**PROMOTING AND  
PROTECTING THE  
HEALTH OF VULNERABLE  
POPULATIONS**

# Working with Vulnerable People

## LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Describe what the term “vulnerable populations” means.
- ◆ Describe and explain a conceptual model of vulnerability.
- ◆ Discuss the effects of vulnerability and relative risk.
- ◆ Differentiate between the concepts of social capital and human capital.
- ◆ Identify the key premise of the differential vulnerability hypothesis.
- ◆ List three of the most common factors related to vulnerability.
- ◆ Explain the socioeconomic gradient in health.
- ◆ Describe three types of health disparities.

*“How far you go in life depends on your being tender with the young, compassionate with the aged, sympathetic with the striving, and tolerant of the weak and the strong—because someday you will have been all of these.”*

—George Washington Carver

## KEY TERMS

Differential vulnerability hypothesis  
 Environmental resources  
 Health disparity  
 Human capital  
 Participatory action research  
 Relative risk  
 Resilience  
 Social capital  
 Social determinants of health  
 Socioeconomic gradient  
 Socioeconomic resources  
 Vulnerability  
 Vulnerable populations

**Vulnerability** has been defined as being susceptible to neglect or harm, or being at risk of poor social, psychological, and/or physical health outcomes (Aday, 2001). The public health nurse (PHN) caseload is largely comprised of those who represent vulnerable populations. The term “vulnerable” comes from a Latin word that means *wound*, and **vulnerable populations** are groups who have a heightened risk of adverse health outcomes (Leight, 2003). They often have higher mortality rates, less access to health care (and disparities in the quality of care), are uninsured or underinsured, have lower life expectancy, and an overall diminished quality of life (Shi & Stevens, 2004; University of California Los Angeles [UCLA] Center for Vulnerable Populations Research, 2007). Some researchers feel that vulnerability stems from “developmental problems, personal incapacities, disadvantaged social status, inadequacy of interpersonal networks and supports, degraded neighborhoods and environments, and the complex interactions of these factors over the life course” (Mechanic & Tanner, 2007, p. 1220).

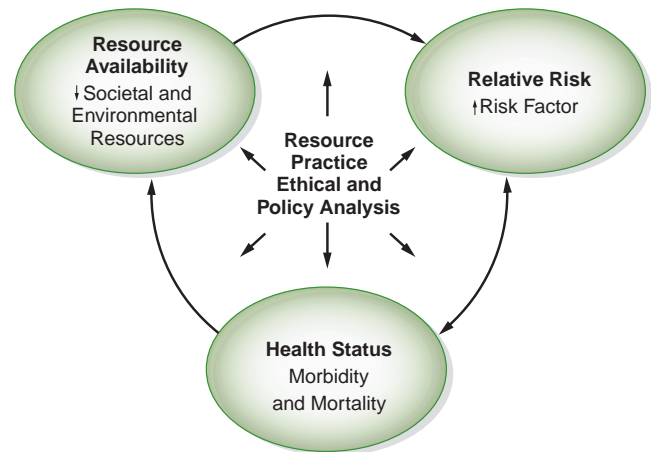

This section provides information on aggregates that are often considered vulnerable populations: the disabled and chronically ill, mentally ill and substance abusers, the homeless, and vulnerable groups living in rural and urban areas. Different researchers and authors characterize vulnerable populations in their own way. For the purposes of this introductory chapter, we will examine popular models and theories of vulnerability, as well as important concepts and contributing factors. We will also briefly discuss health disparities that often plague the more vulnerable members of our society, and the role of PHNs working with these groups. This chapter provides an overview of this subject and lays the foundation for further chapters within this section.

## THE CONCEPT OF VULNERABLE POPULATIONS

### Models and Theories of Vulnerability

A popular conceptual framework developed by a nursing professor and postdoctoral fellow at the University of California, Los Angeles examines three related concepts: resource availability, relative risk, and health status (Flaskerud & Winslow, 1998). They posit that a lack of resources (e.g., socioeconomic and environmental) increases a population’s exposure to risk factors and reduces their ability to avoid illness. A community’s health status can be observed by noting disease prevalence along with morbidity and mortality rates. Within this framework, the more risk a population faces, the greater the impact on their health status (e.g., higher morbidity and mortality rates). A feedback loop exists from health status to resource availability, as higher morbidity and mortality further deplete community resources (see Fig. 25.1).

To further define model components, Flaskerud and Winslow (1998) explain that **socioeconomic resources** can include such things as human capital (e.g., jobs, income, housing, education), social connectedness or integration (e.g., social networks or ties, social support or the lack of it, characterized by marginalization), and social status (e.g., position, power, role). **Environmental resources** deal mostly with access to health care and the quality of that care. The authors note the differential access to health care among

**FIGURE 25.1** Vulnerable populations conceptual model. Adapted from Flaskerud, J. & Winslow, B. (1998). Conceptualizing vulnerable populations health-related research. *Nursing Research*, 47(2), 69–78.

the poor, different ethnic and racial groups, and other underserved populations. Decreased access to care can arise from many sources, including crime-ridden neighborhoods, insufficient transportation systems, lack of adequate numbers and types of providers, and limited choices of health care plans or no health insurance. **Relative risk** refers to exposure to risk factors identified by a substantial body of research as lifestyle, behaviors and choices (e.g., diet, exercise, use of tobacco, alcohol and other drugs, sexual behaviors), use of health screening services (e.g., immunizations, health promotion, use of seatbelts), and stressful events (e.g., crime, violence, abuse, firearm use). They note, for instance, that in populations of single-parent female-headed homes in poverty with little or no access to social programs, violence and homicide are more prevalent. They provide evidence of the link between poor health status and socioeconomic resource availability through the loss of income, jobs, and health insurance. In the case of environmental resources, high morbidity in an already underserved population will only exacerbate access problems.

Gelberg, Andersen, and Leake (2000) advanced The Behavioral Model for Vulnerable Populations that looked at population characteristics (predisposing and enabling factors and needs) as an explanation for health behaviors and eventual health outcomes. Predisposing factors included demographic variables (e.g., gender, age, marital status), social variables (e.g., education, employment, ethnicity, social networks), and health beliefs (e.g., values and attitudes toward health and health care services, knowledge of disease). Social structures (e.g., acculturation and immigration), sexual orientation, and childhood characteristics (e.g., mobility, living conditions, history of substance abuse, criminal behavior, victimization, or mental illness) were also considered as predisposing factors. Enabling factors included personal and family resources, as well as community resources (e.g., income, insurance, social support, region, health services resources, public benefits, transportation, telephone, crime rates, social services resources). Perceived health needs and population health conditions also were considered, as were health behaviors including

diet, exercise, tobacco use, self-care, and adherence to care. The use of health services (e.g., ambulatory and inpatient care, long-term care, and alternative health care) and personal health practices (e.g., hygiene, unsafe sexual behaviors, food sources) combined with the other factors to produce outcomes, such as perceived and evaluated health and general satisfaction with health care services.

LuAnn Aday, a sociologist born and raised in rural Texas and a professor at the University of Texas School of Public Health, developed a Framework for Studying Vulnerable Populations that includes both macro and micro perspectives (2001). Aday describes the effects of policies on both communities and individuals, including social and economic policies, community-oriented health policies, and medical care and public health policies. She notes that community resources (e.g., strong neighborhoods, close ties between citizens) have a direct effect on individual resources (e.g., social status, social ties, human capital). For instance, a community with a high proportion of children, adolescents, and elderly, and a majority of single female-headed households will likely also be characterized by lower education levels, higher unemployment, and lower income levels, along with a subsequently higher relative risk of poor health status. When strong social networks are present and housing is adequate, the relative risk of poor psychological, social, or physical health decreases. Aday (2001) subscribes to a **differential vulnerability hypothesis** that “negative or stressful events (such as unemployment, divorce, or death of a loved one) hurt some people more than others” (p. 4). Even though we all are subjected to stressful events (nursing school, for instance), Aday cites research showing that low socioeconomic status (SES) groups, for example, are more adversely affected by stressful or negative events than those with higher SES. The “chronic psychosocial stresses” of lack of material resources and social marginalization experienced in childhood and early adolescence can make real physical changes by influencing “gene expression via neuroendocrine regulatory dysfunction” and are the basis of vulnerability to poor health in adulthood (Furumoto-Dawson, Gehlert, Sohmer, Olopade, & Sacks, 2007, p. 1238). The expression and interaction of these developmental genes with physical and social environments can produce long-term poor health outcomes. In other words, early chronic stressors can induce physiological changes that lead to later negative health outcomes.

Like Flakerud and Winslow (1998), Aday notes that social status (e.g., age, gender, race, and ethnicity) affects social capital and human capital. **Social capital** consists of marital status, family structure, social ties and networks, and membership in voluntary organizations, such as church or clubs. Aday links **human capital** to investments in individuals’ capabilities and skills (e.g., education, job training), and notes that it comprises jobs, income, housing, and education. Aday (2001) describes research showing that better health status is associated with higher education levels, and notes that the personal and political power of individuals and communities differentially affects their efforts to gain access to adequate schools, housing, and employment. “The social status and social capital resources of individuals and groups in a community influence the level of investments that are likely to be made in the schools, jobs, housing, and associated earning potential of the families and individuals living within it” (p. 8). Deficient social networks and social status

can lead to a cycle of poverty or vulnerability that can be difficult to break (Jones, 2003).

The importance of social capital is sometimes missed, as it can be subtle and less obvious than the lack of money or jobs. But the presence of friends and family, or someone to rely on in case of an emergency, can be invaluable in assisting individuals through many of life’s difficulties. This can be very helpful to an individual while completing schooling or during employment. Social support, or a close confidant, can promote social and psychological health and help counteract the effects of stressful events. In our mobile society, many people live great distances from family members and have difficulty establishing new friendships. Those who live alone or who are socially isolated are at greatest risk, and PHNs should be aware of this and strive to provide additional support and resources (Aday, 2001).

### Who Is Considered Vulnerable?

The most commonly cited causes of vulnerability or increased risk of poor health are income and education, along with race or ethnic background (Frist, 2005; Williams & Jackson, 2005). Aday (2001) includes the following factors and populations in her description of vulnerable populations:

- ◆ Income and education
- ◆ Age and gender
- ◆ Race and ethnicity
- ◆ Chronic illness and disability
- ◆ Human immunodeficiency virus (HIV)/acquired immune deficiency syndrome (AIDS)
- ◆ Mental illness and disability
- ◆ Alcohol and substance abuse
- ◆ Familial abuse
- ◆ Homelessness
- ◆ Suicide and homicide risk
- ◆ High-risk mothers and infants
- ◆ Immigrants and refugees

Other authors consider the uninsured and underinsured as vulnerable populations due to their difficulties with health care access and potential for poor health outcomes (Pauly & Pagan, 2007; Shi & Stevens, 2004). Single parents and those living in violent environments may also be recognized as vulnerable populations (Gitterman, 2001). Evans (2006) notes that those without liberty (e.g., prisoners, detainees) and rural populations, or those living in areas prone to natural disasters, are also vulnerable. As mentioned earlier, the higher SES groups generally have better access to health care and report that they are in better health. The very young and the very old have particular risk factors that increase their chances of poor health, as well as unique issues with access to health care. Some chronic illnesses and conditions are more prevalent in men than women, and vice versa. And, an extensive body of research substantiates the reality of health disparities and increased morbidity and mortality rates for racial and ethnic minorities (Aday, 2001; Byrd & Clayton, 2002; Institute of Medicine [IOM], 2003).

### Prevalence of Vulnerable Populations and Causative Factors

Because many of these conditions and categories have overlapping populations, it is difficult to access accurate data

and statistics for each group or category. For example, someone with lower education and income may also be a member of a racial or ethnic minority and may have inadequate housing along with a chronic illness and high-risk births. Aday (2001) notes that rates of low birth weight and infant mortality, along with teenage pregnancy and inadequate prenatal care for mothers, are indicators of substantial problems in that particular area. Similar evidence for each of the listed areas reveals less than stellar progress toward *Healthy People 2010* objectives and further reiterates the gravity of the problem (Agency for Healthcare Research & Quality [AHRQ], 2006).

Root causes of vulnerability, such as SES, insurance coverage, and race or ethnicity, have been widely researched. Which factor is considered most important? The exact weight of the interaction of these variables has been difficult to ascertain. Haas and Adler (2001) have examined multiple, large-scale studies and determined that SES, race/ethnicity, and insurance coverage “each independently influence the utilization of health care and health status” (p. 28).

### Poverty

If only one indicator is measured—poverty—it is evident that vulnerability touches a large segment of the American population, as well as the global one. Census data in 2005 indicated that about 37 million people in the United States live below the federal poverty level—\$9,570 yearly for one person and \$19,350 yearly for a family of four (Pugh, 2007; U.S. Department of Health & Human Services, 2007). Most disturbingly, over 43% of the poor live in deep or severe poverty—\$5,080 per year for one person—and that level has been increasing dramatically. It grew 26% between 2000 and 2005 to reach the highest level in 32 years (Pugh, 2007). Almost one-third of those in deep poverty were under the age of 17, and about two-thirds were female and White. However, Blacks are 300% more likely to live in deep poverty than Whites (Pugh, 2007). In 2002, 12.1% of Americans were classified as living in poverty, with the rate for African Americans over two times higher than that of the total population (Semple, 2003).

How does poverty make one vulnerable to poor health outcomes? The obvious conclusion is that having less money also means being less able to afford adequate housing in a safe neighborhood. This may lead to fewer opportunities for exercise, especially if walking outside puts one at risk of becoming a victim of violence. Fewer community resources are usually available, such as gyms, grocery stores, and shopping areas. Lower income level is associated with less education and often results in a person having to work at jobs in which they are exposed to higher risks (e.g., mining), or the need to work at more than one job in order to make ends meet. Because of the lack of free time, one may be less likely to shop for fresh fruits and vegetables and to cook healthy meals, with a consequent reliance on fast foods. Inadequate child-care, lower social class, and stigmatization can cause ongoing psychological stress. There may be less control over transportation and work schedules, along with a greater degree of stress on the job and at home. Chronic stress takes a toll on one’s body as it “can lead to health damage through neuroendocrine, sympathetic nervous system, vascular, and immune pathways” (Braveman, 2007, p. 2). The resulting consequences of chronic stress may lead to rapid aging and “induce health-damaging behaviors such as smoking” (Aday, 2005, p. 195) (see Perspectives: Student Voices).

Research has shown that poverty and lower education levels are associated with greater functional losses, certain diseases, more incidences of physical and cognitive impairment, and higher mortality rates (Crimmins, Hayward, & Seeman, 2004). Lower SES can affect health outcomes throughout life as different life trajectories encompass prenatal care, childhood learning activities, family experiences, educational and career opportunities, neighborhood environment, and opportunities for health care (Blackwell, Hayward, & Crimmins, 2001). As one example, poor prenatal nutrition can lead to type 2 diabetes and cardiovascular disease in later life (Aday, 2005).

Poverty and race/ethnicity are often intertwined, but SES is a better predictor of health outcomes in Whites than it is within other racial or ethnic groups (Crimmins, Hayward, & Seeman, 2004). Poor White populations suffer poor health outcomes, but in other racial or ethnic minorities, the association is much less straightforward.

If we examine just one aspect of poverty—access to healthy food—research has found that race and environment play a significant role. An audit of supermarkets and fast food restaurants in St. Louis, Missouri found that low-fat food options and fresh fruits and vegetables were more often found in higher-income, predominately White neighborhoods. African American and mixed-race areas, along with White high-poverty areas, were less likely to have access to these foods that are often crucial in making healthy dietary choices and adhering to federal dietary guidelines (Baker, Schootman, Barnidge, & Kelly, 2006).

Another risk factor for the poor is the finding that the highest amount of pollution is most often found in neighborhoods where there is more poverty, lower education levels, and higher rates of unemployment (Evans, 2006). Also, interventions like smoking cessation, have been shown to more often be accepted and successful among populations with higher levels of education, which are most often associated with higher income levels (Bulatao & Anderson, 2004).

At the population level, increases in total income and reductions in poverty levels are “strongly associated with subsequent improvements in population health” (Aday, 2005, p. 190). Income affects health, and poor health can affect the income of an individual as well as that of a nation (see Chapter 6). For a visual representation of the disparities found between the poor, near poor, and middle- to high-income groups, see *Healthy People 2010—Health Disparities by Income*, Figure 25.2.

### Uninsured and Underinsured

If the number of uninsured are also classified as a vulnerable population, even more Americans join the ranks, because the majority of those without health insurance are working adults and are not eligible for Medicaid or Medicare. More than 45 million Americans in 2005 were without any form of health insurance coverage (Collins, Davis, Schoen, Doty, Kriss, & Holmgren, 2006). One year later, in 2006, that number jumped to 47 million (Hansen, 2007). The percentage of Whites who are uninsured is estimated at 12%, Blacks at 19%, and Latinos/ Hispanics at 34%, indicating racial and ethnic disparity in this area. In addition, about two-thirds of those who are uninsured are living in poverty, with many of them classed as the *working poor* (Collins, 2007; Haas & Adler, 2001). However, a good number of research studies

## PERSPECTIVES STUDENT VOICES

### A Nursing Student's View of the Aftermath of Hurricane Katrina

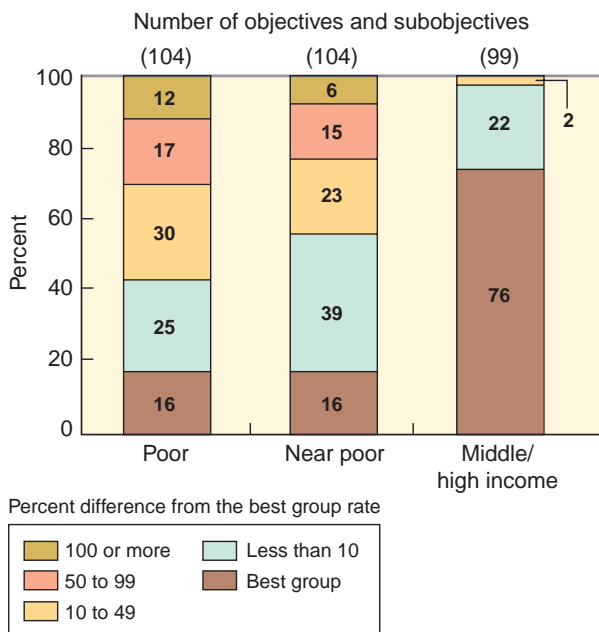

I was beginning my last year of nursing school when Hurricanes Katrina and Rita hit the Gulf Coast of Louisiana and Mississippi. Like most people, I was fixated on the television coverage of this natural disaster. A lot of the round-the-clock coverage focused on New Orleans, and much of that city seemed to be under water. People in flooded areas were stranded on housetops, while families could be seen walking on highways to get to Red Cross shelters. A horrifying image that I recall clearly was one of yellow school buses, mostly underwater, that were part of the city's disaster plan and were supposed to be used to assist those without personal means of transportation to move to higher ground.

It was like watching a very bad dream. We have had disasters in this country, but I did not expect to witness the lack of organization and preparation that seemed to abound with Katrina. I couldn't understand why masses of people didn't leave the area before the storms hit, and why it took so long for the federal government to respond to the needs of American citizens. Those people who tried to leave found themselves delayed by the slowly moving parking lots that had once been interstate freeways. Even with personal transportation, evacuation was difficult!

What seemed very clear after Katrina was that there are large numbers of poor and vulnerable people in this country; I had not been previously aware of this. Did you know that most of those who died were poor and Black? This doesn't seem right; didn't we abolish segregation and advance civil rights? In our community health nursing class, we discussed vulnerable populations and read some articles about this disaster. We talked about health disparities. I had never really thought about that before, but it rings true to me now. Some groups of people have higher numbers of deaths and more problems with certain diseases than other groups. We do have different levels of health care for different groups, and some people can only access the health care system by coming to the ER.

I now have a better understanding of how things happened with Katrina. When you have little money, no reliable transportation, no extended support systems, and inadequate information about an impending disaster, you are vulnerable and at the mercy of government systems that often cannot respond quickly. I often wonder how I would fare if something happened suddenly, and I couldn't access cash from my bank account, or my car was low on gas, and I hadn't bought groceries in a couple of weeks. Would I be able to survive a natural disaster like an earthquake? I have family close by and many friends, some in nursing school, who could help me. That makes me less vulnerable, but I still should do a better job of being prepared.

*Brooke, Nursing Student*

**FIGURE 25.2** Percent distribution of *Healthy People 2010* objectives and subobjectives by size of disparity for income groups at the most recent data point. Adapted from [http://www.healthypeople.gov/Data/midcourse/pdf/Executive\\_Summary.pdf](http://www.healthypeople.gov/Data/midcourse/pdf/Executive_Summary.pdf), Figure 13.

indicate that disparities in access to health care and sometimes health outcomes, independent of SES or race, are often found in uninsured populations (Haas & Adler, 2001).

A 2003 study found that at least 16 million Americans with health insurance could be classified as underinsured (Mahon, 2005). When that number is added to the uninsured population, at least 63 million of a total population of over 300 million people could be characterized as vulnerable (Hellander, 2006).

How does having inadequate or no health insurance lead to poor health outcomes? As explained in Chapter 6, those with few or no resources in this area do not utilize early screenings and preventive measures, and they delay getting treatment in an effort to save money. Because they don't often have regular health checks, they may lack a medical "home" or a consistent health care provider (Collins, 2007). Many utilize emergency rooms or urgent care facilities when their conditions worsen, and they have no real continuity of care (Davis, 2003). They only receive care for the problem at hand, and not always for underlying causes. They do not get regular physical examinations and may be inadequately immunized against common diseases. Thus, they are at risk for poorer general health as well (Himmelstein, Warren, Thorne, & Woolhandler, 2005). Also, when examination and subsequent treatment are delayed, diseases such as cancer or cardiovascular illness may result in earlier death.

## Race and Ethnicity

The United States is a multiracial, multiethnic country. About one-third of the population belongs to a racial or ethnic minority group, and this proportion will continue to increase, as currently “45% of children under the age of 5 are minorities” (Population Reference Bureau, 2006, p. 1). Hispanics represent the largest minority group (about half of the 98 million total), and they are also the fastest-growing group, with a fertility rate of 2.80; the rate for non-Hispanic Whites is 1.85 (Haub, 2006). Blacks (13.3%), Asians (<5%), American Indians/Alaska Natives (1.5%), and Hawaiians/Pacific Islanders (<1%) also contribute to this minority population growth (Population Reference Bureau, 2006; U.S. Census Bureau, 2007).

Considering Hispanics alone, over 100 million Americans could potentially be part of a vulnerable group (U.S. Census Bureau, 2007). According to all major indicators of health, Hispanics, Blacks, and Native Americans are “more likely to be in poor health than are majority Whites” (Aday, 2001, p. 56). Although infant mortality, substance use and abuse, and HIV/AIDS prevalence, however, are lower for Asians overall, some Asians—most notably Southeast Asians—have poorer morbidity and mortality rates (Aday, 2001). Blacks and Hispanics report higher levels of metabolic and vascular diseases, as well as cognitive impairment (Crimmins, Hayward, & Seeman, 2004).

In 2005, Blacks represented 12.3% of the population, but they accounted for 40% of the total AIDS cases since the epidemic began in this country in 1981 (Andriote, 2005). Hispanics report higher incidences of diabetes, but are more often found to be obese—a condition that is linked closely with type 2 diabetes (Crimmins et al., 2004; Bulatao & Anderson, 2004). A recent study found an increased incidence of pulmonary embolism for Blacks, but no differences in hospital fatality rates (Schneider, Lilienfeld, & Im, 2006), whereas no racial or ethnic differences were noted in a study of interventions post myocardial infarction (Jacobi et al., 2007). Low birth weights and infant mortality are often more prevalent among Blacks (Nanyonjo, Montgomery, Modeste, & Fujimoto, 2007), and over a 15-year period, child mortality rates for Blacks and Hispanics have been consistently higher than those for Whites (Gitterman, 2001). Life expectancy for all minority races has been consistently lower than that of Whites since 1901. Life expectancy for Blacks was only 33.7 years in 1901, whereas for Whites it was 49.4 years—a difference of 15.7 years. The gap narrowed to 5.5 years by 2001, and to 4.7 years by 2004, but the racial/ethnic disparity still exists (Centers for Disease Control & Prevention [CDC], 2004, 2007).

Why does simply being a member of a racial/ethnic minority group make someone vulnerable? The reasons are complex and not well understood. Poorer health outcomes for Blacks have been attributed to cultural barriers, discrimination, and lack of access to appropriate health care (Evans, 2006). Some believe, as stated earlier, that race or ethnicity and poverty are related (Winkleby & Cubbin, 2004). But even when SES is controlled, racial disparities in health remain, especially among the Black population (Crimmins, Hayward, & Seeman, 2004; Chandra & Skinner, 2004). Some believe that the childhood experiences of the Black population may explain the disparity in mortality rates (Warner & Hayward, 2002) or that disparities may be related to differing cultural norms and values (Winkleby & Cubbin,

2004). Recent immigrants (i.e., foreign-born Mexican Americans) have healthier exercise and dietary patterns than those born inside the United States (Winkleby & Cubbin, 2004). Others note the generational link between minority group membership and low educational attainment (e.g., father’s education level), and the tie between education and health (Crimmins, Hayward, & Seeman, 2004). A majority of Hispanics and Blacks have spent a lifetime at a lower level of educational attainment.

In examining racial and ethnic differences in the health of older people, Bulatao and Anderson (2004) note differential health and risk behaviors. For instance, Whites are less likely to get mammograms and Pap smears and more likely to smoke, whereas Blacks and Hispanics have more problems with obesity and report less physical activity or exercise. These differences in exercise were not explained by SES. Of note, health behaviors have been found to differ within racial and ethnic groups, especially by age, income, education, country of origin, and language spoken in the home. A high prevalence of unhealthy behaviors could be predicted for Hispanics born in the United States and/or those who spoke English when compared with Hispanics born in Mexico and/or speaking Spanish. They also differed by gender; women are more strongly affected than men, largely due to greater disparity in physical inactivity and obesity (Winkleby & Cubbin, 2004).

Some research has demonstrated racial differences in genetics that could offer an additional explanation for health disparities, whereas some subscribe to the mechanism of genetic risk and environmental risk exposure (Olden & White, 2005). Racial and ethnic genetic predisposition for disease development may be set in play by environmental triggers. Because multiple risk factors may react in a synergistic manner to cause disease, research is lacking to fully explain or predict this possible phenomenon. However, large, randomized trials have shown “race-specific drug response differences between Blacks and Whites” (p. 721).

Whatever the mechanism causing vulnerability among racial and ethnic groups, no one questions the difficulties they experience in accessing quality health care services (see *Healthy People 2010—Health Disparities by Race/Ethnicity*, Fig. 25.3).

## VULNERABILITY AND INEQUALITY IN HEALTH CARE

### Social Determinants of Health

Commonly acknowledged conditions (e.g., economic, social, environmental, genetic) are often associated with health outcomes, and are known as **social determinants of health**. The unequal distribution of these conditions among certain groups is thought to contribute to “persistent and pervasive health disparities” (Baker, Metzler, & Galea, 2005, p. 553). When we try to address health disparities, we must consider these social determinants and work on all levels—individual, aggregate, and population—to reduce them (Marmot & Wilkinson, 2006). For instance, most will acknowledge that a safe and nourishing diet is needed to be healthy. Safe and accessible drinking water is also required, as are adequate housing, a supportive environment, and appropriate levels of exercise. Political resources and social structures can also influence health, and “multiple

### Characteristics: Race and Ethnicity

Population-based objectives	American Indian or Alaska Native	Asian	Native Hawaiian or other Pacific Islander	Two or more races	Hispanic or Latino	Black non-Hispanic	White non-Hispanic	Summary index
1-1. Health insurance: < 65 years (1997, 2003)* <sup>1</sup>							B	
1-3a. Counseled about physical activity: 18+ years (2001)*						B		
1-3b. Counseled about diet and nutrition: 18+ years (2001)*						B		
1-3c. Counseled about smoking cessation: 18+ years (2001)*	b						B	
1-3d. Counseled about reduced alcohol consumption: 18+ years (2001)*						B		
1-3f. Counseled about unintended pregnancy: females 15-44 years (1995)†						B		
1-3h. Counseled about management of menopause: females 45-57 years (2001)*					B			
1-4a. Source of ongoing care: all ages (1998, 2003)* <sup>1</sup>					↑		B	
1-4b. Source of ongoing care: < 18 years (1998, 2003)* <sup>1</sup>						↑↑	B	
1-4c. Source of ongoing care: 18+ years (1998, 2003)* <sup>1</sup>					↑		B	
1-5. Usual primary care provider (1996, 1999)*		2	2				B	
1-6. Delays or difficulties in obtaining needed health care (1996, 1999)*	b	2	2			b	B

1-9b. Hospitalization for uncontrolled diabetes: 18-64 years (1996)†								
1-9c. Hospitalization for immunization-preventable pneumonia or influenza: 65+ years (1996)†								
1-10. Delay or difficulty in getting emergency care (2001)*							B	
1-15a. Access to home health care: 65+ years with long-term care needs (2001)*								
1-15b. Access to adult day care: 65+ years with long-term care needs (2001)*								
1-15c. Access to assisted living: 65+ years with long-term care needs (2001)*								
1-15d. Access to nursing home care: 65+ years with long-term care needs (2001)*								
1-16. Pressure ulcers: nursing home residents (1997, 1999)*								

**Notes:**  
 Data for objectives 1-3g, 1-7a through h, 1-8a through t, 1-11a through g, 1-12, 1-13a through i, and 1-14a and b are unavailable or not applicable. Objectives 1-2 and 1-3e were deleted at the midcourse.  
 Years in parentheses represent the baseline data year and the most recent data year (if available).

Disparity from the best group rate is defined as the percent difference between the best group rate and each of the other group rates for a characteristic (for example, race and ethnicity). The summary index is the average of these percent differences for a characteristic. Change in disparity is estimated by subtracting the disparity at baseline from the disparity at the most recent data point. Change in the summary index is estimated by subtracting the summary index at baseline from the summary index at the most recent data point. See Technical Appendix for more information.

The **best group rate** at the most recent data point.  B The group with the best rate for specified characteristic.  b Most favorable group rate for specified characteristic, but reliability criterion not met.  Best group rate reliability criterion not met.

#### Percent difference from the best group rate

**Disparity from the best group rate** at the most recent data point.  Less than 10 percent or not statistically significant  10-49 percent  50-99 percent  100 percent or more

**Changes in disparity** over time are shown when the change is greater than or equal to 10 percentage points and statistically significant, or when the change is greater than or equal to 10 percentage points and estimates of variability were not available.

**Increase in disparity (percentage points)**

↑ 10-49      ↑↑ 50-99      ↑↑↑ 100 or more

**Decrease in disparity (percentage points)**

↓ 10-49      ↓↓ 50-99      ↓↓↓ 100 or more

**Availability of data.**  Data not available.  Characteristic not selected for this objective.

\* The variability of best group rates was assessed, and disparities of ≥ 10% are statistically significant at the 0.05 level. Changes in disparity over time, noted with arrows, are statistically significant at the 0.05 level. See Technical Appendix.  
 † Measures of variability were not available. Thus, the variability of best group rates was not assessed, and the statistical significance of disparities and changes in disparity over time could not be tested. See Technical Appendix.  
<sup>1</sup> Baseline data by race and ethnicity are for 1999.  
<sup>2</sup> Data are for Asians or Pacific Islanders.  
<sup>3</sup> Baseline data only.  
<sup>4</sup> Median ZIP code income levels: \$25,000 or less, \$25,001-\$35,000, and more than \$35,000.

**FIGURE 25.3** Healthy People 2010: Health disparities by race/ethnicity. Adapted from <http://www.healthypeople.gov/Data/midcourse/html/tables/dt/DT-01a.htm>.

disadvantages and inequities are profoundly associated with poor health” (Baker, Metzler, & Galea, 2005, p. 554). Political and participatory action research are vital tools in reducing the effects of these conditions, as are methods of community empowerment (Metzler, 2007) (see Chapters 4 and 13).

In an effort to improve the health of disadvantaged groups, early public health efforts addressed social determinants of health, such as sanitation and poverty, along with living conditions and other environmental issues (Metzler, 2007). A quantitative tool, the Community Need Index, uses data on socioeconomic indicators that can lead to health disparity—income, education, housing, insurance coverage, and culture/language—and provides a score for each zip code in the United States (Roth & Barsi, 2005). This can be useful to researchers and policy makers, as well as PHNs. The present need to address underlying social conditions to improve health status is borne out by current research on race and socioeconomic class (Satcher, Fryer, McCann, Troutman, Woolf, & Rust, 2005; Isaacs & Schroeder, 2004). The federal government has acknowledged the need to improve social conditions that impact the health of our population:

*Healthy People 2010* recognizes that communities, states, and national organizations will need to take a multidisciplinary approach to achieving health equity—an approach that involves improving health, education, housing, labor, justice, transportation, agriculture, and the environment, as well as data collection itself. (U.S. Department of Health & Human Services, 2000, p. 16)

### Socioeconomic Gradient of Health

A series of large-scale, longitudinal studies in England, the now classic Whitehall studies, divided British civil servants into socioeconomic groups based upon their occupational status (e.g., executives to unskilled workers). What they discovered, over time, was an improvement in mortality and morbidity rates as the level of occupation and pay increased. Those at the lowest levels had the poorest health, but as they moved up the salary scale and occupational level, their health improved. What makes this so interesting is that all of the workers had basic health insurance coverage and free medical care—no real problems with access to health care existed. Even when the researchers adjusted for diet, exercise, and smoking, the gradient persisted, although it was less pronounced (Marmot, Ryff, Bumpass, Shipley, & Marks, 1997; Marmot et al., 1991). One of the studies found higher prevalence of heart disease for all participants at the lower end of the social stratus. It also found death rates for diabetic participants to be about 200% higher in the lowest social group when compared to the highest (Chaturvedi, 1998).

This inverse relationship between social class or income and health has been termed the **socioeconomic gradient**. It has been found in populations around the world, although not always unfaillingly, and has been related to poor health outcomes regarding incidence of stroke in Swedish women (Kuper, Adami, Theorell, & Weiderpass, 2007); diabetes morbidity and mortality in a multinational population (Chaturvedi, 1998); cancer mortality in U.S. males (Singh, Miller, Hankey, Feuer, & Pickle, 2002); South Korean adolescent mortality rates, especially by suicide, circulatory dis-

ease, and “transport accident death” (Cho, Khang, Yang, Harper, & Lynch, 2007, p. 50); disability and functional limitation in the U.S. population (Minkler, Fuller-Thomson, & Guralnik, 2006); chronic illness, such as diabetes, hypertension, mental problems, and respiratory diseases in Australia (Glover, Hetzel, & Tennant, 2004); and mortality from acute myocardial infarction in industrialized countries (Alboni, Amadei, Scarfo, Bettioli, Ippolito, & Baggioni, 2003).

The socioeconomic gradient has also been noted in behaviors such as smoking—it is highest among those who are from the working class and who have low income and low educational levels (Barbeau, Krieger, & Soobader, 2004). The gradient is also apparent in studies of hospital deaths. Hospital mortality rates in England and Wales among low SES patients admitted for elective surgery demonstrated a statistically significant difference from those of higher SES patients (Hutchings, Raine, Brady, Wildman, & Rowan, 2004). Low birth weights and breast-feeding also demonstrate a socioeconomic gradient. Lower levels of education and income are associated with higher rates of low birth weight, while those at the higher levels of occupation and income are more likely to breast-feed their infants than those at the lower levels (Finch, 2003; Heck, Braveman, Cubbin, Chavez, & Kiely, 2006). The differences between high and low social and economic groups can be viewed as a disparity in health outcomes.

### Health Disparities

One definition of **health disparity** is a “chain of events signified by a difference in: (1) environment, (2) access to, utilization of, and quality of care, (3) health status, or (4) a particular health outcome that deserves scrutiny” (Carter-Porras & Baquet, 2002, p. 427). Health disparities may be unavoidable, such as health-damaging behaviors that are chosen by an individual despite health education and counseling efforts, but most are thought to be due to inequities than can be corrected (Carter-Porras & Baquet, 2002). A long-held belief about health inequities adopted by the World Health Organization (WHO) is that health differences that are avoidable and unnecessary are patently unfair and unjust (Whitehead, 1991). Health disparities can be objectively viewed as a disproportionate burden of morbidity, disability, and mortality found in a specific portion of the population in contrast to another.

*Healthy People 2010* goals include increasing the quality and years of healthy life of Americans, along with the elimination of health disparities among segments of our population (U.S. Department of Health and Human Services, 2000.) However, some overall progress has been made on the first goal; many feel it has been at the expense of the second, and encourage a more focused approach to eliminating health disparities (Keppel, Bilheimer, & Gurley, 2007). The 2006 *National Health Care Disparities Report* reveals that disparities “remain prevalent” and that, while some disparities are decreasing, others are increasing (AHRQ, 2006, p. 2). Reported disparities exist in the areas of quality of health care, access to care, levels and types of care, and care settings; they exist within subpopulations (e.g., elderly, women, children, rural residents, disabled) and across clinical conditions.

Poor access to quality care and overt discrimination are examples of disparities under investigation (Williams & Jackson, 2005). Discrimination can occur during service

delivery if health care providers are biased against a specific group or hold stereotypical beliefs about that group. Providers may also not be confident about providing care for a racial or ethnic group with which they are unfamiliar. Language may be a problem, as can cultural values and norms that are unfamiliar to providers. Patients can also react to providers in a way that promotes disparities; they may not trust the information given to them and may not follow it as explained, leading to inadequate care (IOM, 2003). A survey conducted in 2006 found that in a large sample of over 4,000 U.S. adults from 14 racial and ethnic groups, many of the minority respondents viewed their health care as more negative than the care received by Whites. A good number of them reported discrimination in the health care setting, and did not think that they would be able to receive the best care if they became ill. These differences persisted despite controlling for socioeconomic variables, although a good deal of variation occurred across the racial and ethnic groups (Blendon, et al., 2007). Another study involving “severely disadvantaged people with HIV infection” found that almost 40% reported “experiencing discrimination in the health care system” (Sohler, Li, & Cunningham, 2007, p. 347). Higher perceived discrimination was associated with HIV infection, homelessness, drug use, and race/ethnicity, emphasizing the perceived poor quality of care and difficulties with access to care.

## Access to Care

The Institute of Medicine’s (IOM, 2003) *Unequal Treatment: Confronting Racial and Ethnic Disparities in Health Care* noted a large body of research highlighting the higher morbidity and mortality rates among all racial and ethnic minority groups when compared to Whites. Differences in health care access were also explained—be it in the form of inadequate or no health insurance, problems getting health care, the quality of that care, fewer choices in where to go for care, or the lack of a regular health care provider. For instance, there are fewer numbers of health care providers in minority neighborhoods and thus it is more difficult for those living in these areas to find a medical home. Often, sufficient transportation is not available or clinic hours may be unrealistic for individuals working long hours (IOM, 2003).

Residential segregation, although illegal, still exists and can play a role in health disparities; people of color often live in poorer areas where alcohol and tobacco are more heavily marketed (Williams & Jackson, 2005). Many vulnerable populations, especially racial and ethnic minority groups and low-income populations, find health care at safety net hospitals and community clinics, where they are at the mercy of balanced budgets and vast bureaucratic systems (IOM, 2003). Other geographic factors can affect access to health care services (Coberley et al., 2007). For example, only 25% of pharmacies in non-White neighborhoods, compared with 72% in predominately White neighborhoods, stocked sufficient opioid drugs to meet the needs of palliative care patients in different New York neighborhoods (IOM, 2003). This lack of access to proper medication represents a disparity in health care. In a Canadian study (Lemstra, Neudorf, & Opondo, 2006), significantly different patterns of health care utilization were found in neighborhoods characterized as low income, and differences

were noted for a wide variety of conditions (e.g., all-cause mortality, coronary heart disease, diabetes, poisonings, and injuries). In 2004, a survey of medical directors at all federally qualified community health clinics revealed that it was more difficult for uninsured patients to obtain access to specialty services outside the clinics (e.g., diagnostic tests, referrals to specialists) than for Medicare and Medicaid patients or those with private health insurance (Cook et al., 2007).

Health care access is also problematic for other vulnerable groups. For example, services and resources for the mentally ill and substance abusers are often fragmented and inadequate, as are those for abusing families and homeless persons. Refugees and immigrants may have difficulty finding affordable and easily accessible health care, largely due to their lack of health insurance and the need to find care at free clinics or emergency rooms (Aday, 2001). When vulnerable individuals cannot get appropriate health care or treatment for illness or disease, for whatever reason, they are more likely to have health deficits.

## Quality of Care

Quality of care should result in an “increased likelihood of desired health outcomes” and should be “consistent with current professional knowledge” (IOM, 2003, p. 31). It can include such things as patient safety issues, timeliness and effectiveness of patient care, and patient centeredness (AHRQ, 2006). Research indicates that racial and ethnic minority clients feel more comfortable and satisfied with care from a health care provider who comes from the same racial and/or ethnic group (IOM, 2003). However, a shortage of ethnically diverse health care providers exists. Despite racial and ethnic minorities comprising 28% of the U.S. population, less than 10% of registered nurses (RNs) represent these same minorities (National Advisory Council on Nurse Education & Practice, 2000).

Lack of access to quality health care services is common among racial and ethnic minority groups. In examining racial disparities in diabetes care, researchers noted that the differences in receipt of eye examinations was most likely due to Blacks receiving care at “lower-performing facilities” (Heisler, Smith, Hayward, Krein, & Kerr, 2003, p. 1221). Other measures, like poor control of hypertension and cholesterol, were thought to be due to disparities in care within the same facilities as Whites and not an indication of the inadequacies of the health care agency.

Communication can be a widespread factor in poor quality of care (Yeo, 2004). A recent study reported between 24% and 36% of low-income parents of children felt that the communication they had with their child’s health care provider in a Spanish interview was “poor” (Clemans-Cope & Kenney, 2007, p. 206). Marginalized vulnerable populations, such as substance abusers, at-risk mothers and infants, abusing families, suicide- and homicide-prone individuals, and the mentally ill or disabled may feel that they are treated as “second class citizens,” and cultural barriers and misunderstandings can lead to a discontinuation of recommended regimens. Poor health outcomes may result, as effectiveness of health care for vulnerable populations is not often considered or even well defined (Aday, 2001; Nanyonjo, Montgomery, Modeste, & Fujimoto, 2007).

