviors that influence health promotion. The PRECEDE-PROCEED model is designed to guide health educational program development. The model has a strong focus on the perceived problems and priorities of a particular individual or group as they impact quality of life. Educational interventions are developed following a thorough assessment, which includes administrative and policy issues, and evaluation is conducted at three levels: process, impact, and outcome.

Teaching in community health nursing is the facilitation of learning that leads to behavioral change in the client. Ideally, this is done at the primary level of prevention. However, much of the nurse's work is done at the secondary and tertiary levels. The nurse uses several teaching-learning principles to facilitate the learning process, such as clients' readiness for learning, clients' perceptions, learners' physical and emotional comfort within an educational setting, degree of client participation, relevant subject matter, allowing clients to derive satisfaction from learning, and reinforcing learning through application.

The teaching process in community health nursing is similar to the nursing process, including steps of interaction, assessment and diagnosis, goal setting, planning, teaching, and evaluation. The teaching may be formal or informal, planned or unplanned, and methods may range from structured lecture presentations and discussions to demonstration and role-playing.

Selection of teaching materials depends on how well they suit learners and help to meet the desired objectives. Sources of teaching materials that are free or inexpensive can enhance the nurses' teaching efforts, but need to be evaluated for effectiveness and appropriateness. The nurse needs to know how to help learners with special needs, those with physical or mental disabilities, those who are from a different culture or who speak a different language, and those who monopolize the discussion, become emotional, or are hostile. The nurse must be prepared for each situation to effectively teach the individual, family, or group. ■

### ACTIVITIES TO PROMOTE CRITICAL THINKING

1. As a staff community health nurse, you have been asked to chair an ad hoc committee in your health department made up of interdisciplinary colleagues and community members. The committee's task is to plan a health fair for the local community.
  - a. Outline the specific planned change steps that your committee needs to ensure a successful health fair with outcomes that promote improved levels of community health.
  - b. Select one specific objective of your health fair (e.g., cholesterol screening of an at-risk aggregate with the goal of reduced cholesterol levels in a year). Does the proposed objective require an evolutionary or revolutionary change in citizens' health-related behaviors? Justify your choice of the type of change.

- c. Explain the strategies that you would use to effect the change.
  - d. Six principles for effecting positive change are presented in this chapter. Briefly discuss how you would use each one as you and your committee develop the health fair.
2. What learning theories discussed in this chapter most closely reflect your own position? How can they be applied in your practice?
3. A child day care center is in your service area. What populations in this setting are potential recipients of health teaching? How would you assess each group's learning needs?
4. Your city governmental officials often make decisions that appear to reflect a lack of knowledge regarding health and health care. How might you "educate" them using the concepts and principles described in this chapter?
5. Discuss the differences between cognitive, affective, and psychomotor learning. Why do cognitive and affective learning need to be linked in health teaching?
6. Using behavioral objectives that match the learning level desired, develop a flyer or program for an educational presentation for clients.
7. Select one of the health-teaching models. Use the model to plan an educational program for a group of teenagers. How did the use of the model enhance your teaching?
8. You are teaching an aggregate of middle-aged women about menopause. One woman monopolizes the class by telling stories and talking negatively about her husband. The other women are getting upset with her. How do you resolve the situation?
9. Using the list of Internet resources at the end of this chapter, review the type and quality of free or low-cost educational materials that they offer. Try to locate additional resources from other companies, public service agencies, and voluntary health agencies. Either request useful material to be used with clients now or bookmark a selection of sites to refer to later as needed, developing a resource file.

## Planning and Developing Community Programs and Services

### LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ List sources of information that can be used to identify group and community health problems.
- ◆ Identify change strategies that maximize cooperation of target populations.
- ◆ Identify methods to gain input from target populations to define the scope of a health problem.
- ◆ Identify and evaluate the effectiveness of intervention methods targeting health problems.
- ◆ Classify health problems based on their changeability.
- ◆ Identify barriers to solving health problems.
- ◆ Discuss the role of the nurse within quality measurement and improvement programs in community health nursing.
- ◆ Recognize the role of social marketing in health promotion programs.
- ◆ Locate appropriate grant funding sources for select health promotion programs.

*“True genius resides in the capacity for evaluation of uncertain, hazardous, and conflicting information.”*

—Winston Churchill (1874–1965), British Prime Minister during World War II

 A public health nurse (PHN) collaborates with the county housing authority to implement a comprehensive fall-prevention program for community dwelling seniors; another nurse works into the night to complete a multimillion-dollar grant to fund comprehensive HIV educational programs in Kenya; community health nursing students volunteer to do a weekly radio program on health issues. The efforts described may seem very different, but each represents a health promotion program targeting populations, not just individuals. A fall-prevention program could potentially reduce the number of hospitalizations in the community resulting from serious falls, the HIV program may ultimately save tens of thousands from contracting this dreaded disease, and the radio program may reach thousands in the community, prompting them to think about their own health habits. Each of these examples represents the emerging role of the community health nurse and argues for the acquisition of a new set of skills. The skills of grant writing, radio programming, and collaborating with county officials all require new abilities that may require additional training or work with a mentor. These roles may seem foreign to you now, as you begin your career, but they may be the very skills needed to help bring vital health promotion programs to fruition.

In many communities across the country, local health departments struggle to recruit nurses to provide much-needed services. With shrinking budgets, many communities are forced to change long-held views on the scope and nature of services provided by PHNs. The home visiting model, once a mainstay of public health nursing, has been eliminated in many communities. Increasingly, community nurses/PHNs find themselves providing health promotion and educational programs to larger and larger audiences. To meet this need, community health nurses must become skilled at planning and implementing health promotion programs. As with any activity, the need for the program must be justified and, with limited resources, the benefit to the community must be demonstrated. Additionally, communities are rarely in a position to fund the entire realm of needed health programs and must turn to outside agencies for funding, either through grants or contracts. The responsibility for locating, securing, and maintaining grant funding is often assumed by the community health nurse.

Whether the program is funded by the county or an outside agency, results must be assessed. Evaluation of programs is vital for their continuation and is a requirement of most funders, whether public or private. A nurse who receives \$500 to start an emergency preparedness program with low-income families may not be expected to provide the level of evaluation data that a million-dollar effort to address methamphetamine use in the community would likely require. However, some level of evidence showing the impact of the program will be needed. Even the populations served want to know whether the programs were successful, and why. For instance, a mother agrees to have her daughter enrolled in an after-school program to increase self-esteem. At the end of the first 6-week session, the mother is asked to give permission for her daughter to attend the second session. Her daughter says she enjoys the sessions but would also like to go to a dance class that is held at the same time. With competing demands on the daughter's time, the mother may ask for details on what was accomplished in the first session and what expectations the providers have for this

second session. With this information, she can discuss various options with her daughter. The funders, consumers, and the nurse all need to be aware of the demonstrated outcomes of programs.

In Chapter 11, you were introduced to the concept of change—how it influences the adoption of health behaviors and what factors impede change in individuals. Educational methods are often used to influence change in behaviors and play a vital role in those efforts. In this chapter, we build on the concepts of change and appropriate educational techniques, and apply them to larger groups and populations. The discussion of the PRECEED-PROCEED model (Green & Kreuter, 2005) will be expanded upon as you are introduced to the basics of health program planning, intervention, and evaluation to maximize successful results. *Social marketing*, a relatively new tool for reaching large audiences with health information will be presented. Several well-known models familiar to nurses will be explored in terms of facilitating the evaluation of programs and services. Finally, as the need for grant funding becomes increasingly important, information on the various types of available funding will be provided.

## PROGRAM PLANNING: THE BASICS

Ottoson and Green (2008, p. 590) define public health education programs as interventions “designed to inform, elicit, facilitate, and maintain positive health practices in large numbers of people.” Even the American Nurses Association (ANA), *Public Health Nursing: Scope and Standards of Practice* (2007) is centered on the role of the nurse in planning, implementing, and evaluating population-focused health promotion/health education programs. Specifically, Standard 5B calls on the PHN to “employ multiple strategies to promote health, prevent disease, and ensure a safe environment for populations” (p. 23), through programs and services that include appropriate teaching–learning methods, that are culturally and age-appropriate, and that include an evaluation component.

With so much emphasis on planning and developing health education/health promotion programs, the process can seem overwhelming to the new community health nurse, or even to the acute-care nurse who may be involved in some aspect of health initiatives development within her agency. The first part of this chapter is designed to take some of the mystery out of the process. You will be guided through the complex problem of obesity in school-aged children. This particular issue is of great importance to the health of our children, and the principles applicable to this example can be utilized in other situations and other programs, even those that are very broad in scope and involve many practice partners. In your nursing program, you may even have been tasked with developing a health program, working on an existing community program, or simulating the process in a written assignment. Whatever your experience level, the essential elements are the same. As you begin this next section, think about past experiences you have had such as taking blood pressures at a local health fair or developing a pamphlet on the need for prostate screening in non-English speaking residents. Did these actions have the impact you hoped for? Successful health promotion programs do not occur by accident; they take skill, time, patience, and most of all listening to and understanding

the needs and opinions of the individuals who are the focus of your program (the target population).

## IDENTIFYING GROUP OR COMMUNITY HEALTH PROBLEMS

Nursing education emphasizes practice with a focus on individuals, families, and communities, yet nurses often practice at the individual and family level. When is it appropriate for a nurse to expand her practice to the community level? Perhaps the most natural time is when a nurse identifies an ongoing issue that does not change with traditional interventions. Examples might include overuse of the emergency room for urgent care; recurrent hospitalization of the elderly from several nursing homes for dehydration, sepsis, and malnutrition; or hospitalization of 6- to 8-year-olds for injuries caused by insufficient car seat restraint. These types of recurrent problems might lead the nurse to investigate the feasibility of a community-based intervention.

Individually or in a group, identify a possible issue to explore—one that you believe is leading to poor health outcomes in your community. How do you know if this problem is widespread or if others also find it to be a problem? Several methods can be used to validate the importance of the issue. One method would be to consider *Healthy People 2010* objectives for the nation (U.S. Department of Health and Human Services [USDHHS], 2000). What are the major issues that are of concern to improving health outcomes for the United States? What are the priorities of the state in which you live? You might take some time to review websites for federal agencies to identify the programs they are promoting to meet the *Healthy People 2010* goals and objectives. Your state department of health may also have a website with information on achievement of *Healthy People 2010* objectives, including those objectives that remain challenging. Local communities also establish priorities that reflect the *Healthy People 2010* objectives for the nation. As *Healthy People 2020: The Road Ahead* is being developed, the public is invited to submit comments on all aspects of the effort, including the mission, vision, and overarching goals (USDHHS, 2008). The comments submitted by others may provide information on current health concerns across the country, and are available for review on the Healthy People website.