## WORKING WITH VULNERABLE POPULATIONS

### The Role of Public Health Nurses

Historically, community and public health nurses have focused their efforts on the most vulnerable populations. In Lillian Wald’s time, PHNs worked and lived among the tenements (see Chapter 2). Today, most PHNs travel a good distance to reach the homes of vulnerable clients, knowing that they can leave and go back to their comfortable circumstances when they choose to do so. Coming from various different circumstances, some nursing students feel unsure and insecure when going into certain areas of the community, and not everyone is comfortable working with vulnerable populations (Martino-Maze, 2005, 2006). Research has demonstrated that clinical work with vulnerable populations helps nursing students become more aware of inequities and promotes critical engagement and a commitment to social change (Reimer-Kirkham, Van Hofwegen, & Hoe-Harwood, 2005). Recognizing that demeaning or dehumanizing behaviors or language directed toward clients or neighborhoods exemplifies disrespect and is often fear-based, helps us all to focus our efforts (see Fig. 25.4). One PHN succinctly described this fear:

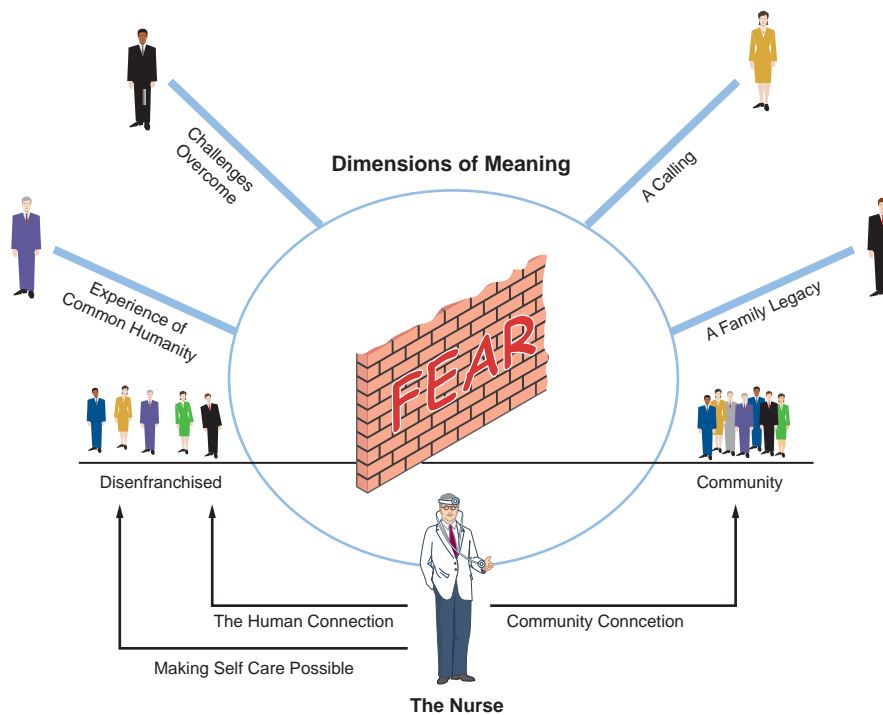

All of us, at some level, have a fear of the disenfranchised, whether it’s because we could be in that place or because there may be potential harm to us. But I seek to break that fear and see someone as a human. The more I work with her, the more I see her as human (Zerwekh, 2000, p. 47).

Working with vulnerable clients is an important component of students’ clinical experiences, and necessary to better

understand client circumstances and needs, as well as to be competent as nurses. What then is the PHN’s role, and how can we be most effective when working with vulnerable groups?

### Effective Caring

Our goal for clients is to help them develop their capabilities to “take charge of their own lives and make their own choices” by helping them identify all possible choices, guiding them to think through all of the issues and possible consequences, providing honest feedback, and affirming their reality (Zerwekh, 2000, p. 48). This can be challenging when working with the most vulnerable clients, as they are often the most disenfranchised and fearful of others. One nurse described vulnerable individuals as being behind a locked door—“the door is shut and you can’t get back in” (Zerwekh, 2000, p. 50). Opening that door is the first step to working effectively with these clients. Engagement and development of rapport are essential. Because vulnerability often equates with feelings of powerlessness, the actions of community health nurses can either promote engagement or destroy any chances for rapport. A Canadian study found three phases of PHN–client engagement: getting past the fear, working to build trust, and “seeking mutuality” (Jack, DiCenso, & Lohfeld, 2005, p. 182). The personal values, experiences, characteristics, and actions of both nurses and clients influenced the speed at which this process took place and the eventual level of connection. Helping clients identify their fears and clearly defining the PHN role with the client and family were also important. Earlier research described the process as “finding common ground” and “building trust” (Jack, DiCenso, & Lohfeld, 2002, p. 59).

**FIGURE 25.4** Breaking through the wall. Fearless caring with separated and often frightened clients has 10 themes that can be organized into three meta-themes: the Human Connection, the Community Connection, and Making Self-Care Possible. The nurse goes around the separating wall of fear. Adapted from Zerwekh, J. (2000). Caring on the ragged edge: Nursing persons who are disenfranchised. *Advances in Nursing Science*, 22(4), 47–61.

In a small qualitative study of expert PHNs with proven experience and a degree of success in working with disenfranchised populations, Zerwekh (2000) found three overarching themes—*human connection*, *community connection*, and *making self-care possible*. Those PHNs who can see the worth of clients as human beings and share their own humanity by expressing themselves and staying connected were part of the main theme of *human connection*. Another important component was becoming familiar with a client by learning about his past, his patterns, and the most effective means of communicating with him to draw him out. For the theme of *community connection*, subthemes of connecting clients to each other and to the community, as well as mediating bureaucratic red tape and occasionally making exceptions, were foremost, as was “haunting the case” or being a persistent advocate to get the client’s needs met (p. 57). The meta-theme of *making self-care possible* was characterized by “getting them through emotionally” (p. 59), or being able to listen to and counsel clients who are often on the edge with their emotions (e.g., fear, anger). Additional components of this theme include teaching clients to have self-awareness and to better understand their bodies and their feelings, and coaching them to take control and foster their strengths. Confronting fear at the community level was another subtheme, as PHNs worked to break down barriers and work through longstanding prejudices and fears. Some authors believe that advocacy for vulnerable populations is an ethical responsibility for nurses who may need to help individuals and families find needed assistance (Erlen, 2006).

Working with disadvantaged populations can be challenging and exhausting, and the psychic distress should be “anticipated and addressed” (Beidler, 2005, p. 759; Beauchesne & Patsdaughter, 2005). Often, novice community health nurses feel overwhelmed and suffer “compassion fatigue” when confronted with the crushing realities that their vulnerable, disenfranchised clients face on a daily basis (p. 53). Feelings of guilt sometimes surface when nurses contrast their own life experiences with those of their clients. To be effective in working with vulnerable populations, it is often more helpful to donate money and items on a group level rather than an individual level, and to work for substantial changes in community attitudes. Also, it is vital to remain grounded in order to continue to have the necessary energy and compassion.

### Empowerment

Chapter 13 discusses the concept of empowerment and applies it to the PHN role when working with communities. When dealing with individual clients, empowerment is defined as “an active, internal process of growth” that is reached by actualizing the full potential inherent within each client and occurring “within the context of a nurturing nurse–client relationship” (Falk-Raphael, 2001, p. 4). Public health nurses describe the process of empowerment as a two-way street, with clients gaining knowledge and skills and “acting on informed choices,” but also further empowering the nurse to continue the work of empowerment (p. 6). In Paulo Freire’s (1993) *Pedagogy of the Oppressed*, this reciprocity is explained as he notes that the oppressed (or vulnerable) liberate themselves as well as those who may oppress them (or the more advantaged members of society).

What community health nursing activities or actions are most effective in promoting empowerment among their

vulnerable clients? In Falk-Raphael’s (2001) qualitative study of PHNs and their clients, several themes were noted:

- ◆ *Having a client-centered approach*, denoted by flexibility in dealing with clients (e.g., “meeting them where they are”; “communicating at their level”; “backing off and following client’s agenda,” p. 6)
- ◆ *Developing a trusting relationship* based on mutual respect and dignity (e.g., clients as active partners with the PHN assuming more or less responsibility as needed; being empathetic, nonjudgmental, and “creating a safe environment,” p. 7)
- ◆ *Employing advocacy*, both at an individual level as well as political advocacy (e.g., using their role and power as a professional to cut through bureaucratic red tape, connecting clients with available community resources, supporting clients in reaching their health goals, making their expertise available, and being a client resource as someone who is open and “available,” p. 8)
- ◆ *Being a teacher and role model*, using a variety of strategies and providing opportunities for clients to safely practice new skills (e.g., teaching classes, providing individual coaching, providing positive reinforcement and support, demonstrating skills such as assertiveness and community action/ participation)
- ◆ *Capacity building* through encouraging and supporting of clients’ work toward attainment of health goals (e.g., “reflective listening and an empathetic approach” focusing on strengths, not limitations; facilitating client “self-exploration” and providing encouragement for them to “act on their choices” while being “realistic about barriers to success;” or having expectations for client accountability regarding their decisions and actions (p. 9)

Outcomes of empowerment for clients included increased self-esteem and confidence, improved self-efficacy, and the ability to “reframe situations in a positive way” (p. 10). Clients also subsequently made better choices regarding their health and utilized resources more appropriately. They were better able to seek information and services, and became more politically active. Their focus became more proactive than reactive, and they felt that they could communicate more effectively to define boundaries or express feelings. Consequently, clients were also better able to collaborate with their health care providers, becoming more trusting partners in care by “taking ownership for their health” (p. 10). Some clients noted a newfound ability to see their communities in a more holistic way and looked for ways to change things for the better.

### Making a Difference

Social scientists often frame the topic of vulnerability and risk by examining protective factors and resiliency at an individual level (McGee, 2006). **Resilience** is the ability to “bounce back” or recover from life’s stressors without permanent injury. Some at-risk individuals fare better than others, but much of the research conducted on resiliency has dealt with life outcomes, not necessarily health (Gitterman, 2001). External support, along with temperament and other individual factors, has been associated with resiliency. This support can be

from neighbors, friends, teachers, or others. Public health nurses can provide external support at both the individual and population levels (see Perspectives: Voices from the Community). For example, research has shown the effectiveness of social support, provided by nurses and health visitors, in promoting consistent program participation and positive social and health outcomes among low-income pregnant women (Shepard, Williams, & Richardson, 2004). Nurse visitation and support can also “successfully address informational needs and increase the likelihood that women will use existing community-based resources” (Tough, et al., 2006, p. 183).

Community health nurses can assist vulnerable individuals through “difficult life transitions” or stressful events (Gitterman, 2001, p. 23). They can also work as neighborhood nurses, becoming familiar with the community’s resources and strengths. Through work with individual clients, PHNs can expand their empowerment strategies to serve the community. Being aware of the “pulse of the community” is vital, and can be accomplished not only through home visits but by attending community-level meetings and through the development of partnerships organized around specific health issues or community problems (SmithBattle, Diekemper, & Drake, 1999, p. 219). Community collaboratives can be formed, especially in areas with high-risk vulnerable populations, to address needs identified by the members of that community (Campbell-Grossman, Brage-Hudson, Keating-Lefler, & Ofe-Fleck, 2005). Early detection of problems at the community level can lead to the development of programs and services to provide early

intervention and avert costly tertiary care (Penprase, 2006; Salinsky & Gursky, 2006), or to proactively meet the needs of specific groups, such as low-income elderly (Artis, 2005).

To make a difference in the lives of vulnerable individuals, families, and communities, the community health nurse may need to reexamine the way in which public health nursing services are organized and delivered. To be effective in decreasing and eliminating health disparities, innovative and uncharted approaches may be necessary (Pritchard & de-Verteuil, 2007), and political advocacy to influence health policy should become a component of community health nursing practice (SmithBattle, Diekemper, & Drake, 1999; Salinsky & Gursky, 2006; Falk-Raphael, 2005). For example, because of the long-researched, strong connection between education and health outcomes noted in many classic studies (Marmot, Ryff, Bumpass, Shipley, & Marks, 1997), nurses and other public health professionals could become engaged with schools to reduce dropout rates and promote school completion by raising public awareness, organizing task forces, studying the reciprocity between health and school achievement, supporting school-based health education and quality teachers, and advocating for evidence-based practice (EBP) to improve dropout rates (Freudenberg & Ruglis, 2007).

## Conducting Research with Vulnerable Populations

Until fairly recently, research studies were most often conducted utilizing middle-class, majority populations (IOM,

### PERSPECTIVES VOICES FROM THE COMMUNITY

#### A View of Katrina’s Aftermath—Nurse Volunteer

I had never been a Red Cross volunteer before, but Katrina touched my heart and I signed up. Suddenly I was headed to New Orleans to help in a shelter. The sheer numbers of people streaming into the shelter astounded me—people who had lost everything. Some of these people had waited on housetops to be rescued. Others had walked for hours to reach the shelter. A common theme among them was their vulnerability. Many were members of vulnerable populations even before Katrina struck.

At first, most were relieved to be safe and dry. However, that changed as they realized what they had lost and how uncertain their futures were. Many of the older people and those with chronic illnesses had significant health problems that worsened while they were residents of the shelter. Although they were provided with food, it was sometimes difficult for them to get the exact food they needed for their special diets. Some of them did not have all of their medications, and it took some time to complete health histories and secure necessary prescriptions. The weather was very muggy and hot, and there was little privacy. Even though the governor had called out the National Guard, people had to protect their few belongings, as theft was rampant. Toilet and bathing facilities were inadequate,

space was limited, and fights often broke out between people who had been pushed to the limits of their composure.

People had to show identification in order to apply for emergency loans or to receive other assistance. Some of them had lost all documents in the flooding, or had lost things on the way to the shelter. Standing in line was physically difficult for many people, but lines were long and standing was necessary in order to get assistance.

Many people were displaced, and a good number of them were separated from their families and friends, with no idea whether they were dead or alive. It was difficult to reconnect people, as individuals were evacuated to diverse locations. Communication was often a problem until phone lines and cell towers were back up and running.

I was there to help and to listen and provide care, but sometimes I felt frustrated and ineffective. I wanted to advocate for people and improve on systems of care, but this was almost impossible in such an erratic and crisis-driven system. Better systems need to be in place before the next disaster strikes, especially for the most vulnerable. All in all, it was a rewarding experience, and I was able to make a difference for some people on an individual basis. But there were so many who needed significant and long-term assistance!

*Helena, RN, PHN, Red Cross Volunteer*

Adapted from Saunders, J. (2007). Vulnerable populations in an American Red Cross shelter after hurricane Katrina. *Perspectives in Psychiatric Care*, 43(1), 30–37.

2003). Vulnerable groups, such as racially and ethnically diverse populations or even women, were often excluded from mainstream research. The focus has changed, and now there is a recognized need for research into the mechanisms of health disparities among diverse populations. However, even when federal regulations called for inclusion of “special populations” in the 1990s, they required adherence to strict guidelines that sometimes discouraged researchers (Meaux & Bell, 2001, p. 241). This paternalistic stance denied many vulnerable groups access to the “benefits of research by ‘protecting’ them” (List, 2005, p. 54). To more equitably distribute information about effective treatments and EBP, it is important to investigate broadly and to include disadvantaged and disenfranchised individuals in current research studies and trials (Rogers, 2004).

Researchers interested in working with vulnerable populations perform a balancing act between accessing or recruiting vulnerable populations and protecting them (Meaux & Bell, 2001). Institutional Review Boards must always be utilized (see Chapter 4), and vulnerable populations (e.g., children, prisoners/other institutionalized individuals, mentally/emotionally/physically disabled persons, pregnant women/ fetuses) require greater scrutiny and additional procedures (Polit & Beck, 2005). Ruof (2004) notes that special justifications are required when including vulnerable individuals or groups as research subjects in order to protect against potential human rights abuses. The *Annual Review of Nursing Research* (Fitzpatrick, Nyamathi, & Koniak-Griffin, 2007) highlights the state of nursing science with regard to research with vulnerable populations and the promotion of health disparities studies, as well as culturally appropriated interventions.

Because of the various restraints related to conducting research studies and the categorical nature of many research-oriented grants, research with vulnerable populations is often fragmented and isolated rather than interdisciplinary in nature, and thus it often fails to produce a clear picture (Aday, 2001). Ethical issues are often raised when research is conducted, especially with vulnerable populations (Beattie & VandenBosch, 2007). Questions concerning the ethical principles of autonomy, beneficence, and justice must be addressed. Research with vulnerable populations is carefully examined and generally requires a full review by all members of an institutional review board. The board examines the invasiveness of the study and the risk–benefit ratio. They also review the need for informed consents (Baren & Fish, 2005), the inducements that may be offered to participants (e.g., money), and any perception of coercion or undue influence over prospective participants (Singer & Bossarte, 2006). This is especially important with children and others who are not able to choose freely or may easily be coerced to participate (Lynn & Nelson, 2005; Locher, Bronstein, Robinson, Williams, & Ritchie, 2006).

Because public health agencies are continually collecting data in the capacity of evaluation and monitoring health status of populations, surveillance (e.g., reporting of certain diseases), and epidemiologic investigations (e.g., disease outbreaks, epidemics)—most often involving diverse vulnerable populations—it is especially necessary for them to delineate between these public health functions and research involving actual human subjects that should be evaluated by an institutional review board (Hodge, 2005). Most public health research deals with information applied to specific geographic

populations, with the aim of benefiting that community, while human subjects research contributes to testing hypotheses that contribute to more “generalizable knowledge” (p. 127).

### Participatory Action Research

Community-based participatory research or **participatory action research** (PAR) is often used among vulnerable populations around the world because it calls upon the expertise and perspectives of the community in identifying needs and developing appropriate interventions (Dickson & Green, 2001; Etowa, Thomas-Bernard, Oyinsan, & Clow, 2007; Schrader-McMillan, 2007). It is an iterative, cyclical process of problem identification and problem solving using reflection and analysis that empowers vulnerable disadvantaged people to effect change in their neighborhoods. It may begin with an investigator posing a research question to a group of individuals from a selected community. Feedback is given, and more information or data may be gathered and then collectively analyzed; this analysis becomes the basis for further actions. As interventions are suggested and community action moves forward, the community members are viewed as co-researchers and are invested in the outcomes and results. Corbett, Francis, and Chapman (2007) identify three main components of PAR:

- ◆ Problem inquiry
- ◆ Organization of participants
- ◆ Awareness and action

They also note the success of this research method with vulnerable groups such as immigrants/refugees, oppressed women, mentally ill or disabled individuals, and rural or inner-city poor, and in examining issues related to education, health, housing, and community development.

One example of the use of this research method was a study to engage at-risk adolescents in organizational change at two youth-serving government agencies (Schulman, 2006). Researchers and adolescent participants worked “as one” to “disrupt the status quo and spark social change” (p. 28). Discussion groups, journals, review of documents, and structured interviews were utilized to answer research questions about youth engagement and how well the two agencies incorporated that concept. Data were analyzed and key elements were identified and shared with the agencies, so that changes could be initiated. One outcome of the study was continued engagement of adolescent participants in social planning and agency programs.

Public health nurses are natural choices for involvement in PAR. Visibility and credibility in disadvantaged communities provide entrée for PHNs who may wish to partner with agency or university researchers wanting to engage vulnerable populations and address social justice facets of health disparities, but needing assistance in making the study operational (Malone, Yerger, McGruder, & Froelicher, 2006). The PHN’s connections to vulnerable populations may provide ideas or suggest areas requiring further research and intervention.

### Summary

Vulnerable populations are at a higher risk of poor health outcomes. Various models or theoretical frameworks examine personal and environmental resources and risks relative to vulnerability. Vulnerability is associated with increased

risk for morbidity and mortality. Vulnerable groups can include chronically ill or disabled, high-risk mothers and infants, those with HIV/AIDS, and the mentally ill or disabled. Alcohol and substance abusers, the suicide and homicide prone, the homeless, abusing families, and immigrants or refugees can also be characterized as vulnerable. Poverty, age, gender, and race or ethnicity can also constitute vulnerability, as can being uninsured or underinsured, a single parent, and those with little or no education.

It is difficult to calculate the exact numbers of Americans who are members of vulnerable groups, largely because of the overlap in populations, but it involves a significant proportion of the total population. Low-income status is often associated with underinsurance or race and ethnicity, and may also be related to homelessness and high-risk births.

Social determinants of health are commonly associated with health outcomes. Such things as economic, social, environmental, and genetic factors are considered social determinants of health. The socioeconomic gradient—an inverse relationship between social class/income, and health—has been repeatedly demonstrated in research conducted around the world.

Health disparities are defined as differences in access to quality health care and health outcomes, and are usually characterized as avoidable and unfair. One of the two main goals of *Healthy People 2010* is to decrease health disparities; however, this outcome has not been as successful as increasing life expectancy. Many disparities occur along income/class or racial/ethnic lines. A good deal of research is under way to determine more specifically the causes and consequences of health disparities.

Community health nurses often work with vulnerable populations, and nurses must learn to break through barriers of fear—their own and that of their clients. To be effective, PHNs must establish a sense of trust and rapport with their clients by finding common ground. Connecting with clients and connecting clients to the community and its available resources are key factors in successful PHN–client relationships. Coaching and mentoring clients to solve their own problems and make necessary changes are also effective behaviors of community health nurses.

Empowerment strategies with individual clients can help them to meet their full potential, while also providing empowerment to the nurses working with them. Flexible, client-centered approaches, based on trust and mutual respect, have been found to be most effective. A nonjudgmental attitude and openness with clients lays the foundation for development of mentoring relationship. Public health nurses who work at empowering clients are advocates at the individual as well as political levels. They are a resource to clients without being paternalistic. They provide a safe place for clients to try to out skills and demonstrate new, healthier behaviors. They build capacity through active, reflective, empathetic listening, and serve as role models and teachers. Empowered clients have greater self-confidence and are better able to collaborate with health care providers. Often, they become more engaged with their communities and neighborhoods.

Resiliency, or the ability to recover from the stressors of life, can be accentuated by external support from friends, teachers, or nurses. Community health nurses can provide individual support as well as support and leadership in vulnerable communities. Political action can involve not only health policy issues, but political activism on the part of

underserved populations to improve housing, education, and employment.

Vulnerable populations research may involve stricter guidelines and closer scrutiny from institutional review boards because of ethical considerations. Research with vulnerable populations may provide better treatments and health outcomes, and should be encouraged. Public health nurses may serve as a liaison between academic or agency investigators and vulnerable populations in the communities they serve. It is important to note the difference between public health functions (e.g., surveillance, epidemiologic studies) and human subjects research. Many public health agencies conduct studies of their programs and practices within a confined geographic area, to improve care for the populations they serve. These do not always require permission from institutional review boards.

Participatory action research (PAR) is often used with vulnerable populations, as it draws them into the research process. They join as partners with the investigators in assessing the needs of the community and designing interventions or marshalling resources for change.

This chapter covered some basic information about the role of the community health nurse when serving vulnerable populations. Other chapters in this section will deal with specific vulnerable groups. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Identify at least four vulnerable groups within your community. Using the Flaskerud and Winslow (1998) model depicted in this chapter, determine the health status for each of these groups. Describe the relative risk for each group.
2. Find available community resources for each of the identified groups. Where are they located? How easily accessible are they? What outreach services do they provide for the vulnerable population they serve? Describe some socioeconomic resources—what areas are most deficient?
3. Pick a client from your community health nursing clinical assignment. In a respectful way, discuss your fears of working in the community and ask about any fears they may have experienced in permitting you access to their home. Outline ways in which you could build upon this mutual sharing to achieve mutual trust and rapport.
4. Talk to two expert PHNs and discuss with them the concept of empowerment. What strategies have they used with clients? Ask them to each share an example in which they felt that they made a real difference in the lives of their clients.
5. Locate a community collaborative that is addressing the needs of vulnerable groups in your community. Who are the members? Note the agencies represented. Are there any community members present? If possible, attend a meeting and determine the types of issues being discussed. Is there a sense of community involvement and participation?

# Clients with Disabilities and Chronic Illnesses

## LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Discuss the national and global implications of disability and chronic illness.
- ◆ Describe the economic, social, and political factors affecting the well-being of individuals with disabilities and chronic illness.
- ◆ Provide an example of primary, secondary, and tertiary prevention practices for disabled individuals.
- ◆ Describe the Americans with Disabilities Act.
- ◆ Discuss the benefits of universal design for all persons.

*“It was ability that mattered, not disability, which is a word I’m not crazy about using.”*

—Marlee Matlin, Deaf Academy Award–Winning Actress

## KEY TERMS

Activity  
 Activity limitations  
 American Sign Language  
 Americans with Disabilities Act  
 Assistive devices and technology  
 Body functions  
 Body structures  
 Braille  
 Chronic disease  
 Disability  
 Environmental factors  
 Functioning  
 Handicap  
 Health promotion  
 Impairments  
 Participation  
 Participation restrictions  
 People with disabilities  
 Personal factors  
 Secondary conditions  
 Universal design

At some point in our lives, most of us will be diagnosed with a chronic illness or develop some type of disability. We may be lucky enough to get early diagnosis and treatment of our health conditions so that they can be easily managed. We might find ourselves temporarily incapacitated, unable to manage our daily lives, and needing assistance from others. We can hope our ability to resume more normal activities will return swiftly. An estimated 54 million Americans (almost 20% of the population) live with some ongoing level of disability (U.S. Department of Health and Human Services [USDHHS], 2005b). In 2006 alone, over 34 million persons reported limitations in their usual activities as the result of chronic conditions (USDHHS, 2008). The human costs associated with disabilities aside, the cost of direct medical care and indirect annual costs related to disability have reached almost \$300 million in the United States alone.

In the *Final Review of Healthy People 2000* (USDHHS, 2001), the rates of some disabling conditions, such as significant hearing and vision impairments, decreased between 1991 and 2000. The rates of many other conditions however, either remained stable or increased during that same decade. In the ensuing years, disabilities and chronic health conditions continued to pose significant personal and public costs. The results of the *Midcourse Review: Healthy People 2010* (USDHHS, 2005a) demonstrate both positive and negative changes in the first half of the present decade. Many findings continue to cause concern for health professionals. For instance, arthritis remains the leading cause of disability in the United States. It affects approximately 43 million individuals and more than 20% of the adult population. Asthma remains a national health concern for all ages, most particularly for those under 18 years of age, and represents one of the four most common causes of chronic illness in children. Although asthma death rates for persons over 65 years have declined, racial and ethnic disparities persist. End-stage renal disease continues to increase, with over 45% of all new cases attributed to type 2 diabetes. Back pain will impact the lives of a staggering 80% of all people, with risk factors including age, fitness level, race, ethnicity, and occupation. Osteoporosis is estimated to be present in 10% of all persons over the age of 50 (USDHHS, 2005a), with the additional risk of serious injury or death following a fall. The need to address health issues of disability and chronic illness is vital to the well-being of affected individuals and families and crucial to the financial health of the country.

This chapter discusses important and necessary health promotion and preventive efforts at every level. Although treatment of chronic conditions has long been a mainstay of health care in the United States and globally, limited attention has been paid to the additional health promotion required to maintain and improve overall well-being of individuals with chronic conditions. Nor has enough attention been directed to those same needs for people with physical or psychological disabilities. This chapter begins with an overview of disabilities and chronic illnesses, then discusses the current national and global trends in addressing these issues. The various organizations that focus on improving the well-being of those affected, the impact on families, and the role of the community health nurse in addressing the chronic

health care needs of individuals, families, and aggregates are discussed. The benefits of universal design and issues of easy access for all ages and abilities are also discussed.

## PERSPECTIVES ON DISABILITY, CHRONIC ILLNESS, AND HEALTH

What does the word *disabled* mean to you? What thoughts come to mind when you think about the word as it applies to an individual? It is defined in one dictionary as “the incapacity to do something because of a handicap—physical, mental, etc.” (Morehead & Morehead, 1995). Disability is linked with *inability*, which is defined as “the lack of ability to do something, whatever the reason, but usually through incompetence, weakness, lack of training, etc.” (Morehead & Morehead, 1995). **Handicap** is explained in the same volume as “any encumbrance or disadvantage.” **Chronic disease** is any illness that is prolonged, does not resolve spontaneously, and is rarely cured completely; these diseases are often preventable, and they pose a significant burden in terms of mortality, morbidity, and cost (Centers for Disease Control and Prevention [CDC], 2007). Each of these definitions provides a decidedly negative connotation, similar in nature to the typical societal view faced daily by people with disabilities.

Challenges differ from one individual to the next and require different degrees of accommodation. Fortunately, long-held negative views of disabled persons and their conditions are being replaced with new and more positive approaches that view individuals and their challenges from a more holistic standpoint.

### *International Classification of Functioning, Disability, and Health*

One such change in thinking about disability and chronic illness was expressed in *International Classification of Functioning, Disability, and Health* (ICF), published by the World Health Organization (WHO) in 2001. This document, the result of 5 years of work, replaced *International Classification of Impairments, Disabilities, and Handicaps* (ICIDH) (World Health Organization [WHO], 1980). Even the change in terminology in the title showed the dramatic shift in thinking by the World Health Assembly; both *impairments* and *handicaps* were removed. In the revised document, **disability** serves as a broad term for impairments, activity limitations, or participation restrictions. It is linked with **functioning**, a term that encompasses all body functions, activities, and participation.

The ICF was an attempt to provide a universal classification system with standardized language and a way to view the domains of health from a holistic vantage point. It took into account body functions and structures, activities and participation, environmental factors, and personal factors. This allows a multidimensional evaluation of an individual's circumstances in terms of functioning, disability, and health. Melding the “medical model” of health and health care for disabled persons with the “social model,” the ICF provided a biopsychosocial approach for assessing people with disabilities, emphasizing the observation that no two people with the same disease or disability have the same level of functioning.

The purpose of the ICF reaches far beyond simply categorizing the health status of people with disabilities. The specific aims of the document are (WHO, 2001, p. 5):

- ◆ Provide a scientific basis for understanding and studying health and health-related states, outcomes, and determinations
- ◆ Establish a common language for describing health and health-related states to improve communication between different users such as health care workers, researchers, policy makers, and the public, including people with disabilities
- ◆ Permit comparison of data across countries, health care disciplines, services, and time
- ◆ Provide a systematic coding scheme for health information systems

The document provides a roadmap for using the ICF, based on experience with the ICIDH for more than 20 years. Table 26.1 shows the current and potential uses of the document by various entities ranging from insurance companies and health care providers to policy makers and educators.

In addition to the just discussed definitions of disability and functioning, the following definitions serve to explain the ICF in terms of health (WHO, 2001, p. 10):

- ◆ **Body functions** are the physiologic functions of body systems and include psychological functions.
- ◆ **Body structures** are anatomic parts of the body such as organs, limbs, and their components.
- ◆ **Impairments** are problems in body function or structure, such as a significant deviation or loss.
- ◆ **Activity** is the execution of a task or action by an individual.

- ◆ **Participation** is involvement in a life situation, including personal and interpersonal roles and activities.
- ◆ **Activity limitations** are difficulties an individual may have in executing activities.
- ◆ **Participation restrictions** are problems an individual may experience when involved in life situations.
- ◆ **Environmental factors** make up the physical, social, and attitudinal environments in which people live and conduct their lives.
- ◆ **Personal factors** are the features of an individual's background, life, and living that are not part of a health condition or health status, such as gender, race, age, other health conditions, fitness, lifestyle habits, upbringing, coping styles, social background, education, profession, past and current experience, overall behavior pattern and character style, individual psychological assets, and other characteristics—all or any of which may play a role in disability at any level.

For the community health nurse, the ICF facilitates assessment of an individual client based on a wide range of factors. Disability or disease is just one factor to be considered in planning and implementing a care plan for clients in the community. Two individuals may have the same disability, such as a below-the-knee amputation, but their health and well-being can be quite different. One may have a more positive outlook, one may have more social support than the other, or one may suffer more than the other from additional health issues that impede rehabilitation. The community health nurse must always consider the totality of the situation, including the biologic, psychological, sociocultural, and environmental realms. Diseases and disabilities are conditions, yet a client may often be referred to as “the paraplegic” or “the amputee” and not by her name. This type of designation should be avoided: a disease or disability is something one has, not something one is. Figure 26.1 depicts the interactions among the various components addressed by the ICF in the evaluation and assessment of clients with disabilities. It can serve as a useful model for community health nursing practice in the overall assessment of people with disabilities.

## The World Health Report

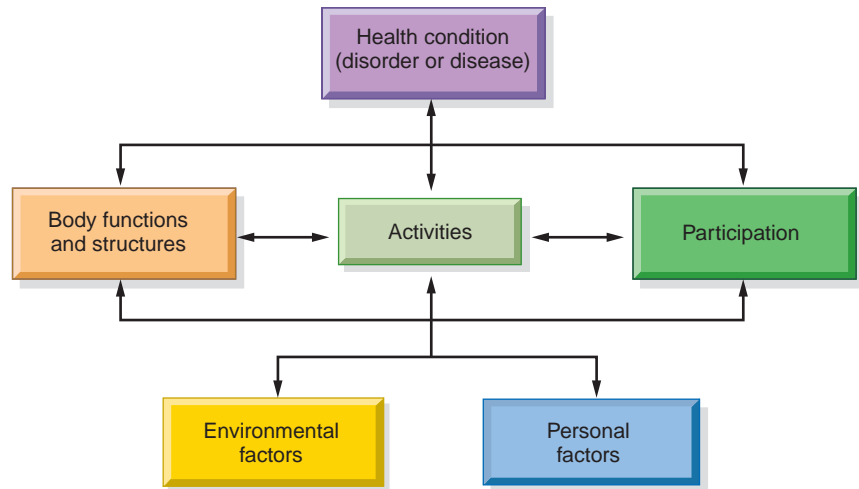

The 2002 release of the annual report by the WHO (*The World Health Report 2002: Reducing Risks, Promoting Healthy Life*) set a new standard for addressing global health. It challenged the world community to focus more attention on unhealthy behaviors that lead ultimately to chronic disease, disability, and early mortality. The report stressed that, although infectious diseases and malnutrition require ongoing vigilance because they continue to plague many parts of the world, they are not the only threat. It is increasingly clear that lifestyle choices play a major role in morbidity and mortality levels in affluent and poor countries alike, and intervention at all levels (local, national, and international) is a high priority. With this new reality in mind, this document had a twofold purpose: to quantify the most important risks to health, and to assess the cost-effectiveness

**FIGURE 26.1** Model of functioning and disability. From the World Health Organization (WHO). (2001). *ICF introduction*. Geneva, Switzerland: Author.

of interventions designed to reduce those risks. The overall goal was “to help governments of all countries lower these risks and raise the healthy life expectancy of their populations” (WHO, 2002, p. 7).

No longer can health care providers across the globe continue to address acute illness by itself; lifestyle and behavior must be considered because of the impact they have on healthy years of life. The risks to health that the WHO report focused on include some that are the direct result of poverty, but many can be more aptly linked to excesses, notably in the more affluent countries. The 10 leading health risks are (1) underweight, (2) unsafe sex, (3) high blood pressure, (4) tobacco consumption, (5) alcohol consumption, (6) unsafe water, sanitation, and hygiene, (7) iron deficiency, (8) indoor smoke from solid fuels, (9) high cholesterol, and (10) obesity. Globally, these 10 health risks are responsible for more than 33% of all deaths and untold disability. Half of these risks—tobacco and alcohol consumption, high blood pressure, high cholesterol, and obesity—can be directly related to lifestyle and behavioral choices.

Nutrition is vital to health; nutritional imbalances can lead to severe chronic illness, disability, and premature death. Of the leading 10 health risks, five are directly related to consumption: underweight, hypertension, iron deficiency, high cholesterol, and obesity (WHO, 2002). The prevalence of obesity worldwide is estimated at more than 1 billion adults, with some 300 million who can be classified as clinically obese (WHO, 2008). In stark contrast, there are 170 million underweight children in poor countries, more than 3 million of whom will die each year from malnutrition. Being overweight increases the risk of coronary heart disease, stroke, diabetes, and some types of cancer. Malnutrition and the lack of important nutrients can lead to a wide array of preventable disabilities. For instance, the leading cause of acquired blindness in children is vitamin A deficiency, and the leading cause of mental retardation and brain damage is iodine deficiency (WHO, 2002).

The significance of the WHO report lies in its simplicity. If countries can make even minimal strides toward improving the health of their citizens, a dramatic improvement in health outlook can occur within those countries and worldwide. Governments must take a proactive role in addressing the preventive health care needs of their citizens

(Display 26.1). A shift in focus from the most high-risk individuals to the general population is essential. Primary and secondary prevention as the main focus is the approach that public health care professionals have stressed for decades. As difficult as it has been in the United States to implement a shift in emphasis to health promotion efforts, it will be interesting to see if this “call to action” by WHO will result in less emphasis on tertiary prevention. The old adage, “An ounce of prevention is worth a pound of cure,” is most appropriate for the years ahead.

#### DISPLAY 26.1

### WORLD HEALTH ORGANIZATION RECOMMENDATIONS TO IMPROVE GLOBAL HEALTH

- Government/health ministry support for scientific research, improved surveillance systems, and better access to global information
- Development of effective, committed policies for the prevention of health risks such as tobacco consumption, unsafe sex associated with HIV/AIDS, and unhealthy diet and obesity
- Implementation of cost-effectiveness analysis to identify the most cost-effective and affordable interventions to reduce priority health risks
- Collaborative efforts (intersectoral and international) to reduce major extraneous risk to health caused by unsafe water, poor sanitation, or lack of education
- Supportive and balanced approach in addressing these major health risks that includes government, community, and individual action
- Empowerment and encouragement of individuals to make positive, life-enhancing health decisions (such as eliminating tobacco use, excessive alcohol consumption, unhealthy diet, and unsafe sex)

Adapted from World Health Organization. (2002). *The world health report 2002: Reducing risks, promoting healthy life*. Geneva, Switzerland: Author.

Taken together, the ICF and the 2002 WHO report set a standard for health care in the 21st century. Chronic disease and disability prevention are vital to world health. The cost of health care treatment is high, but the cost in terms of lost productivity and decreased quality of life is even higher. Without control of preventable disability and chronic disease, these conditions could very well become the “new plagues” of the coming decades.

## United Nations’ Convention on the Rights of Persons with Disabilities

An estimated 650 million people live with disabilities worldwide (United Nations [UN], 2007a). Factoring in the nearly 2 billion family members affected by the disability, the WHO stressed that almost one-third of the world population is directly impacted by disabilities. The sheer magnitude of this issue, and the recognition that people with disabilities are a “significantly overlooked development challenge” across the world, led to the United Nations (U.N.) Convention on the Rights of Persons with Disabilities in 2006. The Convention was opened for signature in March 2007 and, as of May 2008, had been ratified by 129 countries. Specific principles of the convention include (United Nations [UN], 2007b):

- ◆ Respect for inherent dignity and individual autonomy, including the freedom to make one’s own choices and independence of persons
- ◆ Nondiscrimination
- ◆ Full and effective participation and inclusion in society
- ◆ Respect for difference and acceptance of persons with disabilities as part of human diversity and humanity
- ◆ Equality of opportunity
- ◆ Accessibility
- ◆ Equality between men and women
- ◆ Respect for evolving capacities of children with disabilities and respect for the right of children with disabilities to preserve their identities

The convention, once entered into force, will be serviced by both the U.N. Department of Economic and Social Affairs (New York) and the Office of the High Commissioner for Human Rights (Geneva). The United States was not one of the signatories of the convention, joining countries such as Pakistan, the Russian Federation, Saudi Arabia, Switzerland, Ukraine, and Zimbabwe. Although the United States was an active participant in committee work on the convention and congratulated the convention’s work, reasons cited for not signing the document appeared related to issues of sovereignty. In a December 2006 press release from Ambassador Richard Miller, U.S. Mission to the U.N. (2006), the following explanation was provided: “Our nation’s commitment to the rights and dignities of persons with disabilities is embodied in our vast array of strong national laws, notably the historic Americans with Disabilities Act. . . . The United States believes that the most effective way for states to improve the real world situation of persons with disabilities from a legal perspective is to strengthen their domestic legal frameworks related to nondiscrimination and equality.” The actual impact of the convention will only be realized in the coming years. Building on the Americans with Disabilities Act (ADA, discussed later in this chapter) the convention can only be

viewed as a positive step in the progress toward equality. It should be noted that the National Council on Disability (NCD) has taken an approach to the convention that is profoundly different from the official U.S. government position. Noting the administration’s concern that the convention would provide a baseline standard much lower than that provided for in the ADA, the NCD still urged the signing of the treaty. In a March 2007 letter to the President, they argued that signing the convention would provide “clear support for the principles of this landmark treaty and to continue our country’s tradition as a world leader for people with disabilities” (National Council on Disability [NCD], 2008a, Preamble).

## Healthy People 2010

The most influential document addressing health in the United States, *Healthy People 2010* (USDHHS, 2000) defines those areas of health and well-being that are most in need of attention. With its clearly delineated and measurable objectives, *Healthy People 2010* has far-reaching influence on national and state health initiatives, health care policy, research priorities, and funding. In terms of disability and chronic illness, *Healthy People 2010* has placed added emphasis on conditions expected to take a toll on the nation’s health in the coming years. It also reflects a growing realization by health care providers, insurance companies, public health agencies, and health care facilities of the need to act proactively to avoid the economic toll that lack of attention can produce.

It is difficult to discuss *Healthy People 2010* (USDHHS, 2000) without some mention of *Healthy People 2000* (USDHHS, 1991). A comparison of the two documents reveals some striking differences regarding disabilities and chronic conditions. Increased attention has been given to the growing national need to reduce the incidence of disability and chronic disease and improve the health of people affected by them. In *Healthy People 2000*, only one priority area was devoted to disability and chronic illness. Priority Area 17, “Diabetes and Chronic Disabling Conditions,” emphasized diabetes, with only limited attention to the broader range of other disabilities (asthma, chronic kidney disease, arthritis, deformities or orthopedic impairments, mental retardation, peptic ulcer disease, visual and hearing impairments, and overweight). In contrast, almost half of the *Healthy People 2010* focus areas directly address chronic illness and disability, and almost all of the focus areas can be related to these issues in some manner. Moreover, the section on “Disability and Secondary Conditions” is devoted exclusively to issues most relevant to people with disabilities.

The definition of disability in *Healthy People 2010* is somewhat different and more explicit than that used in the ICF (WHO, 2001); it is stated as “the general term used to represent the interactions between individuals with a health condition and barriers in their environment” (USDHHS, 2000, p. 25). Moreover, **people with disabilities** are “identified as having an activity limitation or who use assistance or who perceive themselves as having a disability” (USDHHS, 2000, p. 6–25).

This change in emphasis between the two documents was noted in *Healthy People 2010* (USDHHS, 2000), which cited lack of parity between disabled and nondisabled populations in terms of several selected objectives: leisure-time activity, use of community support programs, and receipt of clinical preventive services. One such example was the finding

that the percentage of people with disabilities who reported some type of leisure-time activity was the lowest of any of the groups identified (including those older than 65 years of age and low-income persons). On the positive side, the percentage of people with disabilities who reported no leisure-time physical activity actually declined from the 1985 level of 35% to 29% in 1995, although it was still far short of the 2000 target of 20%. Additional disparities noted for people with disabilities included increased likelihood of being overweight, adverse effects from stress, and reduced rates of preventive services (e.g., tetanus boosters, Pap tests, breast examinations, and mammograms). Recognition that the health needs of disabled persons were not receiving needed attention resulted in increasing the priority of improving the health of people with disabilities.