Community agencies and organizations frequently network to establish community-wide goals. This work is often spearheaded by the local health department. It may also be organized by community-based health agencies and volunteer organizations. Improved outcomes for individuals who have diabetes or asthma are issues a local community might want to address. Another topic of concern is childhood obesity. Nurses can work collaboratively with these types of special interest groups to find solutions for individuals and families with identified problems.

As a specific problem is identified, it is crucial to analyze the extent to which individuals and families are affected by the problem. It is a poor use of resources to set up a program if there is a very small incidence of the condition or situation. For example, it would be a waste of resources to establish a program on diabetes and pregnancy for a local homeless shelter that only serves 35 women a year. Of those 35 women, none may be pregnant, and since 2.5% of the population of pregnant women develops gestational diabetes (Xiong, Saunders,

Wang, & Demianczuk, 2001), it may be a number of years before an eligible client is found. A better use of resources would be to target a community with a higher proportion of individuals at risk for diabetes and pregnancy. An example might be a program targeting a community with a large population of young Hispanic or Southeast Asian families, as the incidence of gestational diabetes is higher in these populations than in the general population (up to 11% of Southeast Asian pregnant women) (Dabelea et al., 2005; Thorpe et al., 2005).

There are many ways a nurse can decide if a problem has affected a sufficient percentage of the population to warrant intervention. The best way to start is by reviewing the local, state, and national data available through government repositories. This can be done through the Internet, by going to a university library for assistance, and by asking for sources of specific data from your local health and social service agencies, police and judicial departments, and local school districts. Hospital discharge data is also reported to state agencies, and this information is sometimes available at the local level. As nurses and other community groups narrow their focus, they can often map data by zip codes and neighborhoods, which helps to identify the best places to target groups and communities. Currently, many organizations have this ability and are able to identify target groups by race, age, and family status. This type of data, known as **geographic information system (GIS)** information is widely available. At the federal level, the National Center for Health Statistics (NCHS) website maintains GIS maps on the major causes of mortality in the country (NCHS, 2008).

Another effective approach is to talk to other nurses and other health care professionals within and outside of your organization. Get their ideas about the problem, and ideas about what should be done to alleviate the problem. In addition, find out what has been tried in the past, and get their input on why past interventions failed. One very helpful source of information is the *Guide to Community Preventive Services: Systematic Reviews and Evidence-based Recommendations* (2008), a federally sponsored initiative that provides recommendations regarding population-based interventions, including which are recommended, which need more evidence to determine effectiveness, and which are not recommended. The interventions with limited evidence may actually be very effective, but they need to be demonstrated by more studies; perhaps your idea is among those listed. Publication of program results is not only professionally gratifying, but adds to the body of evidence on which health promotion programs can be evaluated.

The next step of intervention is the most important of all, as it will determine whether your interventions succeed or fail. A nurse may think, “I know what the problem is—now I will think up an intervention to alleviate it!” This approach may be well-intentioned, but will lead the nurse down the path of failure. At this point, only part of the assessment is completed; the most important part of the assessment is to find out the views of the target population about the identified problem. What do they think causes it? What ideas do they have about solving it? Which approaches do they think will work, and which are doomed to failure? These are all important questions the nurse needs to ask. It is crucial that the views of the target population be heard and respected. Anthropologists talk about a concept

called **authoritative knowledge**. This is “whose knowledge is respected,” not “whose knowledge is right” (Davis-Floyd & Sargent, 1997). Nurses may think that they know more about a topic, such as diabetes, than their target population does, and therefore their solutions are better than the target population’s solutions. Members of a target population hold just as strongly to their own belief systems. If nurses don’t learn about the target population’s beliefs, and only consider their own, they will not be able to work out an acceptable and appropriate solution with the target population. Interventions that fail to engage the target population will likely be unsuccessful because of this. It is crucial that interventions utilize health resources effectively, and that positive working relationships be established with high-risk target communities.

## Getting Started

When working with target groups it’s important to get as much information about the population as possible. Start by asking those whom you know as colleagues and as patients/clients about their local community. What do they see as issues regarding the problem about which you are concerned? What do they think about the quality of services currently available? What do they see as barriers to services? What about barriers to adherence to treatment and other health care recommendations?

Additional issues to explore include: Who else do they think you should speak with to gain insight about the issues relevant to this problem? Who are key people with whom you should build relationships? What are their customs in regard to health care? Who are the leaders within a family? If you want to establish linkages with this population, what is the best method? Who are their *formal* and *informal leaders*? What types of events bring them together? What are the roles of family, church, and health care providers within their community? Should you go through church groups, school groups, or other organizations? What radio stations do they listen to, and what television stations are they most likely to watch? This information will not only help you gain insight into factors influencing the health problem, it will also give you information about how most effectively to reach out to the target population.

As you start to gain insight into the environmental and social factors that influence the problems about which you are concerned, you are also building interest in the issue. As you participate in discussions with others, be open to their input. It may be that the ideas you start out with need to change in response to feedback from members of the target and service communities. For example, an experienced PHN was involved in a project developed to serve Hispanic women with gestational diabetes. When interviewed, the monolingual Spanish-speaking women expressed concern that they were told to go on a diabetic “diet” and were then chastised for not eating enough. To these women, going on a “diet” meant they should eat less. They were also told that if they followed the diabetic diet they wouldn’t have such “big babies.” They thought a “big” baby was a healthy baby and couldn’t understand why they were being told to avoid having a larger baby. These were simple issues to fix, but required knowledge of how the “diabetic teaching plan” was interpreted by the target audience. Another key factor was

that the clinic was a family event, thus all of the children were brought along. The clinic staff had been consistently irritated by the presence of large groups of children, but learned that they needed to alter the clinic set-up and resources to accommodate the expectations of their clients. Modifications were made based on dialogue with members of the target population that positively influenced the eventual success of the clinic’s program.

This example demonstrates how use of *local knowledge* can increase the effectiveness of a community-based intervention. The participation of members of the target population also builds greater community capacity for resolution of health problems within target communities. Working with community partners, including members of target populations, is a technique that has been used in work within developing countries. This type of approach ensures community *buy-in* for an intervention. It also builds networks that can continue to increase the capacity of communities to resolve other health care issues, both current and emerging (Goodman et al., 1998; Poole, 1997).

It is essential to review literature regarding health problems, factors influencing the outcomes of interventions, and the role of families and communities in adherence to interventions. The literature review can offer the opportunity to develop additional insights that may shape interviews with members of the target and service communities. How does this target group compare to other target groups? What else should be addressed that wasn’t found in the literature? Another PHN conducted a study that addressed use of the emergency room for after-hours urgent care. The literature focused heavily on “mis-use” of emergency rooms by parents to treat urgent ambulatory care health problems, such as otitis media. Based on input from an emergency room nurse, families were asked what their doctors had told them to do if their child became ill at night. The families indicated that they were told to take their children to the emergency room! None of the literature addressed what the families had been told to do for after-hours care. This is an example of how being open to information from a variety of sources (in this case the emergency room nurse) enhanced the researcher’s understanding of the problem beyond what could be learned by solely relying on the literature.

As nurses work with community members to identify factors contributing to a health problem, individuals will begin to stand out because of their knowledge, their network capabilities, and their interest in the subject. A key factor for ensuring the success of any intervention is to appoint an **advisory group** that includes representatives from the target and service communities. Findings from interviews, literature reviews, and data analyses need to be reviewed with this advisory group. To ensure success of the advisory group, all meetings should be carefully planned, so that they are well organized, punctual, and efficient. Strategies to encourage input from the advisory group should be employed; meetings should focus on getting the advisory group to interpret findings and community feedback, and to develop possible solutions. Contributions from each member should be sought and valued equally. Depending on the size of the group, it may be most effective to have some break-out sessions, as well as larger group sessions. An evaluation should be done by each member after each meeting, so that any

problems can be addressed before the next meeting. Maintaining a record of these meetings—either in the form of minutes or a brief written overview—is also very helpful. Be certain to also keep a record of attendees. Maintaining a *paper trail* is always important.

### Delineating the Problem to Be Addressed

With the help of the advisory group, it's important to delineate the problem or problems to be addressed. The following is a case example. A group of nurses identified childhood obesity as a problem. Input from community members, as well as a review of data, demonstrated a higher rate of childhood obesity in a local elementary school, where a high proportion of the children were African American. Although the original plan made by the nurses was to establish a special educational program for overweight children, ages 10 to 12, input from members of the service and target community indicated major problems with this approach:

1. It would be embarrassing for any child identified as needing the program.
2. Children this age usually don't pick the menu for their home or school.
3. Diet is culturally dependent, and the nurses knew very little about the dietary practices of African American families within the targeted community.

The use of an advisory group helped the nurses first identify what behavioral factors contributed to childhood obesity in the target population. These behavioral factors included the following:

- ◆ School breakfasts and lunches served were high in fat and salt, with limited fresh vegetable and fruit choices.
- ◆ Physical education classes were conducted for 45 minutes, once a week.
- ◆ No sports equipment was available for use during school recess and lunch periods.
- ◆ Participation in after-school sports cost \$150 per student for uniforms and fees.
- ◆ The students aged 10 to 12 preferred to drink sodas and eat French fries for lunch.
- ◆ Most parents were working and often bought “fast food” for their children for dinner.
- ◆ Local parks were unsafe for children to play in, and there were no outdoor recreational activities that were free (no cost).
- ◆ Children in the target group described feeling very stressed due to high homework demands and expectations to score well on national tests.
- ◆ Children in the target group indicated that they went home after school and watched TV or played video games because their parents wouldn't allow them to play outside while they were at work.
- ◆ When asked what they did when stressed, children in the target group indicated they watched TV, listened to music, played videogames, and had snacks.
- ◆ The favorite after-school snacks eaten by children in the target group were macaroni and cheese from

a box or packaged noodles—both of which are high in fat, carbohydrates, and salt.

### Rating the Importance and Changeability of Identified Behavioral Factors

To achieve success, programs must narrow their focus to a limited number of health behaviors that can be addressed successfully within a specific timeframe (Green & Kreuter, 1999, 2005). To prioritize which behaviors to address, Green and Kreuter (2005) suggest that they be rated in terms of importance and changeability. The final list should include problems that are both important and easy to change.

Importance is determined by rating how frequently the identified behavior occurs and how strongly it is linked to a health problem. The advisory group for childhood obesity ranked the importance of the identified behaviors; their ranking and rationale (basis) for the ranking can be seen in Table 12.1. For instance, the lack of available sports equipment was not rated very highly since the advisory group observed that children can be physically active without sports equipment. A highly rated item was the poor quality of the school-provided breakfasts and lunches; as a primary source of nutrition for many of the school's children, it could contribute to obesity in this population.

The advisory group was then asked to rate the changeability of the behaviors. Green and Kreuter (1999, p. 138) indicate that those that are easiest to change:

- ◆ Are still in the developmental stages
- ◆ Have only recently been established
- ◆ Are not deeply rooted in cultural patterns or lifestyle
- ◆ Have been found to change in previous attempts

The advisory group's changeability ratings for the behaviors can be seen in Table 12.2. In this round of assessments, the advisory group found that the lack of sports equipment, although not as important, could be potentially changed. This rating was based on the fact that the underfunding of the play equipment was a relatively new occurrence, and funding might be redirected if attention was brought to the problem. The poor nutritional quality of the breakfasts and lunches was seen as less changeable due to existing contracts with outside businesses to provide the meals.

After rating the identified problems based on changeability and importance, the nurses and advisory group sought to narrow their focus to specific goals. Green and Kreuter (1999) suggest ranking the behaviors in a simple table, as seen in Table 12.3. This effort yielded a table with the problems categorized in four groups: more important/more changeable, less important/more changeable, more important/less changeable, and less important/less changeable. The issues seen as most important and changeable included fifth and sixth grade students choosing high fat, high sugar foods for lunch and breakfast; children feeling stressed by homework demands; and children engaging in sedentary activities.

The use of this grid enabled the advisory group to focus on more changeable and important issues. They wrote behavioral objectives for each identified factor they hoped to change. These objectives identified *who* was targeted, *what* they hoped would change or what action would be taken, *how* the change would be measured, and what the *timeframe*

**TABLE 12.1 Importance of Behaviors Contributing to Childhood Obesity at Stevens Place Elementary School**

Important	Basis for Rating
<ul style="list-style-type: none"> <li>School breakfasts and lunches were served that were high in fat and carbohydrate, with limited fresh vegetable and fruit choices.</li> </ul>	A number of children ate their main meals at school, and studies have shown that high fat, high carbohydrate diets contribute to childhood obesity.
<ul style="list-style-type: none"> <li>Physical education classes were conducted for 45 minutes once a week.</li> </ul>	Increasing exercise frequency will increase muscle mass as well as metabolic rates.
<ul style="list-style-type: none"> <li>The students aged 10–12 preferred to drink sodas and eat French fries for lunch.</li> </ul>	Peer pressure can adversely influence food choices.
<ul style="list-style-type: none"> <li>Most parents were working and often bought “fast food” for their children for dinner.</li> </ul>	Fast foods are high in carbohydrates and fat.
<ul style="list-style-type: none"> <li>Children in the target group described feeling very stressed due to high homework demands and expectations to score well on national tests.</li> </ul>	High stress levels in adults contribute to obesity by increasing cortisol levels.
<ul style="list-style-type: none"> <li>Children in the target group indicated they went home after school and watched TV or played video games because their parents wouldn’t allow them to play outside while they were at work.</li> </ul>	Sedentary activities contribute to childhood obesity.
<ul style="list-style-type: none"> <li>When asked what they did when stressed, children in the target group indicated they watched TV, listened to music, played videogames, and had snacks.</li> </ul>	Sedentary activities contribute to childhood obesity.
<ul style="list-style-type: none"> <li>The favorite after-school snacks eaten by children in the target group were macaroni and cheese from a box or packaged noodles—both of which are high fat, high carbohydrate and high salt.</li> </ul>	These foods are high in fat and carbohydrates.
Less Important	
<ul style="list-style-type: none"> <li>There was no sports equipment available for use during school recess and lunch periods.</li> </ul>	Children can be physically active without sports equipment.
<ul style="list-style-type: none"> <li>Participation in after-school sports cost \$150 per student for uniforms and fees.</li> </ul>	High costs for participation in sports are a deterrent for low-income children.
<ul style="list-style-type: none"> <li>Local parks were unsafe for children to play in and there were no outdoor recreational activities that were free.</li> </ul>	Although important, there isn’t a direct linkage between the lack of safe parks and free recreation and childhood obesity.

was for achieving the expected outcome. The following are their behavioral objectives:

- By the end of the fall semester, 75% of the fifth and sixth grade students will choose a breakfast and lunch diet that includes fruit, vegetables, protein, dairy, and starch (bread, potatoes) at each meal.
- By the end of the school year, the teachers will schedule homework that can easily be done by a low-average student within a half-hour.
- By the end of the fall semester, all fifth and sixth grade students who have the support equipment will be provided physically interactive games free of charge (such as Wii).

### Factors That Influence Behavior Change: Predisposing, Reinforcing, and Enabling Factors

Green and Kreuter (1999, 2005) suggest that three categories of factors affecting individual behavior be addressed, as they can break down factors that contribute to successful

behavioral change and create barriers to behavioral change. These factors are:

**Predisposing factors** are antecedents to behavior that provide the rationale or *motivation* for the behavior.

**Reinforcing factors** are factors following a behavior that provide the continuing reward or incentive for the persistence or repetition of the behavior.

**Enabling factors** are antecedents to behavior that allow a motivation to be realized. (1999, p. 153)

**Predisposing factors** include the knowledge, beliefs, values, attitudes, and confidence of the target population that influence their behavioral choices. **Reinforcing factors** include the knowledge, values, beliefs, and attitudes of the family and friends of the target population. It also includes authority figures such as teachers or managers, as well as agency and community decision makers, as these individuals also influence the target population. Finally, **enabling factors** include the availability of resources, the accessibility of

**TABLE 12.2 Changeability Ratings of Behaviors Contributing to Childhood Obesity at Stevens Place Elementary School**

More Changeable	Basis for Rating Behavior
There was no sports equipment available for use during school recess and lunch periods.	Trends in under-funding school play equipment are relatively recent.
The students aged 10–12 preferred to drink sodas and eat French fries for lunch.	Peer pressure often changed student behavior, and could be used to encourage healthy choices.
Children in the target group described feeling very stressed due to high homework demands and expectations to score well on national tests.	Pressure for children to perform well on standardized tests is a recent phenomenon of questionable value.
When asked what they did when stressed, children in the target group indicated they watched TV, listened to music, played videogames and had snacks.	This was rated as easier to change due to the newer interactive video games that include movement.
Less Changeable	
Physical education (PE) classes were conducted for 45 minutes once a week.	Trends to decrease PE time per week are relatively recent—limited funding creates barriers to PE.
School breakfasts and lunches were served that were high in fat and salt, with limited fresh vegetable and fruit choices.	For a number of years schools have contracted out for lunch services from businesses based on bids.
Participation in after-school sports cost \$150 per student for uniforms and fees.	Sports have been privately funded for a number of years.
Most parents were working and often bought “fast food” for their children for dinner.	Most parents are working, and fast food restaurants have become part of the American culture.
Local parks were unsafe for children to play in and there were no outdoor recreational activities that were free.	Funding for parks and recreation have steadily declined for a number of years.
Children in the target group indicated they went home after school and watched TV or played video games because their parents wouldn’t allow them to play outside while they were at work.	This has become common place in the modern culture.
The favorite after-school snacks eaten by children in the target group were macaroni and cheese from a box or packaged noodles—both of which are high fat, high carbohydrate and high salt.	These are cheap and easy foods to fix.

resources, laws, and government support for the health behaviors or for the health program, as well as skills (Green & Kreuter, 2005).

The advisory group, following the Green and Kreuter model, identified the predisposing, enabling, and reinforcing

factors that affected each behavioral objective. Table 12.4 shows the grid they developed for the first behavior objective—“By the end of the fall semester, 75% of the fifth and sixth grade students will choose a breakfast and lunch diet that includes fruit, vegetables, protein, dairy and

**TABLE 12.3 Rankings of Behaviors Contributing to Childhood Obesity at Stevens Place Elementary School by Importance and Changeability**

	More Important	Less Important
More Changeable	Fifth and sixth grade students chose high fat, high sugar foods for lunch and breakfast Children stressed by homework demands Children engaged in sedentary activities (watch TV, play videogames) after school	Limited sports equipment
Less Changeable	High-fat and high-carbohydrate school food Limited physical education classes Favorite after-school snacks high fat, high carbohydrate, and high salt	Participation in after-school sports cost \$150 per student Parents often bought “fast food” for dinner Local parks unsafe; lack of free recreational activities

**TABLE 12.4 Predisposing, Enabling, and Reinforcing Factors That Influence Meal Choices of Fifth and Sixth Grade Students Attending Stevens Place Elementary School**

Factors That Support the Change	Factors That Inhibit the Change
<p><b>Predisposing</b> Fifth and sixth grade students tend to believe what they are taught by teachers, thus educating them on food choices could positively affect their choices Fifth and sixth grade students like to be similar to other children their age</p>	<p>Fifth and sixth grade students are beginning to feel some independence from adults and may like to eat what they want versus what adults tell them they should do Students like the taste of sodas and French fries more than balanced food choices</p>
<p><b>Reinforcing</b> Students emulate behavior of popular students Teachers and parents are concerned about poor food choices being made by fifth and sixth grades students Local community leaders expressed outrage about the obesity rates of African American children at Stevens Place Elementary School</p>	<p>Media shows teens eating French fries and drinking sodas</p>
<p><b>Enabling</b> A local community-based organization has offered to provide incentives to students who model positive food choices The principal has offered to allow time for the nurses to work with an identified group of student leaders to educate them about modeling better food choices The local Parent Teacher Association has offered to help monitor student behavioral changes.</p>	<p>The school has no funding for educational intervention programs for obese children</p>

starch (bread, potatoes) at each meal.” For example, one enabling factor that supported the change was the identification of a community group that agreed to provide incentives to students making positive food choices. On the other hand, the lack of school funding for educational intervention programs for obese children was seen as inhibiting change.

The advisory group decided to establish a peer mentoring program, in which student leaders would work with the advisory group and model food choices from all food groups. The advisory group had teachers nominate students for this intervention. The principal allowed the nominated students to attend special educational classes conducted by the nurses to increase their knowledge about the food groups. The nurses worked collaboratively with the students to ensure their teaching approaches were effective. Students suggested rewards that the students could work for that would encourage them to eat more balanced meals. One of the rewards students felt should be offered is sports equipment for student use during recess and lunch periods. One local community-based organization offered to sponsor a fund raising event that would allow them to purchase sports equipment for the school.

Grids similar to that shown in Table 12.4 were developed for the remaining two objectives. This process allowed the nurses and the advisory group to develop program intervention strategies that maximized their potential to achieve desired outcomes. Working with the advisory group, the nurses developed a program plan map outlining activities for each objective, as well as who was responsible for the activity, date by which the activities were to be accomplished, and how outcomes would be documented. Display 12.1 shows

the program plan that was developed for the first objective. This type of mapping allows the group to stay focused, share responsibilities, and monitor outcomes. For instance, student leaders were tasked with modeling balanced food choices at breakfast and lunch and completing a checklist of their food choices each day. The nurses were tasked with meeting each week with the student leaders to provide peer mentoring training sessions.