Improving the health of the nation requires a multifaceted approach to improve parity among all individuals. *Healthy People 2010* states that “every person in every community across the nation deserves equal access to comprehensive, culturally competent, community-based health care systems that are committed to serving the needs of the individual and promoting community health” (USDHHS, 2000, p.16). The goal of *Healthy People 2010* specific to disabled persons is to “promote the health of people with disabilities, prevent secondary conditions, and eliminate disparities between people with and without disabilities in the U.S. population” (USDHHS, 2000, p. 6-8). Thirteen individual objectives have been selected to measure progress toward this goal (Table 26.2). The most significant changes in the *Healthy People 2010* objectives specific to disabled persons are the emphasis on healthy life-years and improved quality of life, similar to the recommendations by the WHO (2002). Although the issues of function stressed in the ICF (WHO, 2001) were not as explicit in *Healthy People 2010*, the 13 objectives indicate a growing emphasis on a holistic approach that recognizes that life satisfaction is just as important to health and well-being as preventive services. It also indicates a growing realization that healthy life-years for persons with disabilities equate to decreased health costs at local, state, and national levels, just as they do for persons without disabilities.

Building on the Healthy People initiative, in 2005, then current Surgeon General Richard Carmona released a *Call to Action to Improve the Health and Wellness of Persons with Disabilities* (USDHHS, 2005b). This document cited ongoing challenges faced by persons with disabilities and their families. Four major goals were proposed:

- ◆ People nationwide understand that persons with disabilities can lead long, healthy, productive lives.
- ◆ Health care providers have the knowledge and tools to screen, diagnose, and treat the whole person with a disability with dignity.
- ◆ Persons with disabilities can promote their own good health by developing and maintaining healthy lifestyles.
- ◆ Accessible health care and support services promote independence for persons with disabilities (p. 2).

The Surgeon General’s attention to the need to “promote accessible, comprehensive health care that enables persons with disabilities to have a full life in the community with integration of services . . . .” (p. v) is in alignment with *Healthy People 2010* goals in this area. The emphasis placed on personal responsibility for maintaining a healthy lifestyle

**TABLE 26.2 Healthy People 2010: Disability and Secondary Conditions—Objectives**

- Include in the core of all relevant Healthy People 2010 surveillance instruments a standardized set of questions that identify “people with disabilities”
- Reduce the proportion of children and adolescents with disabilities who are reported to be sad, unhappy, or depressed
- Reduce the proportion of adults with disabilities who report feelings such as sadness, unhappiness, or depression that prevent them from being active
- Increase the proportion of adults with disabilities who participate in social activities
- Increase the proportion of adults with disabilities reporting sufficient emotional support
- Increase the proportion of adults with disabilities reporting satisfaction with life
- Reduce the number of people with disabilities in congregate care facilities, consistent with permanency planning principles
- Eliminate disparities in employment rates between working-age adults with and without disabilities
- Increase the proportion of children and youth with disabilities who spend at least 80% of their time in regular education programs
- Increase the proportion of health and wellness and treatment programs and facilities that provide full access for people with disabilities
- Reduce the proportion of people with disabilities who report not having the assistive devices and technology needed
- Reduce the proportion of people with disabilities reporting barriers to participation in home, school, work or community activities
- Increase the number of Tribes, States, and the District of Columbia that have public health surveillance and health promotion programs for people with disabilities and caregivers

From U.S. Department of Health and Human Services. (2000). *Healthy people 2010: Understanding and improving health*. Washington, DC: U.S. Government Printing Office.

is unique to this document; this approach is increasingly emphasized in health promotion education and will very likely be an important feature in efforts to reduce health care costs.

The development of *Healthy People 2020: The Road Ahead* is due for release in January 2010. This document will include the vision, mission, goals, focus areas, and objectives for the next decade. Utilizing an extensive review of current and evolving research and national surveys, as well as public and professional input, the document will provide a blueprint for the nation’s health into the first quarter of the 21st century. This document will likely include insight gained from the earlier *Healthy People 2010* effort and the *Midcourse Review* released in 2005. One emerging issue noted in the *Midcourse Review* was the recognition of

“insufficient inclusion of persons with disabilities in disaster management processes, training for first responders, county-level data to locate and evacuate persons with disabilities, and resources to meet disability needs during a disaster” (USDHHS, 2005a, p. 6-7). Of additional concern was the finding that two objectives moved away from their 2010 targets. A 7% increase occurred in the proportion of adults who expressed that negative feelings were impacting their lives; 32% in 2003 versus the 28% level reported in 1997. With respect to employment, the proportion of adults with disabilities who were employed dropped to between 1997 and 2003. As with the recession of 2001, the disproportionate impact of the economic instability of 2008 on persons with disabilities will likely reflect decreased progression toward the employment goals set for 2010. Although the national health priorities are not yet established, clearly, issues of depression, employment parity, and disaster preparedness will need to be addressed. In addition, as noted in the 2005 Surgeon General’s *Call to Action*, personal responsibility for lifestyle choices will very likely have increasing emphasis.

## CIVIL RIGHTS LEGISLATION

Policies such as *Healthy People 2010* are important features of an overall plan to address the health of people with disabilities and chronic diseases in the United States. Although it has a great deal of influence on the direction and type of programs initiated, policy alone cannot assure individuals with disabilities that the needed services and accommodations are or will be available. As has often been the case, an

act of legislation is vital to ensure that every individual’s rights are protected and that legal recourse is available if such protection is denied. But, as is true for other issues of equality, legislation is only the first of many steps that must be taken. The struggle for civil rights for disabled persons in this country is still in its infancy, although it has begun to gain the level of attention that racial and gender equality receive.

The **Americans with Disabilities Act (ADA)** was signed into law in 1990 to protect the civil liberties of the many Americans living with disabilities. This legislation was the result of a long and difficult struggle. Individuals with disabilities and their advocates made their voices heard by repeatedly demanding an end to inferior treatment and lack of equal protection under the law, which impeded their daily lives. The ADA set the standard for a number of subsequent laws that, together with pre-ADA legislation, offer a broad spectrum of protections for disabled persons. These additional laws are listed in Table 26.3 and cover a variety of issues, including telecommunications, architectural barriers, and voter registration.

The ADA essentially “prohibits discrimination on the basis of disability in employment, state and local government, public accommodations, commercial facilities, transportation, and telecommunications [and] also applies to the United States Congress” (United States Department of Justice [USDOJ], 2005, p. 3). For an individual to be protected under the ADA, she must have a disability or some type of relationship or association with an individual who has a disability. The definition of a disabled person used in the application of the ADA is “a person who has a physical or

**TABLE 26.3 Disability Rights Laws**

Law	Summary	Contact
Telecommunications Act of 1996	Equipment and services are accessible	Federal Communications Commission (FCC)
Fair Housing Act (amended 1988)	Prohibits housing discrimination	U.S. Department of Housing and Urban Development (HUD)
Air Carrier Access Act	Prohibits discrimination in air transportation by domestic and foreign carriers	U.S. Department of Transportation
Voting Accessibility for the Elderly and Handicapped Act of 1984	Requires polling places to be physically accessible for federal elections	U.S. Department of Justice—Civil Rights Division
National Voter Registration Act of 1993	“Motor Voter Act”—makes it easier to vote by increasing low registration rates by minorities and persons with disabilities	U.S. Department of Justice—Civil Rights Division
Individuals with Disabilities Education Act	Make available free public education in the least restrictive environment for all children with disabilities	U.S. Department of Education—Office of Special Education Programs
Rehabilitation Act	Prohibits discrimination in all federal programs or programs receiving federal financial assistance	Agency’s Equal Employment Opportunity Office U.S. Department of Labor—Office of Federal Contract Compliance Programs U.S. Department of Justice
Architectural Barriers Act	Buildings constructed or altered with federal funds must meet federal accessibility standards	U.S. Architectural and Transportation Barriers Compliance Board

From the U.S. Department of Justice. (2005). *A guide to disability rights law*. Retrieved August 18, 2008 from: <http://www.ada.gov/cguide.htm>.

mental impairment that substantially limits one or more major life activities, a person who has a history or record of such an impairment, or a person who is perceived by others as having such an impairment” (USDOJ, 2005, p. 2). A listing of the specific impairments covered under the law is notably absent, leaving open a broad range of interpretations and legal challenges with respect to who is actually covered.

Although there is ongoing debate as to who is actually protected by the ADA, an equal amount of confusion exists as to who is actually required to comply with the provisions of the act and what specific actions are necessary. The following is a short summary of the ADA. All employers, including religious organizations with 15 or more employees, are subject to the act, as are all activities of state and local governments irrespective of size. Before 1994, the act applied only to employers with 25 or more employees. Public transportation, businesses that provide public accommodation, and telecommunications entities are all required to provide access for individuals with disabilities. It is important to note that the ADA does not override federal and state health and safety laws. However, successful legal challenges to those statutes have been made when they were clearly outdated or when it could be argued that the public safety was not actually at risk in a specific situation. Considerable gray areas exist within the ADA, leaving open the prospect of challenges by those who are subject to the law and those who are protected by it.

Individuals who believe that their legal rights under the ADA have been violated may seek remedy by filing a lawsuit or submitting a complaint to one of four federal offices, depending on the specific type of alleged violation: (1) the U.S. Department of Justice–Civil Rights Division, (2) any U.S. Equal Employment Opportunity Commission field office, (3) the Office of Civil Rights–Federal Transit Administration, or (4) the Federal Communications Commission. The process for filing a complaint is not a simple task, and many seek the assistance of attorneys, legal aid societies, or various private organizations, some of which are discussed later in this chapter (see Display 26.2).

#### DISPLAY 26.2

#### OFFICE OF CIVIL RIGHTS: COMPLIANCE WITH ADA

The responsibility of the U.S. Department of Justice, Office of Civil Rights (OCR), is to investigate complaints of alleged violations of the Americans with Disabilities Act (ADA). An example of one of those complaints involved a 22-year-old Connecticut woman with cerebral palsy. She had been placed in a nursing home because of changes in her living situation and health care status and wanted to move back into the community. The OCR intervened to ensure that the woman secured appropriate housing and that counseling and intensive case management services were in place when she moved back into the community. Without the protection afforded under the ADA, the outcome could have been much different.

Source: USDHHS (2006, September). *Delivering on the promise: OCR's compliance activities promote community integration*. Retrieved May 19, 2008 from Office for Civil Rights via: <http://www.hhs.gov/ocr/complianceactiv.html>.

In a report on the enforcement history of the ADA between its inception and 1999, the National Council on Disability (NCD) noted that many of the federal agencies charged with protecting the civil rights of disabled persons suffered from insufficient funding and lack of a coherent and unifying national strategy (NCD, 2000). The NCD recommendations included clarification of specific elements that provide a basis for evaluating agency performance and thereby serve to improve the full expression of the law as it was intended. These 11 elements or criteria are (1) proactive and reactive strategies, (2) communication with consumers and complainants, (3) policy and subregulatory guidance, (4) enforcement actions, (5) strategic litigation, (6) timely resolution of complaints, (7) competent and credible investigative processes, (8) technical assistance for protected persons and covered entities, (9) adequate agency resources, (10) interagency collaboration and coordination, and (11) outreach and consultation with the community. In a follow-up report in 2005, the NCD's ADA Impact Study, progress was noted in the following areas:

- ◆ Telephone relay services are being used at high levels, and changes in technology are making usage higher.
- ◆ Public transit systems in the United States have made dramatic progress in becoming more accessible, especially to wheelchair users.
- ◆ The percentage of Americans with disabilities voting in 2004 increased dramatically.
- ◆ The education gap between people with disabilities and people without disabilities is shrinking, and people with disabilities are attending postsecondary institutions in record numbers.
- ◆ People with disabilities are experiencing less discrimination in employment (NCD, 2005, p. 3).

It is important to those with disabilities and the professionals who serve them that a structure be in place to provide protection under the law, but this does not prevent discrimination, nor does the existence of such a structure suggest that immediate remedies will be available. Laws aside, the most difficult aspect of change comes when attempts are made to alter the perceptions and misunderstandings of others about people with disabilities. The perspective of one community member offers one such example (see Perspectives: Voices from the Community).

#### ORGANIZATIONS SERVING THE NEEDS OF THE DISABLED AND CHRONICALLY ILL

Although the impact of civil rights legislation cannot be underestimated, it did not come about without demands for change from the chorus of voices from all those who deal on a daily basis with the issue of disability (the individuals themselves, their families, coworkers, employers, and advocates). Without the hard work of those individuals and groups, it is unlikely that the efforts envisioned and accomplished by legislation would have occurred. Much of the credit for the legislative focus belongs to advocacy groups. The following section provides an overview of some of the groups that advocate for the disabled and chronically ill and their families. In serving those specific populations, they offer others an opportunity to learn more about the lives and struggles of disabled persons. Each of the organizations

## PERSPECTIVES

### VOICES FROM THE COMMUNITY

I was always such an active and healthy person, so when I was diagnosed with multiple sclerosis it hit me like a ton of bricks. Here I was with two small children and I was only 30 years old; it just wasn't fair. Some days are good and some days are just awful. I finally broke down and applied for one of those disabled parking stickers. The doctor had to approve it, and he said it was a good thing to help me save my energy for the important things, like taking care of my family. I hated to use it, but I was just getting so tired. What is so awful are the looks on people's faces when I park in the special areas near the door. I know I don't look like I'm sick. I just hate those looks—I can hear them saying under their breath, "She can't be sick . . . I'll bet that sticker is for a family member and she's just abusing it—how lazy!" If I wasn't so tired I'd park in the regular parking places.

*Pat N., Tampa, Florida*

listed offers a wide range of information, some of which can be accessed via the Internet. For community health nurses, these organizations provide a starting point for exploring specific topics pertinent to practice. They also can be a source of valuable information for clients and families to access on their own. Families who cannot afford Internet service or computers can use them at public libraries, most of which now offer this service. Many Internet sites are not reliable or accurate, so it is important for the nurse to prescreen any specific sites that are recommended to clients and their families.

## Government

The NCD is an independent federal agency tasked with making recommendations to the President and to Congress about issues that face Americans with disabilities. The NCD has 15 Presidential appointees (all confirmed by the U.S. Senate) whose charge is to promote "policies, programs, practices, and procedures that guarantee equal opportunity for all individuals with disabilities, regardless of the nature or severity of the disability, and to empower individuals with disabilities to achieve economic self-sufficiency, independent living, and inclusion and integration into all aspects of society" (NCD, 2008b). In its 1986 report, *Toward Independence*, the NCD proposed that Congress should enact a civil rights law for people with disabilities; the result was the 1990 ADA.

## Private

Many private organizations—local, national, and international—deal with a variety of disabilities and chronic diseases. Many of the better-known organizations such as the American Heart Association and the American Cancer Association are discussed in other chapters of this book and therefore are not covered here. Instead, examples of groups that deal most directly with disability and chronic illness are described. The reader is encouraged to search the Internet or

print resources for additional entities that deal with specific disabilities or chronic illnesses.

The National Association of the Deaf (NAD), headquartered in Washington, D.C., is a private, nonprofit organization that was established in 1880. As the oldest U.S. organization serving this population, it has the stated mission to "preserve, protect and promote the civil, human and linguistic rights of all deaf Americans" (National Association of the Deaf [NAD], 2008b, p. 1). Specific programs and activities that NAD is involved with include advocacy, captioned media, certification of **American Sign Language** (ASL) professionals and interpreters, legal assistance, and policy development and research (NAD, 2008a). ASL uses "handshapes" to communicate ideas and concepts; it is used primarily in America and Canada by the deaf community (Grayson, 2003). Display 26.3 offers a brief summary of sign languages.

The National Organization on Disability (NOD), headquartered in Washington, D.C., has as its mission statement "to expand the participation and contribution of America's 54 million men, women, and children with disabilities in all aspects of life" (National Organization on Disability [NOD], 2008, p. 1). An important contribution of NOD is the *2004 NOD/Harris Survey of Americans with Disabilities*, which sought to quantify the gaps between people with and without disabilities in terms of employment, income, education, health care, access to transportation, entertainment or going out, socializing, attending religious services, political participation/voter registration, life satisfaction, and trends (NOD, 2004). This was the fifth national survey sponsored by NOD since it was first initiated in 1986. Although improvements in all indicators have been demonstrated over this 18-year period, progress is described as both slow and modest in the final report. People with disabilities are more likely than nondisabled persons to have low incomes, are

### DISPLAY 26.3

### SIGN LANGUAGES IN BRIEF

- Sign languages are not universal
- Sign language is the use of "handshapes" and gestures to communicate ideas or concepts
- American Sign Language is a unique language with its own rules of grammar and syntax
- American Sign Language is primarily used in America and Canada and is the natural language of the deaf community
- International Sign Language (Gestuno) is composed of vocabulary signs from various sign languages for use at international events or meetings to aid communication
- Systems of Manually Coded English (i.e., Signed English, Signing Exact English) are not natural languages but systems designed to represent the translation of spoken language word for word

From Grayson G. (2003). *Talking with your hands, listening with your eyes. A complete photographic guide to American Sign Language*. Garden City Park, NY: Square One Publishers.

twice as likely to drop out of high school, are more likely to go without needed health care, and they report considerably lower satisfaction with life than persons without disabilities. The NOD Web site connects visitors to a rich variety of sources on community involvement, economic/employment topics, and access issues (<http://www.nod.org>).

The American Council of the Blind (ACB) was founded in 1961 and states as its purpose, “to improve the well-being of all blind and visually impaired people” (American Council of the Blind [ACB], 2008, p. 1). Services advertised by the organization include information and referral, scholarship assistance, public education, and industry consultation, as well as governmental monitoring, consultation, and advocacy. Some of the major issues currently being pursued by the organization include improved education and rehabilitation for the blind and increased production and use of reading materials for the blind and visually impaired.

Guide Dogs for the Blind is a nonprofit charitable organization established to train and make available guide dogs for the visually impaired (Guide Dogs for the Blind, 2008). The dogs and services are free, and the organization relies on donations. It currently has two training sites, one in California and one in Oregon, with puppy raisers located throughout the Western states. The organization can be reached through its Web site at <http://www.guidedogs.com>.

Another organization dealing with issues affecting the blind and visually impaired is the National Federation of the Blind (NFB). Founded in 1940, it seeks to help “blind persons achieve self-confidence and self-respect and to act as a vehicle for collective self-expression by the blind” (National Federation of the Blind [NFB], 2008, p. 1). Citing the need for assistance to the more than 1.1 million people in the United States who are blind, the organization fulfills its mission by providing public education, information and referral, and support for increased availability of materials in **Braille** (Display 26.4).

The oldest organization devoted to eliminating barriers for the blind and visually impaired is the American Foundation for the Blind (AFB), which was founded in 1921. The AFB advocates for the visually impaired through increased funding at the federal and state levels in areas such as rehabilitation research for older, visually impaired persons; improved literacy for the visually impaired, including use of Braille and

assistive technology; improved employment opportunities; and increased accessibility of technology. In addition, AFB houses the Helen Keller Archives, which contain her correspondence, photographs, and various personal items and documents (American Foundation for the Blind [AFB], 2008).

The Obesity Society has as its mission to promote “research, education and advocacy to better understand, prevent, and treat obesity and improve the lives of those affected” (Obesity Society, 2008). The organization addresses such issues as the need for attention to the impact of obesity on death and disability and for increased research, improved insurance coverage, and elimination of discrimination and mistreatment of people with obesity. The organization’s Web site (<http://www.obesity.org>) offers informational literature covering topics that range from the global problem of obesity to treatment of obesity-related disability.

With growing awareness that, in many cases, human immunodeficiency virus (HIV)/acquired immune deficiency syndrome (AIDS) is a chronic condition, the long-term needs of those impacted by this disease are gaining attention. Hundreds of websites and organizations are available to provide information, assistance, and support. One website, *The Body: The Complete HIV/AIDS Resource* (2008) offers state-by-state links to a variety of resources. The site also includes resources in Canada and specific sites for American Indians and Alaskan Natives. The website can be accessed at <http://www.thebody.com/index/hotlines/other.html>.

Begun in the aftermath of World War I, the Disabled American Veterans organization has provided free services to military veterans seeking to obtain benefits for service-related injuries (Disabled American Veterans, 2008). The organization is not a government agency and receives no federal funds, instead providing services through membership dues and public contributions. The mission of the organization is to help disabled veterans build better lives for themselves and their families. With the growing number of military injuries resulting from the Iraq and Afghanistan conflicts, the organization finds its service delivery even more stretched. The volunteers provide transportation to Veterans Administration (VA) medical facilities and provide ongoing service at VA hospitals, clinics, and nursing homes. The organization’s website can be accessed at <http://www.dav.org/>.

## HEALTH PROMOTION AND PREVENTION NEEDS OF THE DISABLED AND CHRONICALLY ILL

### Misconceptions Impede Improvement

Earlier, the influence of *Healthy People 2010* as it relates to people with disabilities was discussed. One of the most influential aspects of the document is its emphasis on a change in thinking within the health care community about the health promotion needs of people with disabilities. This shift is needed because the lack of health promotion and disease prevention activities for this population leads to an increase in the number and extent of **secondary conditions**, defined as “medical, social, emotional, mental, family, or community problems that a person with a disabling condition likely experiences” (USDHHS, 2000, p. 6-25). Approaching the health needs of disabled persons from the traditional standpoint of asking what medical, rehabilitative, or long-term care is needed has failed to reduce illness or improve the

#### DISPLAY 26.4

#### WHAT IS BRAILLE?

Braille takes its name from Louis Braille, an 18-year-old blind Frenchman who created a system of raised dots for reading and writing by modifying a system used on board sailing ships for night reading. Persons experienced in Braille can read at speeds of 200 to 400 words per minute, comparable to print readers. Braille consists of arrangements of dots to form symbols. The text can be written either by hand with a slate and stylus, with a Braille writing machine, or with the use of specialized computer software and a Braille embossing device attached to the printer.

Source: National Federation of the Blind. (2003). *What is Braille and what does it mean to the blind?* Retrieved May 19, 2008, from <http://www.nfb.org/images/nfb/Publications/fr/fr15/Issue1/f150113.html>.

overall well-being of the disabled or chronically ill. Moreover, a number of misconceptions have resulted that impede progress in this area: (a) that all people with disabilities have poor health, (b) that public health activities need to focus only on preventing disability, (c) that there is no need for a clear definition of “disability” or “people with disabilities” in public health practice, and (d) that environment does not play a significant role in the disability process. Increased national attention to the needs of the disabled (those needs specific to disabled persons as well as needs that are universal to all) should greatly improve the outlook. This change of focus is clearly evident in the definition of **health promotion** used in *Healthy People 2010*: “efforts to create healthy lifestyles and a healthy environment to prevent medical and other secondary conditions, such as teaching people how to address their health care needs and increasing opportunities to participate in usual life activities” (USDHHS, 2000, p. 6-25).

### Missed Opportunities by Health Care Providers or Missed Opportunities to Affect Quality of Life

In this age of rapid growth in technology, it is easy to forget that clean water is a far more important commodity than having the latest prescription drug or surgical procedure. All of us, whether healthy, disabled, or chronically ill, require some

basic elements to maintain health. Those elements are the same all over the world and include clean air and water, a safe place to live, sunshine, exercise, nutritious food, socialization, and the opportunity to be successful in life’s pursuits. As self-evident as these health promoting elements may seem, for the millions of persons who deal with disability, chronic disease, or both, such basic needs seem too often to take second place to other issues. It is equally problematic that preventive measures, most notably at the primary and secondary levels, are often nonexistent or lacking (see Evidence-Based Practice).

The issue of missed opportunities in health promotion and prevention is depicted in Figure 26.2. The focus of the health care delivery system is increasingly skewed toward secondary and tertiary prevention efforts, and limited emphasis is placed on the health promotion and primary prevention needs of the population. Although this is a concern for all persons, it is of particular importance for persons with disabilities and chronic illnesses, because they are more likely to have these needs ignored altogether. As Figure 26.2 shows, an entire area of issues may be addressed with a basically healthy person but not with a disabled or chronically ill individual. Some areas of secondary and tertiary prevention unique to persons with disabilities or chronic illnesses may be completely ignored. This nonreceipt of health promoting or preventive education or actions

## EVIDENCE-BASED PRACTICE

### Influenza Vaccine for Vulnerable Children

Influenza vaccination coverage was examined in an Italian study of children with chronic illnesses. The 274 children identified in the study were all at high risk of influenza complications as a result of their illness. The study sample was obtained from the over 5,000 children (younger than 14 years of age) who presented at an emergency room in the first 4 months of 2003. High risk included conditions such as asthma, chronic pulmonary disease, hemodynamically significant cardiac disease, chronic metabolic disease, sickle cell anemia, and HIV infection. The study involved a parental questionnaire regarding medical history, influenza vaccination status for the past 3 years, and parental perceptions of the need for vaccination. In addition, each of the children’s pediatrician was contacted by phone to complete a separate survey regarding their opinions on the need for influenza vaccination in high risk children. The researchers found that children with asthma or cardiac disease showed the lowest rates of vaccination. Of particular interest was the finding that the “parents and primary care pediatricians had only a marginal knowledge of influenza and the benefits of prevention” (p. 5253). The findings of this study support the need for improved vaccination rates for high risk children against influenza. Further, the lack of awareness by the pediatricians points to the need for increased professional educational efforts. Parents rely on their child’s pediatrician for guidance on health promoting interventions such

as immunization, and that guidance should be clear, accurate, and up-to-date.

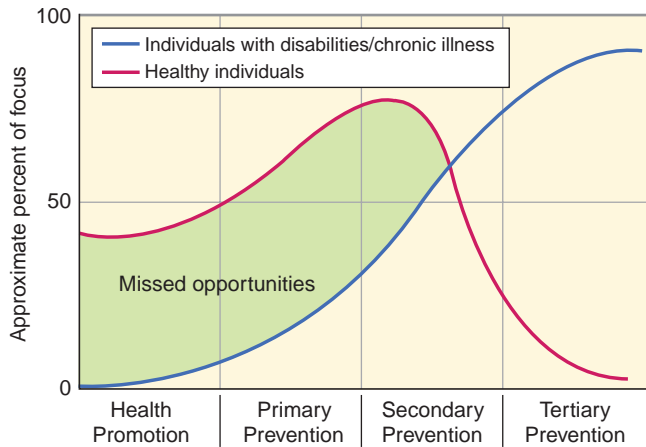

#### Nursing Implications

As this study emphasizes, children who are most at risk for severe sequel or even death from influenza may not be adequately immunized. The study findings are consistent with the results of the 2005 National Health Interview Survey showing that children with current asthma had a vaccination rate of only 29%. Although this rate was higher than the reported rate for children without current asthma, it underscores the need to reduce barriers to vaccination in these children. One such method that can be utilized by the community health nurse is to vigorously promote the need for influenza vaccination with all parents, and especially with parents of children with chronic health conditions.

**FIGURE 26.2** Difference in client focus between individuals with and without a chronic illness or disability.

vital to the health and well-being of those with disabilities or chronic illnesses is of grave concern. For example, issues such as sexuality are often not explored with the disabled or chronically ill. This skewed view of the lifestyles, behaviors, and needs of the disabled as “different” from those of the

“able-bodied” is a clear example of lack of understanding by health professionals and the public alike.

It is likely that disability or chronic illness serves as the initial reason for an individual’s encounter with the health care community, including the community health nurse. As a result, the disability or illness often drives the selection of prevention efforts, to the possible exclusion of other, equally important health issues. For example, for an individual with a primary diagnosis of type 2 diabetes, secondary prevention efforts often center on that disease (e.g., screening for diabetic retinopathy). The need to refer the client for a Pap test or a baseline mammogram may be overlooked. Likewise, the treatment plan may include a consultation with a dietitian but fail to address the basic needs for leisure-time activities, regular physical activity, a varied and interesting diet, fresh air and sunshine, and socialization—all of which may help prevent the development of depression, a common result of chronic illness. Display 26.5 offers several examples of missed opportunities in the areas of primary and secondary prevention. It is of particular concern to the practice of community health nursing that the broad range of health promotion and prevention needs of all clients be addressed.

A study by Wei, Findley, and Sambamoorthi (2006) demonstrated the risk for missed opportunities for clinical preventive services among women. Of the 3,183 individuals

#### DISPLAY 26.5

### MISSED OPPORTUNITIES

#### Example 1

A 60-year-old woman, blind since birth, self-sufficient and active all of her life, has developed severe arthritis. She encounters a health care system that far too often focuses on her “disabilities” and not her “abilities.” The focus is placed squarely on her tertiary health promotion needs, often at the expense of health-promoting or lifestyle-enhancing needs. The result is a failure to recognize that the “disability” of arthritis is likely no less and no more an issue for her than for a sighted person. She receives the same medication therapy as a sighted person but may not be offered a physical therapy program due to her disability. Her need for physical therapy is no less important, but locating an appropriate, safe, and easily accessible program requires some additional work on the part of her provider. At issue is that options potentially discussed with a sighted person are more apt to be omitted completely, which may negatively affect the client’s overall health and well-being.

#### Example 2

A 20-year-old man with learning disabilities, who is employed at a local factory, receives a regularly scheduled physical examination with a new provider. He lives in a **congregate care facility**, which is an out-of-home facility that provides housing for people with disabilities in which rotating staff members provide care for 16 or more adults or any number of children/youth younger than 21 years of age. It excludes foster care, adoptive homes, residential schools, correctional facilities, and nursing facilities (USDHHS, 2000). The major finding of the examination is that he is due for a tetanus booster and should also begin the series for hep-

atitis A, because he lives in a high-risk area of the western United States. He takes the referral slip and leaves the office. One year later, at his regularly scheduled visit, it becomes clear that he never received his immunizations. Apparently, he didn’t know what he was supposed to do with the paper, because he has difficulty reading, and he had no idea where to go to get his “shots.” The primary prevention elements were provided, but clearly not in a manner appropriate for this individual. With additional explanation and follow-up, perhaps the outcome would have been quite different.

#### Example 3

A 34-year-old woman who has been severely obese since the birth of her last child (4 years ago) has not had a gynecologic examination since that birth. She is aware of the need to have regular examinations, yet she cannot bring herself to make an appointment. The reason is that she knows she will have to be weighed, and this terrifies her, especially because it is done in an open area where others can see. She finally gets the courage to call for an appointment and tells the clerk that she does not want to be weighed. The clerk’s response is less than helpful and she is essentially told that it is “policy.” She makes the appointment but does not keep it. This situation could have been handled in a compassionate manner, recognizing the painful experience that weighing is for many individuals and suggesting alternatives, one of which could have been simply to bypass the scales until after the interview and examination. At that point, the woman may have been more amenable to the measurement and a more discreet area could have been offered. In this case, the opportunities to provide primary, secondary, and tertiary prevention were lost.

sampled in this study, 23% were disabled. When compared to the other study participants, the disabled women were less likely to receive cancer screening (mammograms and Pap smears) within the recommended intervals. Interestingly, this group was more likely to receive influenza vaccination, cholesterol screening, and colorectal screenings as recommended. The researchers found that, overall, having a usual source of care and health insurance were predictive of preventive service receipt. They stressed the need for improving women's health care by identifying those who are most at risk and targeting efforts to reduce disparities.

## Health Care Disparities and Discrimination

It is a growing concern to those who are disabled, and to their families and advocates, that the type and quality of the health-related services, referrals, and care that they receive may not be appropriate to their circumstances. This results in increased illness and disability and potentially decreased quality or length of life. One pointed example of this disparity involved a national sample of low-income female Medicaid recipients. Women with disabilities in this sample had lower rates of receipt of medical services, and were much less likely to receive cervical cancer screenings (Parish & Ellison-Martin, 2007). Although the women each had similar access to health care services, the disparities were of concern. Not surprisingly, those women with disabilities were less likely to report satisfaction with their care.

The issue of health care access was one of a number of elements explored in a study involving 932 independently living Massachusetts adults with a major disability (Wilber et al., 2002). The purpose of the study was to determine whether factors such as having a consistent primary care provider, access to health promotion or disease prevention programs, and accessible transportation were related to the number and severity of secondary conditions experienced. The findings suggested that the more independent the individual and the fewer obstacles faced, the fewer secondary conditions were reported. The study used the definition of secondary conditions in *Healthy People 2010*; the most notable findings were the high prevalence rates of fatigue, depression, spasms, and chronic pain.

Additional disparities may exist in services received by those with chronic illness and disabilities. Racial and ethnic differences in immunization rates were found in a study analyzing data from the National Health Interview Survey of almost 2,000 individuals with diabetes (Egede & Zheng, 2003). Even after controlling for access, health care coverage, and socioeconomic status, the rates of influenza and pneumococcal immunization were lower for certain racial/ethnic groups, primarily Blacks. What is not known from these results is whether the depressed immunization rates resulted from client acceptance issues, from differential provider recommendations, or from some combination of these factors.

A qualitative in-depth survey by Becker and Newsom (2003) that examined the issue of disparities found that economic status also appeared to affect dissatisfaction with health care among chronically ill African Americans. In this study, low-income individuals were less satisfied with both the quality and the quantity of their care than were middle-income respondents. The potential impact of low satisfac-

tion for selected groups is of real concern in addressing the ongoing needs of those individuals. Although neither study was confirmatory, it is nevertheless an issue that needs to be explored further.

It is discriminatory practice when an individual receives unequal, inappropriate, or limited services compared with those offered to others. Although the difference in treatment is often due to lack of understanding of the needs of disabled persons, it is nonetheless discriminatory. Such bias may not be intentional, but it can dramatically affect the health of clients and must be changed.

The good news is that the incidence of unequal and inappropriate practices can be reduced with education and training of health care providers, agency staff, and insurance carriers. A crucial aspect of community health practice is to ensure that those individuals with disabilities or chronic illnesses are afforded the best possible care, treatment options, and opportunities to improve their health—the same options as are provided for nondisabled persons and those who do not suffer from chronic illness.

Health promotion and primary, secondary, and tertiary prevention activities are essential aspects of quality care for all persons. Those with disabilities require specialized attention to needs resulting from or related to their disabilities, yet they also require the same attention to health and well-being as the rest of the population. Community health nurses are in a prime position to advocate needed changes for those with disabilities and chronic illnesses. Such changes can include increased attention to health promotion and disease prevention needs, accessible and appropriate delivery of those services, and specialized treatment plans that incorporate the latest knowledge of a specific illness or disability (see Perspectives: Student Voices).

## FAMILIES WITH A DISABLED OR CHRONICALLY ILL MEMBER

### The Family's Role in Advocacy

Families that have a member with a chronic illness or disability face many challenges. They are required to navigate a health care system that they know little about and with which they often feel at odds. They serve as advocates for their member in need (whether child, spouse, or parent) and often feel tired and frustrated from their efforts, especially if they have been less than successful in meeting their goals. Many are forced to ask for or demand assistance from health care agencies, social services, or transportation sources to achieve the level of care needed by the family member. Many are required to open their home to others (e.g., community health nurses, social workers) to access the services. Families may have little understanding of what services they are entitled to because of language barriers, difficult agency policies, or disjointed service delivery.

The community health nurse is usually not the first health care professional that the family encounters. They may already have been through a lengthy struggle to receive assistance. In these circumstances, the nurse often is confronted by a frustrated family that distrusts yet another "professional." The nurse must gain the trust and confidence of the family by practicing consistency, following through with promised actions, and always being truthful.

## PERSPECTIVES STUDENT VOICES

For as long as I can remember, I have wanted to work with children. When I was finally accepted into the nursing program, I was so disappointed when I learned that we would only have 7 weeks in our pediatric rotation. Then, I found out about an opportunity to work with children at a school in my community health practicum—marvelous I thought. I just knew I'd be giving immunizations, physical assessments, and performing hearing checks. Then I found out that I would actually be working with school-aged children with disabilities and their parents in a special after-school health promotion program. The nurse I was assigned to asked me to come in before the program started, so that she could fill me in on the program and my role. It actually sounded great, and I was confident that I could handle this. Then she asked me something that made me worried; she asked if I had ever worked with a child who used a wheelchair, or had a continuous insulin pump, or had seizures. I told her that I had some experience in the hospital, and that I was sure that I would be prepared for any health care issues that might occur. "You misunderstand," she said, "that's not what I meant. Have you ever gotten to know a child with a disability?" I really hadn't, and it suddenly made me a bit worried. She explained to me that many people don't treat children with disabilities just like any other child. They also don't always know how to talk to the parents about their child. She suggested that one way to give me a bit of information was to go home and do some reading and look at some websites she recommended. One in particular, the National Organization on Disability (<http://www.nod.org/>), had a great feature called "Disability Etiquette Tips" that I have already found to be a big help with the kids and their parents. She also directed me to the Easter Seals Disability Services (<http://www.easterseals.com>), which has a great deal of information on programs that are currently available for children and adults. I even learned that this organization used to be called the National Society for Crippled Children . . . I'm sure glad they changed the name.

*Eileen S.*

Not all problems that the family faces can be remedied, and even for problems that do have solutions, time and effort may be needed to obtain the desired result.

### The Impact on Families

A literature review of the needs of parents with chronically ill children reported a number of common themes in the studies surveyed, among them the need for normalcy and certainty, the need for information, and the need for partnership (Fisher, 2001). Although these needs were associated with the presence of a chronically ill child in the family, the same needs are likely to occur in other families. These are

certainly areas that can be addressed by the community health nurse in a practical way.

Wong and Heriot (2007), found somewhat similar results in their study of 35 parents of children with cystic fibrosis (CF). The parents who sought support from family and friends experienced less emotional distress than those who didn't, analogous to the need for partnership noted by Fisher (2001). Additional findings revealed that parents who used self-blame as a coping strategy were also more likely to report experiencing depression and were more likely to report lower levels of mental health in their children. Suggestions to assist the family include parental counseling to reduce self-blame, encouraging the children's important life goals, and providing information on available supportive social networks. With the current median life expectancy of patients with CF well above 30 years, the issue of long-term family support is vital.

One major obstacle for families with a disabled or chronically ill member may be obtaining needed **assistive devices and technology**. These are defined in *Healthy People 2010* as "any item, piece of equipment, or product system, whether acquired commercially, modified, or customized, that is used to increase, maintain, or improve the functional capabilities of individuals with disabilities" (USDHHS, 2000, p. 6-25). With constant changes in available equipment, financing, and technology, it is little wonder that families struggle to find the best alternatives. Just because the technology exists does not mean that it can be obtained. Often, the insurance carrier, whether private or governmental, sets limits on which products can be obtained or which brands are acceptable. The overriding issue of financing is no small hurdle. It is often left up to the family to learn about options and legal rights through a process of trial and error. Intervention by the community health nurse can greatly reduce the burden on the family. With so many product lines available on the Internet, the nurse can assist families in this area, especially those without access to or understanding of computer technology. It is equally helpful for the nurse to intervene with insurance providers if coverage of equipment is not easily obtained or to find sources of funding for the equipment from private agencies if possible. Referring families to community groups or organizations that provide specific assistance can be very helpful. Other families that share similar struggles can provide a vital link to needed services and can be contacted through self-help groups or other sources. Here, the community health nurse can provide expertise on available community resources.

Respite care is another area of great importance for families of the disabled and the chronically ill. It can be emotionally draining to meet the daily needs of a member who cannot perform self-care. This often leads to caregiver fatigue and increased stress. It is also important to recognize the effect of the situation on noncaregivers in the family, particularly nondisabled siblings of a disabled child. With focus placed on the needs of one member, children may feel that their own needs are not as important. This can lead to behavioral and health-related problems. Respite care offers some needed relief to the family and allows for uninterrupted attention to the nondisabled children. This service can occur within the home or at an outside facility. Respite care may be provided by a private organization at little or no cost to the family, or it may be quite expensive and require financing by the insurance company or by the family itself. Whatever the

## USING THE NURSING PROCESS WITH VULNERABLE POPULATIONS

### Assessment

Anna Lopez is a mother of three children aged 2 to 9 years old. The eldest, Ernesto, was diagnosed with severe Down syndrome at birth. He is confined to a wheelchair, requires total care, and remains at home with his mother and younger siblings, who are not yet in school. Anna's husband works long hours as a computer repairman for a large company. They have health insurance, but it does not cover additional expenses, such as day care for Ernesto. The family has done very well in providing for Ernesto's needs, and they receive periodic visits from you, the community health nurse, to evaluate his condition and check on the feeding tube used for his nourishment. Physically, Ernesto is stable, but you notice that Anna has been increasingly withdrawn at the visits, rarely offering information, but responding to questions appropriately. She seems less engaged with her other children as well, only occasionally smiling at them.

### Nursing Diagnoses

1. At risk for depression related to ongoing caregiver demands and lack of respite care
2. At risk for altered health status due to limited focus on self-care needs

### Plan/Implementation

#### Diagnosis 1

The community health nurse will discuss with the client the need for a thorough physical assessment, including an evaluation for depression. The community health nurse will contact the insurance provider to discuss day care/respite options for Ernesto. If unavailable, local community organizations will be contacted for appropriate referrals. In addition, the need for more frequent visits to the family will be

discussed with the insurance carrier to address the needs of the mother as caregiver.

#### Diagnosis 2

The community health nurse will discuss with the client her concerns about her overall physical and mental health and discuss some self-care options that may improve her well-being: improved nutrition, physical activity, leisure time options, and adjustment of family schedule to accommodate more free time for self-care.

### Evaluation

The client was at first very reticent to make an appointment for an evaluation, but after thinking it over for a week and discussing it with her husband, she did so. Her husband was relieved that she had suggested the appointment, because he was growing increasingly concerned over her withdrawal but did not know how to bring up the subject. The family physician referred Anna to a psychologist for evaluation of the depression. The insurance carrier agreed to increase home visits on a short-term basis but did not have a respite care option available for Ernesto. Fortunately, a local faith-based community group was able to provide limited assistance to the family. They identified several members who had raised children with similar disabilities and were willing to stay with Ernesto and the other children once a week for 4 hours. This allowed Anna some free time to make appointments with her psychologist, shop, or visit friends. After several months, Anna has begun to smile more and seems much more relaxed at the home visits. The children are all doing fine, and the respite care is expected to continue for at least the next 6 months. The need for ongoing attention to her own self-care needs is emphasized with Anna by the community health nurse.

source, some type of respite care is often vital to the family's health and should be a priority in the overall treatment plan of the family (see Using the Nursing Process).

With the enactment of the 1996 welfare reform legislation (the Personal Responsibility and Work Opportunity Reconciliation Act), a number of significant changes were implemented that potentially affect families with a chronically ill child, especially those living in poverty. Changes included the stipulation of a 5-year lifetime limit on receipt of benefits, institution of work requirements, and elimination of entitlement to cash benefits. The impact of these changes is of growing concern within the public health community. Smith, Wise, and Wampler (2002) explored this issue in a study of knowledge of welfare reform among families with a chronically ill child. They found that respondents often had incomplete knowledge of work requirements, even if they were entitled to exemptions because their children received Supplemental Security Income. In those cases, 37% of the respondents were unaware that they qualified for work exemptions, and 70% had not applied for the exemptions. This indicates that eligible families might not be receiving the exemptions to which they are entitled, adding additional and unnecessary burdens to families already at risk.