Working with the advisory group allowed the nurses to contextualize the problem about which they were concerned within the target community. The advisory group ensured that the nurses identified solutions that were culturally acceptable, appropriate, and ultimately effective. This process also helped them to develop outcome measures that were consistent with the concerns of the community. As data were gathered, findings could be interpreted with input from the advisory group. This approach grounded the findings and ensured that interpretations were culturally consistent with the target population. Evaluation was facilitated by clearly defined goals that could be measured against actual results.

This particular case study is an example of the program development needed in schools to address obesity and overweight. The Guide to Community Preventive Services (2005) systematic review of published school-based programs indicated that more evidence was needed to determine the effectiveness of these programs. Although they noted some positive effects in the studies reviewed, the results were too varied to make any conclusions. Their review supports continued efforts to demonstrate program effectiveness in school-based programs. Clear and verifiable outcome measures are needed.

## DISPLAY 12.1

## SAMPLE PROJECT PLAN MAP

**Goal:** Fifth and sixth grade students attending Stevens Elementary School will engage in behaviors designed to decrease their obesity levels.

Objective	Activity	Who Responsible	Due Date	Evaluation
1. By the end of the Fall semester, 75% of the fifth and sixth grade students will choose a breakfast and lunch diet that includes fruit, vegetables, protein, dairy, and starch (bread, potatoes) at each meal	1a. Teachers will identify student leaders from the fifth and sixth grade classes who can participate in leadership training for peer mentoring	1a. J. Jamison, school principal	September 20, 2008	1a. A list of student leaders will be available for review
	1b. Students will be approached to participate in the program	1b. J. Jamison, school principal	September 25, 2008	1b. Student response will be documented
	1c. Permission slips for student leaders to participate will be sent home to parents	1c. J. Jamison, school principal	September 27, 2008	1c. Copies of permission slips will be maintained by the principal
	1d. Nurses will meet with the student leaders weekly during the designated time period to provide them training for their peer mentoring	1d. Nurses	September 28–October 31, 2008	1d. Copies of the meeting notes and educational plans will be maintained by the nurses
	1e. Student leaders will model balanced food choices during breakfast and lunch meals	1e. Student leaders	November 1–December 22, 2008	1e. Student leaders will provide a check list of their food choices to the principal at the end of each day
	1f. A check list of possible food choices for students' breakfast and lunch meals using the school menus will be developed	1f. Nurses	December 1, 2008	
	1g. PTA volunteers will monitor student food choices during breakfast and lunch meals one day each week for 3 weeks	1g. PTA volunteers	December 3, 12, 17, 2008	1g. Results of checklists will be tabulated and available for review

## EVALUATION OF OUTCOMES

The Institute of Medicine (IOM) report, *The Future of the Public's Health in the 21st Century* (2002), called for examining the benefits of accrediting governmental public health departments (Benjamin, Fallon, Jarris, & Libbey, 2006; IOM, 2002). Responding to this challenge, the Exploring Accreditation Steering Committee published *Final Recommendations for a Voluntary National Accreditation Program for State and Local Public Health Departments* in 2006, outlining this first-ever accreditation program for health departments (Benjamin et al., 2006). The benefits of this program were described as:

- ◆ Promoting high performance and continuous quality improvement.
- ◆ Recognizing high performers that meet nationally accepted standards of quality.
- ◆ Clarifying the public's expectations of state and local health departments.
- ◆ Increasing the visibility and public awareness of governmental public health, leading to greater public trust, increased health department credibility and accountability, and ultimately a stronger constituency for public health funding and infrastructure (p. 4).

In 2008, 16 states were selected to “lead a national initiative to advance accreditation efforts and quality improvement strategies in public health departments” (National Network of Public Health Institutes, 2008, p. 1). Areas explored by these states in the initiative included culturally appropriate services, use of health data, and integration of customer service into health programs. Made clear in both the IOM report and the voluntary accreditation program under development is the effort to assure quality through measurable outcomes and standards of practice in the programs and services provided by both state and local health departments. The previous section of this chapter discussed the issues of program planning, implementation, and evaluation as they related to a small health program. This section focuses on the programs and services provided by the agencies. Although the scope of the effort to address outcome evaluation is understandably broader, the concepts are essentially the same. The accreditation initiative has raised the issue of demonstrating in real and objective terms the outcomes resulting from health promotion programs provided through public health agencies. The principles discussed have relevance in many community settings and should be considered whenever health promotion programs and services are provided. PHNs are instrumental to many of the health promotion programs and services offered through health departments; their expertise with and understanding of the communities served is invaluable to assuring ongoing quality assurance and outcome evaluation.

### Setting Measurable Goals and Objectives

Planned programs should have specific goals to help identify who the program is supposed to serve, what services are provided, the length of time the services are to be provided, and the resources that are needed. Then, measurable objectives are developed that describe the expected outcomes.

Use of selected verbs indicates the expected level of achievement, such as “clients will be able to demonstrate safe administration of insulin after three home visits,” or “parents will have their infants’ recommended immunizations up to date by 24 months of age.” Goal setting is imperative when developing an educational program (see Chapter 11) for an entire health program or service. These statements of measurable goals are then examined during the program evaluation. Without such statements, accurate evaluations cannot be conducted.

In evaluating programs and care, outcomes must be measured against certain standards. *Standards* are generic guidelines of expected functioning. They can focus on the client, the caregiver, or the organization (finances). All care and services must also be measured against these guidelines. The core standards of care, practice, and finance must be integrated and compatible if they are to ensure quality care.

### Evaluating Outcomes

The outcomes or results of care (having the right things happen) are the desired effect of the structure (having the right things) and the processes (doing the right things). The focus on client outcomes demands continued analysis of structure and process, because these two components produce the desirable or undesirable outcomes. With the focus on outcomes, there has been an impetus to include positive outcome terms such as improved health status, functional ability, perceived quality of life, and client satisfaction. Client satisfaction is measured by how closely a client's expectations of nursing care match the perception of the nursing care actually received (Gordon, 1998). Client satisfaction, as one outcome measurement, can be determined by a telephone survey or a mailed questionnaire (Donabedian, 1969).

If the responses indicate that a program is meeting its goals, maintaining set standards, and having positive client outcomes and satisfied clients, the program is providing quality care. However, the accuracy of using outcomes as a primary measure of quality care is limited, because some clients have unsatisfactory outcomes despite receiving good care. Factors other than specific health interventions influence outcomes. These factors include a client's adherence to medically prescribed treatments; the progress of chronic or terminal disease beyond the capabilities of medicine, nursing care, or client behaviors; and the client's ability to respond to care as a result of such situations as a compromised immune system. Community health nurses need to keep such factors in mind when evaluating care.

Quality indicators of client outcomes are the quantitative measures of a client's response to care (Gordon, 1998). Defining and quantifying client outcomes from these indicators are worthwhile processes that enable the nursing staff to evaluate the results of the care they provide. The goal of care in the community is successful client outcomes. By starting with measurable indicators, successful outcomes can be demonstrated in quantifiable terms. When client care meets the standards set, client satisfaction—another quality outcome indicator—is greater.

Quality indicators are part of the broader quality management program and are used to determine goal achievement. A chart audit is a useful method by which to measure the frequency of quality indicator occurrence. For example,

## DISPLAY 12.2

## QUANTIFYING OUTCOME INDICATORS

$$\text{Outcome indicators} = \frac{\text{Number of patient care events}}{\text{Total number of clients of total number of times at risk for event during a given period}}$$

**Example:**

$$\text{Occurrence of urinary tract infections in clients with indwelling urinary catheters} = \frac{\text{Number of clients experiencing urinary tract infections related to long-term use of indwelling urinary catheters from January 1 to March 1, 2008}}{\text{Number of clients with long-term indwelling urinary catheters from January 1 to March 1, 2008}}$$

an agency may have a quality indicator such as, “all infants younger than 6 months of age are weighed on each home visit.” Every fifth chart of infants visited in March, June, September, and December during a designated year is audited for documentation of the number of home visits and the number of infant weights recorded. A sampling of charts is sufficient to measure goal achievement and specific quality indicators. It is generally accepted that a sample of 20 randomly selected cases will provide useful information. If the population to be sampled numbers more than 200, some sources recommend that the sample include more than 20 cases.

Quantifying the indicators also can be accomplished through a rate or ratio of events for a defined population and timeframe. Such indicators can be tailored to express almost any patient outcome (Williams, 1991). For example, in Display 12.2, the nursing staff sets a standard for the number of urinary tract infections (UTIs) the agency will tolerate in clients with indwelling urinary catheters (perhaps 5% to 7%, depending on client age, diagnosis, family support, and home environment). In another situation, a public health nursing service has a standard to make home visits within 5 days of delivery to first-time mothers and babies born at one hospital 95% of the time. To evaluate this goal, the dates of initial home visits to first-time mothers and the birth dates of the infants are measured from a sample of client records during several measurement periods. These are both examples of assessing quality outcome indicators.

It is necessary to have indicators when setting standards in order to measure the success and quality of programs at home or in the community. The same types of indicators are used in acute care settings, with the focus appropriate to that population. If the standards are being met, but client outcomes are unacceptable, the process indicators are explored for possible areas of weakness. Such areas may need further study to identify the cause of the poor client outcomes. For example, a process indicator such as the catheter-care protocol used by an agency or the communication system between hospital and health department nurses may be examined to determine, respectively, the cause of infections or the reason why initial home visits are delayed. In addition, Medicaid and Medicare regulations in some states mandate that a percentage of records be audited each year.

While striving for excellence and best practices, agencies use the benchmarking process. **Benchmarking** uses continuous, collaborative, and systematic processes for measuring and examining internal programs’ strengths and weaknesses; benchmarking includes studying another’s processes in order

to improve one’s own (Lewis & Latney, 2002). Internal benchmarking occurs within the organization, between departments or programs. External benchmarking occurs between similar agencies providing like services. For example, a home care agency may have developed a clinical pathway that has proved useful with clients with congestive heart failure; another agency could benefit by using the same clinical pathway. In another example, an agency may use clinical practice guidelines obtained from a specialty organization along with information from a national database; another agency could benefit from this knowledge. In this way, an agency identifies what is achievable while comparing and contrasting how others provide quality services.

### Role of the Nurse in Quality Measurement and Improvement

Although nurses who deliver care directly to clients are not managers as such, improving quality is a “management” activity, not only of administration personnel but of the practicing nurses, as members of the team. Community health nurses may not be responsible for a staff or agency budget and functioning, but they may be responsible for managing a caseload of clients with needs of varying degrees of urgency. With judicious use of the resources available, they must provide priority services that promote the highest possible level of personal and group functioning and health. Any activities the community health nurse engages in to realize these goals contribute to the quality management program.