Another study explored the relationship between welfare status, health insurance status, and the health and medical care received by children with asthma (Wood et al., 2002). The most significant findings were (a) children of parents who had been denied Temporary Assistance for Needy Families (TANF) experienced more severe asthma symptoms and had more acute care visits than children in families that did not access the welfare system, (b) children of recent TANF applicants were more likely to be uninsured or transiently insured than those who had not applied, and (c) recent TANF applicants had the poorest mental health scores. The significance of this study is that it demonstrated the high-risk status of those families with a chronically ill child and the need to provide access to health insurance and health services.

Even for families that are ineligible for public assistance, the issue of employment is generally of great significance. Employment options may be quite limited when a family has a member with special needs. The family may have to remain in a particular location to access needed health and social services, reducing the possibility of increased earning potential at a different location or in another field of employment. The working family members may choose less favorable employment options because the position is convenient or has

more flexible hours. For instance, a person may take a part-time position at a local convenience store that does not pay particularly well in preference to a higher-paying, full-time factory position because the store is close to home and allows for frequent adjustments in schedule.

Having a chronically ill family member often means that working individuals must take time off from work. Although some legal protections are provided under the Family and Medical Leave Act of 1993, the Act does not apply in all situations. More importantly, it allows only for time off; it does not mandate payment during those periods. The choice becomes an issue of taking unpaid time off or continuing to work and deal with the needs of the family member as best one can. Some individuals choose to work part-time or not to work at all, so that they can care for family members. At a time when many families have two earners to help meet financial commitments, these families may have to rely on only one income. Limitations in income are particularly difficult when one considers the myriad needs of the disabled and chronically ill, many of which may not be covered by insurance.

Caregiver health needs and mental health status are yet another area of concern for families who must provide for a disabled or chronically ill member. One of the largest longitudinal studies in the United States, the Nurses' Health Study, provided the data for an investigation of the impact of informal caregiving on the mental health status of caregivers (Cannuscio et al., 2002). Using data collected over a 4-year period (1992–1996), the study found that women who provided 36 or more hours per week of care for a disabled spouse were six times more likely than noncaregivers to report depressive or anxious symptoms. The frequency of symptoms was elevated but less dramatic if the women cared for a disabled or ill parent as opposed to a spouse. The findings support the necessity of attention to the needs of caregivers, the majority of whom are women. A follow-up study by Cannuscio and colleagues (2004) found that higher weekly time commitment to informal care was associated with an increased risk of depression, regardless of level of social support. For those with few social ties and high spousal time commitment, the level of depressive symptoms was much higher. Interestingly, employment status didn't appear to have an impact on depressive symptoms of caregivers. Access to social ties was, however, strongly correlated with more positive health outcomes in the caregivers (Cannuscio et al., 2004). Poor health outcomes, both physical and mental, are of growing concern as the population ages and the need for family caregiving rises. Recognizing that caregivers within a family are at increased risk for poor health outcomes, the community health nurse must select appropriate interventions to address the health needs of the other family members.

Families of individuals with a disability or chronic illness are at increased risk for a number of negative consequences. Although families do not all have the same level of risk or disruption, the community health nurse should recognize the potential impact of the dependent member's needs on the entire family. Families may suffer from financial difficulties, poor physical or mental health, and a variety of other challenges. They are often ill prepared to deal with the complicated systems that must be accessed to obtain needed care. The community health nurse is in an optimal position to interpret those systems to the families and to advocate for the needed care, services, and equipment. The nurse must view the family holistically, recognizing additional needs that may develop as a result of the situation they currently face.

## Universal Design

“**Universal design** is the design of products and environments to be usable by all people, to the greatest extent possible, without the need for adaptation or specialized design” (Mace, n.d.). The term “Universal Design” has been attributed to Ron Mace, founder of the Center for Universal Design (North Carolina State University). Mace, who had suffered from polio as a child, died suddenly in 1998, leaving behind a long legacy of advocacy on behalf of accessibility in design.

For those who live with a disability or chronic disease, and their family members, the issue of access is of utmost importance. As was noted earlier, the cost to a family to accommodate the needs of a disabled person can be enormous. Consider, that, as the U.S. population ages, more and more of us will have need of accessibility in housing, business, and recreation in order to remain active and healthy as long as possible. Accessibility was taken one step further in the concept of universal design, making tools, houses, and workplaces accessible to all. The cost of building our environments in a way that promotes access for all can be far less than the cost of remodeling those environments after the fact.

The issue of accessibility is not new. The ADA (discussed earlier) addresses issues of access in employment, governmental building, and public accommodations. The Fair Housing Accessibility Guidelines (HUD, 2008) published in 1990 provides for design and construction of multifamily dwellings (four or more units) in accordance with accessibility requirements. The specific provisions include:

- ◆ Public use and common use portions of the dwellings are readily accessible to and usable by persons with handicaps;
- ◆ All doors within such dwellings which are designed to allow passage into and within the premises are sufficiently wide to allow passage by persons in wheelchairs; and
- ◆ All premises within such dwellings contain the following features of adaptive design:
  1. An accessible route into and through the dwelling;
  2. Light switches, electrical outlets, thermostats, and other environmental controls in accessible locations;
  3. Reinforcements in bathroom walls to allow later installation of grab bars; and
  4. Usable kitchens and bathrooms such that an individual in a wheelchair can maneuver about the space.

Universal design incorporates access, but access does not necessarily imply universal design. The design of a community's built environment and its impact on individuals plays a role in the overall health and well-being of those living there. Universal design and access play a key role in this discussion, but the importance of accessible design is more far-reaching. According to the CDC, the built environment

includes all of the physical parts of where we live and work (e.g., homes, buildings, streets, open spaces, and infrastructure). The built environment influences a person's level of physical activity. For example, inaccessible or nonexistent sidewalks and bicycle or walking paths contribute to sedentary habits. These habits lead to poor health outcomes such as obesity, cardiovascular disease, diabetes, and some types of cancer. (2006, p. 1)

For those with existing disabilities, assuring ease of access to all manner of recreation and exercise options is of paramount importance. For those who may develop disabilities or chronic illnesses, having the opportunities for healthy participation in physical activity may forestall or prevent the development of illness. For the community, having an environment that promotes rather than restricts a healthy lifestyle can be economically advantageous. Even schools have a role to play (CDC, 2008a). Building new schools away from residential areas decreases opportunities for exercise and after-school activities. As parents are increasingly forced to drive their children to school, the children remain sedentary, the pollution from cars is increased, and the risk of automobile accidents increases. Community design is a complicated and evolving issue, but the point remains: a healthier population may be achieved with attention to the environmental barriers that impede healthy lifestyles for all persons.

## THE ROLE OF THE COMMUNITY HEALTH NURSE

This chapter has discussed a number of areas in which the community health nurse plays a key role. It is important to review those roles in the context of the individual, the family, and the community as prime areas for nursing intervention. Chapter 3 first examined the broad spectrum of roles that the professional nurse takes on within the community. It is helpful to review those roles and think about their application to disabled and chronically ill clients, their families, and the communities in which they live.

Table 26.4 provides a grid on which to record specific examples of the roles that community health nurses assume in relation to disabilities and chronic illnesses. Take note of each role that you participate in or observe while completing your clinical experience. If you cannot find examples of the various roles at each level, perhaps you can interview a community health nurse during your clinical experience and find examples of how she performs activities in each of

those roles. You will probably find that, while addressing a single issue with a client, the community health nurse serves in a variety of roles and at different levels.

Consider as an example of the variety of roles and multilevel practice that the community health nurse assumes with respect to a 55-year-old female client who uses a wheelchair. The client has difficulty obtaining a gynecologic examination because of the lack of accessible examination tables at the local clinic; as a result, she has not had an examination for more than 20 years. Recognizing the need for a complete examination, the community health nurse arranges with the clinic to find appropriate alternatives that will aid the client in receiving the needed examination, possibly by ensuring that additional personnel are provided (Advocate Role–Individual Level).

Because this solution is temporary and less than optimal, the nurse contacts a number of clinics in neighboring communities and finds one that has appropriate equipment for people who have difficulty transferring to a standard examination table. Unfortunately, this clinic is 1 hour away. The nurse then contacts a number of other community health nurses and discovers that they also have a significant number of women clients with this problem who have not received a gynecologic examination in many years (Research Role–Community Level).

Through a coordinated effort with a local transportation company and the clinic, the nurse is able to arrange a twice-yearly gynecologic screening program for the women in the community who require special accommodations (Advocate and Coordinator Roles–Community Level). Information sheets that discuss the need for annual gynecologic examinations and advertise the program are distributed to area public health nurses, employers, and health clinics (Educator Role–Community Level). Data collection on examinations provided over the next few years shows a 65% increase in the number of women with special needs who have received a gynecologic examination within the past year (Research Role–Community Level).

Role	Individual	Family	Community
Clinician			
Educator			
Advocate			
Manager			
Collaborator			
Leaders			
Researcher			

This is not an uncommon scenario in the practice of community health nursing. Often, the needs of an individual open the door to areas of concern for many in a community and provide a basis for intervention that can benefit a larger population.

Like nursing practice in general, the role of the community health nurse with respect to disabilities and chronic illness requires broad and holistic practice. The complexity of issues surrounding these conditions requires creativity, tenacity, honesty, and, most of all, knowledge. Community health nurses who are informed about the issues that affect the disabled and chronically ill at local, state, and national levels are prepared to offer assistance to their clients and to their communities. Knowledge of civil rights for these individuals is crucial in serving as advocates.

The issues facing individuals and families with disabilities require strong and sustained efforts to achieve results. Although successes at the individual level are laudable, the extent to which the health and well-being of those affected is improved must be the ultimate goal. Community health nursing is in a prime position to initiate and support efforts to improve the health status of those populations. We can either leave the issues to other professionals or use our expertise and long history of caring for those less fortunate to make major and lasting changes. It is up to us.

## Summary

The issue of disability and chronic illness is of growing importance in community health, both nationally and internationally. Through the efforts of the WHO, the international community has been challenged to provide increased attention to health promotion and disease prevention. Even in less developed countries, behavioral patterns linked to excesses in consumption (overweight and tobacco/alcohol use) have an impact on the quality and quantity of healthy years of life. The ICF provides a universal classification system that standardizes language and takes into account the biopsychosocial realms in health assessment and well-being of disabled persons. Along with the *World Health Report 2002*, this document now places the emphasis squarely on prevention of disease and disability. This means, of course, that the health promotion and disease prevention needs of the disabled and chronically ill must be given the same emphasis as the needs of those who are not disabled or ill.

The aging of the U.S. population and the rise in lifestyle-related illnesses such as diabetes and obesity are often linked with increasing rates of disability. Prevention of disability and disease is emphasized in *Healthy People 2010*, which serves as a wake-up call to Americans about the need to give serious attention to health promoting and disease prevention activities. In this current edition of *Healthy People*, unique emphasis is placed on health promotion and disease prevention needs of those with disabilities and chronic illness. It is no longer acceptable that these individuals be treated solely for tertiary health needs. Research has shown that when health promoting (lifestyle) issues are addressed with these clients, the rates of secondary conditions are reduced, including medical, social, emotional, mental, family, and community problems. Like the ICF, *Healthy People 2010* takes the position that disability and

chronic conditions are not universally debilitating and that the overall well-being and health of these individuals must be a priority.

Legislation is but one step toward equality for those affected by disabilities and chronic illnesses. The ADA has provided for many improvements in accessibility and specific legal protections for the disabled, but it is only the beginning. Discrimination can occur at many levels; some is hurtful and intentional, but most results from misunderstanding of the needs and desires of disabled persons and their families. This may even occur in relation to the provision of health care because of lack of education. Improvement can be found only with increased community education programs for professionals and the public that target the myths and misunderstandings about those with disabilities and chronic illnesses.

Community health nurses are in a prime position to advocate for the health needs of the disabled and chronically ill. With a long history of serving those who are most vulnerable, community health nurses can help make needed changes at the individual, family, and community levels. Although it is often easier to focus on the needs of the individual, those needs are most often shared by many others. Nurses have long recognized the need to collaborate with other professionals in reaching the goal of improved health care for their clients; this continues to be an important aspect of successful efforts on behalf of the disabled and the chronically ill. It will take the concerted efforts of many to implement the changes necessary to improve the lives of those most affected, their families, and the communities in which they live.

The next time you have difficulty opening a door that is unusually heavy or struggle to open the lid of a jar or feel that you were treated differently than someone else in the receipt of services, take a moment to think. Think about the challenges, struggles, and pain that face so many citizens. Consider the impact of universal design at improving your life or the life of a family member or friend. Although many argue against improving accessibility of city streets and sidewalks because of the expense, those same people may one day find that they, too, are faced with trying to master a curb that is just a bit too high. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Arrange to interview an individual with a disability (e.g., hearing, vision, mobility) about the challenges that he has faced in interactions with nondisabled persons.
2. Visit some of the nongovernmental sites listed under Internet Resources and read some of the personal stories that are included.
3. Take an inventory of your house or apartment and make a list of modifications you would need to make if you were suddenly confined to a wheelchair. Would you even be able to stay in your current residence?
4. As part of your regular clinical assignment in community health nursing, look at those clients and families who are dealing with either a disability or

chronic illness and assess how often you or other community health nurses have addressed health promotion activities (e.g., healthy eating, physical activity, leisure-time activities) with those clients.

- Review your family history for chronic health conditions. Are you at risk? If so, what have you done to reduce your risk over the past 12 months?

# Behavioral Health in the Community

## LEARNING OBJECTIVES

*Upon mastery of this chapter, you should be able to:*

- ◆ Discuss the incidence and prevalence of mental illness and substance use in the United States.
- ◆ Compare and contrast various theories on the etiology of substance use disorders.
- ◆ Discuss the treatment approaches at the community level related to behavioral health.
- ◆ Identify and describe community behavioral health resources.
- ◆ Identify the *Healthy People 2010* objectives for reducing substance use and addressing behavioral health needs in the United States.
- ◆ Discuss health-promoting interventions for community behavioral health.
- ◆ Describe the role of the community health nurse in the prevention of substance use and mental health disorders.

*“Make your own recovery the first priority in your life.”*

—Robin Norwood

## KEY TERMS

Addiction  
 Community mental health  
 Community mental health centers  
 Community mental health nurse  
 Dependence  
 Mental health  
 Mental health care system  
 Mental illness  
 Relapse  
 Screening  
 Serious mental illness (SMI)  
 Serious and persistent mental illness (SPMI)  
 Substance use disorders  
 Tolerance

 This chapter describes the role behavioral health plays in the overall health of a community and provides an overview of behavioral health prevention and treatment from the perspective of community health nursing practice with a focus on community level interventions. The following questions should be kept in mind while reading about the issues surrounding behavioral health: in what sense does behavioral health relate to the health of communities? What are the global implications related to an increase in mental health-related diagnoses and risky-to-dependent substance use? What is the role of a community health nurse in helping individuals, families, and communities to promote optimal mental health and responsible substance use and thereby decrease the prevalence and incidence of mental and substance use disorders (SUDs)?

## BEHAVIORAL HEALTH TERMINOLOGY

Several terms that are useful for community health nurses working in the behavioral and mental health fields are defined below.

- ◆ **Community mental health nurse:** An individual whose practice is centered on the mental health needs of the populations served.
- ◆ **Community mental health:** A field of practice that seeks to promote the mental health of the community by preventing mental illness and addressing the needs of the mentally ill.
- ◆ **Community mental health centers (CMHCs):** Facilities that provide comprehensive, publicly funded services to the mentally ill population.
- ◆ **Mental health care system:** The collective programs designed for anyone with a mental illness. These programs may include treatments, services, or other types of supports, such as housing, employment, or disability benefits through government, private nonprofit, or private for-profit systems.
- ◆ **Mental health:** As defined in *Healthy People 2010*, mental health is “a state of successful mental functioning, resulting in productive activities, fulfilling relationships, and the ability to adapt to change and cope with adversity” (U.S. Department of Health and Human Services [USDHHS], 2000, p. 37).
- ◆ **Mental illness:** “Refers collectively to all diagnosable mental disorders [which] are health conditions that are characterized by alterations in thinking, mood, or behavior (or some combination thereof) associated with distress and/or impaired functioning” (USDHHS, 1999). The American Psychiatric Association (APA) (2000) further defines mental illness or mental disorder as “a clinically significant behavioral or psychological syndrome or pattern that occurs in a person and that is associated with present distress (e.g., a painful symptom) or disability (i.e., impairment in one or more important areas of functioning), or with a significantly increased risk of suffering, death, pain, disability, or an important loss of freedom . . . and is not merely an expectable and culturally sanctioned response to a particular event (e.g., the death of a loved one)” (p. xxxi).
- ◆ **Serious mental illness (SMI):** Mental illness that has compromised both the client’s level of function and his or her quality of life is known as SMI.
- ◆ **Serious and persistent mental illness (SPMI)** is the preferred term for serious mental illness of a chronic nature. For example, schizophrenia is usually classified as an SPMI.
- ◆ **Addiction:** A complex neuro biobehavioral disorder characterized by impaired control, compulsive use, dependency, and craving for the activity, substance, or food. Relapses are possible even after long periods of abstinence (Armstrong, Feigenbaum, Savage, & Vourakis, 2006; National Institute on Drug Abuse [NIDA], 2004a).
- ◆ **Substance use disorders:** The spectrum of disorders that include substance abuse and dependence and are attributed to problematic consumption or illicit use of alcohol, tobacco, illicit, and legal drugs (Armstrong et al., 2006).
- ◆ **Levels of alcohol use** (National Institute on Alcohol Abuse and Alcoholism [NIAAA], 2007):
  - Abstinence:* Consumption of fewer than four standard drinks per year.
  - Low-risk drinking:* Low-level alcohol use that is not problematic (see below).
  - Risky/hazardous use:* Pattern of alcohol consumption that increases the risk of harmful consequences for the user or others.
  - Harmful use:* Alcohol consumption that results in consequences to physical and mental health.
  - Alcoholism:* Also known as “alcohol dependence,” a disease that includes four symptoms: craving, loss of control, physical dependence, and tolerance.
- ◆ **Dependence:** An adaptive physiological state that includes craving, loss of control, physical dependence, and usually tolerance (NIAAA, 2007; NIDA, 2004a).
- ◆ **Screening:** A mechanism used to evaluate the presence of substance use problems and to estimate the probability of a specific disorder. This may include evaluation of a client’s blood alcohol level or other tools, such as questionnaires (NIAAA, 2007).
- ◆ **Tolerance:** The need for significantly increased amounts of alcohol or drug to achieve intoxication or the desired effect or a markedly diminished effect with the continued use of the same amount of alcohol or drug (Armstrong et al., 2006).
- ◆ **Relapse:** Return to heavy alcohol, tobacco, or drug use after a period of abstinence or moderate use (NIAAA, 2007).

## MENTAL HEALTH IN TRANSITION

The advances in research today and evolving best evidence-based practice models of mental health care are gaining ground across the world in various mental health centers of excellence. At the same time, numerous centers provide care with declining resources such that services are compromised. The science on brain structure functions and how learning occurs over time has impacted mental health services by expanding the possibilities of available therapies. Today,

provision of care requires neurophysiologic, neurochemical, genetic, and endocrine considerations. This means that community health nurse approaches require holistic assessment that integrates physical, psychological, and sociocultural knowledge in the provision of care.

Several documents address the need for prevention and treatment for mental health disorders, such as *Healthy People 2010* (USDHHS, 2000), the National Health Promotion and Disease Prevention Objectives (2000), and the Report of the Surgeon General on Mental Health, submitted by David Satcher (USDHHS, 1999). The health care goals addressed within *Healthy People 2010* (USDHHS, 2000) are relevant to community mental health nursing (see Table 27.1). Noted are improvements in mental health including reduction of suicide rates in the general population, reduction of suicide attempts by adolescents, reduction in the number of homeless persons with severe mental illness, and increase in employment of persons with serious mental illness. Several objectives focusing on treatment expansion for the mentally ill include the following:

1. Reduction of relapse rates for persons with eating disorders;
2. Increase in mental health screening and assessment in primary care settings;
3. Increase in the numbers of children and adults with mental illness who receive treatment;
4. Increase in treatment for persons with dual diagnosis (including substance abuse);

5. Increase in treatment for mentally ill persons in juvenile justice facilities and jails.

The Report of the Surgeon General on Mental Health (USDHHS, 1999) was the first Surgeon General’s report ever published on the topic of mental health and mental illness. The report concluded that effective treatments are available for most adults with a serious mental illness who are age 18 and over and who currently or at any time during the past year have had a diagnosable mental, behavioral, or emotional disorder of sufficient duration to meet diagnostic criteria specified within DSM-IV, TR (Diagnostic and Statistical Manual for Mental Disorders, Text Revision; APA, 2000). The focus on the promotion of increased access to educational and employment opportunities for people with disabilities (both physical and psychiatric) was evident in President George W. Bush’s New Freedom Initiative in 2001. The initiative also noted the need to increase access to assistive and universally designed technologies (2004). The Commission on Mental Health identified three impediments to the provision of quality mental health care on April 29, 2002 (Commission on Mental Health, 2003):

1. Stigma that surrounds mental illnesses
2. Unfair treatment limitations and financial requirements placed on mental health benefits in private health insurance
3. Fragmented mental health service delivery system

**TABLE 27.1 *Healthy People 2010*—Summary of Objectives Focus Area 18**

**Goal:** Improve mental health and ensure access to appropriate, quality mental health services.

**Number Objective**

***Mental Health Status Improvement***

18-1	Reduce the suicide rate
18-2	Reduce the suicide attempts by adolescents
18-3	Reduce the proportion of homeless adults who have serious mental illness (SMI)
18-4	Increase the proportion of persons with serious mental illness (SMI) who are employed
18-5	(Developmental) Reduce the relapse rates for persons with eating disorders including anorexia nervosa and bulimia nervosa

***Treatment Expansion***

18-6	(Developmental) Increase the number of persons seen in primary health care who receive mental health screening and assessment
18-7	(Developmental) Increase the proportion of children with mental health problems who receive treatment
18-8	(Developmental) Increase the proportion of juvenile justice facilities that screen new admissions for mental health problems
18-9	(Developmental) Increase the proportion of adults with mental disorders who receive treatment
18-10	(Developmental) Increase the proportion of persons with co-occurring substance abuse and mental disorders who receive treatment for both disorders
18-11	(Developmental) Increase the proportion of local governments with community-based jail diversion programs for adults with serious mental illness (SMI)

***State Activities***

18-12	State tracking of consumer satisfaction
18-13	State plans addressing cultural competence
18-14	State plans addressing elderly persons

## Incidence and Prevalence of Mental Disorders

Mental illness is a global problem (World Health Organization [WHO], 2007). In its Global Burden of Disease Study, WHO showed that mental illness, including suicide, accounts for more than 15% of mortality worldwide. In the United States alone, more than 57.7 million people experience a diagnosable mental disorder (National Institute of Mental Health [NIMH], 2006a). Of this group, more than 6.5 million, including 4 million children and adolescents, are disabled by a SMI (USDHHS, 1999).

An estimated 7.6% of adults age 18 or older (approximately 16.4 million adults) reported at least one major depressive episode during the past year (Office of Applied Studies [OAS], 2007). More than 19 million Americans older than 18 years of age will suffer from a depressive illness at some time during their lives, and many of these individuals will be incapacitated for significant lengths of time by their illness. The age-adjusted suicide rate per 100,000 population for 2004 was 15.2% for men and 3.6% for women, with almost half of these with a diagnosed mental disorder (Centers for Disease Control and Prevention [CDC], 2006). Over two-thirds of suicides in the United States each year are caused by major depression. More than 2 million Americans 18 years of age and older, about 1% to 1.6% of the population, suffer from bipolar disorder, and an almost equal number of adults suffer from schizophrenia (NIMH, 2006a).

The poor, poorly educated, and the unemployed typically experience higher rates of mental illness than the general population. A large portion of the mentally ill population, many of whom are homeless, remain untreated in the community. The poor, disproportionately representative of racial and ethnic minorities, are even more vulnerable due to the lack of access to care and the questionable quality of the care that is received (Substance Abuse and Mental Health Services Administration [SAMSHA], 2003). The homeless are more likely to experience behavioral health issues, such as substance use disorders and mental illness. Alcohol use disorders (AUDs) are as high as 84% in homeless men and 58% of homeless women (D'Amore, Hung, Chiang, & Goldfrank, 2001; North, Eyrich, Pollio, & Spitznagel, 2004). The majority of hospital admissions among the homeless are for treatment of substance use or mental illness. In one study on the homeless, 33.2% of the population reported depression, and 9.6% had been professionally diagnosed with a mental illness other than depression (Greater Cincinnati Coalition for the Homeless, 2001).

Age influences the patterns of mental illness in the community. Each year about one of every five children and adolescents has the signs and symptoms of a mental health disorder described and defined by the APA in the fourth edition of DSM-IV, TR. The most commonly occurring conditions among American children ages 9 to 17 years are anxiety disorders, disruptive disorders, mood disorders, and substance use disorders. Attention-deficit/hyperactivity disorder (ADHD) affects approximately 3% to 5% of U.S. children, or about 2 million school-age children, with boys two to three times more likely to be affected than girls (NIMH, 2006a). Autism, a developmental disorder, affects 3.4 out of every 1,000 children ages 3 to 10 (NIMH, 2006a) and is four times more common in boys than in girls (NIMH, 2006b). For American adults, the most prevalent mental disorders are anxiety

disorders, followed by mood disorders, especially major depression and bipolar disorder. Anxiety, depression, and schizophrenia present special problems for this age group— anxiety and depression because they contribute to such high rates of suicide, and schizophrenia because it is so persistently disabling. For the growing number of older adults, there is increased incidence of Alzheimer disease (8%–15% of adults age 65 and over); major depression (8%–20%); anxiety (11.4%), and other disabling mental disorders.

Gender differences also arise in the prevalence of certain mental disorders. Anxiety disorders and mood disorders, including major depression, occur twice as frequently in women as in men. Women of color, women on welfare, poor women, and uneducated women are more likely to experience depression than women in the general population. The three main types of eating disorders (anorexia, bulimia nervosa, and binge eating) also affect more women than men (Hudson, Hiripi, Pope, & Kessler, 2007).

Although suicide attempts are more common in women, men are more likely to be successful (National Center for Health Statistics [NCHS], 2004). Analysis of national suicide data from 1991 to 1996 suggested that White and African American widowed men younger than age 50 were at particular risk to commit suicide, compared with the general population of married men, and young African American men were most at risk (Luoma & Pearson, 2002). White men aged 85 and over, living alone, with a recent loss of a spouse or significant other account for 50% of suicides.

## Cost of Mental Health Disorders

Adding to the heavy toll that mental illness exacts is the financial burden it creates. Costs associated with treatment of mental disorders—poor productivity, lost work time, and disability payments—are astronomical. The direct and indirect costs of mental illness and addictive disorders in the United States are greater than \$273 billion annually. Furthermore, the cost to society when treatment is not provided for these illnesses is three times the cost of direct treatment (National Alliance on Mental Illness [NAMI], 2007). Certainly, these facts have policy implications and suggest the need for greater preventive and mental health-promoting efforts. The final report of the President's New Freedom Commission on Mental Health (2003) notes the governmental efforts to transform mental health care (see Display 27.1).

## SUBSTANCE USE AND THE COMMUNITY HEALTH NURSE

Substances used in the United States that have the potential for dependence include alcohol, tobacco, and other drugs both legal and illegal. Substance use occurs across a continuum that includes abstinence, low-risk use, risky/hazardous use, harmful use, and dependence (Babor, Higgins-Biddle, Saunders, & Monteiro, 2001) (Fig. 27.1). From a community perspective, all substance use other than abstinence or low-risk use poses a threat to the overall health of the community as well as individuals and families. Reductions in substance use (including tobacco) are two of the 28 focus areas in *Healthy People 2010* (USDHHS, 2000). The community health nurse plays a vital role in developing successful prevention and treatment programs related to substance

## DISPLAY 27.1

## THE FINAL REPORT OF THE PRESIDENT'S NEW FREEDOM COMMISSION ON MENTAL HEALTH

### Achieving the Promise: Transforming Mental Health Care in America

This *Final Report* conveys the Commission's bold vision for transforming the existing, often intimidating maze of mental health services into a coordinated, consumer-centered, recovery-oriented mental health system. Although barriers stand in the way, with national resolve and leadership, they will be overcome.

The Commission recognizes that historically Americans have assumed responsibility locally and regionally for working together to meet challenges and to support their neighbors and communities. A major step toward achieving the vision will require genuine collaborative efforts from all parties who deliver or use mental health services and supports. All must recognize the interwoven nature of the diverse programs that make up the mental health system and, in turn, must see where program flexibility and cooperation can be strengthened in the interest of consumers and families.

To transform the mental health care system, the Commission proposes a combination of goals and recommendations that together represent a strong plan for action. No single goal or recommendation alone can achieve the needed changes. No level or branch of government, no element of the private sector can accomplish needed change on its own. To transform mental health care as proposed, collaboration between the private and public sectors and among levels of government is crucial.

Mental illness is the only category of illness for which State and local governments operate distinct treatment systems, making comprehensive care unavailable in the larger

health care system. Ultimately, this situation must change, but to do so requires health care reform beyond the Commission's scope.

As has long been the case in America, local innovations under the mantle of national leadership can lead the way for successful transformation throughout the country.

Health care in America is at a pivotal point where reform must occur and mental health must share in that reform. The Nation has a vested interest and a tremendous stake in doing what is right to correct a system with problems that resulted from layering multiple, well-intentioned programs.

The integrated strategy outlined in this *Final Report* can achieve the transformation that will allow adults with serious mental illness and children with serious emotional disturbances to live, work, learn, and participate fully in their communities. Indeed, as has long been the case in America, local innovations under the mantle of national leadership can lead the way for successful transformation throughout the country.

As a Commission, we are grateful to the many strong and courageous individuals who gave their time, and in some cases traveled great distances to share their stories. It is for these individuals—as well as for the ones who continue to go unserved—that we must take swift, courageous action to transform the current maze of services, treatments, and supports into an efficient and cohesive mental health care delivery system. We owe them, their families, and future generations nothing less.

use in a community. These prevention programs are not limited to prevention of dependence but rather include the entire spectrum of use.

The community health nurse must begin with a basic understanding of the differences between substances of abuse since different substances pose different threats to the health of a community. This understanding can help the community health nurse match the community intervention to the substance in question, the desired outcome, and the particular needs of the target population. For example, the development of a tobacco smoking-prevention program in adolescents is quite different from a program to reduce drug-related intentional injuries.

Not only must the community health nurse understand the issues related to a specific substance of abuse (e.g.,

tobacco versus alcohol or versus cocaine), the nurse must also have a clear idea of the desired outcomes related to a treatment or prevention program. The key to successful community health interventions is to know initially what the over-arching goal of the intervention is. In other words, what aspect of substance use is the program addressing? To help in this process the nurse must also have a basic understanding of the different substances that have addictive potential (see Table 27.2), types of interventions available, the evidence to support their use, and the impact the substance use is having on the community. Examples of different over-arching goals include increasing access to treatment for SUDs, reducing alcohol-related motor vehicle crashes, reducing illicit drug related crime, or reducing secondary smoke exposure in public areas.

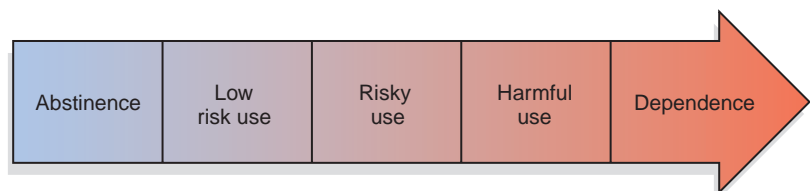

FIGURE 27.1 Continuum of substance use.

TABLE 27.2 Drugs Involved in Substance Abuse

Drug Type	Facts	Possible Signs of Use/Abuse	Possible Health Risks of Use/Abuse
<p><b>Cannabis</b>            Hashish (hash, herb, kif)            Hashish oil (hash oil, honey)            Marijuana (grass, weed, dope, ganja, reefer, pot, Acapulco gold, Thai sticks)</p>	<p>Cannabis is made from the hemp plant, <i>Cannabis sativa</i>. When smoked or ingested produces mild euphoria, relaxation, and intense sensory perception. Users may develop tolerance and physical dependence. Sinsemilla is a highly potent form of marijuana.</p>	<p>Relaxation and euphoria            Altered perceptions of time and space            Hallucinations or anxiety attacks with sinsemilla use</p>	<p>Damage to heart and lungs            Damage to brain nerve cells            Memory disorders            Temporary loss of fertility            Psychological dependence</p>
<p><b>Depressants</b>            Alcohol (brew, juice, liquor)            Barbiturates (downers, barbs)            Benzodiazepines (Valium, Librium, tranquilizers)            Chloral hydrate (knockout, Mickey Finn)            Glutethimide (Doriden)            Methaqualone (Quaalude, Ludes)            Other Depressants (Equanil, Miltown, Noludar, Placidylm, Valmid)</p>	<p>Depressants depress or slow down the central nervous system by relaxing muscles, calming nerves, and producing sleep. Alcohol is a depressant. Depressants are composed of sedative-hypnotic and tranquilizer drugs. Depressants are addictive. Users of depressants develop a tolerance to the drugs, meaning larger doses must be taken each time to produce the same effect.</p>	<p>Relaxation and drowsiness; lack of concentration; disorientation; loss of inhibitions; lack of coordination; dilated pupils; slurred speech; weak and rapid pulse; distorted vision; low blood pressure; shallow breathing; staggering; clammy skin; fever, sweating; stomach cramps; hallucinations, tremors; and delirium</p>	<p>Liver damage; convulsions; addiction with severe withdrawal symptoms; coma; death due to overdose. For pregnant women: the newborn may be dependent and experience withdrawal or suffer from birth defects and behavioral problems</p>
<p><b>Hallucinogens</b>            Lysergic acid diethylamide (LSD)            Phencyclidine (PCP, angel dust)            Mescaline and peyote (Mesc, buttons, cactus)            Psilocybin (mushrooms)            Amphetamine variants (MDMA/Ecstasy, MDA/Love Drug, TMA, DOM, DOB, PMA, STP, 2.5-DMA)            Phencyclidine analogues (PCE, PCPy, TCP)            Other hallucinogens (Bufotenine, Ibogaine, DMT, DET)</p>	<p>Hallucinogens are psychedelic, mind-altering drugs that affect a person's perception, feelings, thinking, self-awareness, and emotions. A "bad trip" may result in the user's experiencing panic, confusion, paranoia, anxiety, unpleasant sensory images, feelings of helplessness, and loss of control. A "flash back" is a reoccurrence of the original drug experience without taking the drug again.</p>	<p>Dilated pupils, increased body temperature, heart rate, and blood pressure; sweating; loss of appetite; sleeplessness; dry mouth; tremors; hallucinations; disorientation; confusion; paranoia; violence; euphoria; anxiety; and panic</p>	<p>Agitation; extreme hyperactivity; psychosis; convulsions; mental or emotional problems; death</p>
<p><b>Inhalants</b>            Amyl nitrate (poppers, snappers)            Butyl nitrate (rush, bolt, bullet)            Chlorohydrocarbons (aerosol sprays, cleaning fluids)            Hydrocarbons (solvents, airplane glue, gasoline, paint thinner)            Nitrous oxide (laughing gas, whippets)</p>	<p>Inhalants are substances that are breathed or inhaled through the nose. Inhalants are depressants and depress or slow down the body's functions. Inhalants are normally not thought of as drugs because they are often common household or industrial products. However, inhalants are often the most dangerous drugs per dose.</p>	<p>Euphoria and lightheadedness; excitability; loss of appetite; forgetfulness; weight loss; sneezing; coughing; nausea and vomiting; lack of coordination; bad breath; red eyes; sores on nose and mouth; delayed reflexes; decreased blood pressure; flushing (skin appears to be reddish); headache; dizziness; and violence</p>	<p>Depression; damage to the nervous system and body tissues; damage to liver and brain; heart failure; respiratory arrest; suffocation; unconsciousness; seizures; heart failure; sudden death from sniffing</p>

TABLE 27.2 Drugs Involved in Substance Abuse (*Continued*)

Drug Type	Facts	Possible Signs of Use/Abuse	Possible Health Risks of Use/Abuse
<b>Narcotics</b>			
Codeine (school boy) Heroin (H, harry, junk, brown sugar, smack) Meperidine (doctors) Methadone (dollies, methadose) Morphine (morpho, Miss Emma) Opium (Dover's powder) Other narcotics (Percodan, Talwin, Lomotil, Darvon, Numorphan, Percocet, Tylox, Tussionex, fentanyl)	<p>Narcotics are composed of opiates and synthetic drugs. Opiates are derived from the seed pod of the Asian poppy. Synthetic drugs called opioids are chemically developed to produce the effects of opiates.</p> <p>Initially, narcotics stimulate the higher centers of the brain, but then slow down the activity of the central nervous system.</p> <p>Narcotics relieve pain and induce sleep.</p> <p>Narcotics, such as heroin, are often diluted with other substances (i.e., water, sugar) and injected.</p> <p>Other narcotics are taken orally or inhaled.</p> <p>Narcotics are extremely addictive.</p> <p>Users of narcotics develop a tolerance to the drugs, meaning larger doses must be taken each time to produce the same effect.</p>	<p>Euphoria; restlessness and lack of motivation; drowsiness; lethargy; decreased pulse rate; constricted pupils; flushing (skin appears to be reddish); constipation; nausea and vomiting; needle marks on extremities; skin abscess at injection sites; shallow breathing; watery eyes; and itching</p>	<p>Pulmonary edema; respiratory arrest; convulsions; addiction; coma; death due to overdose. For users who share or use unsterile needles to inject narcotics: tetanus, hepatitis, HIV/AIDS. For pregnant women: premature births; stillbirth, and acute infections among newborns</p>
<b>Steroids</b>			
Anabolic-Androgenic (roids, juice, d-ball)	<p>Steroids may contribute to increases in body weight and muscular strength. The acceleration of physical development is what makes steroids appealing to athletes and young adults.</p> <p>Anabolic-androgenic steroids are chemically related to the male sex hormone testosterone.</p> <p>Anabolic means to build up the muscles and other tissues of the body.</p> <p>Steroids are injected directly into the muscle or taken orally.</p>	<p>Sudden increase in muscle and weight; increase in aggression and combativeness; violence ("roid rage"); hallucinations; jaundice; purple or red spots on body, inside mouth, or nose; swelling of feet or lower legs (edema); tremors; and bad breath.</p> <p>For women: breast reduction, enlarged clitoris, facial hair and baldness, deepened voice. For men: enlarged nipples and breasts, testicle reduction, enlarged prostate, baldness.</p>	<p>Acne; high blood pressure; liver and kidney damage; heart disease; increased risk of injury to ligaments and tendons; bowel and urinary problems; gallstones and kidney stones; liver cancer. For men: impotence and sterility. For women: menstrual problems. For users who share or use unsterile needles to inject steroids: hepatitis, tetanus, AIDS</p>
<b>Stimulants</b>			
Amphetamines (uppers, pep pills) Cocaine (coke, flake, snow) Crack (rock) Methamphetamines (ice, crank, crystal) Methylphenidate (Ritalin) Phenmetrazine (Preludin, Preludes) Other stimulants (Adipex, Cylert, Didrex, Ionamin, Melfiat, Plegine, Sanorex, Tenuate, Tepanil, Prelu-2)	<p>Stimulants stimulate the central nervous system, increasing alertness and activity.</p> <p>Users of stimulants develop a tolerance, meaning larger doses must be taken to get the same effect.</p> <p>Stimulants are psychologically addictive.</p>	<p>Increased alertness; excessive activity; agitation; euphoria; excitability; increased pulse rate, blood pressure, and body temperature; insomnia; loss of appetite; sweating; dry mouth and lips; bad breath; disorientation; apathy; hallucinations; irritability; and nervousness</p>	<p>Headaches; depression; malnutrition; hypertension; psychosis; cardiac arrest; damage to the brain and lungs; convulsions; coma; death</p>

From Spradley, B.W., & Allender, J.A. (1996). *Community health nursing* (4th ed.). Philadelphia: Lippincott-Raven.

## Trends of Substance Use

How does the community health nurse start the process? First, it is important to know the trends related to substance use across different populations and communities. This information is useful to the community health nurse when developing a prevention program. If the target population is young adults, prevention of heavy episodic (binge) drinking may be a top concern because of the high prevalence of heavy episodic drinking in this population (Toumbourou, Stocwell, Neighbors, Marlatt, & Rehm, 2007). If the target population is the homeless adult then the community health nurse will need to know about chronic alcohol, cocaine, and heroin use in the local homeless community because of the high prevalence of SUDs in this population (Lynch & Greaves, 2000).

## Difference Between Legal and Illegal Substance Use

The second step for the community health nurse is to appreciate the difference between legal and illegal substance use. Alcohol and tobacco are legal substances in the United States, but other drugs such as marijuana, heroin, and cocaine are illegal. Use of illegal drugs affects the community not only in relation to the morbidity associated with drug use in individuals but also in relation to problems of drug trafficking and other illegal activities engaged in by the user and the seller. Thus, cultural, environmental, and pharmacological differences related to a specific substance influence the type of community health interventions needed as well as the planned outcomes.

## Consequences of Substance Use

The third step is to understand the consequences of substance use that affect a community as a whole. These consequences include violence, motor vehicle crashes, and injuries, especially related to alcohol and illicit drug use (Cherptel, 2007). These risks are present in all age groups. For example, alcohol use increases the risk for injury in the elderly (Zautcke, Coker, Morris, & Stein-Spencer, 2002).

Another serious consequence to the community is the increased risk of morbidity and mortality related to substance use. This affects the community by decreasing the healthy work force and increasing the cost of providing health care. For example, although protective at low levels of use, alcohol in excess of recommended levels increases the risk of developing serious health consequences, such as cancer or heart disease (Bagnardi, Blangiardo, LaVecchia, & Corrao, 2001). There is no safe level of alcohol consumption during pregnancy; women who drink alcohol during pregnancy are at increased risk for having a baby with fetal alcohol spectrum disorder (FASD) or fetal alcohol syndrome (FAS) (NIAAA, 2006a). Members of the community with FASD and FAS require lifelong support, resulting in increased costs related to education, health care, and social services (Bloss, 1994).

## Substance Use and the Environment

The last step is to view substance use from an environmental perspective. The impact of substance use varies based on the substance. Tobacco is an environmental pollutant. Exposure

to secondary tobacco smoke increases the risk for health issues related to tobacco use including cancer and respiratory complications. Alcohol interacts with the environment in relation to point of sale. Sociologic studies have demonstrated an increase in motor vehicle crashes related to the location of bars and liquor stores, especially drive-through stores (Scribner, MacKinnon, & Dwyer, 1994, 1995).

The health care objectives addressed within *Healthy People 2010* (USDHHS, 2000) relevant to substance use are listed under Focus Area 26 (Table 27.3). The goal is to “reduce substance abuse to protect the health, safety, and quality of life for all, especially children.” Among the 25 objectives listed are reducing the consequences of use, reducing actual use, reducing risk factors associated with harmful use, increasing access to treatment, and supporting policy initiatives.