Some quality improvement activities for community health nurses include daily prioritizing of care needs for a caseload of clients, seeking supervision or skills development for a difficult case, systematizing charting so that needed documentation is efficiently completed (e.g., using flow sheets to chart maternal–child health visits), proposing better ways to organize care of chronically ill clients, and establishing new agency procedures. All of these actions demonstrate that nurses are evaluating their work and looking for ways to improve care. Staff meetings, peer review, and case conferences are common settings for nurses to bring the lessons of their practices to the larger group for examination and potential adoption.

It is the role of nursing administration to develop a formalized quality management program that includes a three-pronged focus, based on a classic approach to quality management: (1) review organizational structure, personnel, and environment; (2) focus on standards of nursing care and

methods of delivering nursing care (process); and (3) focus on the outcomes of that care (Donabedian, 1985). These formal evaluations include peer review audits (documented care delivered by peers), client satisfaction assessments, review of agency policies and procedures, analysis of demographic information, and the like (Ellis & Hartley, 2001).

Nurses who are new to formal quality improvement activities in the work setting need to recognize the value of these efforts and their part in ensuring that quality care is being delivered. Direct service providers are the best judges of care problems and their potential solutions. For this reason, it is critical that quality assurance reviews and other quality improvement activities focus on issues relevant to staff and client concerns and be structured so that they can be accomplished quickly and with minimal effort. When these activities are clear, concise, and well-integrated into daily routines, they become less time-consuming, and staff members can see the positive client outcomes as rewards for their contributions to the process. Moreover, when health care providers have the opportunity to systematically examine the care they provide, they can generate useful ideas for improving that care and can identify care issues sooner.

Whether small or large, health care agencies are complex organizations with interrelated components. The nursing staff has input into or some control over the quality of care delivered to clients who use the services of the agency. The following paragraphs review the nurse's role in each of the three areas of structure, process, and outcomes.

### Structure

The organizational structure and financial stability of the agency should allow the mission statement or philosophy to be realized. The agency should be client-focused, with sufficient resources to maintain present services and introduce additional services as needed. Public agencies need to operate within budget and also have a well-developed system of acquiring additional funding for new services through grants and contract expansion. Private agencies should operate efficiently enough to realize a profit that encourages the owners and boards of directors to continue to support the services. They should look for additional ways to solicit clients, in addition to employing highly motivated and qualified staff.

### Process

The agency should maintain standards set by the professional staff that comply with or surpass those recommended by the relevant accrediting bodies. The staff is encouraged to contribute to the evaluation of the standards and to revise them as needed. Staff members need to keep themselves current by attending in-service training sessions and acquiring additional education appropriate to their job requirements. The staff members work collaboratively with others across disciplines to improve the quality of care given in the community by using a variety of participative management tools (e.g., audit instruments, peer review). The agency is supportive of its staff and the needs of individuals. Staff turnover is minimal because employee values are compatible with the goals of the agency. Administration and staff have a compatible working relationship. A system of quality review is in place, and each staff member contributes to this process

as a member of a peer review committee or quality improvement or assurance committee. Staff members also listen to clients and provide an outlet to evaluate the care received (e.g., questionnaires, surveys, interviews), and the agency acts on client suggestions and comments.

### Outcomes

All services an agency provides should be reviewed periodically to determine whether standards are meeting the present needs of the population and whether the nursing staff are implementing these standards. The nursing services used most frequently, such as well-child care, self-care education with chronically ill adults, and various screening programs, are excellent places to begin the review. Usually, these services involve the entire nursing staff and consume a significant amount of nursing care time.

The focus on commonly served high-risk groups presents an opportunity to optimize care delivery as well as to benefit high-risk clients. Children living in neighborhoods that are known to have high lead toxicity rates from leaded paint in older homes stand to benefit tremendously from a consistently implemented lead screening, treatment, and advocacy program. Without review, such a program may not achieve its goals of decreasing toxic levels of lead in area children.

Incidents of poor client outcomes are important areas for further study. Through clinic or home visit records, community nurses can routinely review documentation of deceased or hospitalized clients to assess whether any aspect of the clinic's care or home visit activities might have prevented these occurrences. For instance, the case of a child with repeated high serum lead levels who requires hospitalization for chelation might stimulate a clinic's examination of the adequacy of parent education regarding environmental sources of lead. The clinic could also explore the effectiveness of its advocacy with the area's lead-abatement staff to ensure needed repairs in leaded homes and the removal of families to safe housing while repairs are being made.

As another example, a review of the charts of hospitalized clients who take multiple medications can be conducted to ascertain whether teaching or compliance issues regarding medication contributed to each client's hospitalization. The results may prompt a change in home-visit teaching techniques, an increase in the frequency of visits, or a change in vital-sign parameters for notifying a physician. Persistence of problems and deficiencies could be a clue that the community health nurse needs additional education in this area or that the nurse's caseload is too heavy and therefore exceeds the ability of the nurse to provide minimally expected care. Once the cause is determined, implementation of appropriate changes can commence, after allowing adequate time for the staff to address critical issues. Should additional education be needed, it is the responsibility of the coordinating, in-service, or staff education nurse to provide or arrange for the needed education.

Given adequate resources, including sufficient time, information, and support, good care is the norm. Occasionally, quality-of-care problems result from an individual provider's performance. Recommendations are made for counseling or another type of intervention by that person's supervisor, and appropriate corrective action should be

taken to resolve the problem and preserve the employee’s potential contributions as a successful team member.

Identification of quality health care characteristics and “checkpoints” for quality helps the community health care practitioner recognize the quality indicators of best practice. These also give community health nurses direction for their role in quality measurement and improvement. This role is grounded in the structure, process, and outcomes of caregiving and services provided.

### MODELS USEFUL IN PROGRAM EVALUATION

Models of client caregiving are based on structure, process, and outcome; ideally, they provide *structure* to guide nurses through the *nursing process* to reach desired *client outcomes*. Each of the following models has all three components; some work more effectively than others, depending on the agency and its philosophy.

#### Donabedian Model

Donabedian (1966, 1969, 1981, 1985, 2002), the country’s premier researcher on health care quality, proposed a model for the structure, process, and outcome of quality that has been widely used over the past 35 years as the framework for more elaborate models. The care environment structure—from philosophy, to facility resources, to personnel—is the first component. Next are the processes responsible for improving or stabilizing the client’s health status, such as standards, attitudes, and effectiveness of tools used in caregiving (e.g., nursing care plans). Finally, the resultant outcomes are causally linked indicators of quality, such as client health care goals and effectiveness of service. The Donabedian model is recognized as a simplistic and basic method of measuring quality. Structure, process, and outcome can be depicted in a box-shaped model (Fig. 12.1).

#### Quality Health Outcomes Model

Mitchell and colleagues (1998) took the time-tested Donabedian model a step further. The Quality Health Outcomes model includes the client in the model and proposes a two-dimensional relationship among components. Interventions always act through the system and the client, creating a dynamic model. The uniqueness of this model is the postulate

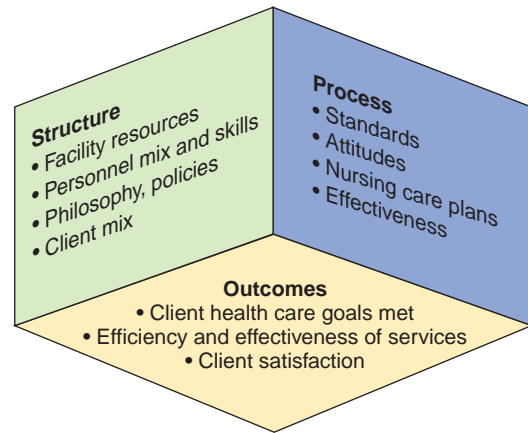

FIGURE 12.1 Structure, process, and outcome of quality model.

that there are “dynamic relationships with indicators that not only act upon, but reciprocally affect the various components” (Mitchell, Ferketich, & Jennings, 1998, p. 43). A major criticism of other models is that they do not lend themselves to the population focus of community health nursing. However, this model includes community as a client. Figure 12.2 depicts the Quality Health Outcomes model.

#### American Nurses Association Model

The ANA provides a quality improvement model based on standards of care and quality indicators within the Donabedian framework of structure, process, and outcome. Adopted by the ANA in 1975, the model was developed by Lang to depict the multiple components of evaluation of client care (ANA, 1975). The ANA model has changed as more information has been gathered through research and as the profession of nursing has grown; however, it has proved beneficial over time (Bull, 1996). This circular and continuous model suggests ongoing evaluation. Its core includes the agency’s philosophy or mission statement, which identifies the values of the agency and reflects its views of clients, nursing, the community, and health. Defining the beliefs of the agency is the first step in improving quality. The three components of structure, process, and outcome are depicted as pie-shaped wedges located around this central core. Specific nursing actions are added to more closely interrelate

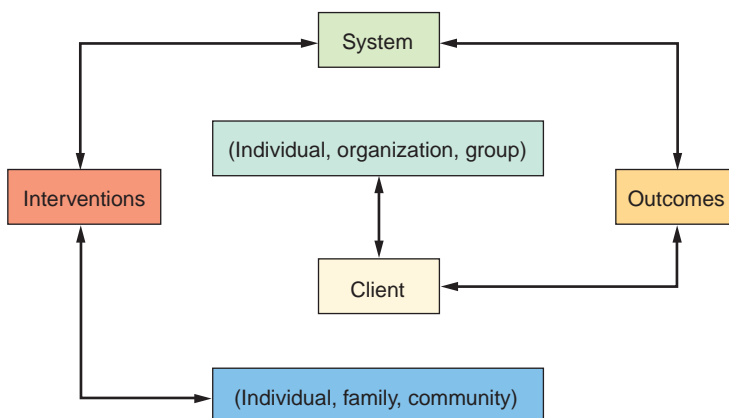

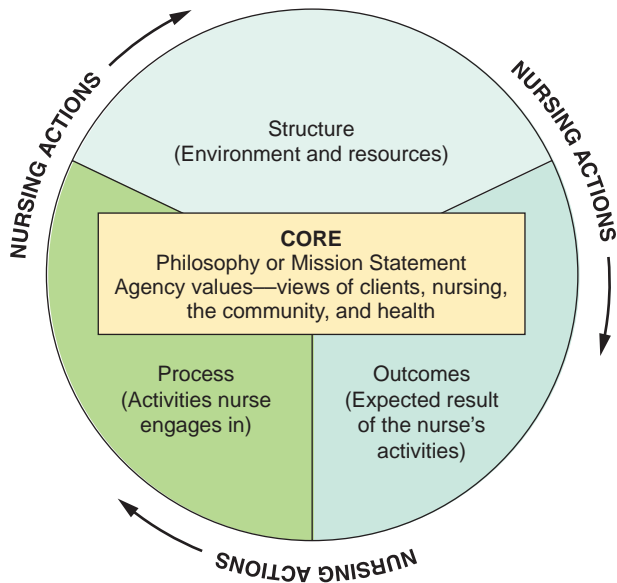

FIGURE 12.2 Quality Health Outcomes model.

**FIGURE 12.3** The American Nurses Association quality assurance model.

each section and make the transition to the next section smoother (Fig. 12.3).

Although each component is important, agencies rely on positive client outcomes as key indicators of success. Successful outcomes are the purpose of the agency's existence and the key to positive evaluation by accrediting bodies. Moreover, continued reimbursement by third-party payers, such as private insurance companies, Medicare, and Medicaid, depends on successful outcomes.

## Omaha System

Also discussed in Chapter 14, the Omaha System has measurement approaches that make it a useful model for determining the quality of nursing care provided to individuals, families, and communities. Evaluation focuses on process indicators, client outcome measures, and satisfaction with care (Bowles & Naylor, 1996; Martin, Leak, & Aden, 1997). With the use of this multifocal approach, measurement of nursing practice becomes comprehensive. Although originally designed to evaluate care to individuals and families, the model has been modified to include the community (Martin, 2005). This revision was prompted by the wider use of the model to document population-based and community-level interventions. The inclusion of community as a modifier is seen as a work in progress, awaiting further research and testing.

Community is defined as “groups, schools, clinics, neighborhoods, or other larger geographic areas that share a common physical environment and ownership of a health-related problem” (Martin, 2005, p. 464). In this model, outcomes are rated in terms of knowledge (what the client knows), behavior (what the client does), and status (how the client is). This approach allows for quantifying a range of severity, as well as progress toward or away from optimal health. Ongoing monitoring of these aspects as they relate to individual, family, or community problems allows for evaluation of nursing interventions—a necessary component of

both quality assurance and outcome assessment. For instance, individuals enrolled in a 6-week health promotion program on weight management can be assessed initially for their knowledge of healthy eating and exercise, their current behaviors relative to both, and their current health status (e.g., body mass index [BMI]). The outcome of the program can be assessed by measuring those same indicators and then comparing the initially obtained individual and aggregated data with data collected after the program is concluded. Whereas individual positive changes, such as decreased BMI, are a positive indicator, the impact on the entire group is of even more importance in terms of community-level health status.

The following is a case study exemplifying another use of the Omaha System. A group of county health department community health nurses conducted an assessment of a community's need for a satellite health clinic in a rural part of the county. The nurses gathered data on population needs, age, health status, and accessibility to health care by surveying clients who lived in rural zip code areas and used the main health department. They also conducted a survey by mail of additional residents who were not presently using the health department clinic system for immunizations, screening for tuberculosis or sexually transmitted diseases, or well-baby visits, to see whether these people had unmet needs. After carefully analyzing the data, they began operating three 4-hour clinics during the first week of each month in an empty storeroom of the community pharmacy.

After funding the clinics for 6 months, the health department evaluated the effectiveness of this nursing service. The number of emergency-room visits for infants in the area was compared with the number of visits during a similar period before the satellite clinic was established, as was the number of cases of influenza and pneumonia among residents older than 65 years of age. Finally, clients were surveyed in regard to their satisfaction with nursing care and services and were asked if there were any additional services they needed. Survey outcomes were supportive of continuing the clinics and adding an additional well-baby clinic, a dental clinic, and a prenatal clinic. Clients liked the convenience—older residents did not have to drive the 35 miles to the main clinic, parents were able to keep more closely to the recommended schedule for their children's immunizations, and they liked the shorter wait. Follow-up after human immunodeficiency virus (HIV) screening included the formation of an HIV/AIDS support group for clients and families in the rural area, meeting a need that no one had previously identified. The nurses combined clinic responsibilities with home visits in the area on clinic days and were able to do case finding, thus improving the overall health of this rural area.

The nurses were evaluated and their charts were audited with the use of traditional tools, and clients received the same periodic surveys. Case conferences continued to be held among the nurses serving the rural area and, at times, cases were presented among the larger group of nurses. By utilizing the comprehensive Omaha Visiting Nursing Association measurement approaches, they met the quality measurement needs of a population. The Omaha System provides an organized method to assess individual-, family-, and community-level health. With ongoing research efforts, the utility of the model with respect to program evaluation will be enhanced.

### The Quality Practice Setting Attributes Model

This model, developed by the College of Nurses of Ontario in Canada, provides the foundational framework for a unique quality improvement approach to creating quality practice environments. The College of Nurses of Ontario is the regulatory body for registered nurses and registered practical nurses in the Province of Ontario, Canada; it has functions similar to those of the Boards of Registered Nursing in each state in the United States. The Quality Practice Setting Attributes Model is used as a tool to assist in ensuring the quality of nursing practice and the nursing profession by promoting continuing competence among nurses in Canada (Mackay & Risk, 2001).

This nurse-centered model of quality improvement is designed to contribute to the best possible health outcome for the client, regardless of health care setting. The components of this quality assurance program include reflective nursing practice, practice review, and practice setting consultation. The first two components focus on the nurse’s individual responsibility for maintaining competence throughout her careers; the practice setting consultation

focuses on the practice environment in which nursing care is delivered.

The governing body for nurses in Ontario, Canada, has relied on the Quality Practice Setting Attributes Model to improve nursing care quality in their province. The model identifies seven key systems attributes in the work environment that create a quality practice setting. Figure 12.4 portrays this model and its components.

### SOCIAL MARKETING

Each of the five program evaluation models presented provides a mechanism to plan, implement, and evaluate community-based programs and services. Emphasizing the importance of demonstrating quality through measurable outcomes is a crucial aspect of community health. Health promotion and health education programs must demonstrate achievement of stated goals to justify continuation. Likewise, the overall program, be it a health department or a community-based health center staffed by volunteers, is challenged to demonstrate quality outcomes through ongoing evaluation efforts. Community health services are also

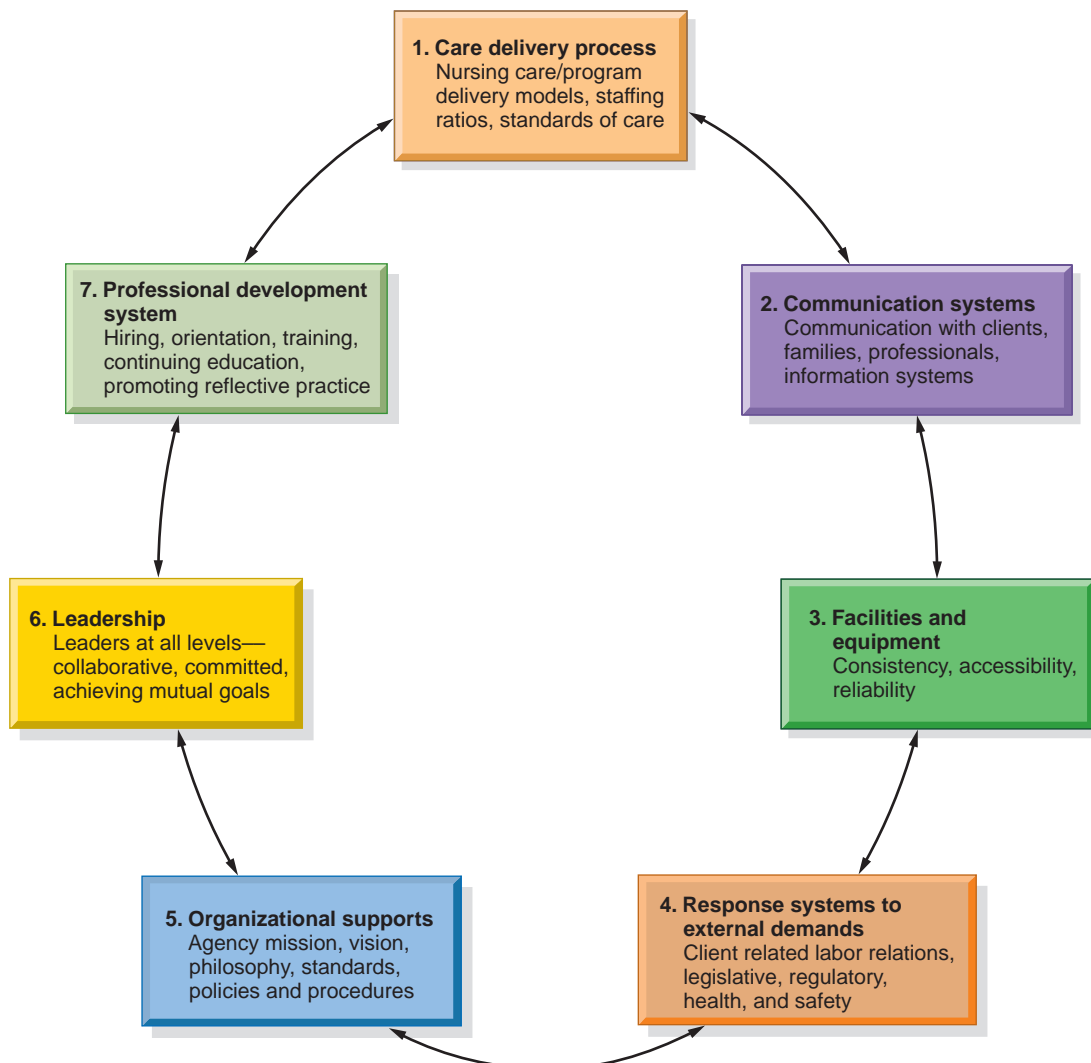

FIGURE 12.4 The quality practice setting attributes model.

challenged to provide programs in ways that reach and engage their target populations. In this section, the role of social marketing is explored as an additional tool for community health care professionals to influence health behaviors and lifestyle choices. These methods must be selected carefully and evaluated against the same standards as previously presented, perhaps more so, due to the potentially higher costs of this type of intervention.

Are you of an age that when you hear the words “*Smoky the Bear*,” your mind finishes the phrase with “*only you can prevent forest fires!*”? Or, perhaps, when you see two golden arches you start craving a hamburger and fries? The ideas that are imbedded in your psyche are all due to marketing. Businesses have long recognized that providing “catchy” advertisements in a way that is memorable to the potential customer is vital to their success. Marketing can literally make or break their business. If the message is effective, they often have more business; if not, they may lose customers. The military has even begun to recognize the effectiveness of these advertising methods, using those same techniques in television and print advertising to increase recruitment. Children as young as 2 years have been found to be “branded” with current fast food items and beverages, meaning they recognize and prefer one particular brand or logo over another. The techniques used by some of these businesses and corporations have in many ways contributed to health issues we currently face as a nation (i.e., obesity in children; teenage smoking).