**TABLE 27.3** *Healthy People 2010—Focus Area 26: Substance Abuse*

**Goal:** Reduce substance abuse to protect the health, safety, and quality of life for all, especially children.

Number	Objective Short Title
--------	-----------------------

### *Adverse Consequences of Substance Use and Abuse*

26-1	Motor vehicle crash deaths and injuries
26-2	Cirrhosis deaths
26-3	Drug-induced deaths
26-4	Drug-related hospital emergency department visits
26-5	Alcohol-related hospital emergency department visits
26-6	Adolescents riding with a driver who has been drinking
26-7	Alcohol- and drug-related violence
26-8	Lost productivity

### *Substance Use and Abuse*

26-9	Substance-free youth
26-10	Adolescent and adult use of illicit substances
26-11	Binge drinking
26-12	Average annual alcohol consumption
26-13	Low-risk drinking among adults
26-14	Steroid use among adolescents
26-15	Inhalant use among adolescents

### *Risk of Substance Use and Abuse*

26-16	Peer disapproval of substance abuse
26-17	Perception of risk associated with substance abuse

### *Treatment for Substance Abuse*

26-18	Treatment gap for illicit drugs
26-19	Treatment in correctional institutions
26-20	Treatment for injection drug use
26-21	Treatment gap for problem alcohol use

### *State and Local Efforts*

26-22	Hospital emergency department referrals
26-23	Community partnerships and coalitions
26-24	Administrative license revocation laws
26-25	Blood alcohol concentration (BAC) levels for motor vehicle drivers

## EVIDENCE-BASED PRACTICE

### Substance Use Prevention with Adolescents: What Works and What Does Not Work?

As nurses, when we move from an individual-based approach to a community-based approach we need to evaluate evidence from a population perspective. A major step in preventing SUDs is to focus on substance use in adolescents. A recent article by Toumbourou et al. (2007) provides us with a well-conducted systematic review of the literature related to the effectiveness of interventions aimed at reducing harm associated with adolescent substance use. A systematic review should be comprehensive and unbiased; it should use a strict scientific design to select and assess research articles. This article is a good example of a rigorous review and provides us with a broad overview of what works and what does not.

The authors examined evidence related to public health policies, harm reduction, prevention, screening, brief intervention, and treatment related to adolescents. They reported that public health policies related to substance use do work, such as taxation and ignition interlocks. They also reported that prevention interventions were more successful when the intervention was maintained over several years and used more than one strategy. They stated that screening and brief intervention holds promise as an effective means of reducing harmful alcohol or tobacco use and there is growing evidence that it may work with other drugs.

They concluded that harm reduction strategies were also effective in reducing harmful substance use. However, for treatment of SUDs with adolescents, the results were inconsistent. In addition, although there is evidence of the efficacy of many practices related to the prevention and treatment of SUDs in adolescents, more research is needed to demonstrate their effectiveness in real-world settings. Therefore, we can with confidence support a number of practices related to prevention of SUDs in adolescents but should also be aware of the need for more field research, especially in relation to treatment.

## Prevalence of Substance Use and Substance Use Disorders

This section discusses the prevalence of substance use and SUDs. Different levels of use across populations are described based on the quantity, frequency, duration, and pattern of the use, as well as levels related to the prevalence of dependence. To obtain prevalence data related to substance use, surveys are conducted nationwide on a regular basis. The community health nurse can easily get updates on the results of surveys by accessing the websites of both the NIDA and NIAAA. Prevalence data are reported in different ways, and it is important to distinguish between the types of reports. Some reports focus on consumption rates based on gender, ethnic/racial group, or age group. Others focus on the prevalence of SUDs.

## Alcohol

Over 50% of the adult population report current alcohol use. Alcohol is an integral part of the American culture, with 80% of adults reporting use of alcohol over their lifetime. In the United States and other countries, people use alcohol in religious ceremonies, celebrations, and sporting events, and as the beverage of choice at a meal. Unlike other drugs of abuse, alcohol can be consumed in moderation without resulting in alcohol dependence. To help distinguish risky and harmful use from responsible use of alcohol, NIAAA has published recommended drinking limits. For the general male adult population the recommended drinking limits are fewer than five standard drinks daily or 14 weekly. For the general female adult population the recommended drinking limits are fewer than four standard drinks daily or eight weekly, and for people age 65 and older, recommended drinking limits are no more than one standard drink daily or seven standard drinks weekly. The NIAAA recommends that pregnant women and women who may become pregnant abstain from alcohol (NIAAA, 2007).

A standard drink contains about 14 grams of alcohol (0.6 fluid ounces or 1.2 tablespoons) which is equivalent to one 12-ounce bottle of beer or wine cooler; 8 to 9 ounces of malt liquor; one 5-ounce glass of table wine; 3 to 4 ounces of fortified wine; 2 to 3 ounces of cordial, liqueur, or aperitif; 1.5 ounces of brandy; or 1.5 ounces of 80-proof distilled spirits (Fig. 27.2). Heavy use is defined as drinking more than the recommended limits per drinking day, at least five different days in a month. Episodic heavy drinking (binge drinking) is defined as drinking above the recommended limits per drinking occasion at least once in the past month (NIAAA, 2007).

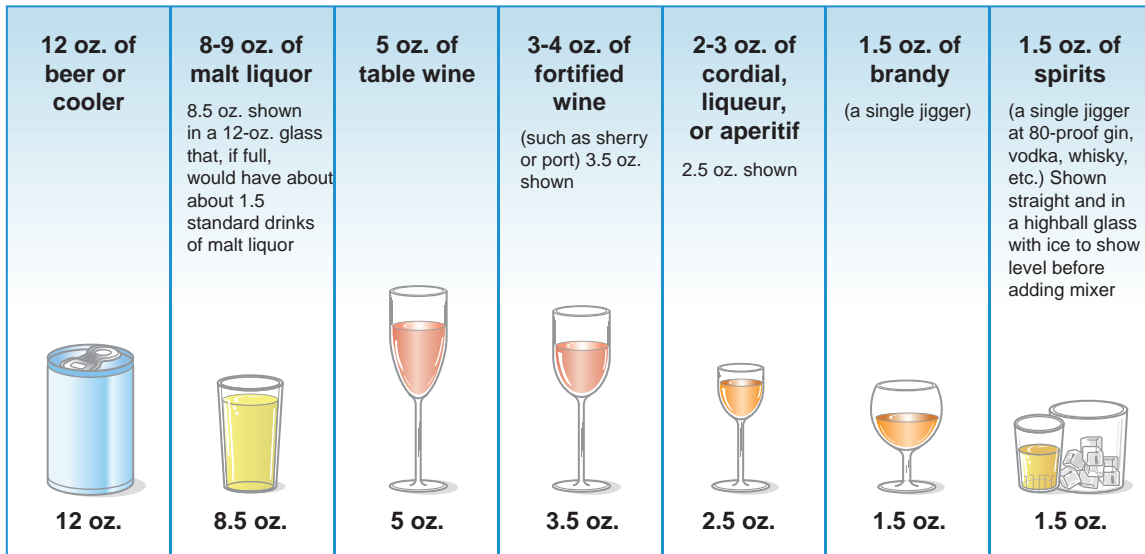

Trends in alcohol use in the United States differ across subsets of the population. Young adults (age 18 to 25) have the highest incidence of problem drinking (Monti, Tevyaw, & Borsari, 2006). Based on recently published information, a little less than 5% of the total population met the criteria for alcohol dependence in 2001–2002. The highest percentage was in the 18 to 29 year age group (6.95%) and the lowest (1.2%) was in those over age 65 (Fig. 27.3) (Grant et al., 2004; NIAAA, 2004).

Although the reported prevalence of alcohol use disorders (AUDs) in the elderly is low, the prevalence of AUDs and alcohol-related consequences in the elderly may increase over the next few decades due to a cohort effect. Currently over 60% of baby boomers (age 45–64) consume alcohol (O'Connell et al., 2004). Another problem is underdetection of AUDs in this population. Thus, current estimates of AUDs in this population may not be a true picture.

One population with the highest prevalence of AUDs is the homeless; AUDs are as high as 84% in homeless men and 58% of homeless women (North et al., 2004). This high prevalence in a population most likely to experience problems with access to treatment can result in increased hospital admissions as well as increased alcohol-related morbidity (Salit, Kuhn, Hartz, Vu, & Mosso, 1998).

## Tobacco

Tobacco use is the primary cause of one in every six deaths and is the most prevalent addictive disorder. Encouragingly there has been an overall decline in tobacco use over the

NOTE: People buy many of these drinks in containers that hold multiple standard drinks. For example, malt liquor is often sold in 16-22, or 40 oz. containers that contain between two and five standard drinks, and table wine is typically sold in 25 oz. (750 ml) bottles that hold five standard drinks.

**FIGURE 27.2** Standard drink. Adapted from NIAAA (2007).

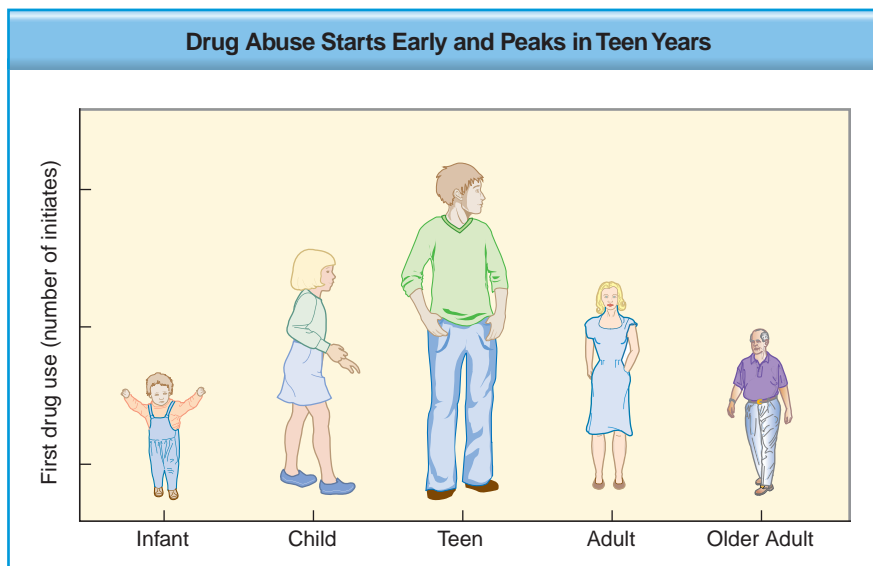

past decade, but this decline is not consistent across age groups and genders. An estimated 70.3 million Americans aged 12 or older consumed tobacco. Tobacco consumption includes cigarettes, pipes, cigars, and smokeless tobacco (chew). Between 2001 and 2006, daily tobacco use declined among eighth, tenth, and twelfth graders, but the decline in tobacco use is slowing. The high prevalence of tobacco use among youth is one of the top 10 statistical global public health highlights (WHO, 2007). Also, there is no decline in tobacco use among those with mental illness. Those with a mental illness other than schizophrenia have a prevalence of tobacco use two to four times higher. Ninety percent of those diagnosed with schizophrenia use tobacco (NIDA, 2006).

### Other Drugs

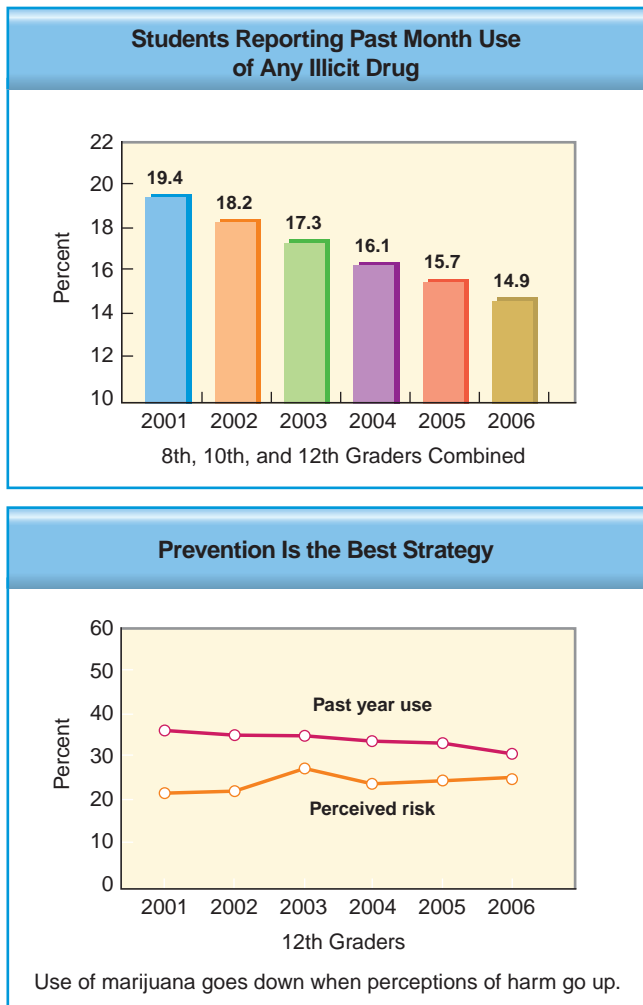

The overall national statistics related to illicit drug use are encouraging. In a survey of students in the eighth, tenth, and twelfth grades, reported use of any illicit drug in the past month declined by almost 23% in a five-year period, from 19.4% in 2001 to 14.9% in 2006 (NIDA, 2006) (Fig. 27.4). However, illicit drug use continues in the United States especially among those aged 18 to 25.

### Marijuana

Marijuana is the most frequently reported illicit drug. More than 94 million Americans age 12 and older have tried

**FIGURE 27.3** Prevalence of drug abuse across the lifespan. Adapted from National Institute on Drug Abuse (2006). *Monitoring the Future Survey*. Retrieved August 19, 2008 from <http://www.nida.nih.gov/DrugPages/MTF.html>.

**FIGURE 27.4** Trends in illicit drug use in youth. Adapted from National Institute on Drug Abuse. (2006). *Monitoring the Future Survey*. Retrieved August 19, 2008 from <http://www.nida.nih.gov/DrugPages/MTF.html>.

marijuana at least once, with most current users being adolescents and young adults. Lifetime use by 12th graders has declined slightly (NIAAA, 2006b). However, from 1992 to 2002 the prevalence of marijuana-related disorders increased particularly among older Americans, young Blacks, and Hispanic men (NIDA, 2004a; Zickler, 2005). Compton, Grant, Colliver, Glantz, and Stinson (2004) concluded that one explanation might be the increased potency of marijuana. Another explanation for the increase in use by older Americans may be a possible cohort effect among baby boomers.

### Cocaine

Cocaine is a powerful addictive stimulant that directly affects the brain. In 2002, approximately 1.5 million Americans were dependent on or abusing cocaine, the majority of them males between the ages of 18 and 25. There are approximately 2 million current users of cocaine. In a study of 14 metropolitan areas, up to 49% of male offenders tested positive for cocaine. From 1992 to 2002, cocaine-related emergency department visits increased 33% (NIDA, 2004b).

### Heroin

According to a 2003 survey, an estimated 3.7 million people had used heroin in their lifetime and more than 314,000 used it in the past year (NIDA, 2006). Most were over age 18 and male. Approximately 57.4% of past-year users were classified with a heroin use disorder. In 2002, approximately 93,000 emergency department visits were related to heroin use.

### Meth, Ecstasy, and PCP

There are numerous other drugs of abuse. Examples include methamphetamine, MDMA (methylenedioxyamphetamine or Ecstasy), phencyclidine (PCP), and inhalants. Methamphetamine use is spreading geographically especially into nontraditional drug use areas, such as the suburban and rural Midwest with an increase in “mom and pop” labs (NIDA, 2004a). MDMA has spread outside the club scene with an increase in emergency department visits related to MDMA. The use of PCP, a drug popularly in use during the late 1980s and early 1990s, has reemerged.

### Prescription Drugs

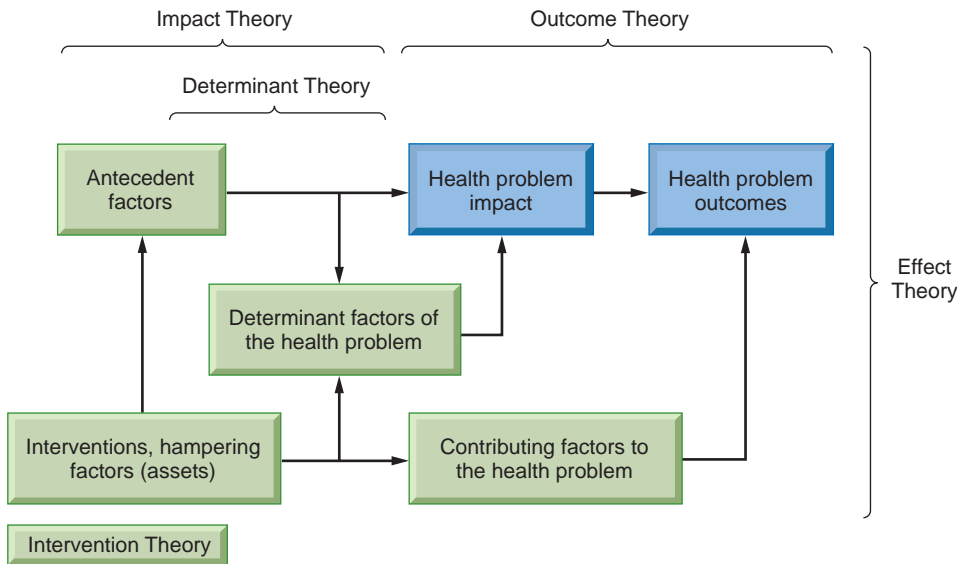

Abuse of prescription drugs occurs across all age groups, and there has been a rise in prescription drug abuse among college students over the last few years (Whitten, 2006). Prescription drugs for managing pain, especially, can be misused. These drugs include oxycodone (OxyContin), a medication designed to alleviate pain related to cancer; hydrocodone (Vicodin); and meperidine (Demerol). Stimulant drugs such as methylphenidate (Ritalin) are also misused.

## THEORETICAL FRAMEWORKS

Effective community and population-based interventions begin with the application of specific frameworks that help the planners identify why and how the intervention will work. Two theoretical frameworks used in community/public health science are *process theory* and *effect theory*. They are both part of the Logic Model of Program Theory and are used to plan the program, deliver the program, and evaluate the program (Issel, 2004). In relation to behavioral health, process theory helps the community health nurse identify the resources and structure needed to develop, implement, and evaluate the program. Effect theory provides the rationale for why the intervention will work (Fig. 27.5).

### Effect Theory: Component of Program Theory

The challenge for the community health nurse in developing interventions related to behavioral health is the fact that both mental health and substance use have a strong behavioral component. Effect theory is a useful framework for behavioral health. There are four components to the theory: determinant theory, intervention theory, impact theory, and outcome theory (Issel, 2004). Determinant theory relates to what contributes to the health problem. This is an essential component since an intervention usually focuses on one or more determinants of the health problem, either by reducing risk or providing protection against the risk. Intervention theory relates to what is actually being done (see From the Case Files).

**FIGURE 27.5** Elements of Effect Theory, incorporating need or problem statement components. From Issel, L.M. (2004). *Health planning and evaluation*. Boston: Jones and Bartlett Publishers, with permission.

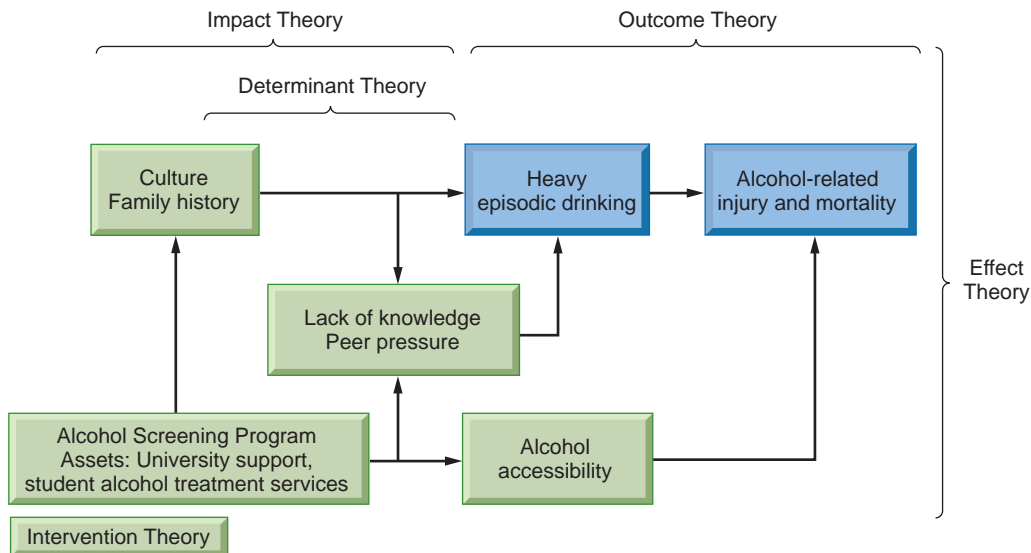

## From the Case Files

### Smoking Cessation Program for Mothers in a Rural County

You have been working in the public health department well-child clinic in a rural Appalachian county and noticed that more than one-third of the mothers you are seeing are smokers and that their babies seem to be smaller than the babies of moms who do not smoke. When you mention smoking to individual mothers, they tell you they want to stop, but just are not able to. You are interested in putting together a smoking cessation program. You decide to use Issel's effect theory as a framework for building your intervention and convincing the county to fund the program. What data do you need before you begin to look at interventions (see strategy 1 below)? What data can you get using existing databases, and what data will you need to collect yourself? Once you have reviewed the data, you decide that you want to include smoking cessation as part of well-baby visits for all mothers who are current smokers. What do you need to do before you put together the program (see strategy 2 below)? After you have gathered all this information, what final piece is needed before you present your proposal to your public health department (see strategy 3 below)? If you are able to implement the program what immediate impact do you expect to have and what long-term outcomes are you hoping for?

#### Strategies

1. Preliminary data needed:
  - a. Low-birth-weight rates compared to state and national rates. (Available vital statistics public health data)
  - b. Low-birth-weight rates for smokers versus nonsmokers in your county, compared with the state and the nation. (Protected vital statistics public health data that will need approval from the state for you to access and analyze)
  - c. Comparison of asthma rates in children in your county with smoke-free homes versus homes with a parent smoking. (Available survey data using prior studies, but may not be current. Will most likely need to conduct a survey at the county level. Check with state public health department for state level data.)
  - d. County tobacco use rates based on gender and age, and trends among adolescent girls in your county schools compared to state and national rates. (Available public health survey data at state and national levels. May need to conduct a survey at the county level.)
2. A review of the evidence related to smoking-cessation interventions with women of child-bearing age. Were any of the studies conducted with Appalachian women? Will you need to make some adjustments to interventions that work based on culture? Are there possible economic constraints for this population in relation to pharmacologic interventions? Are the time frames reasonable in your setting?
3. You need to do an analysis of the cost to implement the program, complete a cost-benefit projection, have clear program goals and objectives, and formulate a plan to evaluate the effectiveness of the program.

**FIGURE 27.6** Elements of Effect Theory, example for reduction of alcohol-related injury and mortality in college students.

The desired health impact refers to the immediate impact expected from the program. For example, if the health problem is heavy episodic (binge) alcohol consumption among college students, a logical approach may be to institute an alcohol-screening program. For such a program the immediate *impact* for the program may be that 25% of students are screened and 75% of those who require a brief intervention and/or a referral for further assessment receive those interventions. However, the desired *outcome* of the program is an overall reduction in heavy episodic alcohol consumption on campus over the next 2 years. Remember that not all desired impact is related to change. The goal may be to stabilize, prevent, or maintain a health state or problem. Having a clear understanding of what a behavioral program can actually accomplish and what long-term goal it hopes to achieve prior to implementing the program will provide a clearer picture of how to proceed with the program.

When using effect theory to design a prevention program for behavioral health, a good place to start is to identify the specific health problem and then the desired health problem impact and health problem outcome (Fig. 27.6). As the program is developed, the community health nurse starts by identifying the antecedent factors that led to behavioral health problems. This provides a clear rationale for why the intervention should provide the desired impact.

### Public Health Prevention Theory and Behavioral Health

Three public health models of prevention provide the nurse with a guide to decide what level of prevention is the focus of the program, the type of intervention to use, and the target population. The Centers for Disease Control and Prevention (CDC) (1992) presented two complementary prevention models: the primary, secondary, and tertiary prevention model based on the natural history of disease and the behavioral, clinical, and environmental model based on how the prevention technology is delivered (CDC, 1992; Savage, 2006).

Primary prevention is conducted when no disease is present in the target population, the primary goal being prevention of disease development. Secondary prevention is conducted when the disease is subclinical with no symptoms or early symptoms present, the goal being early identification and treatment. Tertiary prevention is conducted when disease is present with symptoms, the goal being to prevent consequences of the disease, such as disability or death.

Behavioral prevention includes a broad array of strategies aimed at changing lifestyles, (e.g., exercise, smoking cessation, balanced nutrition). It is a complex, sequential process targeted at individuals or groups. The goal of the intervention is to change behaviors that put the person at risk for developing the disease or to prevent consequences of the disease. Clinical prevention is based on the medical model for preventive services. It relies on one-to-one, provider-to-patient interaction and occurs within the traditional health care delivery system. Environmental prevention relies on a societal commitment for the implementation of the interventions and aims to alter the environment by reducing risk (e.g., community-wide decrease in availability of the substance, underage drinking law enforcement).

Another model used in the behavioral health field for developing prevention programs is the model used by the Institute of Medicine (IOM) based on Gordon's model: Classification of Disease Prevention. This model helps to frame the focus of the intervention, relying on three levels of prevention: universal, selected, and indicated. Universal prevention strategies address the entire population (national, local community, school, neighborhood), with messages and programs aimed, for example, at preventing or delaying the abuse of alcohol. Selective prevention strategies target subsets of the total population that are deemed to be at risk for alcohol abuse by virtue of their membership in a particular population segment. Indicated prevention strategies are designed to prevent the onset of abuse in individuals who do not meet DSM-IV, TR criteria for addiction, but who are showing early danger signs, such as falling grades and

consumption of alcohol and other gateway drugs (Mrazek & Haggerty, 1994).

One example of the application of this model is a description of different interventions aimed at prevention of FAS. Universal prevention strategies would address the entire population of women of childbearing age (national, local community, school, neighborhood), with messages and programs aimed at preventing the use of alcohol if pregnancy is a possibility. Selective prevention strategies would target subsets of women of childbearing age who are deemed to be at risk for alcohol use by virtue of their membership in a particular population segment. Indicated prevention strategies would be designed to prevent the use of alcohol in pregnant women who had screened positive for alcohol use during pregnancy or already had a child diagnosed with FAS or FASD.

## DETERMINANTS OF BEHAVIORAL HEALTH

What determines a person as mentally healthy or mentally ill, or as a casual substance user or a serious substance abuser, is complex. Genetics, environment, the societal frame of reference and context, and other factors play a role.

### Determinants of Mental Health

Characterizing mental health versus mental illness is difficult because human beings evolve over the years with varied developmental tasks to achieve at each life stage while confronting day-to-day stressors associated with one's role functions. Complicating the issue is the frame of reference used in each society. Cultural beliefs differ regarding what one's behavior should or should not be and the level of tolerance for certain actions. There are expectations, standards, or legal parameters that put one's actions or behavior in a particular context that suggests health or illness. The APA (2003) defined mental health as *a state of being that is relative rather than absolute. The successful performance of mental functions shown by productive activities, fulfilling relationships with other people, and the ability to adapt to change and to cope with adversity.*

The process of adaptation can be a source of stress. Several factors influence each individual's perception of stress and subsequent response. Lazarus and Folkman (1984) define stress as the person's appraisal of the environment as "taxing" or endangering well-being. This implies that an event's significance is an individual personal experience. Certain elements are involved in this process: genetic factors, such as physical and psychological characteristics; learned patterns of coping or adaptation reinforced over time; and prevailing circumstances in each person's life. Correspondingly, the responses evoked may reflect adaptive or maladaptive functioning as evidenced by thoughts, feelings, and behaviors that are age-appropriate and congruent with sociocultural mores or standards. It is essential that individual coping mechanisms enable the person to function appropriately at home, work, and in various social settings. At times, the situation experienced may be perceived as overwhelming without adequate family or social support systems, thus creating a fertile ground for alcohol or drug dependency as a way of dysfunctional coping.

## Determinants of Substance Use Disorders

Determining the etiology of SUDs has challenged researchers for decades. The debate has centered on *nature versus nurture*, that is, how much is related to genetics (nature) and how much to the environment (nurture) (Bozarth, 1990). With the mapping of the human genome, hope has increased that the genes related to SUDs could be identified. Genetics has a major role in the development of alcohol dependence, which is thought to be a multigenomic disorder influenced by the environment (gene-environment interaction) (Hardie, 2007). Both alcohol and drug dependence share common genetic risk factors (Luo et al., 2006). In addition to genetic heritability both personal and environmental factors are involved comparably in the etiology and course of SUDs (McLellan, Lewis, O'Brien, & Kleber, 2000).

Researchers have made significant progress in understanding the determinants of SUDs. Environmental influences connected to development of SUDs include influence of peers, lower socioeconomic status, partner use, and substance use by family members (Kendler et al., 2000; Kilpatrick et al., 2000). Individual factors associated with the development of AUDs include high antisocial behavior, high impulsivity, major depression, social anxiety problems, a history of childhood sexual abuse, hyperactivity, attention problems, and seminal events, such as loss of a spouse in the elderly (Knopik et al. 2004; Poikolainen, 2000; Reinherz et al., 2000).

## SCREENING AND BRIEF INTERVENTION IN BEHAVIORAL HEALTH

This section discusses the use of screening in behavioral health as a means for preventing development of mental health and SUDs and for providing early intervention. As mentioned earlier, screening is the presumptive identification of an unrecognized disease or defect by the application of tests, examinations, or other procedures that can be applied rapidly. From an apparently well population, screening tests sort out persons who potentially have or are at increased risk for a disease from those who probably do not have the disease. Screening is the first step in a process that may or may not lead to a diagnosis of disease; it is not intended to be diagnostic. If a screening test result is positive, a diagnostic work-up should follow. Treatment should be initiated after a disease state is diagnosed.

### Screening for Mental Health Disorders: BPRS, MADRS, CES-D10

The need for early detection has been highlighted in the New Freedom Commission on Mental Health report (2003). The reports calls for early mental health screening, assessment, and referral to mental health service programs. About 10% of children and adolescents in the United States have a mental illness that impairs functioning, yet only about 20% of this population receive treatment and services. It is critical that community health nurses focus on early detection and treatment of mental illness in this vulnerable population. Notably, suicide in the United States represents a major public health problem resulting in about 3,000 young lives lost every year. About 90% of those who commit suicide have a mental illness (USDHHS, 1999). Reducing suicide among

youth requires mental health screening. Several mental health screening programs are available.

The National Depression and Anxiety Screening Day is an example of a community-level mental health awareness, disease-prevention program. The resources and materials, such as a comprehensive kit of materials, promotional information, media campaign, training, and technical assistance, are available by visiting the mental health screening website (see Internet Resources at the end of this chapter).

Every community health clinic can implement a routine screening program to capture mental illness problems early. Standardized screening tools for anxiety or depression are also available, such as the Brief Psychiatric Rating Scale (BPRS) (Fig. 27.7) (Overall & Gorham, 1988); the Beck Depression Scale, and the Montgomery Ashberg Depression Rating Scale (MADRS). The MADRS is known for its utility of administering the instrument from the practitioner standpoint given time constraints in the clinic.

A commonly used screening instrument for depression developed in the late 1970s is the Center for Epidemiologic Studies Depression Scale (CES-D) (Fig. 27.8) (Radloff, 1977). The CES-D and the shorter version, the CES-D 10, have established reliability and validity across populations and cultures and are widely used clinically to screen for depression (Andresen, Malmgren, Carter, & Patrick, 1994; Boey, 1999; Hann, Winter, & Jacobson, 1999; Radloff, 1991).

## Screening for Substance Use and Substance Use Disorders

When screening for substance use there are three aspects of screening: screening for actual consumption, screening for at-risk drinking, and screening for SUDs. The use of substances represents a continuum of levels of consumption and associated risks for SUDs as well as health and social consequences related to substance use.

**Brief Psychiatric Rating Scale**

Indicate assigned patient age, psychiatric diagnoses, brief history of present illness and prior psychiatric history

0 = Not present    1 = Very mild    2 = Mild    3 = Moderate    4 = Moderate    5 = Severe  
severe

- **SOMATIC CONCERN** - preoccupation with physical health, fear of physical illness, hypochondriasis
- **ANXIETY** - worry, fear, over concern for present or future, uneasiness
- **CONCEPTUAL DISORGANIZATION** - thought processes confused, disconnected, disorganized, disrupted
- **GUILT FEELINGS** - self-blame, shame, remorse for past behavior
- **TENSION** - physical and motor manifestation of nervousness, over-activation
- **MANNERISMS & POSTURING** - peculiar, bizarre unnatural motor behavior (except tic)
- **GRANDIOSITY** - exaggerated self-opinion, arrogance, conviction of unusual power or abilities
- **DEPRESSIVE MOOD** - sorrow, sadness, despondency, pessimism
- **HOSTILITY** - animosity, contempt, belligerence, disdain for others
- **SUSPICIOUSNESS** - mistrust, belief others harbor malicious or discriminatory intent
- **HALLUCINATORY BEHAVIOR** - perceptions w/o normal external stimulus
- **MOTOR RETARDATION** - slowed weakened movements or speech, reduced body tone
- **UNCOOPERATIVENESS** - resistance, guardedness, rejection of authority
- **UNUSUAL THOUGHT CONTENT** - odd, strange, bizarre thought content
- **BLUNTED AFFECT** - reduced emotional tone, reduction in formal intensity of feelings; flatness
- **EXCITEMENT** - heightened emotional tone, agitation, increased reactivity
- **DISORIENTATION** - confusion or lack of proper association for person, place or time
- **NANDA:** (Indicate appropriate nursing diagnoses based on observations noted)

### Level of Risk

Essentially, the continuum of use is based on the level of consumption (Fig. 27.1). This model is well developed in relation to alcohol consumption and serves as a model for understanding risk and how to interpret the screening results (Babor et al., 2001).

### Screening Instruments: Self-reports

The recommendations for screening are well developed and validated in relation to alcohol use and tobacco use. There is less evidence to support the use of a specific screening approach related to other drug use, both illicit and licit. However, the evidence is growing and a growing body of literature supports screening for substance use as a standard of care for all health professionals (Hack & Adger, 2002). The difficulty is to choose a screening instrument that will allow the clinician to screen for consumption, pattern, duration of use, and SUDs, but not all screening instruments include all elements. The other difficulty is determining whether the screening instrument has known sensitivity and specificity in the target population. For most screening instruments the sensitivity and specificity information is based on a general population and may not be as reliable for populations such as pregnant women or the elderly (O'Connell et al., 2004; Savage et al., 2003).

Health researchers began developing and testing screening instruments aimed at identifying SUDs in the 1970s. Examples of these instruments include the Michigan Alcoholism Screening Test (MAST) (Selzer, 1971), the Drug Abuse Screening Test (Skinner, 1982), and the CAGE questionnaire (Ewing, 1984). These self-report instruments were developed for general adult populations with a focus on dependence. They were designed to distinguish persons who probably *are* dependent from those who apparently *are not*. If the clinician only uses a tool that screens for dependence and does not

screen for consumption or onset of consumption, then valuable clinical information may be missing since consumption in general puts a person at risk for negative consequences, such as injury and the potential of negative interactions with other medications. Thus levels and patterns of consumption are as important as early identification of an SUD.

For the community health nurse, screening programs are a valuable prevention tool. Prior to developing a screening program it is important to establish what the screening is for (consumption and/or SUDs) and the target population as well. Then an appropriate screening tool can be chosen.

Two main methods of screening for substance use are self-report and biologic markers. Self-report relies on the person to complete a screening instrument. Examples of screening instruments for alcohol use include the Alcohol Use Disorders Identification Test (AUDIT) (Fig. 27.9) (Babor et al., 2001) and the CAGE questionnaire (Ewing, 1984). Examples of screening instruments for drug use include the Drug Abuse Screening Test (DAST) (Skinner, 1982) and the Drug Use Screening Inventory (DUSI) (Tarter, 1990). These instruments vary based on length and whether or not they include questions related to quantity and frequency. For alcohol use, the screening instrument recommended by the NIAAA is the AUDIT (NIAAA, 2007). The WHO developed this instrument for use across populations, and it has established high reliability and validity across ethnic groups (Reinhart & Allen, 2007).

### Biologic Screens

Biologic markers used to detect substance use include urine, blood, hair, saliva, breath, and meconium. In contrast to self-report, biologic markers provide either direct or indirect evidence of use (Helander, 2001). They are used with self-report as a means of providing corroborating evidence of use (Allen & Litten, 2001). Factors that influence sensitivity and specificity of biologic markers include other metabolic disorders or other diseases, medication use, and reliability of

**During the past 6 months:**

- How often do you have a drink containing alcohol?  
Never (0)  
Monthly or less (1)  
Two to four times a month (2)  
Two to three times a week (3)  
Four or more times a week (4)
- How many drinks containing alcohol do you have on a typical day when you are drinking?  
1 or 2 (0)  
3 or 4 (1)  
5 or 6 (2)  
7 to 9 (3)
- How often do you have six or more drinks on one occasion?  
Never (0)  
Less than monthly (1)  
Monthly (2)  
Weekly (3)
- How often during the last year have you found that you were not able to stop drinking once you had started?  
Never (0)  
Less than monthly (1)  
Monthly (2)  
Weekly (3)
- How often during the last year have you failed to do what was normally expected from you because of drinking?  
Never (0)  
Less than monthly (1)  
Monthly (2)  
Weekly (3)  
Daily or almost daily (4)
- How often during the last year have you needed a first drink in the morning to get yourself going after a heavy drinking session?  
Never (0)  
Less than monthly (1)  
Monthly (2)  
Weekly (3)  
Daily or almost daily (4)
- How often during the last year have you had a feeling of guilt or remorse after drinking?  
Never (0)  
Less than monthly (1)  
Monthly (2)  
Weekly (3)  
Daily or almost daily (4)
- How often during the last year have you been unable to remember what happened the night before because you had been drinking?  
Never (0)  
Less than monthly (1)  
Monthly (2)  
Weekly (3)  
Daily or almost daily (4)
- Have you or someone else been injured as a result of your drinking?  
No (0)  
Yes, but not in the last year (2)  
Yes, during the last year (4)
- Has a relative or friend, or a doctor or other health worker been concerned about your drinking, or suggested you cut down?  
No (0)  
Yes, but not in the last year (2)  
Yes, during the last year (4)

AUDIT Score \_\_\_\_\_

**FIGURE 27.9** Alcohol Use Disorders Identification Test (AUDIT). Adapted from Babor, T.F., Higgins-Biddle, J.C., Saunders, J.B., & Monteiro, M.G. (2001). *The Alcohol Use Disorders Identification Test: Guidelines for use in primary care* (2nd ed.). World Health Organization. Retrieved February 8, 2007 from [http://drugsandstuff.co.uk/drugs/resources/publication\\_pdfs\\_etc/auditbro.pdf](http://drugsandstuff.co.uk/drugs/resources/publication_pdfs_etc/auditbro.pdf).

the method (Musshuff & Daldrup, 1998; Sommers, Wray, Savage, & Dyehouse, 2003). They are rarely used in a community-based screening program due to the cost and the problems with obtaining biologic specimens. Various groups, such as legal authorities, employers, or sports programs, use biologic markers to verify alcohol or drug use.

When developing a screening program for substance use the community health nurse must take a number of things into account. First, a screening program has to be prepared to provide or be able to refer persons who have a positive screen to the appropriate level of services. Since substance use occurs across a continuum, a screening program may identify persons with risky use who may not have a substance use disorder. Therefore, a program should have links to clinically appropriate treatment services for nondependent substance users as well as for dependent substance users. This usually

involves having linkages with community agencies that provide substance abuse treatment. Therefore, it is important to know communities' treatment capacity.

### **Brief Intervention for Positive Screens**

When planning a screening program related to substance abuse, some of the participants in the program will screen positive for risky or hazardous use and are candidates for a Brief Intervention (BI). A BI for alcohol use can be done by any trained health care provider and can be completed in a short time. A BI generally lasts from 5 to 15 minutes, usually over one to three sessions. Strong research evidence exists for the use of BI for heavy or excess nondependent drinkers, especially those identified in primary care settings (NIAAA, 2007). As a whole, providing a BI is generally more effective in the

year after delivery than if no intervention is given at all (Somers, 2007). Less work has been done with other substances.

## COMMUNITY-LEVEL INTERVENTIONS

As described in Chapter 15 the community health nurse begins with a community assessment in order to complete a community diagnosis. Once the nurse establishes a diagnosis, the next step is to decide on an intervention that can address the specific public health issue identified in the diagnosis. A good starting point in the development of community/public health intervention is to begin with the *Healthy People 2010* objectives (Tables 27.1 and 27.3). The nurse can review the objectives and locate the specific focus area that matches the community diagnosis. For example, if the community diagnosis relates to an increase in alcohol-related motor vehicle crashes in adolescents, there are two specific *Healthy People 2010* objectives related to that issue: reduction in motor vehicle crashes and deaths, and reduction in adolescents riding with a driver who has been drinking.

### Level of Intervention from a Community Health Perspective

Once the nurse identifies the focus of the intervention, the next step is to determine the level of prevention (see Chapter 14 for more information on theoretical frameworks). First, the natural history of disease provides the framework for the traditional public health model of primary, secondary, and tertiary prevention. The next step is to decide on the type of intervention: clinical, environmental, or behavioral. The final model relates to the scope of the intervention: universal, selected, or indicated. Because a motor vehicle crash is an event rather than a disease, the desired outcome is to reduce the number of those events related to a behavior rather than a disease. Thus the prevention of SUDs is not the focus but rather the behavior of drinking while driving. Therefore, neither a screening program (secondary prevention) nor an alcohol treatment program (tertiary prevention) is needed. Considering also that almost all adolescents either drive or ride with other adolescents, a primary behavioral intervention using a universal approach would probably work best to address this problem.

### Mental Health Community Interventions

“Integrative health assessment” has gained momentum in various health centers as a method for decreasing utilization of unwarranted procedures. The underlying premise here is that a person experiencing some personal trials and tribulations may manifest the stress through physical manifestations. There is greater recognition of the mind and body interaction. Accordingly, approaches to mental health promotion encompass physical, emotional, sociocultural, and intellectual considerations. Integrative health assessment is the process of identifying relevant factors, such as the following:

1. Treatment history relative to mental or emotions issues. This includes the visit to a psychologist or mental health professional for complaints of anxiety or periods of loneliness.
2. Personal life stressors. Each day, there are daily tasks relative to one’s age and appropriate role function. This may be as a parent, provider, or

employee. Some subtle manifestations include irritability, impulsiveness, or frustration intolerance that the individual cannot cope with in a socially appropriate manner.

3. Disturbances in sleep, appetite, or energy level that are not attributable to a rational explanation given the person’s daily lifestyle.
4. Complaints of chronic pain of somatic nature that is not attributable to a physical dysfunction.
5. History of abuse, trauma, substance use, and family history of mental illness.

One best practice of note is the Intermountain Healthcare program at Salt Lake City, Utah. Information about “mental health integration” can be accessed via the center’s website (see Internet Resources).

Today, the community population is subjected to many uncertainties through instantaneous worldwide communication systems. Threats to personal or family safety are basic to mental health. Problems in global peace, the possibility of bioterrorism, or threats of natural disasters or calamities are unsettling. The exposure to fear and anxiety from disseminated information has untold psychological implications. For instance, the tragic news of the 2007 Virginia Tech student massacre immediately reached the global population via the Internet and was repeatedly aired via television and radio. Everyone felt shock and sorrow, although indirectly. It is clear that the psychological trauma imposed by events of this nature has implications for everyone’s mental well-being.

### Mental Health Promotion

As the field of mental health services has matured through advances in epidemiologic methods, research, and treatment, interest in illness prevention and health promotion has increased (USDHHS, 1999). Treatment and prevention of mental illness are important and ongoing priorities in community mental health, but promoting mental health, which is essential to healthier people for the future, needs greater emphasis.

#### Anticipated Outcomes of Mental Health Promotion

Mental health includes the successful performance of mental function that results in (1) productive activities, (2) fulfilling relationships, (3) the ability to adapt to change, and (4) the ability to cope with adversity. Targeting of these areas becomes a way of prioritizing in planning for health-promoting interventions. Designing programs in community mental health settings encourage productive activities (e.g., sports, hobbies), fulfilling relationships (e.g., foster grandparenting), adapting to change (e.g., volunteering), and coping with adversity (e.g., preparing for developmental crises) (USDHHS, 1999).

### Interventions for Mental Health Promotion

Several different approaches can be used in designing interventions for mental health promotion. Two of them are discussed here: development of interventions to protect people who are potentially at risk for mental disorders, and promotion of healthy activities and lifestyles to the general public.

## Risk-protective Activities

Epidemiologic data, along with the results of a growing body of other kinds of research, provide the community mental health nurse with increasing information about the factors that place people at risk for mental disorders. Targeting at-risk individuals with health promotion interventions gives them the resources needed to raise their own levels of health and protects them from mental disorders. It is known, for example, that consumption of alcohol, illegal drugs, and tobacco during pregnancy can damage the fetus. Consequently, extensive prenatal education and support programs can promote parental health and reduce this risk for the next generation. It also is known that abuse and neglect during childhood are risk factors for certain mental disorders. Promoting healthy parenting and stress-reducing activities through classes, group work, and other means can promote the health of parents and protect the health of their children.

## Lifestyle and Behavior Activities

To promote the well-being of the public, health promotion interventions that are both life-sustaining and life-enhancing can be planned. Life-sustaining activities include proper nutrition and exercise, healthy sleep patterns and adequate rest, healthy coping with stress, and the ability to use family and community supports and resources. Health promotion programs in the community may address any or all of these. An example is educating schoolchildren about the food guide pyramid and encouraging healthy snacks and well-balanced meals in the home. Other examples include fitness programs for all ages, promotion of community playgrounds and walking or biking trails, and establishing networks of support in the community such as Meals on Wheels and other volunteer programs.

Life-enhancing activities include meaningful work, whether through or outside of employment, creative outlets, interpersonal relationships, recreational activities, and opportunities for spiritual and intellectual growth. Again, mental health promotion interventions can address any or all of these areas. For example, arts and crafts classes and fairs encourage creative expression, community sports events promote social outlets, participation in Elderhostel and other kinds of learning experiences promote spiritual and intellectual stimulation, volunteer programs encourage community participation, and classes to develop new skills promote meaningful vocation.

## Role of the Community Mental Health Nurse

The nurse's role in community mental health is multifaceted; this has been evident throughout the chapter. First of all, the nurse must be able to *access and use epidemiologic data* to understand and serve the mentally ill population. This means identifying the incidence and prevalence of mental disorders, examining the causes and risk factors associated with mental illness, and identifying the needs of people with mental disorders. Nurses sometimes serve as part of the epidemiologic investigative team to conduct surveys and assist with data collection.

## Advocacy

Next, an important part of the nurse's role with the mentally ill is *advocacy*. In this role, the nurse seeks to increase client access to mental health services, to reduce stigma and promote improved public understanding of this population, and to improve services in community mental health. The advocacy role requires being politically involved by serving on decision-making boards and committees, lobbying for legislative changes, and helping to influence mental health policy development that will better serve this population. Membership in state and national nursing organizations can be helpful in establishing collaborative partnerships to benefit the mentally ill. Membership in the National Alliance for the Mentally Ill (NAMI, 2001) or other advocacy groups can also effect positive change.

In any of these venues, the vision and expertise of the community mental health nurse can be used to advocate for enhancing existing services, developing new services, and increasing access for the mentally ill to all services.

## Education

Another aspect of the nurse's role is *education*. The community mental health nurse teaches clients individually and in groups about their mental health conditions, their treatment protocols, ways to function more independently in the community, prevention and health-promoting strategies, and much more. The nurse also teaches the public through community education programs and has an educational role with caregivers, family and community members, and health care decision makers by providing information for service planning.

## Case Management, Finding, and Referral

*Case management* for persons with SMIs is also part of the community mental health nurse's role. This includes screening, assessment, care planning, arranging for service delivery, monitoring, reassessment, evaluation, and discharge. It is often offered within the context of a community mental health center (CMHC). Case management helps the person with an SMI to access services and live as independently as possible.

The nurse's role also involves *case-finding and referral*. This means early identification of persons with mental disorders who are in need of treatment and referral of those persons to the appropriate resources for treatment. The purpose of this role is secondary prevention, because early identification and treatment help to ameliorate the severity of the mental disorder and promote a speedier recovery.

## Collaboration

Finally, the nurse's role includes *collaboration*. Whether serving individual clients, groups, or populations, the nurse is part of the larger community mental health team and works in collaboration with many people to accomplish the goals of community mental health. The composition of the team—made up of clients, psychiatric nurses, physicians, social workers, nutritionists, epidemiologists, psychologists, health planners, and many more—is diverse and varies depending on the community health nurse's work setting. Collaboration allows for a pooling of professional expertise

that enhances the quality and effectiveness of services for the mentally ill.

When working with the mentally ill, the nurse must be aware of issues of personal safety. Although most mentally ill clients are no more prone to violence than the population at large, conditions involving paranoia, hallucinations, or mania can increase clients' tendency toward physical violence. There are situations in which social workers, physicians, or nurses have been harmed by psychotic clients. Clients who are under the influence of drugs or alcohol pose a potentially serious threat to the nurse's safety. The nurse should be prepared for this eventuality with those clients suffering from addictions. Nurses working with this population must use caution in any situation that suggests danger and must take action immediately to protect themselves and their clients. This may require the nurse to take self-defense classes or assertiveness training or to carry protective gear. It may help to use an escort from a security service, collaborate with the police, or establish a "buddy system" in which two nurses work together in isolated or dangerous homes or areas. Additionally, the public health agency may consider hiring risk-management consultants to examine dangerous situations and recommend actions to preserve safety.

The nurse serving in community mental health plays many roles that are practiced in a variety of settings in collaboration with other members of the community mental health team. It is the challenge of this role and the opportunity to assist in raising the level of mental health for individuals and communities that make this field of practice so rewarding.

In this century (and beyond) community living is characterized by heightened stress and anxiety levels with daily life impacted by traffic congestion, rising fuel costs, threats of global warming and environmental pollution, increased divorce rates, deterioration of the basic family as a unit, continued reliance on the judicial system to resolve family and social conflicts, and incidence of crimes via the Internet. Indeed, individually and collectively, mental health and wellness must be a *national priority*. Healthy bodies necessitate a healthy mind.

Community organizations, religious groups, and educational institutions play critical roles in enhancing mental wellness by helping each person through the provision of family support as the basic unit of the community. The National Alliance on Mental Illness (NAMI) is a nationwide organization with chapters in each state and county. NAMI's website contains extensive information that can be utilized by both consumer and care provider. As a national organization, NAMI is committed to enhance the care of those with mental illness and improve the quality of life of those who are affected. NAMI has the "Families to Families" program designed to provide education to families and help them learn the requisite skills in caring for a mentally ill family member. Another NAMI program is called "Peer to Peer." This is a support group designed to help the consumers cope with the illness and live productive lives.

Nonprofit organizations focus on advocacy, education, service, and funding research endeavors. Mental Health America (formerly known as the National Mental Health Association [NMHA]) is a leading nonprofit organization that promotes mental health. In its position statement, the organization urged the federal government to address the need for comprehensive, community- and strengths-based, consumer- and family-driven mental health programs. The organization

was established in 1909 as a reform movement by former psychiatric patient Clifford W. Beers who experienced abuse during his stay in public and private mental institutions.

## Substance Use and Community-level Interventions

The National Alcohol Screening Day (NASD) is an example of a population-based nationwide screening program aimed at identifying persons with alcohol use disorders. The program is designed to be implemented on the community level in settings such as primary care, college campuses, the work place, or faith-based agencies. For a small registration fee, NASD supplies community organizations with a screening kit that provides all the necessary information needed to conduct the screening program. This model has the national organization providing the media support and the tools for conducting a community-screening program while the agency supplies the clinicians and facilities for conducting the screening program.

Another example of obtaining ready-made population-based screening programs is to use a company that specializes in conducting such programs. For example, an employer may need a more intensive screening program that includes biologic markers as well as self-report. These programs follow current legal requirements for screening and have higher costs. Another population-based approach to screening for substance use is online screening. A participant can complete a self-report screening tool. Such an approach helps protect the anonymity of the participant. To be effective the program should include a means to connect those who screen positive to health care providers.

Two government agencies provide a major resource for the community health nurse in the development, implementation, and evaluation of programs aimed at the prevention and treatment of SUDs: the Center for Substance Abuse Prevention (CSAP) and the Center for Substance Abuse Treatment (CSAT). They are both divisions of Substance Abuse and Mental Health Services Association (SAMHSA) and have user-friendly websites. Their published programs are evidenced-based and often include resources needed to implement the programs, such as brochures.

Community efforts are essential because only 10% of persons who are in need of treatment seek it. Using a broader community approach can result in reducing harm to the community, preventing the development of SUDs, and reducing the burden of disease on the population.

## Policy-based Interventions

Not-for-profit, private for-profit, and governmental agencies play crucial roles in community health care. The provision of health care to the population requires multidisciplinary approaches that are driven by monetary reimbursements based on health care problems. Community mental health care policies may be instituted by local governments relative to administrative processes or procedural mechanisms. In contrast, however, at the national level the Tax Equity and Fiscal Responsibility Act (TEFRA), put in place in 1985, brought sweeping changes relative to capital outlay expenditures, hospital lengths of stay, and use of outpatient and home care services. This policy change directly and indirectly impacted the health care system.

Policies at the community or state levels aim to ensure the rights of individuals and public safety. Thus, cities or counties with appropriate jurisdiction over a geographic area develop policies and guidelines necessary to encourage mental health program development and implementations that address the needs of the community population. Depending on each county, certain rules or regulations apply. It is important to learn about the community agencies and interrelationships to other county service providers to ensure the coordination of care. At the local level are free-standing programs that focus on support for individuals, families, the indigent, or the homeless. Funding may come from charitable organizations or from local governments through grant moneys obtained from periodic requests for proposals (RFPs) or requests for applications (RFAs) issued by the local governing body. Other governmental agencies have roles in mental health by encouraging employee wellness in the workplace or through rules and regulations that encourage employers to provide benefits, such as mental health insurance, bereavement leave, or stress leave. The incidence of violence in the workplace has necessitated policy initiatives within the business community to respond by developing strategic plans and providing educational programs that address these issues.

### **Mental Health Policy**

In June 2002, a 22-member commission was established by President George W. Bush to analyze the public and private mental health systems, visit innovative model programs throughout the United States, and hear testimony from the mental health systems' stakeholders and from the consumers of mental health care, their families, advocates, public and private providers, administrators and mental health researchers. Fifteen subcommittees were established to examine specific aspects of mental health services and delineate recommendations for improving delivery of care. The final report was submitted to the President in May 2003. The Commission's PowerPoint presentations are all available on-line (see the New Freedom Commission on Mental Health in the Internet Resources section at the end of this chapter). This provides guidance to health practitioners for the delivery and access to mental health services across the spectrum of care.

The WHO, at the international level, provides assistance to each country's policy makers and planners in developing a plan for the population's mental health by utilizing available resources including promoting human rights, enhancing health, and minimizing debility from mental disorders. Many projects involve technical assistance training on comprehensive strategic planning. The WHO Mental Health Policy Project is developing guidelines for use by countries. The guidelines will serve as a framework for the creation of policies and services that, when implemented, can lead to improved mental health care, treatment, and promotion. Specifically the project stresses that mental health outcomes can be optimized when:

- ◆ Mental health is an essential component of public health,
- ◆ Government policies and actions protect and promote the mental health and well-being of its peoples,
- ◆ Services are appropriate, accountable, accessible, and equitable, and
- ◆ People are treated in the least restrictive and intrusive manner. (WHO, n.d.)

### **Substance Use Policy**

Policy related to substance use is defined broadly as any purposeful act on the part of a governmental or nongovernmental group to minimize or prevent adverse consequences related to use of potentially addictive substances. Specific strategies include implementing a law aimed at reducing use, such as taxation or a means to allocate resources related to prevention and/or treatment priorities (Babor et al., 2003).

One consistently used policy approach involves regulating the availability of the substance (AlcoholPolicyMD.com, 2005). In relation to illicit drugs, laws are in place that restrict availability through the classification of the drug. For alcohol and tobacco there are regulations on who may buy and who may sell the products. Other examples of governmental regulations related to alcohol and tobacco include drinking and driving laws, regulation of alcohol and tobacco promotion, regulations pertinent to bars, interlocks for individuals who drive drunk repeatedly, and limits on product outlet density (Toumbourou et al., 2007).

Policies in relation to alcohol and tobacco have a similar approach. Communities set policies that restrict both alcohol availability and consumption. This is done by controlling the number of alcohol outlets, regulating the current outlets, and setting laws that will allow the community to close problem outlets. These measures are implemented through policies related to zoning and the licensing of establishments that sell alcohol. Another measure has been to require responsible alcohol-service training for bartenders. Other examples include keg registration, stricter enforcement of underage sales of alcohol and tobacco, and controlling alcohol outlet density. Major efforts in relation to tobacco consumption in public areas have resulted in a drastic restriction of locations where tobacco users can smoke outside of their own home.

The focus of most policies related to illicit drugs has been to enact laws that criminalize the possession and sale of these substances. Other types of policies that have relevance, for example, are those enacted to prevent methamphetamine use. A number of states have restricted the sale of over-the-counter (OTC) medications that can be used to manufacture methamphetamine in home laboratories. The government enacted a major initiative when federal funding

#### DISPLAY 27.2

#### **HEALTHY PEOPLE 2010 LEADING HEALTH INDICATORS**

##### **Top Ten Health Indicators**

1. Physical Activity
2. Overweight and Obesity
3. Tobacco Use
4. Substance Abuse
5. Responsible Sexual Behavior
6. Mental Health
7. Injury and Violence
8. Environmental Quality
9. Immunization
10. Access to Health Care

was linked to a drug-free workplace. That is, any organization that receives federal funds, such as health care facilities that receive Medicare payments, must follow the SAMHSA guidelines (SAMHSA, n.d.).

## Summary

Behavioral health is a key component in the health of a community. Six of the top ten health indicators from *Healthy People 2010* are closely linked to behavioral health issues: tobacco use, substance use, responsible sexual behavior, mental health, injury and violence, and access to health care (Display 27.2). In every community in the United States and the world, behavioral health directly or indirectly affects every other indicator of health. Harmful substance use overburdens the medical, social, economic, and criminal justice systems of communities and governments.

Researchers have devoted decades to determining the etiology of substance use disorders specifically with regard to *nature versus nurture*—in other words, whether SUDs occur as a result of genetics or environment. Both alcohol and drug dependence share common genetic risk factors, but are also influenced by environmental factors (influence of peers, lower socioeconomic status, partner use, and substance use by family members) and personal factors (high antisocial behavior, high impulsivity, major depression, social anxiety problems, a history of childhood sexual abuse, hyperactivity, attention problems, and seminal events).

Treatment related to behavioral health at the community level begins with a community assessment in order to establish a community diagnosis, followed by intervention that can address the specific public health issue identified in the diagnosis. The community health nurse can use *Healthy People 2010* objectives as a starting point in the development of an intervention.

The community health nurse must incorporate behavioral health in the assessment, planning, and developing of community health interventions and in the evaluation of outcomes. With this comes the need for administrative, managerial, or supervisory support with commitment not only from a philosophical perspective but from a resource perspective as well. Success comes with a unified approach to mental health and substance use, requiring application of research, utilization of best practice models at the clinical level, and education of all concerned. ■

## ACTIVITIES TO PROMOTE CRITICAL THINKING

1. As a community health nurse, you have been asked to design and present a 2-hour program on suicide prevention to the entire student body of the local high school. This activity is representative of which level of prevention? What are some of the considerations involved in planning this program to promote optimal success? How might you measure the effectiveness of this intervention?
2. You are part of a multidisciplinary team whose goal is to identify families in your city who are at risk

for crisis (e.g., single parent, divorce, teen pregnancy, loss of job) and develop a set of interventions. How would you determine who these families are? What interventions would be appropriate to meet their needs? What level of prevention would you be targeting?

3. You have met a few elderly men in your area who live alone and are widowed, and you have heard that there are others. Assuming your advocacy role in community mental health, you decide to take some action to ensure that their needs are being met. How would you determine the risks and needs for this group? What interventions would be appropriate to meet their needs?
4. Select a problem that places people at risk for mental disorders (e.g., child abuse and neglect, drug abuse) and do a search on the Internet to learn all you can about it. What is the incidence and prevalence of this problem? What interventions are most effective in addressing it? What can be done to prevent it?

# Working with the Homeless

## LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Define the concept of homelessness.
- ◆ Describe the demographic characteristics of the homeless living in the United States.
- ◆ Discuss factors predisposing persons to homelessness.
- ◆ Compare and contrast the unique challenges confronting selected subpopulations within the homeless community.
- ◆ Examine the effects of homelessness on health.
- ◆ Analyze the extent and adequacy of public and private resources to combat the problem of homelessness.
- ◆ Assess your beliefs and values toward homelessness.
- ◆ Propose community-based nursing interventions to facilitate primary, secondary, and tertiary prevention in addressing the problem of homelessness.

*“Mid pleasures and palaces though we may roam,  
Be it ever so humble, there’s no place like home.”*

—John Howard Payne (1791–1852)

## KEY TERMS

Chronically homeless  
 Disenfranchised  
 Deinstitutionalization  
 Extremely low-income  
 Homelessness  
 Marginalized  
 Period prevalence counts  
 Point in time counts  
 Single-room occupancy  
 (SRO) housing  
 Survival sex  
 Unaccompanied youth  
 Unsheltered (hidden)  
 homeless

 **What** was once considered unthinkable in a prosperous nation is now an expected occurrence in towns and cities across the United States. Drive through an inner-city or suburban community on any given day and you will see people on street corners holding signs reading “Hungry and homeless.” Where is the public outcry in response to this scene? Has the American conscience been anesthetized to this form of human suffering? Or, is the need simply too overwhelming and the problems too far-reaching to mount an effective campaign to prevent such a tragedy?

The purpose of this chapter is to define the concept of **homelessness**, examine the factors contributing to homelessness, analyze the major issues confronting the homeless, and examine the role of the community health nurse in addressing the needs of the homeless.

*Healthy People 2010* defines a person who lacks housing as being homeless. The definition also includes persons living in transitional housing or persons who spend the majority of nights in public or private facilities with temporary living quarters (*Healthy People 2010*, n.d.a). Table 28.1 outlines selected *Healthy People 2010* goals that relate to the homeless population.

The McKinney-Vento Homeless Assistance Act (Title 42 of the U.S. Code) defines a person as homeless who lacks a fixed, regular, adequate night time residence including supervised public or private shelters that provide temporary accommodations, institutional settings providing temporary shelter, or public or private places that are not designed for or used as a regular sleeping accommodation for human beings (e.g., cars, parks, camp grounds). Incarcerated individuals, however, are not considered homeless under this definition (National Coalition for the Homeless [NCH], 2006r).

The education subtitle of the McKinney-Vento Homeless Assistance Act expands on the definition of homelessness when addressing homeless children and youth. The Act includes as homeless those children who share housing with others due to economic hardship or loss of housing,

are abandoned in hospitals, are awaiting placement in foster care, or are living in motels, trailer parks, or camping grounds (United States Department of Housing and Urban Development [USDHUD], n.d.c).

The Department of Housing and Urban Development interprets the McKinney-Vento definition of homeless to include only people living on the streets or in shelters or those facing imminent eviction (within 1 week). Although this definition may be appropriate for the urban homeless who are more likely to live on the street or in shelters, persons living in rural areas tend to cohabit with relatives or friends in overcrowded, substandard housing (NCH, 2006r).

## SCOPE OF THE PROBLEM

It is difficult to estimate the number of people who are homeless, since homelessness is a temporary condition. Rather than trying to count the number of homeless people on a given day or week (**point in time counts**), it may be more prudent to measure the number of people who have been homeless over a longer time frame (**period prevalence counts**) (NCH, 2006m).

It is also difficult to locate and account for people who are homeless. Most estimates are based upon the number of people served in shelters or soup kitchens or the number of people who can easily be located on the streets. People who frequent places that are difficult to reach (e.g., cars, camp grounds, caves, box cars) are considered “**unsheltered**” or “**hidden**” homeless. Many people are unable to access shelters due to overcrowding and limited capacity. In rural areas, fewer housing options and resources are available for the homeless. As a result, people are forced to live temporarily with friends or family. Although still experiencing homelessness, these individuals may not be counted in homeless statistics or considered eligible for homeless services (NCH, 2006m).

The National Law Center on Homelessness and Poverty estimates that approximately 3.5 million people (of whom 1.35 million are children) experience homelessness in a given year. Approximately 1% of the U.S. population experiences homelessness each year. However, since this data is based on a survey of service providers, and since many homeless people are unable to access services, it is likely that the prevalence of homelessness is even higher. It is unlikely that researchers will ever be able to estimate the exact magnitude of homelessness in America (NCH, 2006m).

In 1996, the Interagency Council on Homelessness, in collaboration with 12 federal agencies, commissioned the United States Bureau of the Census to conduct a National Survey of Homeless Assistance Providers and Clients (NSHAPC). This was a landmark study based on a statistical sample of 76 metropolitan and nonmetropolitan areas, including cities and rural areas. The survey was initiated in response to the lack of national data on the homeless. The survey did not produce a national count of the number of homeless people, but it did provide information about the characteristics of homeless people who were able to access services (USDHUD, n.d.b). Although dated, this was the most recent survey of its kind until January 2007, when the Homelessness Research Institute of the National Alliance to End Homelessness published a report entitled “Homelessness Counts.” This report used local point in time counts of communities across the United States

**TABLE 28.1 Selected *Healthy People 2010* Goals Related to Homelessness**

Overarching Goals	Increase quality and years of healthy life Eliminate health disparities
Related Focus Area Goals	Increase the proportion of persons who have a significant source of ongoing care Increase the proportion of persons with health insurance Reduce the proportion of families that experience difficulties or delays in obtaining health care or do not receive needed care for one or more family members

Source: Healthy People 2010. (n.d.b). Healthy People goals. Retrieved September 29, 2006 from <http://www.healthypeople.gov/About/goals.htm>. Healthy People 2010 (n.d.c). Retrieved August 22, 2008 from <http://www.healthypeople.gov/hpscscripts/KeywordResult.asp?n320=320&Submit=Submit>.

to estimate the number of homeless people nationwide. The study reported that in January 2005 an estimated 744,313 people experienced homelessness. Of these, 56% were living in shelters and 44% were unsheltered (Homelessness Research Institute, 2007).

In 2005, The United States Conference of Mayors Task Force on Hunger and Homelessness conducted a survey of 24 cities across the nation. Seventy-one percent of the survey cities reported an increase in requests for emergency shelter during the past year. Requests for emergency shelter by homeless families with children increased in 63% of the survey cities. The number of emergency shelter beds for homeless people increased by 7%. People remained homeless for an average of 7 months. Eighty-seven percent of the cities reported an increase in the length of time people remained homeless. An average of 14% of shelter requests by homeless people and 32% of shelter requests by homeless families were reported to have gone unmet during the prior year. In 88% of the cities, emergency shelters may have turned away homeless families because of a lack of resources (U.S. Conference of Mayors, 2005).

## DEMOGRAPHICS

Poverty is inextricably linked to homelessness. The increase in poverty and the growing shortage of affordable rental housing have led to a dramatic rise in homelessness over the past two decades (NCH, 2006r). Demographic groups more likely to be poor are also at greater risk of becoming homeless.

### Age

In 2003, children under 18 accounted for 39% of the homeless population. Of these, 42% were under 5 years of age. Twenty-five percent of the homeless are between 25 and 34, and 6% are between 55 and 64 (NCH, 2006r).

### Gender

Single homeless adults are more likely to be male than female. The U.S. Conference of Mayors (2005) survey found that single men comprised 43% and single women 17% of the homeless population. According to the NSHAPC survey, 77% of single homeless clients were male and 23% were female. The majority of homeless clients (85%) were single. Of parents in homeless families, 84% were female and 16% were male (USDHUD, n.d.b).

### Ethnicity

The racial and ethnic makeup of the homeless population varies based upon geographic location. In urban areas, African American males constitute a large percentage of the homeless population while in rural areas the homeless are more likely to be White, Native American, or migrant workers (NCH, 2006r).

### Families

Families with children comprise the fastest growing segment of the homeless population. Families with children represented 33% of the homeless population among the 24

American cities surveyed in the U.S. Conference of Mayors (2005) report. In rural areas, families, single mothers, and children represented the largest segment of homeless. According to the Homelessness Research Institute (2007), there were an estimated 98,452 homeless families in January 2005. Approximately 41% of the homeless population were members of families with children while 59% were individuals.

## CONTRIBUTING FACTORS

A complex array of factors can result in individuals having to choose between necessities of daily living. Scarce resources limit choices. What would you do if you had to choose between eating and buying your child's medication? Housing consumes a substantial portion of one's income and is often the first asset to be lost. Many families find they are only a paycheck away from homelessness.

### Poverty

In 2004, 12.7% of the U.S. population (37 million people) lived in poverty. Thirty-six percent of these were children. The increase in poverty rates over recent years may be attributed to declining wages, loss of jobs that offer security and carry benefits, an increase in temporary and part-time employment, erosion of the true value of the minimum wage, a decline in manufacturing jobs in favor of lower-paying service jobs, globalization and outsourcing, and a decline in public assistance. As wages drop, the potential to secure adequate housing wanes (NCH, 2006d,s). The U.S. Conference of Mayors (2005) found that a person must earn greater than minimum wage to afford a one- or two-bedroom apartment at 30% of income, the federal definition of affordable housing.

Many homeless shelters house people who are employed full time. The U.S. Conference on Mayors (2005) survey found that 15% of people in homeless situations in the cities surveyed were employed. The problem is compounded by a lack of affordable housing (particularly **single-room occupancy [SRO] housing** or housing units intended to be occupied by one person) and limited funding for housing assistance. As rental costs have increased and the number of available low-rent units has declined and federal support for housing assistance has dropped off, the housing gap has widened. People have been forced to pay high rents to obtain shelter. This situation leads to overcrowding and substandard housing (NCH, 2006e).

The average wait for Section 8 housing assistance is 35 months (U.S. Conference of Mayors, 2005). As a result, people remain in shelter situations for a longer period of time. With minimal turnover of shelter beds, shelters running at capacity are forced to turn people away. According to Burt (2006), the single most effective step to reduce the risk of homelessness is to increase housing for **extremely low-income** individuals (i.e., those earning 30% or less of the median income in an area) (National Low Income Housing Coalition (NLIHC), 2006 a,b).

### Lack of Affordable Health Care

In the absence of affordable health care coverage, a serious illness or disability can lead to job loss, savings depletion,

and even eviction. In 2004, approximately 45.8 million Americans (15.7% of the population) were without health care coverage. Approximately one-third of those in poverty have no health insurance. Those who are able to qualify for medical assistance may be reluctant to seek employment, fearing termination of benefits. Many others have limited coverage that requires higher co-pays or deductibles and does not cover major catastrophic illnesses (NCH, 2006f). An adverse health event can potentially plunge an individual into a homeless condition.

## Employment

Many low-income wage earners hold jobs with nonstandard work arrangements. Temporary employees, day laborers, independent contractors, and part-time employees are examples of work arrangements that tend to pay lower wages, offer limited or no benefits, and have less job security. For persons with few or no job skills, it is virtually impossible to compete for jobs that offer a living wage. Barriers to employment among the homeless include lack of education and job skills; lack of transportation, day care, or other supportive services; and disabilities that make it difficult to pursue or retain employment (NCH, 2006d).

## Domestic Violence

Victims of domestic violence often face a choice between living in an abusive situation or leaving and facing life on the streets. According to the U.S. Conference of Mayors (2005) report, 50% of the cities surveyed identified domestic violence as a primary reason for homelessness. Women who are victims of domestic violence may lack the resources necessary to escape an abusive environment and become independent. The lack of affordable housing, long waiting lists for housing and social services, and limited capacity of shelters to accommodate families in crisis only serve to exacerbate the problem (NCH, 2006b).

## Mental Illness

Approximately 22% of the single adult homeless population suffers from severe mental illness (U.S. Conference of Mayors, 2005). **Deinstitutionalization** (being released from institutions into the community), coupled with limited access to services and inadequate discharge planning and referrals, may contribute to the number of severely mentally ill persons represented in the homeless population (NCH, 2006p).

Homeless persons with mental illness tend to remain homeless longer, be in poorer physical health, encounter more barriers to employment, have less support from significant others, and interface with the legal system more often than the homeless who do not have a mental disorder. Although the majority of the homeless mentally ill do not require institutionalization, the lack of community-based treatment and support services and affordable housing reinforce their homeless condition and trap them in a desperate cycle. Moreover, supplemental security income (SSI) benefit levels for persons with disabilities have not kept pace with inflation or the skyrocketing cost of rental housing.

## Addictions Disorders

Rates of alcohol and drug abuse are disproportionately high among the homeless. Thirty percent of the homeless report problems with substance abuse (U.S. Conference of Mayors, 2005). For people already at risk for homelessness, the behaviors associated with an addictive disorder can create instability and jeopardize family and employment support nets. Once homeless, they may resort to drugs or alcohol to dull the pain of being homeless and ease the feelings of hopelessness that accompany such a desperate state. They may also turn to chemical substances in an attempt to self-medicate the disturbing symptoms of an untreated mental illness.

Although some homeless individuals may desire treatment to overcome their addictions, they often encounter obstacles that undermine their recovery and prevent them from obtaining the treatment they need. Limited access to care and lack of community resources make it difficult if not impossible to receive the services needed to achieve a successful recovery. There may be long waiting lists for addictions treatment, and homeless people who do not have phone access and are difficult to locate may be dropped from the waiting list. Lack of transportation and lack of the documentation needed to access programs (e.g., birth certificates, social security cards) further exacerbate the problem. Denial of SSI or Social Security Disability Insurance (SSDI) and Medicaid to persons with substance abuse related disabilities creates a huge barrier to achieving recovery support, proper medical care, and housing and income assistance. Moreover, the federal programs targeting homelessness, mental health, and addictions services (Treatment for Homeless Persons [THP] and Projects for Assistance in Transition from Homelessness [PATH]) lack the funding necessary to exert an impact that would effectively address this problem on a national level (NCH, 2006a).

## Additional Variables

Additional variables impacting homelessness include personal or financial crisis, natural disasters, and personal choice. For example, Hurricanes Katrina and Rita, which devastated portions of the Gulf Coast in 2005, displaced many previously independent and self-sufficient individuals and families, rendering many homeless and in need of emergency shelter.

## HOMELESS SUBPOPULATIONS

Although many of the struggles facing the homeless are universal, subpopulations within the homeless community are uniquely vulnerable. Often, these groups face additional burdens because of their special needs and challenges.

### Homeless Men

According to the U.S. Conference of Mayors (2005) survey, men comprise approximately 48% of the homeless population. The majority of homeless men are single adults. Homeless men are more likely to be employed than their homeless female counterparts yet they usually hold temporary, low-wage jobs that offer little security. They are also more likely than homeless women to have uncontrolled substance abuse

issues. This makes it more difficult for them to access shelters, which tend to require abstinence for admission (National Health Care for the Homeless Council [NHCHC], 2001).

Some men find themselves in a cycle of intermittent homelessness as they move back and forth between prisons, treatment centers, shelters, temporary housing, and the streets. Other men are at risk for becoming **chronically homeless**. These men may have significant health problems due to chronic substance abuse, lack of shelter, and poor access to health and social services (NHCHC, 2001). A chronically homeless adult is someone who has been homeless for long periods of time or has experienced repeated episodes of homelessness. In January 2005, approximately 23% of the homeless population was chronically homeless (Homelessness Research Institute, 2007).

Homeless men are more likely to be treated with disdain than other homeless subgroups (Perspectives: Voices from the Community). Some people perceive homeless men as largely to blame for their plight, believing that they are able

bodied and should be capable of working. Moreover, homeless men may suffer from disabilities that are not severe enough to warrant eligibility for health and social services. Often health and social programs give priority to women and children. Single, low-income men do not qualify for medical assistance unless they are disabled (NHCHC, 2001).

## Homeless Women

The U.S. Conference of Mayors (2005) survey found that women comprised 17% of the homeless population. According to the NSHAPC survey, 23% of single homeless clients are female. Of parents in homeless families, 84% are female (USDHUD, n.d.b).

A high incidence of family violence occurs among homeless mothers, with 63% of homeless mothers reporting being violently abused by an intimate male partner. Ninety-two percent of homeless mothers report a history of physical or sexual assault either during their childhoods or in their adult years. This high rate of violence also correlates with a high rate of emotional disturbances among homeless mothers, including posttraumatic stress (three times the rate of other women), depression (twice the rate of other women), attempted suicide, and prior hospitalization for mental illness (NCFH, n.d.d; NCH, 2006h). Moreover, the potential for exposure to violence and sexual assault on the streets increases the risk for sexually transmitted infections (STIs) and traumatic injuries.

## Homeless Children

In any given week, an estimated 200,000 children have nowhere to live. Approximately 1.4 million children experience homelessness over the course of a year. Forty-two percent of these children are under 5 years of age (U.S. Conference of Mayors, 2005).

Homeless families are the fastest growing segment of the homeless population. Most children living with homeless parents are young (42% are less than 6 years of age). Requests for emergency shelter for families have increased every year since 1985 (NCFH, n.d.c; National Resource and Training Center on Homelessness and Mental Illness [NRTCHMI], n.d.b). In 2005, 32% of requests for shelter by homeless families were denied due to lack of resources (U.S. Conference of Mayors, 2005) (see From the Case Files I).

The majority of homeless children and youth live in shelters, share housing with friends or relatives, or live in motels or camp grounds. More than 30% have been evicted from housing. Homelessness adversely affects children's mental health and can lead to emotional and behavioral problems. Common problems associated with child homelessness include anxiety, depression, and withdrawal (47% versus 18% of other children), as well as delinquent or aggressive behavior. Over 20% of homeless preschoolers have emotional problems severe enough to require professional intervention. Education is also compromised when one is homeless (NCH, 2006c). Although approximately 87% of homeless children are enrolled in school, only about 77% attend regularly. Some schools require a home address prior to enrollment. Other barriers include transportation to and from the shelter, lack of academic and medical records required for registration, unstable living arrangements necessitating multiple moves, and

### PERSPECTIVES VOICES FROM THE COMMUNITY

#### A Nurse's Viewpoint on Working with the Homeless

When I first decided to visit the homeless men's shelter, I was scared to death. Here I was, a veteran nurse with over 20 years experience in community health, and I was afraid. Afraid of what? I couldn't tell you. I suppose I harbored the stereotypes and negative images that most of us associate with homeless addicts. I remember passing this shelter years ago, looking out at the men hanging out on the street corner, and thinking to myself, "Please God, don't let my car break down!" I remember thinking "I would never set foot in a place like that."

Well, my views about homelessness were challenged to the core when I peered into the faces of those men, heard their stories, and began to feel their pain. Theirs were stories of broken lives and lost hope but also of courage in the face of suffering and the will to survive in the midst of great adversity. These men were as diverse as their stories. They were from all walks of life. They possessed incredible gifts and talents. They were musicians, artisans, businessmen, writers, and poets. They had families who loved them and families who left them. Left because they could not continue to watch them die a little each day and be destroyed themselves in the process.

So, here I am. Doing what I can to bring hope and healing. The irony is I came to bring hope and yet I am the one who is being healed. Healed in the broken areas of my life. Healed in my narrow view of life and my internal prejudices. It is a great privilege to serve these men.

Rita, Age 42

## From the Case Files I

### Reaching Out to Homeless Women and Children

Sheila Hendricks, a public health nurse for the Manchester City Health Department, and her colleagues were brainstorming ideas for how to reach the growing population of homeless women and children in their jurisdiction. They arranged a meeting with the director of a local rescue mission in the area. The mission provided emergency shelter to 100 homeless women and children each night. The women were allowed to remain at the shelter for 30 days provided they actively sought employment, social services, or educational opportunities. Families typically left during the day to seek jobs or other forms of assistance and returned in the evening for shelter. The community health nurses negotiated with the rescue mission to establish an on-site nursing clinic twice a week that would provide health education, screenings, and referrals on a drop-in basis. The hours of clinic operation were 4 p.m. to 8 p.m. to accommodate client schedules.

### Assessment

After the clinic was in operation for 2 weeks, the following priority health issues began to emerge:

- Inadequate maternal and child nutrition
- Lack of primary health care services for women and children (e.g., immunizations, screenings, treatment for upper respiratory tract infections, dermatologic problems, asthma, hypertension)
- Depression
- High rate of reported sexually transmitted infections and HIV due to history of violence, survival sex, and injection drug use
- Untreated addiction disorders

### Plan

The following diagnoses were developed (in order of priority):

- Impaired access to health and social services related to lack of insurance, scarce community-based resources, and lack of transportation
- Ineffective family coping related to untreated addictions, mental health issues, and history of intimate partner violence
- At risk for injury related to untreated addictions and mental health disorders, history of intimate partner violence, and hazards of street life
- Altered nutrition less than body requirements related to lack of resources to purchase nutritious foods, addictions disorders, and chronic health issues

After assessing priority needs and establishing relevant diagnoses, the nurses developed a plan of care for this population. The priority goal was to promote access to care by linking clients to essential health and social services. The rationale for establishing this goal as a top priority was that if clients were able to access needed services, the other diagnoses could potentially be addressed (e.g., need for counseling, health care, housing, education).

### Implementation

A nurse practitioner was engaged from the health department to provide primary care services to the women and children at the shelter, including screening and treatment for sexually transmitted infections and treatment of common acute and chronic health conditions. Conditions requiring more extensive follow-up were referred to the local federally funded Health Care for the Homeless clinic. A social worker from the local social service agency was recruited to visit the mission on a monthly basis to assist clients in applying for housing and public assistance programs. Clients were referred to the local community mental health center for counseling related to addictions and violence issues. The nurses conducted health education programs and one-on-one counseling on topics such as parenting, coping, healthy eating, basic hygiene, and safety. They also offered health screenings for blood pressure, diabetes, HIV, and tuberculosis and provided referrals to the health department clinic for cancer screenings (e.g., mammograms, colorectal screening).

### Evaluation

After the clinic had been in operation for 90 days, preliminary evaluation data revealed the following:

Sixty-five women and 28 children had frequented the clinic over the past 3 months. All 65 women received health promotion teaching and a resource packet for further reference. Eighty percent of clients who required referrals to outside agencies were successful in accessing care. Twenty-five women and 15 children were under the care of the nurse practitioner for acute or chronic health conditions. Ten cases of latent TB infection were identified through TB testing, and these clients were referred to the City Health Department TB clinic for follow-up treatment. Seven abnormal PAP smears were identified, and eight clients were diagnosed with sexually transmitted infections. Fifteen clients were found to be HIV positive. Clients with positive screenings were referred to the City Health Department or the local Health Care for the Homeless Clinic, where treatment was initiated. Forty women applied for social service benefits. Most of these clients are still awaiting the receipt of benefits.

urgent needs for food and shelter that take priority over education (NCFH, n.d.a; NRTCHMI, n.d.b).

Homeless children are more likely to repeat grades and to be diagnosed with learning disabilities and language impediments than other children. They are also more likely to go hungry and to experience physical or sexual abuse. Often, they have witnessed acts of violence (usually against their mother) or to have spent time apart from their immediate family (e.g., placed in foster care or with relatives) (NRTCHMI, n.d.b).

Homeless children are more likely to get sick than other children (NCFH, n.d.b). Common health complaints include ear infections, asthma, stomach problems, and speech difficulties. They are twice as likely to be hospitalized for illness. Homeless babies have higher rates of low birth weight than other infants and show significantly slower development. Ninety-seven percent of homeless children move each year, many up to three times a year. Twenty-eight percent of homeless children go to three or more schools in a given year (NRTCHMI, n.d.b).

Despite their many needs, homeless children do not have sufficient access to services. Most homeless preschool aged children are not in preschool programs. Approximately 20% of homeless children have no regular source of medical care. Less than one-third receive interventions for emotional disturbances. Only 50% to 60% of homeless families receive Medicaid and only 37% receive services to assist them in school (NCFH, n.d.a).

## Homeless Youth

Homeless youth are persons under 18 who lack parental, foster, or institutional care. Homeless adolescents are sometimes referred to as “**unaccompanied youth**.” They account for 3% of the urban homeless population (U.S. Conference of Mayors, 2005).

Factors contributing to youth homelessness include physical and sexual abuse, family addiction, parental neglect, strained relationships, or family financial crises that lead to family separation due to inadequate shelter, housing, or child welfare resources. A history of foster care placement is positively correlated with homelessness among youth. Moreover, some youth who are discharged from residential or foster care with inadequate housing or income support may find themselves homeless (NCH, 2006l). The majority of homeless adolescents believe they have no acceptable housing options (O’Sullivan & Lussier-Duynstee, 2006).

Homeless adolescents may have difficulty accessing emergency shelter because of shelter policies that prohibit older youth from the facility or because of a lack of bed space. Due to lack of education or job training skills, many resort to prostitution or **survival sex** (exchanging sex for food, shelter, or other basic necessities). As a result, homeless youth are at higher risk for human immunodeficiency virus (HIV), hepatitis, and sexually transmitted infections. Homeless youth also suffer disproportionately from anxiety, depression, malnutrition, conduct disorders, posttraumatic stress, and low self-esteem (NCH, 2006k) (see Evidence-based Practice).