The public health care sector has only recently begun to recognize the power of marketing health messages. Although used in some capacity since the 1960s, not until the 1990s—when federal agencies, such as the Centers for Disease Control and Prevention (CDC) spearheaded efforts—did it gain the attention it now has in addressing health issues (Andreasen, 2006). The term **social marketing** refers to “influencing the behavior of target audiences” (Andreasen, p. vii). Lotenberg and Siegel go on to explain that in “the public health context, marketing efforts are undertaken to improve societal health, either through influencing changes in health behaviors of individuals, in policies that impact health behaviors, or in perceptions of and support for public health as an institution” (2008, pp. 621–622). The integration of marketing with public health practice is seen as a useful method to increase the effectiveness of public health practitioners (Lotenberg & Siegel).

Concepts that are important in marketing are applicable to social marketing as well. The following concepts are outlined by Lotenger and Siegel (2008):

- ◆ **Exchange:** An individual gives something to get something; the person weighs the cost and the perceived benefits.
- ◆ **Self-interest:** People act in their own interests in most cases.
- ◆ **Behavior change:** Change in behavior is the focus; thoughts and ideas may also need to change but are not the ultimate goal.
- ◆ **Competition:** Selecting one option (or action) inherently involves giving up another option (or action).
- ◆ **Consumer orientation:** Problem-solving process is directed at the target—the consumer (could be an individual, group, or organization).

- ◆ **Product, price, place, and promotion:** Also called the marketing mix; each can be altered to increase market share.
- ◆ **Partners and policy:** Other organizations that share similar interests and could provide opportunities to work together; identification of policy changes necessary for behavioral change, those supportive of the change, and those that the organization could help influence.

These principles seem rather straightforward, yet public health practitioners are often at a disadvantage when attempting to implement social marketing campaigns (Lotenger & Siegel, 2008). They often lack training in the necessary skills, may be outspent by the competition (e.g., the fast food industry), or have limited access for the distribution of their message (e.g., public service announcements). One example of a very successful social marketing campaign is the *Go Red for Women* initiative begun in 2004 by the American Heart Association (2008). Using a red dress as the symbol of the program, the initiative seeks to raise awareness of heart disease among women. Another less well known campaign was the American Cancer Society’s *Polyp Man* campaign, designed to bring awareness to the need for colon cancer screening. The 2002 campaign featured the funny little polyp-shaped man with the line: “Get the test, get the polyp, get the cure” (Cohen & Falco, 2002). These health issues are equally important, but one has a more broadly recognized campaign; the other was humorous but not necessarily well received. Ultimately, the issue is whether or not behaviors have been changed and health outcomes improved as a result of these social marketing campaigns. Time will be the judge of all these efforts.

One international example of social marketing was an effort to increase consumption of iron-fortified soy sauce among women in China (Sun, Guo, Wang, & Sun, 2007). Nearly 400 women living in both urban and rural areas of Guizhou province participated in this study. Using the marketing techniques of product, price, place, promotion, policy, and partnership, they demonstrated that mass-media campaigns can be effective. In the study, availability of the iron-fortified soy sauce increased in all areas and purchases were increased by nearly 30% more in the intervention groups as compared to the control groups. The researchers point to the feasibility of the campaign and the impact it had on knowledge, intention to purchase, and actual consumption as justification for use of other mass-media campaigns. For health care providers, use of mass-media is an option, but for cost reasons it is not always practical.

How can social marketing principles be utilized when you have a limited budget, limited time, and limited creativity? University campuses hold a wealth of oft-untapped expertise. For nursing students working on a health promotion program, the substance of the effort (the health issue) is often pretty straightforward, but the presentation is more challenging. Many schools of nursing are providing collaborative experiences for students, supporting partnering with non-nursing students and faculty in addressing health education needs. The following is one example of how collaboration can be effective: Two nursing students recognized that off-campus housing lacked sufficient smoke detectors due to a loophole in state and local building codes. This meant that

students living in the most high-risk housing for fires (older buildings) might only have one smoke detector in the entire apartment; this was clearly inadequate. After discussing the issue with their faculty member, they sought input from several student organizations. From those discussions they identified a low level of knowledge about the issue and modest concern by the students present. Recognizing that college students are not prone to worrying about how many smoke detectors they have, the nursing students sought help from the university housing department. The staff of housing agreed that this was an important issue, and they were willing to post information on the housing website regarding the need to install additional smoke detectors. The students didn't know how to develop online materials but, based on input from the student groups, they knew that it had to be eye-catching and quickly present a message. In conjunction with their faculty advisor, they contacted the graphic arts department and found an instructor who was willing to include the development of an online smoke detector campaign as part of a class assignment. The nursing students provided the educational information that needed to be included, and the graphic arts students proceeded to develop a campaign within those parameters. In the end, several outstanding examples were submitted, and one was selected and posted on the housing website. The campaign was particularly effective with parents who saw the campaign on the website as they helped in apartment searches. Many messages were sent to the website by the parents regarding the campaign, and the responses were handled by the nursing students. The campaign was not expensive, identified the most skilled individuals for each task (health information: nursing students; web-based campaign: graphic arts students), and provided much-needed health and safety information to the university students and their parents. Even though they had targeted the college students, the nursing students found that the parents were much more interested in the campaign. The results of this initial effort provided vital information for future campaigns that might target parents, students, apartment management, and the local building code enforcement office.

Social marketing is not a panacea, but it does provide techniques that can support health education and health promotion programs. The method can be very expensive and very elaborate, or it can provide simple, straightforward messages. The point is that well-presented marketing can be the difference in whether behavior changes are made or not. Media messages are not a replacement for a sound health promotion program; they are just one tool that can be used for great impact.

## GRANTS

Grants are a reality in public health efforts. They are not easy to locate, easy to secure, or easy to manage once you have one, but they are vital to providing a wide range of programs and services in the community. Many local and county health departments see them as an integral part of their service delivery, even hiring grant writers and grant managers in some cases. For most health departments, community agencies, and volunteer service providers, the task of locating grant funds, writing the grant application, and doing the work stipulated by the grant all falls on the nurses and other professionals within those agencies. On the positive side, it provides an opportunity for community health nurses to explain to others what they can provide to the community in terms of services and

programs targeting the community's health. Some basic knowledge about grants can demystify the topic.

Even if you aren't ever required to write a grant, you will likely be involved in some part of a programmatic grant at some point in your career, either in the delivery of services stipulated by the grant (product) or in evaluating the outcomes of the services provided (i.e., satisfaction surveys). You may even be asked to provide ideas for specific services to be included in the grant application; take advantage of these opportunities. The experience you gain will enhance your knowledge of the process and may prove instrumental in future efforts you may be involved with. The grant process, although arduous, provides the opportunity to focus clearly on what you intend to accomplish, why it is needed, and what part you will play in the successful outcome of the project. This is similar to a job interview, in which your prospective employer asks you "*Why should we hire you? What will you contribute to this organization?*" You have a limited amount of time to express your worth. You have to be very specific and concise about what you and your organization or group will be doing to address a specific need. You are making the case that providing you with support is the best choice.

What exactly is a grant? A **grant** is, very simply, one individual or group providing another individual or group the support (i.e., money) for a specified purpose. In health promotion and education, it generally means funding for program development or project support. These types of grants fall into the following common categories: planning grants (i.e., initial project development), start-up grants (i.e., seed money), management or technical assistance grants (e.g., for fund raising or marketing), and facilities or equipment grants (e.g., money for a building, computer, or van) (Minnesota Council on Foundations, 2008). This money doesn't typically need to be paid back; however, it is a contractual agreement and the terms and conditions are usually clearly delineated. For federal grants, the following definition applies: "award of financial assistance from a federal agency to a recipient to carry out a public purpose of support or stimulation authorized by a law of the United States" (Grants.gov, 2008). Federal grants are available from 26 grant-making agencies. The funding categories most applicable to community health include community development, disaster preparation and relief, food and nutrition, and health. Federal grants are available to a wide variety of groups, but typically health-related grants are available to state or local governments, which includes public health departments, public housing organizations, educational organizations, and nonprofit organizations.

What is a *nonprofit organization*? Nonprofit means that the organization was not established to earn a profit (Agnes & Guralnik, 2004). This does not mean that it doesn't generate income, only that there are restrictions on how those funds can be used. Of particular importance to the discussion of grants is the term *501c3*. This is a designation that refers to the Internal Revenue Service (IRS) tax-exempt status granted to certain nonprofit organizations. To be granted this designation, an organization must be organized and operated exclusively for specific purposes, which include charity, science, education, or the prevention of cruelty to children or animals (Internal Revenue Service [IRS] – Department of the Treasury, 2008). Some grants are only available to 501c3 organizations, and the funders will request proof of this in the grant application. Only corporations, community chests,

funds, or foundations can receive this designation; individuals or partnerships do not qualify (IRS, 2008). Essentially, the 501c3 organization can be the provider of the grant funding or the organization seeking the funding.

Grants are available from government sources, private philanthropic sources, and corporations. Federal grants can be found on the website [www.grants.gov](http://www.grants.gov) or on individual federal agency websites. Private organizations often have sections on their websites with information on available grant funding. This is likewise the case with corporations. This broad search approach is not a terribly effective way to find grants; to improve search efficiency, a number of proprietary grant-locating programs are available. These programs are very expensive and, because of cost considerations, often are licensed only to large organizations, such as universities and medical centers. They allow the user the ability to limit the search (e.g., type of funder, health issue, age group, program or research grant, funding limits, and timeframe for submission). For the small nonprofit organization seeking funding, one effective approach is to partner with a local university, which allows for more access to grant-locating programs, as well as the expertise offered on the campuses (e.g., content area experts, experienced researchers, statisticians, business plan experts). In a discussion of academic/community partnerships, Chorpita and Mueller (2008) caution that these relationships can be complicated and “projects should be based on a win-win-win proposition, in which consumers, researchers, and service agencies all stand to benefit” (pp. 144–145). Sieber (2008) notes that “productive collaboration requires long-term commitment by the academic researcher despite all the conditions that make this difficult” (p. 137). The community organization and the academic institution both stand to gain from these types of arrangements as do, of course, the target populations.

Some grant funders allow letters of inquiry to be submitted prior to an actual full grant application. The letter of inquiry may be by invitation-only or be part of the original advertisement of the grant funding. In any case, this letter is normally only two or three pages in length and includes a concise overview of the project. For example, a **letter of inquiry** would likely include an overview of your organization and its purpose, the reason for the funding request, clearly stated need or problem to be addressed, overview of the proposed project or program, and other funding sources for your project or program (prospective and committed) (Non-profit Guides, 2008). This letter is brief, yet clearly lays out your plan. Your goal is to be invited to submit a full proposal for consideration. If this approach is successful, you will be asked to complete the organization’s application process (the proposal), which can vary in length and complexity depending on the organization.