Martijn & Sharpe (2006) found an increase in drug and alcohol diagnoses and criminal activity following home-

## EVIDENCE-BASED PRACTICE

### Treatment for Homeless Youth

How can we encourage homeless youth with mental health issues to remain in treatment? Darbyshire et al. (2006), in a qualitative study, investigated this question among 10 homeless youths in Australia. The youths were between 16 and 24 years of age and were suffering from mental health problems. The researchers sought to learn their perspectives on accessing and using health and social services. The study found that access to care was less of an issue than the actual quality of care delivered. Concerns were expressed regarding feeling labeled and stigmatized, receiving little time and attention, and being offered little explanation for the care being given. As a result, the youth felt a personal loss of control. Services were often fragmented, with one visit resulting in multiple referrals to other agencies. This magnified their sense of powerlessness, as it is often a challenge to access transportation or to negotiate the bureaucracies and nuances of each agency.

Trust and respect were foundational to facilitating engagement of the youth with health and social services. Acts of kindness, expressions of caring, active listening, and a nonjudgmental attitude facilitated trusting relationships and encouraged the youth to remain active in treatment or counseling. The findings suggest that a respectful, supportive climate is important in delivering health and social services to homeless youth with mental health issues.

Why might trust be hard to develop in this population? What can the CHN do to increase awareness among health and social service providers of the need to foster trusting, respectful encounters? What factors may have accounted for the young people’s negative experiences with the health care system? How are perceptions influenced when persons seek care at times of personal crisis? Why would trust and respect, which are so basic to successful human encounters, be lacking? What are some of the unique stresses that health and social service professionals face when working with marginalized and disenfranchised groups?

lessness among youth. Homeless youth also experience a high rate of substance abuse, injuries, dermatological problems, and teen pregnancies. Barriers to accessing health care among homeless youth include fear of health care settings, long wait times, lack of insurance, concerns regarding confidentiality, confusion over need for parental consent, unclean facilities, lack of transportation, and fear of being judged by health care providers (Hagedorn, 2002). In a qualitative study of ten homeless youth aged 16 to 24 who had experienced mental health problems, Darbyshire and colleagues (2006) found that the most appreciated aspects of service delivery included receiving clear, specific information and advice; accessing multiple services in one location; and being treated with respect and dignity.

## Homeless Families

The lack of affordable housing has contributed greatly to the rise in homeless families. In addition, an increase in the number of people uninsured has placed families at risk. A serious injury or illness can eradicate a family's savings and plunge a family into homelessness (NCFH, n.d.a).

More than 85% of homeless families are headed by single mothers. Although 70% of fathers of homeless children remain in contact with their children, most of these fathers do not live with the family. Families may be separated by shelter policies that prohibit admission of older boys or men. Sometimes, parents are forced to leave their children with family or friends or to place them in foster care to shelter them from becoming homeless (NCH, 2006h). According to the U.S. Conference of Mayors (2005), requests for emergency shelter by homeless families with children increased in 63% of the survey cities. In 57% of the cities, homeless families may have to separate in order to access emergency shelters.

A child is at greater risk for homelessness if his or her father becomes injured or ill, experiences a job loss, has a substance abuse issue, or becomes involved with the criminal justice system. Fifty percent of fathers of homeless children are unemployed. To assist homeless families, attention must be focused on promoting affordable housing; supporting education, job training, and child care; promoting access to school; expanding violence prevention and treatment services; and preventing unnecessary separation of families (NCH, 2006h; NRTCHMI, n.d.b).

## Homeless Veterans

Approximately 40% of homeless men are veterans. On any given night, 200,000 veterans are homeless. Despite the number of homeless veterans, direct combat experience does not seem to be related to homelessness. Although homeless veterans are less likely to have been exposed to combat, they have an increased rate of mental illness and addiction disorders, suggesting that these factors have more to do with homelessness than whether someone has served in the military (NCH, 2006j).

Female homeless veterans represent about 1.6% of the homeless veteran population. They are more likely to be married and have serious psychiatric illnesses but less likely to be employed or have addiction disorders than their male counterparts. No difference exists in rates of mental illness or addictions between veteran and nonveteran homeless women (NCH, 2006j).

Although Black veterans are more likely to be homeless than their White veteran counterparts, the rate of homelessness among Black veterans is lower than among other nonveteran minorities. The reduced risk may be attributed to the educational opportunities and other benefits and entitlements afforded those with veteran status. The U.S. Department of Veteran Affairs (VA) administers the Domiciliary Care for Homeless Veterans (DCHV) and the Health Care for Homeless Veterans (HCHV) programs. These programs provide case management, residential treatment, and other services to homeless veterans and have been found to improve housing, employment, and access to care for the homeless veteran population (NCH, 2006j).

## The Rural Homeless

Homeless people in rural areas are more likely to be White, female, married, working, homeless for the first time, and homeless for a shorter length of time. Because fewer shelters are available in rural areas, they are also less likely to live in shelters or in the streets. They are more likely to be found in cars or campers or living with relatives in substandard or overcrowded housing. As a result, they may not be considered "homeless" for reporting purposes. Moreover, the communities in which they live may not be able to access as much federal funding, because the statistics do not adequately reflect the magnitude of the problem. Families consisting of single mothers and children comprise the largest segment of the rural homeless population. Native Americans and migrant workers are likely to be among the rural homeless. Like urban homelessness, rural homelessness is largely a result of poverty and lack of affordable housing. Housing costs are lower in rural areas, but incomes are also lower (NCH, 2006q).

Homelessness in rural areas may be precipitated by structural or physical housing problems that force families to relocate to safer but more expensive housing. In addition, the lack of job opportunities, the distance between low-income housing and job sites, the lack of transportation, rising rents, geographic isolation, and lack of resources compound the problem. To address the needs of the rural homeless, the definition of homelessness needs to be expanded to include people living in temporary or substandard housing (NCH, 2006q).

## The Older Homeless

As with other groups, the increase in homelessness among older Americans is due in part to poverty and the lack of affordable housing. Many older people live on a fixed income, rendering them more vulnerable to unexpected financial crisis and even homelessness. Isolation also contributes to homelessness. Many older people live alone and lack a support network. Some researchers define the "older homeless" as homeless persons 50 and older because of the decline in physical health that often accompanies street living. Approximately 9% of homeless persons are 55 or older (USDHUD, n.d.a). Since older persons tend to distrust crowds at shelters and clinics, they are more likely to stay on the streets. They are prone to criminal victimization and suffer from a variety of health conditions including chronic diseases and functional disabilities. The Social Security benefits to which many are entitled are inadequate to cover housing costs. They may also encounter difficulties applying for benefits (NCH, 2006l).

## HEALTH CARE AND THE HOMELESS

Acute and chronic health problems prevail in the homeless population. Chronic health conditions such as tuberculosis (TB), HIV/acquired immune deficiency syndrome (AIDS), diabetes, hypertension, addictions, and mental disorders require ongoing monitoring and are often difficult to treat in a population that is transient and lacks stable housing (NCH, 2006f). It is difficult for the homeless to adhere to complex

treatment regimens. For example, where would a homeless person find a refrigerator to store insulin? Where would someone keep supplies for dressings? How could someone with no access to transportation keep regular appointments with health care providers? How does a homeless person keep track of multiple appointment dates? How is a shelter resident, who receives the typical shelter diet high in carbohydrates, fats, and sodium, going to adhere to a low-salt or diabetic diet?

Many homeless people expend their time and energy trying to meet basic survival needs. Health care may take a backseat to finding food, clothing, or shelter. High costs and limited access to health care and negative experiences with the health care system can also result in avoidance or delays in seeking treatment (NHCHC, n.d.).

Frostbite, leg ulcers, and upper respiratory tract infections result from chronic exposure to adverse environmental conditions. The homeless are also at higher risk of trauma and criminal victimization, including muggings, beatings, and rape. When one is homeless, it is difficult to maintain adequate nutrition or personal hygiene or to have access to basic first aid (NCH, 2006f). Communicable diseases such as TB, HIV, hepatitis, and other infections threaten not only the homeless, but also the public in general.

Poverty, substance abuse, poor nutrition, and coexisting medical and psychiatric illnesses also predispose the homeless to severe oral health problems. Among adults aged 35 to 44, twice as many Blacks and African Americans as Whites have tooth decay. African Americans are more likely than Whites to have teeth extracted. Low education levels have been found to be strongly correlated with tooth loss. Oral and pharyngeal cancers tend to be diagnosed at later stages in African Americans than in Whites. Together, alcohol and tobacco account for 90% of all oral cancers (Healthy People 2010, n.d.d).

HIV infection rates among the homeless range from 3% to 20%. Persons with HIV/AIDS are at higher risk of homelessness, because HIV-related illness can impact job stability. Moreover, health care costs associated with treating the illness can place an enormous financial burden on a low-income family. Insufficient funds to adequately house the poor with HIV/AIDS may also contribute to homelessness among HIV-infected individuals. The prevalence of HIV among the homeless is three times greater than that of the general population. Homeless women and adolescents are at risk of acquiring HIV infection due to the high incidence of sexual abuse and exploitation in this population (NCH, 2006g).

“Health Care for the Homeless” was a model for homeless health care developed in 1985 through a 19-city demonstration project funded by the Robert Wood Johnson Foundation and the Pew Memorial Trust. In 1987, federal legislation (the McKinney Homeless Assistance Act) was passed that authorized federal funding for these programs (NHCHC, n.d.). Grants are awarded to community-based organizations that deliver high quality health care to homeless populations. Health Care for the Homeless projects can be found across the nation to address significant gaps in health care delivery for this vulnerable group in society.

## RESOURCES TO COMBAT HOMELESSNESS

Both public and private sectors have promoted a variety of initiatives to address the problem of homelessness. These initiatives are intended to impact homelessness on the local,

state, and national level and to ensure a coordinated, comprehensive, and systematic approach to addressing the problem of homelessness.

## Public Sector

The McKinney-Vento Homeless Assistance Act (PL100-77) was the first and only major piece of federal legislation intended to address the problem of homelessness on a national level. This landmark legislation Act, passed by Congress in 1987, originally consisted of 15 programs to address the major, pressing needs of the homeless. These needs included emergency shelter, transitional housing, job training, primary health care, education, and housing. The current Act has been amended four times in an effort to expand its scope and strengthen its impact. In particular, the amendments made to the Act in 1990 represented significant milestones in advocating for the needs of the homeless. These amendments included the creation of the Shelter Care Plus program, which provides for housing assistance for persons with disabilities, mental illness, AIDS, and drug and alcohol addiction. Another amendment created a demonstration program within the Health Care for the Homeless program to provide primary care and outreach to at-risk and homeless children. In addition, the Community Mental Health Services Program was amended and retitled the Projects for Assistance in Transition from Homelessness (PATH). Finally, the amendments made in 1990 strengthened access to public education for homeless children and youth. For example, states were required to provide grant funding to local educational institutions to ensure access to free, appropriate education for homeless youth and children (NCH, 2006o).

Over the years, Congress has appropriated funding to enable implementation of this federal legislation. The extent of federal funding has fluctuated over the years. In recent years, some of the programs have been repealed or restructured in an effort to contain costs. Homeless advocates acknowledge that the Act was an important step in addressing homelessness, but the lack of adequate funding over recent years threatens its impact on a national level. Moreover, some homeless advocates believe that the legislation focuses more on emergency measures to address the crisis of homelessness rather than on promoting a proactive agenda to address the causes of homelessness (e.g., lack of good paying jobs with benefits, lack of access to affordable health care) (NCH, 2006o).

Another significant milestone in federal initiatives to reduce homelessness occurred in 2001, when the federal government adopted the goal of ending chronic homelessness in 10 years. To meet this goal, annual funding was appropriated to create new permanent supportive housing. These resources helped to stimulate the production of housing. Many communities followed the lead of the federal government and developed their own 10 year plans (Burt, 2006). Table 28.2 summarizes the nine titles of the McKinney-Vento Act. Table 28.3 presents selected federally sponsored programs for addressing the needs of the homeless.

## Private Sector

The private sector has made a concerted effort to organize communities in the battle against homelessness by forming

**TABLE 28.2 McKinney-Vento Homeless Assistance Act Titles I-IX**

Title I	States findings by Congress and definition of homelessness
Title II	Establishes the Interagency Council on Homelessness, a Council comprised of 15 heads of federal agencies charged with providing leadership for activities that assist the homeless
Title III	Authorizes the Emergency Food and Shelter Program, administered by the Federal Emergency Management Agency (FEMA)
Title IV	Authorizes the emergency shelter and transitional housing programs administered by the Department of Housing and Urban Development (HUD) including the Emergency Shelter Grant Program, the Supportive Housing Demonstration Program, Supplemental Assistance for Facilities to Assist the Homeless, and Section 8 Single Room Occupancy Moderate Rehabilitation
Title V	Requires federal agencies to make available land and buildings for states, local governments, and agencies to use to assist the homeless
Title VI	Authorizes programs to provide health care services to the homeless, including Health Care for the Homeless program, Community Mental Health Services Block Grant Program, and two demonstration programs providing substance abuse and mental health treatment services to the homeless
Title VII	Authorizes the Adult Education for the Homeless Program, the Education of Homeless Children and Youth Program (administered by the Department of Education), the Job Training for the Homeless Demonstration Program (administered by the Department of Labor), and the Emergency Community Services Homeless Grant Program (administered by the Department of Health and Human Services)
Title VIII	Amends the Food Stamp Program to facilitate access by the homeless and expands the Temporary Emergency Food Assistance Program (administered by the Department of Agriculture)
Title IX	Extends the Veterans Job Training Act

Source: United States Department of Housing and Urban Development. (n.d.c). McKinney-Vento Homeless Assistance Act. Retrieved September 23, 2006 from <http://www.hud.gov/offices/cpd/homeles/lawsandregs/mckv.cfm>.

coalitions, alliances, and memberships that champion the causes of the homeless. These organized efforts are carried out at the national, state, and local level to positively impact the problem of homelessness in communities across the nation. Table 28.4 presents a list and description of selected resources in the private sector to combat homelessness.

## ROLE OF THE COMMUNITY HEALTH NURSE

Community health nurses maintain a long tradition of providing care to the **marginalized** (persons excluded from mainstream society) and **disenfranchised** (persons deprived of rights) (Wilde et al., 2004). Community health nurses play a vital role in addressing the needs of the homeless. Settings for care include shelters, clinics, soup kitchens, churches, community centers, social service agencies, and even the streets (see Using the Nursing Process).

Trust is an essential ingredient in the development of a therapeutic relationship with the homeless. A caring, consistent relationship is more likely to engage people who are homeless into treatment (NRTCHMI, n.d.a). It is sometimes difficult to establish trust with clients who have experienced negative encounters with the health care system. Often these negative perceptions are intensified by limited resources, inadequate access to care, or prejudicial views. As with other vulnerable populations, the homeless struggle with feelings of powerlessness, loss of control, and low self-esteem. Victim blaming is common. Some members of society perceive the homeless as responsible for their own fate. It is not uncommon to hear people speak

about the homeless in derogatory terms or to suggest that the solution to the problem of homelessness is to simply “get a job.”

Behaviors that would ordinarily be considered lawful in the privacy of one’s home become criminal activity when they are exhibited in public. For example, the homeless can be arrested for loitering, sleeping, urinating, or drinking alcohol in public. These behaviors can trigger a criminal record, thereby jeopardizing future employment or housing opportunities. In some states, men can be incarcerated for failing to pay child support (NHCHC, 2001). Consider a man who is laid off from a low-wage job. He is unable to pay child support and is arrested. His violation generates a criminal record and compromises his ability to secure employment in the future. He becomes trapped in a cycle of poverty and homelessness that is difficult to escape.

Every nurse encounters new situations with prior assumptions and biases. When considering work with the homeless, it is important to clarify one’s own beliefs and values about poverty, homelessness, addictions, and mental disorders. What has been your experience with the homeless? Have you ever observed a homeless individual asking for money or holding up signs at a busy intersection? What thoughts and feelings do encounters such as these provoke? Have you ever volunteered at a soup kitchen or food pantry, fed a group of homeless people, or donated food or clothing? Have you had the opportunity to get to know a homeless individual? Do you have a personal experience with homelessness or poverty? If so, how has it affected your understanding of what it means to be poor or homeless?

TABLE 28.3 Federally Sponsored Programs for the Homeless	
The Interagency Council on Homelessness	The Interagency Council on Homelessness coordinates the federal response to homelessness and creates a national partnership with public and private sectors to reduce and end homelessness in the United States. The major activities of the Council include: (1) planning and coordinating federal programs to assist the homeless; (2) providing technical assistance and evidenced-based best practice information to the public and private sector; (3) monitoring and evaluating assistance provided to the homeless by public and private agencies; and (4) collaborating with communities and governmental bodies to end chronic homelessness (United States Interagency Council on Homelessness, 2006; 2003).
The Center for Mental Health Services	The Center for Mental Health Services, a center of the federal Substance Abuse and Mental Health Services Administration (SAMHSA), supports programs to assist the homeless mentally ill to access primary care, substance abuse, and mental health services, legal assistance, entitlements, and other supportive services. The Center develops models for delivering mental health services to the homeless that programs can then adopt and use. It also provides funding to states to deliver mental health services (SAMHSA, n.d.).
Projects for Assistance in Transition from Homelessness (PATH)	PATH is a grant program created under the McKinney Act to support the delivery of services to persons with severe mental illnesses, including those who are homeless or at risk of becoming homeless. SAMHSA provides technical support to states and local agencies, providing care through the PATH program (PATH, 2006).
The National Resource Center on Homelessness and Mental Illness	This Center operates under SAMHSA to develop workshops and training programs on service delivery to the homeless mentally ill. The Center maintains an extensive database of over 4000 articles (National Mental Health Information Center, n.d.; SAMHSA, n.d.).
Health Care for the Homeless (HCH)	The HCH program (a provision of the McKinney Act) awards grants to community-based organizations that seek to provide quality, accessible health care to the homeless. The HCH program is administered by the United States Department of Health and Human Services (USDHHS). Any local public or private nonprofit organization can apply for HCH funds. In 2004, 172 programs were awarded grants to serve over 600,000 homeless people per year (NCH, 2005).
The U.S. Department of Housing and Urban Development (HUD)	HUD provides funding for supportive housing for low-income families as well as low-income individuals with disabilities, and low-income elderly. Funds can be used for housing development or rental assistance (to cover the difference between what a resident can afford to pay and the cost to operate the project). Grants are also provided to public housing agencies to rehabilitate or replace dilapidated public housing structures. Persons applying for public housing face a long waiting period, sometimes up to as long as 10 years (NCH, 2006e).
The White House Office of Faith-based and Community Initiatives	This Office provides information on federal grants that are available to faith-based and community organizations to address the needs of the homeless (White House Office on Faith Based and Community Initiatives, n.d.). Grants catalog available at: ( <a href="http://www.whitehouse.gov/government/fbci/grants-catalog-homelessness.html">http://www.whitehouse.gov/government/fbci/grants-catalog-homelessness.html</a> )

It may be helpful to interview people who work with the homeless or to visit clinics, shelters, or other settings where the homeless congregate or access services. How are homeless people treated? What is a typical day like for someone who is homeless? How often do homeless persons hear their names? How often are they looked in the eye when addressed by others? How often are they touched in a way that is therapeutic, respectful, and affirming? By reflecting on your personal values and by allowing yourself to get closer to the people and places that are a part of the experi-

ence of homelessness, you will gain a deeper understanding of the homeless condition and be better equipped to serve those suffering from homelessness.

To address the multifaceted problems associated with homelessness effectively, a comprehensive and holistic approach is needed. As such, the community health nurse is responsible for implementing primary, secondary, and tertiary preventive measures to prevent homelessness or to assist those who are homeless to obtain needed services (see Levels of Prevention Pyramid).

**TABLE 28.4 Private Sector Initiatives to Combat Homelessness**

National Coalition for the Homeless (NCH)	The National Coalition for the Homeless is a national network of persons committed to preventing and ending homelessness. This Coalition consists of homelessness activists, service providers, persons who have experienced homelessness or are presently homeless, and others who are concerned with the plight of the homeless. The Coalition works to address issues related to homelessness through activities that promote civil rights and economic, health care, and housing justice. Activities of the Coalition include organizing community events to raise awareness and promote the rights of the homeless, advocating for health policy that protects the homeless, educating the public on facts related to homelessness, and providing research and technical assistance. The NCH also supports local and statewide homeless and housing coalitions (NCH, 2006i). ( <a href="http://www.nch.org">http://www.nch.org</a> )
The National Center on Family Homelessness	The National Center on Family Homelessness is a 501c3 nonprofit organization that seeks to end family homelessness in the United States through the development of innovative programs and services that provide long term solutions for family homelessness and through education of service providers, policy makers, and the public. ( <a href="http://www.familyhomelessness.org">http://www.familyhomelessness.org</a> )
National Coalition for Homeless Veterans	This Coalition seeks to end homelessness among veterans through public policy, collaboration, and building community capacity. ( <a href="http://www.nchv.org">http://www.nchv.org</a> )
National Alliance to End Homelessness	This national membership organization seeks to mobilize leaders in business, nonprofit agencies, service providers, political leaders, and citizens to end homelessness through research, education, and public policy reform. ( <a href="http://www.endhomelessness.org">http://www.endhomelessness.org</a> )
National Center for Homeless Education	This national resource center provides research and information to help communities address the needs of homeless children, youth, and families. ( <a href="http://www.serve.org/nche">http://www.serve.org/nche</a> )
Commission on Homelessness and Poverty, American Bar Association	This Commission works with local and state bar associations and other organizations to develop pro bono programs to address the legal needs of the poor and homeless. ( <a href="http://www.abanet.org/homeless">http://www.abanet.org/homeless</a> )
Homes for the Homeless	This organization attempts to provide homeless families with education, employment training, and support services. ( <a href="http://www.homesforthehomeless.com">http://www.homesforthehomeless.com</a> )
National Low-Income Housing Coalition	The National Low-Income Housing Coalition is a national membership organization dedicated to ending the housing crisis in America. A major priority of the Coalition is to promote legislation that provides funding for the production of rental housing for extremely low-income people (NLIHC, 2005). ( <a href="http://www.nlihc.org">http://www.nlihc.org</a> )

## Primary Prevention

Primary prevention includes advocating for affordable housing, employment opportunities, and better access to health care to prevent the downward spiral into homelessness. Strategies for preventing homelessness may include financial counseling to assist clients to better manage their money; assistance in locating sources of legal or financial aid to prevent eviction (e.g., loans or grants for emergency funds to help pay for rent, utilities, etc.); or assistance in accessing social services, temporary housing, or health care to avoid a housing, health, or family crisis (Anderson & McFarlane, 2004).

Health education that addresses primary prevention may focus on positive parenting skills, violence prevention, anger management, coping skills, healthy eating, or principles of basic hygiene. Immunization programs will help to prevent communicable disease in this high-risk population. Counseling victims of intimate partner violence and helping

them to locate safe shelters can also aid in the prevention of homelessness (Anderson & McFarlane, 2004). Addictions treatment is also important to prevent the likely consequences of untreated addiction: death, incarceration, institutionalization, or homelessness.

## Secondary Prevention

The focus of secondary prevention measures is on the early detection and treatment of adverse health conditions. This requires a thorough assessment of client needs including the need for housing, health care, education, social services, and employment. Clients will also benefit from secondary prevention measures such as screening for communicable and chronic diseases (e.g., hepatitis, TB, STI, HIV, hypertension, diabetes, cancer).

Barriers to accessing services and the extent of community resources available to the homeless also need to be assessed (Anderson & McFarlane, 2004). Resources such

## USING THE NURSING PROCESS

### Conducting a Needs Assessment

As a faith community nurse working in a large church congregation, you are invited to develop an outreach program to minister to the needs of an inner-city mission that is receiving financial support from the church. You begin by visiting the Mission to conduct a needs assessment of its residents and to identify priority health issues. The shelter operates as a faith-based, nonprofit organization and is dedicated to serving the needs of homeless men with addictions. The shelter provides emergency overnight services and operates a 1-year residential faith-based addictions recovery program. Approximately 300 homeless male addicts visit the shelter daily. Staff and residents have expressed concerns regarding a recent outbreak of boils among residents.

Assessment data reveals the following issues:

- Approximately 80% of clients have a history of injection drug use.
- Clients sleep in dormitory-style accommodations and share bathroom facilities.
- An on-site barber shop operated by the residents provides haircuts for a nominal fee.
- Clients have access to a small recreational area with donated exercise equipment.
- Laundry services are available, and residents take their clothing to the laundry on alternate days to have it washed. Laundry is typically washed in cold water and at times the laundry runs out of detergent.

#### Questions:

1. What additional data would you wish to gather to address the outbreak of boils at the shelter? How would you collect this data?
2. What host, agent, and environmental factors may have contributed to the outbreak of boils?
3. Discuss appropriate nursing interventions to address the outbreak. Consider the following levels of prevention: Primary, Secondary, Tertiary.
4. What advocacy role might the CHN play in addressing this issue?

as shelters, soup kitchens, medical clinics, social service agencies, and supportive housing should be readily accessible to the homeless population. Consider hours of operation, wait times, acceptability of services, adequacy of services to meet needs, and transportation issues (Martin, 2003).

Lack of transportation can be a major barrier to accessing care. Some programs have responded to this need by adopting mobile health vans that provide care on street corners and in neighborhoods (Daiski, 2005). Clinics have also been established in shelters to facilitate client access. These clinics are often managed by nurses (Yousey & Carr, 2005). Nursing students also play an important role in promoting access to care for the homeless (Wilde et al., 2004).

The community health nurse should also consider the role of faith-based communities in providing physical and spiritual support to the homeless. Many places of worship have responded to the crisis of homelessness by offering food, shelter, counseling, medical care, and social services within the context of the faith community. Clinics have been built within faith communities to promote access to care.

### Tertiary Prevention

Tertiary preventive measures attempt to limit disability and to restore maximum functioning. The goal is to provide rehabilitative care and support to clients who are already experiencing the consequences of homelessness. Often, homeless individuals suffer from chronic health conditions that have gone untreated for long periods of time. This neglect in attending to health needs results in significant disease morbidity. Treating complications of advanced disease, pro-

viding rehabilitative care, and offering counseling and support are important tertiary preventive strategies.

### Case Management

At each level of prevention, the community health nurse functions as a case manager and coordinator of care to ensure seamless delivery of services as people transition from one level of care to another. It is often difficult for the homeless to keep track of multiple appointments, negotiate the bureaucracy of multiple agencies and services, or maintain communication with providers through follow-up phone calls, letters, or visits. With no permanent address or phone, homeless clients encounter obstacles to adhering to recommendations to follow-up on test results or to notify their provider if symptoms persist or worsen. The community health nurse can help to bridge these gaps in service delivery and promote more effective adherence to therapeutic regimens.

### Advocacy

Advocacy is a vital dimension of the community health nurse's role in working with the homeless (Hatton et al., 2001). Advocacy entails working with different sectors of the community (including public officials, service providers, and persons living in the community) to develop innovative models for responding to the crisis of homelessness. Advocacy creates the broader systemic changes needed to end homelessness (NCH, 2006n). The community health nurse acts as an advocate at each level of prevention to effect positive change. For example, the nurse may advocate for mental health and substance abuse services to promote mental

## LEVELS OF PREVENTION PYRAMID

**SITUATION:** Promoting health and preventing illness among homeless male addicts

**GOAL:** To apply the three levels of prevention to avoid adverse health conditions, diagnose and treat disorders promptly, and assist a homeless male addict population to maintain or regain optimal health.

<b>Tertiary Prevention</b>	
<b>Rehabilitation</b>	<b>Primary Prevention</b>
<ul style="list-style-type: none"> <li>Provide case management of chronic health conditions</li> <li>Advocate for supportive and transitional housing to enable homeless residents with addiction disorders to transition back into the community successfully</li> </ul>	<p style="text-align: center;"><i>Health Promotion &amp; Education</i></p> <ul style="list-style-type: none"> <li>Advocate for expansion of counseling, rehabilitative services, and addiction treatment programs for the homeless</li> </ul> <p style="text-align: center;"><i>Health Protection</i></p>
<b>Secondary Prevention</b>	
<b>Early Diagnosis</b>	<b>Prompt Treatment</b>
<ul style="list-style-type: none"> <li>Conduct mass screenings for diseases commonly found in homeless male populations (TB, HIV, hepatitis, prostate cancer, colorectal cancer)</li> </ul>	<ul style="list-style-type: none"> <li>Develop programs for health screening and early diagnosis and treatment in the community that are culturally sensitive and accessible to the homeless (e.g., mobile vans, faith community, or shelter-based clinics)</li> </ul>
<b>Primary Prevention</b>	
<b>Health Promotion &amp; Education</b>	<b>Health Protection</b>
<ul style="list-style-type: none"> <li>Support employment and job training opportunities that assist clients to obtain jobs with livable wages and benefits</li> <li>Advocate through housing coalitions and legislative efforts to promote affordable housing, employment opportunities, and better access to health care</li> <li>Develop culturally sensitive health education programs that promote healthy coping, positive parenting, communication and relationship building, mental health, and injury and illness prevention</li> <li>Promote programs that offer counseling and support to prevent continued high risk behaviors as a result of untreated addiction</li> </ul>	<ul style="list-style-type: none"> <li>Advocate for legislation to protect citizens from environmental toxins and industrial wastes common to low-income areas</li> <li>Provide immunization services to prevent communicable disease transmission</li> <li>Counsel clients on proper nutrition, exercise, and basic hygiene to promote healthy lifestyles and prevent disease transmission</li> <li>Advocate for funding for nutrition programs for the homeless and for homeless shelters that would allow for the purchase of nutritious foods</li> </ul>

health and prevent homelessness (primary prevention). Alternatively, he or she may advocate for legislation to fund supportive housing, health care, or social services to benefit the homeless with chronically mental illness (NRTCHMI, n.d.a). The community health nurse (CHN) can also assume an advocacy role by becoming involved in local, state, or national coalitions or organizations devoted to protecting the rights of the homeless or by speaking out on legislation that impacts the homeless (NCH, 2006n).

## Summary

Rising poverty and lack of affordable housing have led to a dramatic rise in homelessness over the past two decades. Poverty, lack of housing, domestic violence, mental illness, addictions, personal crises, and natural disasters are factors that may predispose persons to homelessness.

Homeless families represent the fastest growing segment of the homeless population. Acute and chronic health

problems plague the homeless. Conditions such as HIV/AIDS, diabetes, hypertension, addictions, and mental disorders are prevalent among the homeless and are difficult to treat because of the challenges associated with being homeless.

Both the public and private sectors have launched concerted efforts to combat the problem of homelessness through the passage of federal legislation (most notably the McKinney-Vento Homeless Assistance Act) and through the formation of national, state, and local coalitions and alliances to champion the cause of the homeless. Much remains to be done.

Community health nurses maintain a long and distinguished tradition of providing care to the marginalized. As such, they play a vital role in addressing the needs of the homeless in society. At the core of community nursing practice is the development of a trusting relationship. The community health nurse needs to examine his or her values and presuppositions regarding poverty and homelessness to be more effective in rendering care that is respectful, compassionate, and nonjudgmental. The community health nurse implements primary, secondary, and tertiary preventive measures to prevent homelessness or to assist those who are homeless to obtain needed services. Primary prevention includes advocating for affordable housing, employment opportunities, and improved access to health care to prevent the downward spiral into homelessness. Secondary prevention includes screening for communicable and chronic diseases and promoting access to affordable health care and social services. Tertiary prevention includes rehabilitative and supportive care and counseling.

The community health nurse also serves as a case manager to coordinate care and to assist clients to negotiate the bureaucracy of multiple agencies and services. Finally, the CHN acts as an advocate to promote the rights of the homeless and to speak out on legislation impacting homelessness. ■

### ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Reflect in writing on the meaning of “home.” Share your reflections with someone experiencing homelessness.
2. Interview a homeless person regarding the most difficult choices he or she has had to make. What were the conditions surrounding these choices?
3. Volunteer to work at a soup kitchen or homeless shelter. Observe carefully the faces, sounds, attitudes, and activities. What is it like to share in the same spaces as those who are homeless? What would it be like to be receiving rather than giving service?
4. Consider joining a local coalition to support the cause of homelessness in your community.
5. Call or write your local legislator to advocate for legislation impacting the homeless and to share your thoughts and feelings about homelessness.

6. Attend a public meeting that addresses homelessness prevention or low-income housing. Listen to the debate and consider the divergent views. What are the political, economic, and social contexts underlying these views?
7. Perform a windshield survey in a low-income community. What resources are lacking? Where is the nearest bank, school, grocery store, or health clinic? What are the conditions of the roads, homes, and other buildings? How do you feel as you drive through the community? What do you think it would be like to live there?

# Issues with Rural, Migrant, and Urban Health Care

## LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Define the terms *rural*, *migrant*, and *urban*.
- ◆ Discuss the population characteristics of rural residents.
- ◆ Describe five barriers to health care access for rural clients.
- ◆ Describe the migrant lifestyle.
- ◆ Identify at least three health problems common to migrant workers and their families.
- ◆ Discuss barriers and challenges to migrant health care.
- ◆ Identify common health disparities found among urban populations.
- ◆ Propose intervention strategies at the aggregate or community level to assure a healthier *built environment* in both rural and urban areas.
- ◆ Explain the concept of *social justice* and how it relates to public health nursing in urban areas.
- ◆ Compare and contrast the challenges and opportunities related to rural and urban community health nursing practice.

“No city should be too large for a man to walk out of in a morning.”

—Cyril Connolly (1903–1974), British critic

## KEY TERMS

Built environment  
 Critical access hospitals  
 Federally qualified health centers  
 Frontier area  
 Ghettos  
 Health professional shortage areas (HPSAs)  
 In-migration  
 Medically underserved areas (MUAs)  
 Metropolitan statistical area  
 Micropolitan statistical area  
 Migrant farmworkers  
 Migrant streams  
 Out-migration  
 Patterns of migration  
 Population density  
 Rural  
 Rural health clinics  
 Seasonal farmworkers  
 Social justice  
 Telehealth  
 Urban  
 Urban health  
 Urbanized area (UA)  
 Urban cluster (UC)  
 Urban health penalty  
 Urban planning

**About** half the population live in what is known as the suburbs, but the remainder live in one of two diametrically opposed areas: rural or urban. There is a good chance that many of you reading this book live in either very densely populated, bustling urban areas or in sparsely populated, somewhat isolated rural areas. Community health nursing in urban and rural areas requires not only general public health nursing knowledge and skills, but also a unique understanding of how these distinctive environments affect the health of the populations living there. Where you live can and does markedly affect your health outcomes, with rural and urban areas having distinctive problems and issues (van Dis, 2002). These differences are much more than just the ability to shop at “Wal-Mart versus Pottery Barn” (p. 108). Both rural and urban clients have health disparities and disadvantages, although they may be dissimilar in nature.

Rural nursing practice offers many opportunities. Nurses are respected community members—their judgment and opinions count. Rural nurses are key members of the health care team. They can make a difference in the lives of their neighbors, friends, and community. Rural public health nurses (PHNs) often struggle with helping clients gain access to quality health care and the inherent transportation problems found in isolated areas. The challenges are many, but the rewards are great.

Urban public health nurses often specialize in particular areas of interest. They deal with different types of problems, such as homelessness, overcrowding, bioterrorism threats, and violent crime. They are often called upon to advocate for their most vulnerable clients, and they develop collaborative relationships with other professionals. Urban community health nursing can also be very rewarding and satisfying.

This chapter addresses the special health needs and concerns of rural, migrant, and urban clients and the ways in which a community health nurse can address those needs. After reading the chapter, you may come to appreciate the many advantages that rural nurses enjoy and consider rural nursing as a practice choice, or you may find that being a PHN in an urban area offers you more opportunities for specialization and networking. Either way, your contributions can improve the health of populations living at both extremes.

## DEFINITIONS AND DEMOGRAPHICS

Depending on one’s geographic location, professional discipline, agency or institutional affiliation, or other frame of reference, the term *rural* has different and specialized meanings. Moreover, rural populations and characteristics have changed significantly over many years. These differences and their implications are described in this chapter.

### Definitions of Rural

The term *rural* means different things to different people. The community health nurse needs to be aware of the precise meaning of the term as it is used in a particular agency, community, or piece of legislation, because differences in semantics can affect public policy regarding rural communities. For example, federal dollars are often distributed to communities based on rural or urban status.

The U.S. government provides several definitions of rural. These can seem confusing and complicated, but it is

important to understand the terms and how they are used in federal programs and grant funding. The U.S. Census Bureau (2002) identifies **urban** as all “territory, population, and housing units located within an **urbanized area (UA)** or an **urban cluster (UC)**.” A UA consists of densely settled territory with an area of population density of 1,000 people or more per square mile and with surrounding areas with population densities of at least 500 people per square mile. **Population density** refers to the number of persons per square mile—urban areas are much more densely populated than rural areas. The U.S. Census definition of *rural* is all territory, population, and housing units located outside UAs and UCs. Some counties, however, may include both rural and urban designations, as these designations do not follow municipal boundaries but rather denote population density (like the dense grouping of buildings that you might notice from an airplane).

For the 2000 Census, the U.S. Office of Management and Budget (OMB) reclassified the United States into metropolitan and micropolitan statistical areas. This newer nomenclature identifies a **metropolitan statistical area** as a core-based statistical area associated with at least one urbanized area that has a minimum population of 50,000. **Micropolitan statistical areas** are “core-based statistical areas” associated with at least one urban cluster of no less than 10,000 and no more than 50,000 people (U.S. Department of Agriculture [USDA], 2003a). Both metropolitan and micropolitan statistical areas comprise the central county or counties containing the core; also included are adjacent outlying counties that have a high degree of social and economic integration with the central county (based on the number of people who commute—generally considered 25% or more). With such a broad definition, micropolitan statistical areas can include both rural and urban areas. Before 2003, the OMB defined urban and rural in terms of metropolitan and nonmetropolitan counties. By making these changes, the numbers of people living in what used to be considered nonmetropolitan areas decreased from 55 to 49 million (USDA, 2003a).

The U.S. Department of Agriculture (USDA) rural–urban continuum examines metropolitan and nonmetropolitan areas on the basis of counties, and this provides different data apart from census reports. State and federal agencies recognize county-level jurisdictions and governments, and depend upon employment, income, and population data that are available on an annual basis (USDA, 2007a). Many states have offices of rural health or other agencies dealing with issues specific to rural populations.

For the purposes of this chapter, **rural** is defined as *communities with fewer than 10,000 residents and a county population density of less than 1,000 persons per square mile* (Table 29.1). This definition of rural is arbitrary because rural clients do not merely consider population density or community size when defining their *ruralness*. They have a multitude of reasons for defining their community as rural, such as distance from a large city, major occupations in the area (e.g., agriculture), or numbers of students in the local schools. If you have access to a small community, ask some of the residents the reasons why they consider their community to be urban or rural.

The term **frontier area** is used to designate sparsely populated rural places that are isolated from population centers

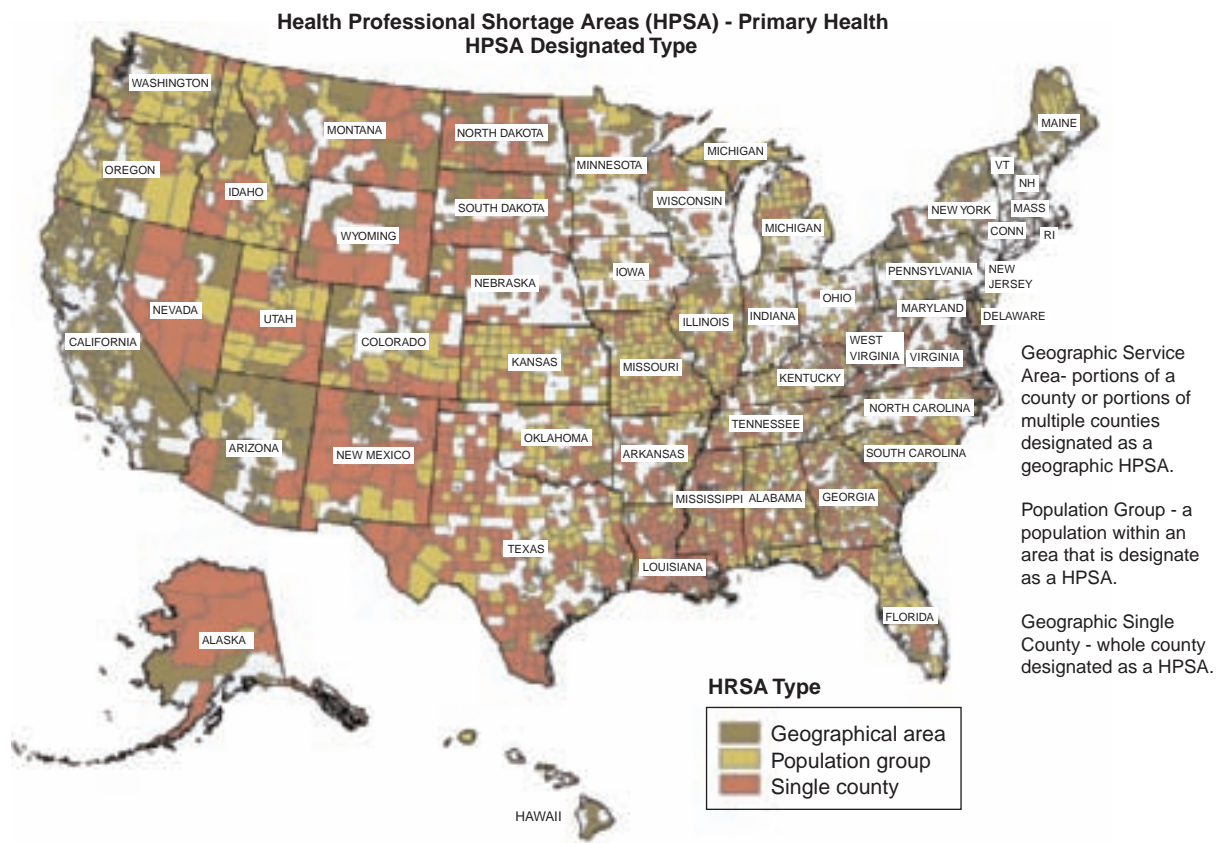

**TABLE 29.1 Definitions of Rural**

Source	Nomenclature	Definition
U. S. Bureau of the Census	Rural	All territory, population, and housing units located outside of urbanized areas (UAs) and urbanized clusters (UCs)
U. S. Office of Management and Budget	Metropolitan statistical area	A core-based statistical area associated with at least one urban cluster of at least 10,000 but <50,000 people.
U. S. Department of Agriculture Rural-Urban Continuum Codes	Completely rural	<2,500 urban population either adjacent to or not adjacent to metropolitan area.
U. S. Government	Frontier area	<6 people per square mile
Author	Rural	Communities with <10,000 residents and county population <1,000 people per square mile.

and services, but specific definitions vary (Rural Assistance Center [RAC], 2007a). A common definition of a frontier area is one with six or fewer persons per square mile, but others include not only population density but distance and travel time to market-service areas (RAC, 2007a; National Center for Frontier Communities, 2006). For instance, 60 miles or 60 minutes of driving on paved roads to the nearest 75-bed (or greater) hospital can constitute a frontier area. It is estimated that 3% of the U.S. population live in frontier areas that comprise 56% of the U.S. land areas; frontier areas are located in 38 states. States with either a high frontier population and/or high frontier land area include Alaska, Texas, Arizona, Montana,

Wyoming, New Mexico, Colorado, North Dakota, and South Dakota (National Center for Frontier Communities, 2006). Rural-urban commuting area (Census data) is used to designate remote areas (RAC, 2007a).