Crucial to either the letter of inquiry or the full proposal is that you have selected a funder that is a good match for your organization and your program/project. For instance, applying to a faith-based organization that supports abstinence-only educational programs would not be a good fit for your program to provide contraceptive information in an after-school program for teens. Before you spend valuable time and energy writing a letter of inquiry or a grant application, be sure to do your homework. The Internet provides a quick method for reviewing potential funders, their vision, mission, and types of previous funding. You may even be able to find out the monetary range of grants funded by the organization. Perhaps

you have a small grant request and find that the organization you are reviewing only funds large multimillion-dollar projects; it might be best to look for other options. The website will likely have contact information; making a phone call can assure you that this organization is a good match for your project and can give you an opportunity to start building a relationship with their staff.

Grants are most often competitive—which means you can expect to have competition from other deserving groups—so be prepared. A well prepared grant—one that carefully follows the application guidelines specified in the Request for Proposals (RFP) and very clearly describes the program you are seeking support for—is more likely to be funded. The **Request for Proposals (RFP)** outlines the specific requirements of the application, the information to include and in what order, and what supplemental forms to include, if any. Submitting a grant after the deadline and not including all required items will mean that your grant application is not likely to be reviewed. If your grant is not selected, make certain to contact the funder to see if they will provide you with a review of your submission; this is common with government-sponsored grants. With knowledge of what hampered your selection, you will be in a much better position to resubmit to this funding source again, or to be more prepared for other grant opportunities. Another suggestion for new grant writers is to seek the help of an experienced mentor—someone who has been successful in grant writing—as they can critique your proposal prior to submission and offer suggestions.

The following tips may be helpful as you begin the process of seeking grant funding (Corporation for Public Broadcasting, 2008):

1. Define your project:
  - Clarify the purpose of your project and write a concise mission statement.
  - Define the scope of work to focus your funding search.
  - Determine the broad project goals, then identify the specific objectives that define how you will focus the work to accomplish those goals.
2. Identify the right funding sources.
3. Contact the funders; think of the funder as a resource.
4. Acquire proposal guidelines.
5. Know the submission deadline.
6. Determine personnel needs.
7. Update your timeline.

One reality of grant funding is that experience counts. If you have a proven record in securing grants and completing the requirements specified in those grants, you or your organization will have an easier time securing additional funding. For the new grant seeker, this can be a bit discouraging. So, where to begin? Don’t start with the most complicated grants available. Look for small local grants with a proven track record in grant management, and build your reputation. Work with partners. A school of nursing could partner with a home health agency to write a grant to provide worksite wellness programs for uninsured agricultural workers. Or, several faith-community groups could partner in a grant application to provide free health screenings for uninsured adults in their area. Finally, be certain that the grant will allow you to meet the mission and goals of your program. The grant funder will also be looking to see if their support will enable you to provide a

service that you have both the skill and expertise to accomplish. With limited funds available, funders are looking for proof of the sustainability of your program after their support ends. For instance, a breast-feeding support program sought funding in a high-risk area where there was a clear need. Although the need was demonstrated, the agency had no plan for continuing the program after the funding ended; they did not receive funding. Grant support is often seen as funding to get programs started—not to provide for long-term operations.

Many courses are available to assist you in understanding how to locate grants, write them, and be successful in your attempts. Your local library is another source of information, and a wide variety of information is available on the Internet. Some examples of helpful websites are included in the Internet Resources at the end of this chapter.

## Summary

Successful community health programs require that the nurse listen to the target population, and not determine the problem and solution without their assistance. Awareness of predisposing, reinforcing, and enabling factors facilitates the assessment of health-related behaviors. Importance and changeability are important considerations when determining priorities among competing behavioral targets. An advisory group, with representation from the target and service communities, is an effective tool in helping to identify the problem, select appropriate interventions to address the problem, and evaluate the outcomes of the interventions chosen. Outcome measures should be consistent with the concerns of the community. Evaluation can be facilitated by clearly defined goals that can be measured against actual results.

The multiple models or frameworks on which quality management systems are based include a classic way of looking at programs through organizational structure, process, and outcomes, along with the interrelatedness of each component. The five models presented in this chapter are structured in unique ways that enable them to meet the differing needs of community agencies. Whether quality measurement and improvement techniques are formally or informally practiced, whenever nurses monitor, assess, and judge the quality and appropriateness of care as measured against professional standards, the interests of clients are being served.

Social marketing is one tool that can enhance health promotion efforts in the community. Media messages are particularly helpful in reaching large audiences. The basis of social marketing is similar to product marketing to consumers. The goal of consumer marketing is not necessarily to change the way people think, but the way they behave. Social marketing seeks to first change behavior and then to influence how people think about health, lifestyle, and the choices they make every day that influence their health. One example of social marketing is the American Heart Association, *Go Red for Women* campaign, which seeks to bring attention to heart disease risk among women. Social marketing, like any consumer-focused marketing, must consider the target population in the design, implementation, and evaluation of the effort. Successful outcomes are imperative for continuation of this type of program, as with any other health promotion campaign.

Grants are increasingly vital to providing health promotion programs and services in the community. Community health nurses frequently are involved in some aspect of a grant program, whether in the writing, implementation of the

program or services stipulated in the grant, or in the evaluation of the outcomes for the grant. Grants are available from government sources, private philanthropic sources, and corporations. Successful grant proposals comply with the instructions provided in the Request for Proposals. Community agencies and academic programs can collaborate in providing community services and evaluation research that seeks to improve the lives of the target population. Mastering the grant process, from formulating the goal to defining the evaluation methods, is a skill that can benefit all manner of health promotion programs, whether funded or not.

Community health nurses are in a key position to plan, implement, and evaluate all types of health promotion/health education programs. Knowledge of the target population and engaging the target population in determining the problem and solutions is vital to successful outcomes. Ongoing use of quality measurement techniques and application of recognized professional standards helps assure effective and appropriate service delivery. Social marketing is a tool that can be effective in reaching large audiences with valuable health messages. Finally, the skills gained in working on any portion of a grant effort can be utilized in future programmatic efforts, whether supported through funding or not. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. A group of student PHNs are approached by a faculty member who teaches acute care nursing. She informs them that there is a high incidence of chlamydia infection in a local community among Spanish-speaking people. The hospital where she has students wants to do something to reduce the incidence of chlamydia. The faculty member has found a pamphlet online that describes chlamydia infection, how it's diagnosed, and how it's treated. She thinks it would be a wonderful idea for the student PHNs to translate the pamphlet into Spanish.
  - a. Is this the appropriate intervention?
  - b. What data should be gathered? What literature should be reviewed?
  - c. What agencies, organizations, and groups should the students contact?
  - d. Who is the target population?
  - e. What outreach should be done with this population? What information should be gathered from the population prior to developing any educational materials?
  - f. What steps should the students take to ensure that the target population finds the educational materials they develop to be appropriate, acceptable, and understandable?
2. A school nurse works in a rural agricultural community. The main crop is rice. Every year after harvesting the rice, the local farmers burn their rice fields. The school nurse notes a significant increase in absences during this period for respiratory problems, especially asthma. She notes that even the teachers have increasing respiratory problems. She believes that the respiratory problems are aggravated by the

burning rice fields. She mentions her concerns about the relationship between the fields burning and increased respiratory-related illnesses to the school principal. He responds that while it may be true, the local farmers control the local community—without them, the community would collapse. He states that kids and adults will just have to adjust.

- a. What can the nurse do to find out if the burning rice fields are a threat to the health of children and adults in the local area? (What data should be gathered, what literature should be reviewed, to whom should she talk?)
  - b. What steps should she take to increase interest in addressing this problem?
  - c. What agencies, organizations, and groups should she contact?
3. Identify a health-related social marketing campaign that you viewed recently on the television or in a store or billboard advertisement. Has this campaign effectively reached out to the target audience?

# Policy Making and Community Health Advocacy

## LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Define health policy and explain how it is established.
- ◆ Analyze the influence of health policy on community health and nursing practice.
- ◆ Explain the role of special interest groups in health care reform and policy making.
- ◆ Explain the role that professional organizations play in public policy.
- ◆ Define power and empowerment and the roles these concepts play in policy development.
- ◆ Identify the four stages in the policy process and briefly explain what each entails.
- ◆ Explain the concepts of policy analysis and strategy development.
- ◆ Explain the role of community health nurses in determining a community's health policy needs.
- ◆ Discuss the difference between advocacy and lobbying and the influence of both on policy.
- ◆ Identify the 10 steps in mobilizing a community for political action.
- ◆ Describe the steps involved in how a bill becomes law.
- ◆ Discuss several methods of communicating with legislators on policy issues.

*“Genuine politics—even politics worthy of the name—the only politics I am willing to devote myself to—is simply a matter of serving those around us: serving the community and serving those who will come after us. Its deepest roots are moral because it is a responsibility expressed through action, to and for the whole.”*

—Vaclav Havel

## KEY TERMS

Advocacy  
 Community health advocacy  
 Distributive health policy  
 Empowerment  
 Grassroots  
 Health policy  
 Lobbying  
 Lobbyists  
 Polarization  
 Policy  
 Policy analysis  
 Political action  
 Political action committee (PAC)  
 Politics  
 Power  
 Public policy  
 Redistributive health policy  
 Regulatory health policy  
 Social justice  
 Special interest groups

 **Behind** all legislation and health care regulation lie power struggles. Only the very naive think that others will be persuaded by facts alone. In all legislative activities and reforms, social and political factions are at work—special interest groups, business, and industry each bring their power into play. Because the outcomes of these struggles determine the availability and quality of all health and social services, nurses need to develop an operational knowledge of health policy and the political process in order to protect the individuals, families, and communities they serve, as well as their own nursing practice. This chapter examines health policy, the political process involved in determining health policy, and the role of community health nursing in the process. Community health nurses should provide not only input to policy circles through advocacy, but also leadership at decision-making tables. Community health nurses must understand and emphasize their powerful role in providing an essential influence and unique perspective in health care.

## EVOLUTION AND EFFECTS OF CURRENT U.S. HEALTH POLICIES

The United States is often touted as having the best health care system in the world. It is recognized worldwide for achievements in the medical and auxiliary sciences that have contributed to the mapping of the genome, advances in biomedical technologies, and increasing numbers of pharmaceuticals that hold promise for addressing the myriad chronic and acute illnesses that affect the world's populations. People often come from other countries to the United States to access our high-quality medical care.

### Uninsured and Underinsured