Health issues of concern to rural areas may be of even greater concern to frontier areas. In rural health circles, the term **health professional shortage areas (HPSAs)**, defines urban or rural geographic areas, population groups, or facilities with chronic shortages of medical, dental, or mental health professionals. The federal government determines which areas are HPSAs. About 20% of the U.S. population live in areas that have been designated as HPSAs (Fig. 29.1). In **medically**

**FIGURE 29.1** Health Professional Shortage Areas (HPSA) – Primary Health HPSA Designated Type. From: Modern-day slavery. (2005). *Palm Beach Post*. Retrieved October 23, 2008 from <http://www.palmbeachpost.com/moderndayslavery/content/moderndayslavery/reports/gr>. Used with permission.

**underserved areas (MUAs)**, residents experience a shortage of health services; these areas are determined by the federal government using a score based on the shortage of primary care physicians, high infant mortality rates, high percentage of the population living below the poverty level, and a high proportion of residents over age 65 (Health Resources & Services Administration [HRSA], 2007a).

## Population Statistics

The number of persons living in urban areas of the United States tripled since the mid-1800s, to 59,367,367 in 2000 (U.S. Census Bureau, 2000a). During the same period, the proportion of persons living in rural communities decreased from about 85% of the U.S. population to 21% (Ricketts, 1999; USDA, 2007a). By 2005, residents in nonmetropolitan counties dropped to just under 50 million (USDA, 2007a). The highest proportion of the rural population is located in the South (35%). The Midwest and West have approximately 23% of rural residents, and the Northeast has the smallest percentage (19%) (Eberhardt et al., 2001). About 11% of the population lives in what is now characterized as urban clusters (USDA, 2007b).

In 2003, of the 250 poorest counties in America, 244 are rural (Congressional Rural Caucus, 2004). Poverty and joblessness are common among rural Americans. Rural areas have a higher percentage of elderly, along with fewer physicians, nurses, hospitals, and other health care resources; almost one-third of rural adults report that they are in poor to fair health (Agency for Healthcare Research & Quality [AHRQ], 2007; Zigmond, 2007). A large-scale study found that rural workers were less likely than urban workers to be offered insurance. They also reported lower wages and were more often working in small businesses or were self-employed (Larson & Hill, 2005).

Rural areas have a slightly higher fertility rate than urban areas (Tarmann, 2003). However, this population growth related to births (termed *natural increase*) is offset by the loss of rural youth moving to more urban areas for education, jobs, and marriage (USDA, 2007c). The loss of 20- to 34-year-olds was greatest in the Northeast (29.1%) and Midwest (16.8%) for the period from 1990 to 2000 (Kirschner, Berry, & Glasgow, 2006).

## Changing Patterns of Migration

Population changes in rural areas are usually related to natural increase through births or through **out-migration**, the process of residents moving out of rural communities and into urban places (USDA, 2007a). When American was a more rural country, there was more natural increase than out-migration, which caused continued growth in the rural population.

In the 1970s, the proportion of births decreased, but many people moved into rural communities, resulting in an increase in population. During the 1980s, the population trends shifted, as most rural areas lost population to out-migration as a result of economic recession and a serious farming crisis. During the first half of the 1990s, the population trend in rural communities changed to **in-migration**, an increase in residents moving into rural communities from urban places. White-collar workers were affected by changing

technologies, and many young professionals with families elected to live in more rural settings (USDA, 2007a). Since 1995, however, the growth rate in many rural communities has decreased. Rural areas with textile jobs experienced out-migration, whereas immigrants moved to fill jobs in states with meat packing and other “food-and-fiber industries” (USDA, 2007a). Rural counties with “natural amenities,” such as beautiful landscapes, desirable climates, or proximity to tourist areas (e.g., ski slopes, lakes, beaches, national parks), have experienced more growth (McGranahan & Sullivan, 2005). Some rural counties have noted increased employment opportunities, with Indian casinos and the proliferation of prisons, helping to stem some of the out-migration of young adults (Tarmann, 2003).

Natural amenity counties and other rural areas are also attractive to retired people, who are responsible for some of the in-migration to those areas. The older adults moving into rural areas are generally healthier, more financially secure, and better educated than the rural elderly population who are aging in place (Tarmann, 2003; USDA, 2007a). The rural West had an increase of 23% among those 75 years and older (Kirschner et al., 2006).

Population trends have many implications for the health services needed by rural people. The patterns of rural migration change shifting sand, adding to the challenge of planning resources for rural communities.

## POPULATION CHARACTERISTICS

The following information is meant to describe, not stereotype, rural clients. Each rural community is unique, as are its residents. The community health nurse must determine whether the population characteristics discussed fit a specific rural community. The nursing student who plans to practice in the international arena will need to seek out relevant information about the specific rural population to be served.

### Age and Gender

Elderly persons, those age 65 and older, are the fastest growing population in the United States in every location, including rural America. About 7% of the total U.S. population lives in rural counties, but 10% of the country’s older population resides there (Tarmann, 2003). In 2000, close to two-thirds of those people 75 years and older living in rural areas were female (Kirschner et al., 2006). However, population projections through 2020 show that females will outnumber males in all but the oldest age groups, indicating a shift from a male-dominated to a female-dominated rural population (Maternal Child Health Branch, 2002). In 2002, 17.3% of rural women were between 65 and 90 years, compared with 13.8% of rural men and 13.4% of women in metropolitan areas—indicating a higher proportion of older rural women (Maternal Child Health Branch, 2005). Because of the preponderance of elderly in rural America, Medicare is a primary funding source for health care (HRSA, 2002).

The median age for nonmetropolitan areas in 2000 was over 35, approximately 4 years greater than for urban areas. The ratio of males per 100 females is slightly higher in nonmetropolitan areas when compared to suburban or metropolitan areas, but there are still more women than men (Kirschner et al., 2006). Population estimates of projected

rural age distribution between 1996 and 2020 indicate (Maternal Child Health Branch, 2002) the following:

- ◆ 19% ages 0 to 14 years
- ◆ 12.2% between 15 and 24 years
- ◆ 11.9% ages 25 to 34
- ◆ 12.9% between 35 and 44 years
- ◆ 23.5% ages 45 to 64
- ◆ 20.2% over the age of 65

Population trends have a direct relationship to the kinds of health services that are needed in rural communities. Growing families with young children need maternity, pediatric, and family health medical services, along with dental care and mental health services. They also can benefit from health promotion and disease prevention activities. The elderly, on the other hand, need health care to manage increased numbers of chronic health conditions. Rural communities need to provide access to nursing homes and rehabilitative services, as well as to hospitals, clinics, and health promotion programs that serve the elderly and the entire community.

### Race and Ethnicity

Rural areas have historically had less racial diversity than urban areas. In 1998, the U.S. Census Bureau estimated that 83.3% of nonmetropolitan (rural) residents were White, 9.1% were African American, 4.8% were Hispanic, 1.8% were American Indian or Alaskan Native, and 1% were Asian or Pacific Islander (Eberhardt et al., 2001). Racial and ethnic groups have historically been concentrated in certain

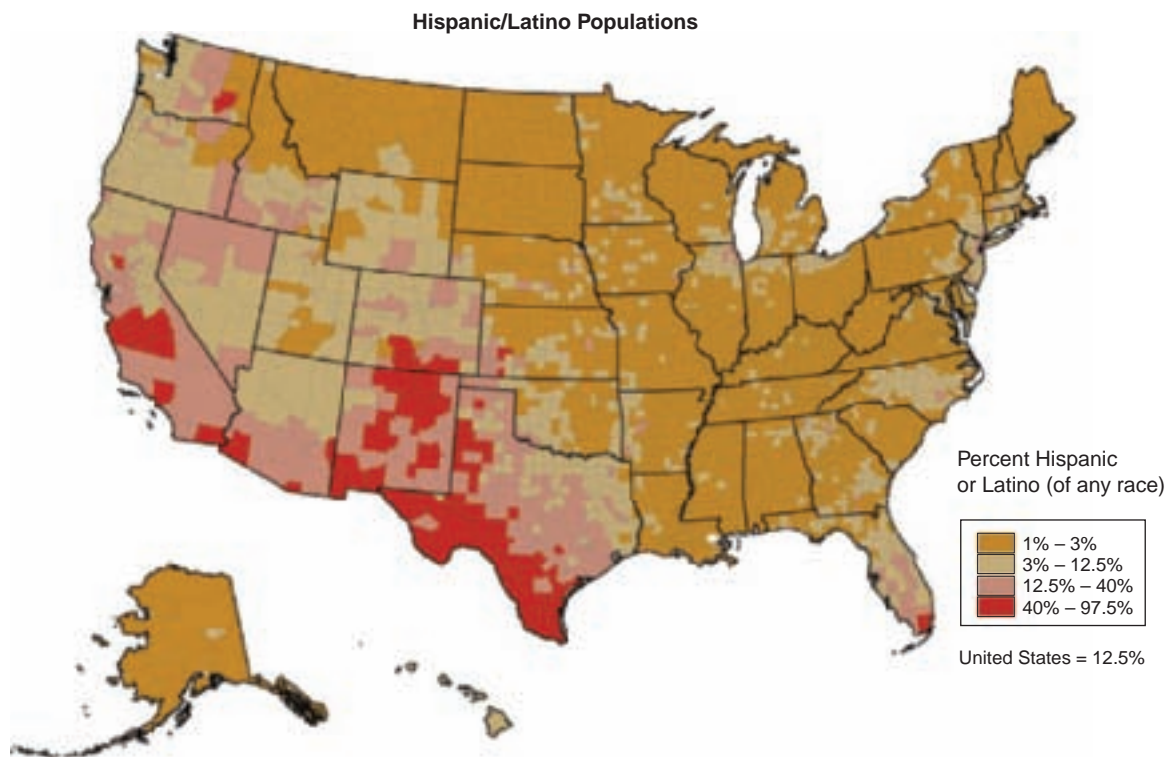

areas of the country—for example, Blacks in the rural South and American Indians in the rural Southwest and West, as well as Mexican Americans in the border states of the Southwest (Kirschner et al., 2006). However, these patterns are changing. Rapid Hispanic growth areas are found in the Midwest and Southeast (see Figs. 29.2 and 29.3).

Lower median age and higher birth rates signal faster growth of this population, and this can lead to a need for changing health policies and practices. For instance, in rural counties with a high elderly population and established case-loads of chronic disease patients, an influx of younger Hispanic populations may require a shift in policies and resources to include more pediatric and obstetric care (Kandel & Parrado, 2006). All of these changes influence geographic patterns of health status.

### Education

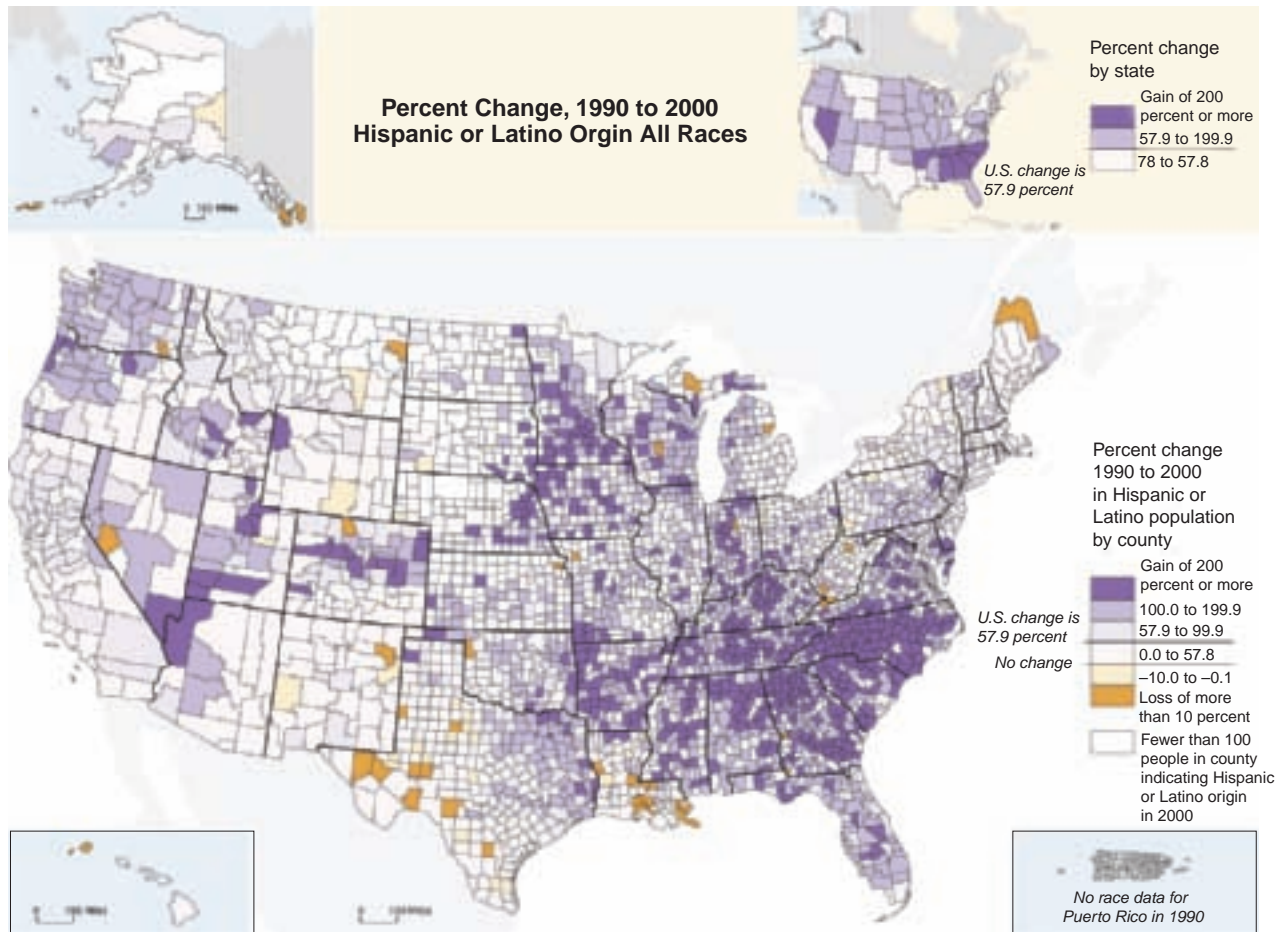

Rural clients in the United States generally have lower educational attainment than those in urban areas. In 1998, some 15% of adults (25 years of age and older) in nonmetropolitan areas had college degrees, but this percentage increased to 15.5% in 2000. This compares with 26.6% of urban adults with college degrees in 2000. More than 23% of rural adults do not have a high school diploma—an all time low—compared with 18.7% of urban adults (USDA, 2003b).

Rural Hispanic people have the lowest percentage of educational attainment—more than half never finished high school and only 6.5% graduated from college. However, in counties with a rapid growth of Hispanic populations,

**FIGURE 29.3** Percent change in Hispanic/Latino populations from 1990 to 2000.

enrollment in K–8 schools has grown by over 500% (Kandel & Parrado, 2006). For Blacks, urban residents were two times more likely to complete college than rural citizens, even though Black high school completion rates have jumped 12 points in the last decade (USDA, 2003b).

Lower levels of education are consistently and “highly correlated with persistent poverty,” with 23.5% of adults over age 25 without a high school education living in poverty and only 7.1% for those with some college (USDA, 2003b, p. 4). Rural clients have little access to higher educational facilities, such as community colleges or universities close to home. Travel to urban areas for educational pursuits adds to the burden of obtaining additional education beyond high school.

### Income, Housing, and Jobs

Some rural communities are home to some very wealthy residents, many of them landowners, business owners, farmers, or ranchers. On the average, however, the income of people in rural communities is lower than that of persons living in urban communities. This is reflected in higher unemployment and lower per capita income (Hummel, 2001). In 2004, some 4.5% of urban residents were unemployed, whereas unemployment was 5.7% for rural residents (Gibbs, 2004). Of the 386 counties noted for persistent poverty, 340 are rural. Over 14% of rural Americans live below the poverty level, and over 13% of

them report being hungry and having difficulty securing sufficient food for their families. In agricultural communities, over one-third of the residents have incomes below \$15,000. In 2000, the median income for metropolitan households was \$44,984, whereas the median rural income was \$32,837. Poverty is deeply entrenched in rural America. In one-fourth of rural counties, 20% of people have lived below the poverty level for a minimum of four decades (Food Security Learning Center, 2007). The percentage of working poor in rural areas is higher than in urban areas (Merchant, Coussens, & Gilbert, 2006). In a number of low-income communities, up to 50% of income may derive from federal support through health and social services (HRSA, 2002).

Living in a rural area, however, has a number of economic advantages. The cost of land is lower than in urban areas; therefore, housing costs are also lower, with \$79,000 as the median value, opposed to an urban median value of \$121,000 in 1999 (Wills, 2002). Taxes are usually less, and restrictions on land use are not as stringent. Less expensive land is advantageous to businesses, such as manufacturing, which may need large parcels of land. However, transportation costs are higher and nonmetropolitan rural median housing values grew faster (57.9%) than any urban or suburban areas (around 35%) during the decade between 1989 and 1999 (Wills, 2002). This growth corresponded with rural in-migration, but posed several problems. For cash-strapped

families whose house values rose, subprime mortgages allowed them to trade equity for cash, and foreclosure rates have now skyrocketed. In Minnesota, rural county foreclosures outpaced foreclosures in metropolitan counties (Oakes, 2008). Low-income families who are renters have found it difficult to find affordable housing (USDA, 2007d). Most low-income housing in rural areas consists of single-family homes, not large apartment complexes, and housing availability is problematic. A consistent problem in rural areas is housing quality; many units are substandard and in need of repair (Rural Assistance Center, 2007b; U.S. Department of Housing & Urban Development [USDHUD], 2007).

Some government assistance is available to help low-income renters. The USDA offers rent subsidies to low-income elderly or disabled residents of multifamily housing units through Section 521 (USDA, 2007d). Section 8, a rental voucher program administered by the U.S. Department of Housing and Urban Development (HUD), is targeted to very low-income families who can choose from privately owned rental housing (USDHUD, 2004). However, funds for this program are limited and applicants can wait years for approval. Both programs supplement participants' rental costs above 30% of their income.

Although many people equate farming with rural life, only 7.6% of rural employment is related to agriculture (HRSA, 2002). The United States is unique in that it feeds its population with a small proportion of workers committed to food production and still exports food products to the rest of the world. Rural workers are two times more likely than urban and suburban workers to earn only the minimum wage, and they are "more likely to be underemployed and are less likely to improve their employment circumstances over time" (HRSA, 2002).

When compared with urban areas, rural communities typically offer fewer job options. Types of rural work, such as crop agriculture, manufacturing, and forestry, vary by locale, and these employment opportunities have been diminishing along with concomitant decreases in population and the shift from a goods-based to a service-based economy (HRSA, 2002; Gibbs, Kusmin, & Cromartie, 2004). Examples of goods-producing industries in rural areas include yarn, thread, and fabric mills, and apparel industries, along with lumbering, mining, and agriculture. Construction and livestock agriculture are also included in this category. Service industries that have increased in rural areas include trucking, tourism (hotels/motels), department stores, banking, and insurance (Gibbs et al., 2004).

Even though rural salaries on the whole are less than urban, the evolution from goods- to a more service-based economy has spurred skills and earnings increases for rural residents, with Black women reporting the greatest gains (Gibbs et al., 2004). Rural areas have manufacturing, business, education, and service occupations just as urban communities do. In fact, in many rural communities, health care provides 15% to 20% of total jobs (HRSA, 2002). Education and government are also major employers.

Although the use of the telephone and Internet for commerce is now very common in urban and suburban areas, the "rural digital divide" still exists (HRSA, 2002). Smaller public health departments (those serving fewer than 25,000) are less likely to have access to the Web (Quiram, Meit, Carpender, Pennel, Castillo, & Duchicela, 2004). Many

rural communities cannot provide access to Internet service, thus limiting the proliferation of information technology-based businesses and services (HRSA, 2002). The benefits of broadband services not only apply to wider employment opportunities, but also to job retraining, education, and medicine (Cooper, 2002). Where Internet services are readily available, higher-skilled "remote workers" can remain in rural areas while still providing high-tech services to clients across the country, thus reducing the out-migration of young adults (Berkes, 2005).

## RURAL HEALTH ISSUES

Health concerns of populations in rural areas are related to the environment, occupations, injuries, and distance from health care providers. Environment issues particularly relate to agriculture and the health risks that accompany farming and other rural lifestyles.

### Agriculture and Health

Although farming is not characteristic of all rural areas, where agricultural production occurs, both direct and indirect effects on health can exist (Merchant et al., 2006). The water, air, and soil can be affected by pesticides and fertilizers; air can be polluted by the dust created from plowing for crops. An "estimated 70% of antibiotics are used for non-therapeutic purposes in intensive livestock production," and this practice puts workers at risk for developing antibiotic-resistant infections (p. 4). Occupational exposures to wind-blown soil, organic dust, pesticides, mycotoxins, ammonia, animal dander, and hydrogen sulfite are only some of the air quality issues in rural areas. In Iowa, for instance, it is estimated that for every pound of corn harvested, two pounds of soil are "exported" (p. 7). Livestock growth-producing agents, along with radon, pesticides, and fertilizers, can contaminate ground water. Many rural residents depend on their own well water for drinking, and water quality is monitored only sporadically by well owners, and then usually only for "coliform bacteria and nitrates" (p. 19). About 30% of rural residents obtain drinking water from very small water systems, without the monitoring and regulations associated with large urban water suppliers.

Agricultural-related morbidity and mortality are relatively high. Agriculture ranks second, behind mining, in occupational death rate (Smith, 2007). The fatality rate for farming is 28 per 100,000, and almost 28,000 children and adolescents were injured in farming accidents in 2004 (National Institute for Occupational Safety & Health [NIOSH], 2007). Farming injuries can result from tractor rollovers, suffocations in grain bins, exposure to harmful substances, falls, fires or explosions, accidents with other farm equipment, and on- or off-road collisions. About 5% of injuries result in permanent disability, and worker-training programs to recognize hazards and prevent injuries are rare (Merchant et al., 2006). See Display 29.1 for two examples of agricultural accidents.

Almost 70% of farm families have a member working off the farm. This is sometimes due to required additional income, but most often attributed to a need for health insurance through outside employment (Merchant et al., 2006). This contributes to the time spent in travel and its attendant

## DISPLAY 29.1

## AGRICULTURAL ACCIDENTS

It was an average day for Sampson Parker, a part-time farmer in South Carolina who also worked in construction. He was trying to get a cornstalk out of the rusty old harvester when the glove he was wearing got stuck in the rollers of the machine and pulled his hand into it. He couldn't get it out and waited more than an hour-and-a-half for someone to come and rescue him. After his hand became numb, he pushed a metal rod into the machine to stop the rollers so that he could cut off his fingers with a penknife. But, the metal rod grinding against the rollers caused a spark and flames began to engulf the harvester. He described watching his skin melt like plastic and began cutting off his arm in order to free himself from the death-trap. He said he felt the nerves in his arm as he cut through them, but was determined not to die in the cornfield. As a tire blew from the heat, he fell and broke his bone, freeing himself from the harvester. He jumped into his van and drove to the front of his property, where a passing firefighter stopped to help him. Farmer Parker is now being fitted for a prosthetic arm and notes that this injury was due to his mistake, not the harvester's.

Jason Silveira, a rambunctious 10-year-old living in the agriculturally rich San Joaquin Valley of California, was spending the day off from school with his younger sister and cousin at their grandparents' ranch in Plainview. He had just helped his grandfather load a bunch of leaves into a manure spreader attached to a tractor and asked his grandfather if he could ride along with him as he

spread them onto a nearby field. His grandfather told Jason to return to the house, as he knew how dangerous farm equipment could be, but Jason decided to play a game of "cat and mouse"—running up to the spreader and falling back as it criss-crossed the field. His grandfather couldn't see him playing this dangerous game, as the tall, boxy implement obscured his view. The spreader has "three rows of tines that turn quickly when engaged," and as soon as his grandfather sensed something was wrong, he stood up from his seat—engaging a safety mechanism that stopped the spreader immediately (para 12). Jason's parents feel that this is what saved his life—as Jason had fallen and become entangled in the tines. Ambulance and fire crews used the Jaws of Life to cut the tines free from the spreader bars, although they were still embedded in Jason's head, neck, and torso. He was taken by helicopter to a regional trauma center where additional fire crews removed more of the bars before he was taken into the emergency room. He remained conscious throughout the ordeal—until he was taken to surgery where the tines were removed. One of the tines had entered the right side of his jaw, traveling diagonally through his head behind his sinus cavity, and another pierced his neck and fell out on the trip to the hospital. The third tine went through his ribs, but miraculously did not puncture his lungs. His parents reported that Jason came through surgery, but that they were still waiting for definitive news from his doctors.

problems. Because of the lack of mass transit, rural commuting increases air pollution and the incidence of injury or death from traffic accidents.

### The Built Environment in Rural Areas: Relationship to Health

Medicine will not be adequate to deal with the health challenges of the 21st century, not even with the help of the sequenced genome and advances in robotic surgery. Even though the United States spends one of every seven dollars on medical care, we will not significantly improve health and the quality of life unless we pay more attention to how we design our living environments. Healthy living environments include not just a clean and heated kitchen, bath, or bedroom, but also the landscape around us. Health for all, especially for the young, aging, poor and disabled, requires that we design healthfulness into our environments as well. (Richard Jackson [2001], National Center for Environmental Health, CDC)

The **built environment** consists of the development of housing, highways, shopping areas, and other manmade features added to the natural environment. As populated

areas expand, stresses are placed on natural habitats, water supplies, and air quality (U.S. Environmental Protection Agency [EPA], 2007).

*Urban sprawl* is a concern in some rural areas, as people move from urban centers to more suburban environments. Urban encroachment into agricultural areas creates problems with air and water pollution, access to health care, and heat islands. *Heat islands* occur when green areas are exchanged for asphalt, resulting in temperature and ecosystem changes that can extend to more rural areas (Merchant et al., 2006). Ozone levels are often highest just outside the city, because "ozone is formed relatively slowly by the action of sunlight on oxides of nitrogen and hydrocarbons" (p. 72). Urban sprawl also causes problems with water pollution and the availability of water. Encroachment of housing areas into natural habitats or farmlands can lead to wider human exposure to pesticides, herbicides, and other hazards such as mosquito-borne illnesses. Mass transit is not often available in suburban areas, and almost never found in rural areas. Opportunities for health-promoting behaviors are often more limited in rural areas. Deteriorating (or no) sidewalks can be a barrier to walking in rural areas. Exercise or fitness facilities, bike paths, jogging trails, and other incentives for physical activity are also often lacking in rural

communities. Obesity is prevalent in rural areas, and the physical environment, along with diet, plays a role in this epidemic (Merchant et al., 2006).

Rural roads are another concern because they are often narrow, without streetlights, and poorly maintained. Slow moving farm equipment traveling on these roads, along with speeding and failure to use safety restraints, has led to injury-related non-farm vehicle crashes in one Iowa study (Peek-Asa, Sprince, Whitten, Falb, Madsen, & Zwerling, 2007).

## Self, Home, and Community Care

In one qualitative study of rural clients, health was described as “being able to function” at both work and play (Lee & Winters, 2004, p. 55). Historically, self-management of health care problems has been the most common way for rural people to cope with illness. This can be viewed as a strength, or it may be seen as a limitation. A rural mental health professional recently noted that the “culture of rural states” is often “one of self-sufficiency, traditional values, and patriarchal social structures” (Merchant et al., 2006, p. 41). Rural residents are often viewed as hardworking, traditional, hardy, self-reliant, and resistant to accepting help or services from outside agencies regarded by them as welfare-type programs (Lee & Winters, 2004; Phillips & McLeroy, 2004). Many rural clients are considered individualistic, independent, and resourceful. They often take care of illnesses or injuries on their own, or have a supportive network to help them get their health needs met (Lee & Winters, 2004). Small communities commonly have strong social networks, but this type of familiarity can lead to problems with privacy and confidentiality, as well as stigma regarding mental health or substance abuse treatment (HRSA, 2002).

Because cost, travel, weather, and distance are barriers to obtaining health services from formal health care providers, rural clients may employ a variety of folk treatments and home remedies before consulting a nurse or a physician; such clients tend to visit providers at a much later stage than do people in urban areas. Research reveals that rural residents have fewer visits to health care providers than their urban counterparts and are less likely to receive all recommended preventive screenings and services (Larson & Fleishman, 2003). They are also more likely to report poor or fair health (one in three adults), to have chronic diseases, such as diabetes, and to die from heart disease than are residents of urban areas (AHRQ, 2005). Rural residents receive care in a less timely manner than urban residents and utilize physicians who are more likely to provide care that is outside their specialty areas (AHRQ, 2002).

The low population density in rural areas makes service delivery more difficult, especially for those with special health needs such as the elderly, the disabled, and others (AHRQ, 2007). Suicide rates in rural areas, especially the rural West, can be as much as three times those in urban areas. Over twice the rate of anxiety and depression has been found in rural women, as opposed to urban women. And, less than half of rural community clinics or primary care settings accurately diagnosed depression in their patients. Designated mental health professional shortage areas are found in 60% of rural areas (Merchant et al., 2006).

Home health care (HHC) is particularly difficult in sparsely populated areas, both for patients and nurses.

### DISPLAY 29.2

## LOCATING A RURAL HOME HEALTH CLIENT

The following written (verbatim) directions were given by a discharge planner to a case manager (home care nurse) when making a referral for Mary, a 67-year-old woman who lived 37 miles from the hospital:

“Drive on the gravel road east of town until you get to the third set of mailboxes. Then, turn left; drive up the road until you see the old church; cross the broken bridge toward the river. Mary lives on the third farm. Her house has some trees and a fence around it” (p. 222).

It took the home health nurse over 2 hours to drive about 30 miles on the narrow country roads after the morning rain. The nurse had to stop four times to ask residents for additional directions and hints for finding Mary’s house. It was finally located, hidden in a large group of trees. The total travel time for this visit was about 4 hours.

From Bushy, A. (2003). Considerations for working with diverse rural client systems. *Lippincott’s Case Management*, 8(5), 214–223.

Locating addresses in very rural areas often takes additional skills. (See Display 29.2 for the story of a home health nurse trying to locate a client’s home.) The benefits of HHC are worthwhile; it allows people to stay at home, supports their hardiness, and compensates for the long distance between home and formal health care. Adams and colleagues (2001) conducted a study to determine whether health status differed between rural and urban HHC clients and whether place of residence was a predictor of HHC direct care time. The study collected data from more than 2,500 episodes of patient care using items from the Outcome Assessment and Information Set (OASIS). Home health nurse time in the home was also measured. The study results showed significant differences in rural versus urban health status, with urban patients being healthier. Rural HHC clients were more ill and received more home health nurse time. This study demonstrated the need for higher Medicare reimbursement for rural patients and supported the importance of the availability of HHC for patients who need these services.

## Access to Acute Care

Rural hospitals have a high risk for financial problems and closures, thus leaving rural patients stranded without services nearby and forcing them to drive long distances for inpatient care. The Balanced Budget Act of 1997 encouraged states to form rural health networks, improve emergency medical services, and improve the financial performance of rural hospitals by designating them critical access hospitals. **Critical access hospitals** (CAHs) are rural hospitals, located a minimum of 35 miles from the next hospital, or 15 miles if the terrain is mountainous or the only routes are on secondary roads (Rural Assistance Center, 2007c). One intention of this designation was to reduce the number of rural hospital closures by providing cost-based Medicare reimbursements, which differ

from the prospective payments given to larger hospitals. Most CAHs are nonprofit, have limited lengths of stay and bed capacity, and are heavily dependent on Medicare and Medicaid funding (Pink et al., 2006).

## Major Health Problems

Among major health problems affecting individuals in rural areas are cardiovascular disease, diabetes, and human immunodeficiency virus (HIV). Geography, economics, and rural lifestyle factors may account for the higher rate of these major health problems.

### Cardiovascular Disease

When it comes to cardiovascular disease, “it is possible that geography is more powerful than any risk factor yet to be discovered” (Taylor, Hughes, & Garrison, 2002, p. 550). Geographic concentrations of cardiovascular disease and other diseases vary from one rural location to the next, possibly related to inadequate health care, distance from care, environmental exposures, infectious disease in the area, and other factors. These multidimensional elements interact in such a way to cause cardiovascular mortality statistics to vary among regions and ethnic groups.

Cardiovascular disease is a leading cause of death in the United States, with ischemic heart disease accounting for more than 60% of deaths (Eberhardt et al., 2001). Clear differences exist in the cardiovascular mortality rates between urban and rural residents. The rates of cardiovascular death from ischemic heart disease for men age 20 and older are highest in the most rural counties. In the South, both men and women are more likely to die of ischemic heart disease than in other parts of the country. In the West, rural adults have less heart disease than urban residents do.

There are many reasons for these data. Cardiovascular disease, like some other chronic diseases, is characterized by a long latency period. Residence of diagnosis is of less interest than residence 10 to 30 years prior to diagnosis (Dennis & Pallotta, 2001). Rural residents may ignore early cardiovascular symptoms and give little heed to preventive interventions such as exercise and low-fat diets. Other risk factors, such as smoking and poverty, affect cardiovascular health. Adults in rural counties are most likely to smoke (Doescher, Jackson, Jerant, & Hart, 2006). This may be related to “delayed access to medical and media resources that help change unhealthy behaviors, and lower educational attainment, which is strongly associated with smoking” (Eberhardt et al., 2001, p. 34). Rural residents are also more likely to be obese and to be more sedentary than urban counterparts (Hartley, Ziller, & MacDonald, 2002).

In addition, rural areas usually have less high-tech health care equipment available, which may affect outcomes for patients with cardiovascular emergencies. However, even low-tech differences can be found. One large-scale study, examining 135,759 Medicare patient records, found significant differences in receipt of recommended treatments for acute myocardial infarction (AMI) between patients in rural hospitals and urban hospitals. Rural patients were less likely to be given heparin, aspirin, and intravenous nitroglycerin than were urban patients, and they had a higher adjusted 30-day post-AMI death rate (Baldwin et al., 2004).

### Diabetes

Rural populations are disproportionately affected by diabetes; the prevalence is generally greater in rural areas (5.54% versus 4.85%), and this is even more pronounced among Hispanics and Blacks (Hartley et al., 2002; HRSA, 2002; Mainous, Koopman, & Geesey, 2004). Causes for these differences are not always well understood, but one study reported less exercise, higher rates of smoking, and greater incidence of obesity in rural populations, all of which put them at a higher risk for type 2 diabetes (Hartley et al., 2002). Rural areas have been cited as promoting obesity “on a population level by encouraging physical inactivity and unhealthy food choices” (Boehmer, Lovegreen, Haire-Joshu, & Brownson, 2006, p. 411). Rural residents spend a great deal of time commuting to work or driving to essential services, and studies have demonstrated that for each additional hour spent driving per day, there is a “6% increase in the likelihood of obesity” (Frank, Andresen, & Schmidt, 2004, p. 87).

Rural populations also face greater barriers in diagnosis, treatment, and follow-up care. Some compliance issues with prescribed medication regimens may relate to the lack of health insurance and low-income levels in rural areas, but could also be due to lower health literacy and education levels. Other problems with accessing care may involve transportation and weather. The lack of appropriate services, such as certified diabetes educators or endocrinologists, is also common in rural America; expensive, up-to-date technologies requiring technical expertise are not readily available in most rural areas (Fraser, Skinner, & Mueller, 2006). Basic follow-up with podiatrists for diabetic foot care, ophthalmologists for retinal health, nutritionists, and health educators, as well as laboratory blood tests, can be extremely complicated for rural individuals who may have to travel great distances to access these services (Hartley et al., 2002). Programs targeted specifically to rural areas, usually provided by additional grant funding and personnel, have demonstrated success in reducing emergency department and outpatient visits for rural diabetics by providing group education on self-management and nutrition. Costs may be as low as \$400 per person, but savings can be astronomical, as one study estimated 12% less coronary heart disease and 15% fewer microvascular disease events over 10 years (Balamurugan, Ohsfeldt, Hughes, & Phillips, 2006).

### Human Immunodeficiency Virus Infection

Human immunodeficiency virus or HIV, the virus that causes acquired immunodeficiency syndrome (AIDS), was first identified among the urban U.S. population in the early 1980s. The Centers for Disease Control and Prevention (CDC) estimates that more than 1 million U.S. residents have HIV, and that more than one-quarter of them are unaware of their HIV infection and remain undiagnosed. In 2005, the estimated number of Americans with AIDS was 41,897, and the cumulative number had reached almost 1 million (CDC, 2007a). About 5% to 8% of all HIV cases in the United States are among rural populations, with the South being hardest hit and African Americans being the largest racial/ethnic group affected (University of California San Francisco [UCSF], 2006; Dean, Steele, Satcher, & Nakashima, 2005).

Among rural areas, 68% of new AIDS cases are from the South, and rates are increasing in this region while other

regions of the country have rates that have either remained stable or posted only small increases from 2000 to 2003 (Reif, Geonnotti, & Whetten, 2006). Highest rural rates of HIV are found in the U.S.–Mexico border region, the Mississippi Delta, the Southeast, and Appalachia (Hall, Li, & McKenna, 2005). Also, 50% of rural AIDS cases are among African Americans (National Rural Health Association [NRHA], 2006; UCSF, 2006; Dean et al., 2005), although one study found that the number of heterosexually acquired HIV cases was significantly decreased for Black men (–2.9%) between 1999 and 2004. Researchers also noted significant increases among Hispanic men (6.1%) and women (4.5%) (Espinoza et al., 2007).

Early diagnosis and treatment of HIV/AIDS are issues that must be faced by all rural communities. Physicians, nurses, and other health practitioners need to be educated about the changing face of the disease. Because relatively few cases of HIV/AIDS may be present in any one rural community, specialized services are often not available, and it can be a challenge to stay up-to-date with the newest treatment protocols (NRHA, 2006). Each state health department has resource persons who can provide information to health professionals in rural communities about the HIV/AIDS epidemic and current treatment protocols.

It may be difficult for a person to seek diagnosis or treatment from a rural health practitioner. Confidentiality is an issue of concern, as is lack of anonymity. People with HIV/AIDS may fear the stigma of HIV/AIDS and the rejection that is often associated with it. They may have concern for their jobs or their position in the community if their diagnosis is divulged, and they frequently fear that health care workers will break confidentiality rules (NRHA, 2006). Instead, rural people may choose to seek out HIV/AIDS testing through an urban health care facility where they know no one. Returning to the community can be devastating because of the lack of needed support services and the fear of sharing their diagnosis with others.

Another issue that may arise is that of urban residents with rural roots who return to their home communities as their illness worsens. These people seek family support and can overwhelm their caregivers, especially if the caregivers do not seek support for themselves. Community health nurses are in a good position to assist families with any health issues and can offer to facilitate connections to other social, spiritual, financial, and health care providers. A recent study of HIV-positive women found that satisfaction with social support and coping that focused on managing HIV disease were the best predictors of adherence to medication regimens (Vyavaharkar et al., 2007).

## Access to Health Care

### *Insurance, Managed Care, and Health Care Services*

Health insurance in today's market is costly, especially for individual purchasers. Some people, therefore, forego health insurance for themselves and their families. As noted earlier, rural workers are less likely to be offered health insurance through their employers, often because they are either self-employed or due to the size or type of employers (Larson & Hill, 2005). Depending on their income, these people may or

may not be eligible for Medicaid or State Children's Health Insurance Programs (S-CHIPs). Even people who are eligible for government health assistance may not apply because of their belief that it is a sign of weakness to accept a handout.

Historically, a traditional fee-for-service model delivered health care in rural and urban communities (see Chapter 6). However, it is challenging for rural providers to deliver the cost-effective, complex health care that rural persons need via solo or small group practices. Rural patients often utilize family practice clinics. The managed care model, which attempts to control costs and improve health care delivery, has slowly diffused into rural communities (AHRQ, 2002). One reason for the sluggishness is that rural practitioners are reluctant to become part of organizations whose "governance, values, and objectives rest in the hands of people who no longer live in the local community" (Rosenblatt, 2001, p. 9). Another reason is the low population density, making this type of health care insurance less profitable.

Building provider networks in rural communities is both time- and effort-intensive because rural providers are often inexperienced with managed care organizations (MCOs). The federal government provides support for **rural health clinics** in areas designated as underserved and nonurban (Finerfrock, 2006; Rural Assistance Center, 2007d). Specialized *migrant clinics* may also be located in rural areas with large migrant worker populations. Many of these are **federally qualified health centers** that provide care to underserved populations through Medicare, Medicaid, or a sliding fee scale (Rural Assistance Center, 2007e). Because only 9% of physicians work in rural areas (where 21% of the population resides), mid-level practitioners, such as physician assistants (PAs) and nurse practitioners (NPs), are often employed in these clinics (AHRQ, 2005; Evans et al, 2006). Also, specialists are most often found in metropolitan areas; rural areas are devoid of most of the smaller-specialty physicians, and residents have difficulty accessing these services (Rosenthal, Zaslavsky, & Newhouse, 2005).

Rural areas are characterized by a lack of "core health care services," defined as primary care, hospital care, emergency medical services, long-term care, mental health and substance abuse counseling services, dental care, and public health services, and it is noted that "the smaller, poorer, and more isolated a rural community is, the more difficult it is to ensure the availability of high-quality health services" (Committee on the Future of Rural Health Care, 2005, p. 1).

Many rural residents depend heavily on public health department services. Two-thirds of all health departments serve populations of fewer than 50,000 people (Rosenblatt, Casey, & Richardson, 2002). Many rural public health agencies are small and isolated, with a need for connections with other agencies in the region or state. Public health nurses "serve in various important capacities" in rural areas, and continuing education has been identified as the "most important training need" (Hajat, Stewart, & Hayes, 2003, p. 481). Rural public health departments generally have lower public funding for programs and services and a potential for "fragmentation of scarce resources" (Phillips & McLeroy, 2004, p. 1662). They also experience difficulty competing against urban agencies in access to grant funding and recruiting specialized staff. Transportation costs and adequate provision of a variety of services are other

## From the Case Files I

### A Lesson in Rural Transportation

I live in a relatively large city of 450,000 people. When I started my community health nursing rotation, I was assigned to a rural county public health department in an adjoining county over 50 miles from my house. To make matters worse, when I got there for my first clinical day, my professor told me that I was assigned to see clients in an isolated community another hour away from the health department! There was nothing but farmland between the county seat and this small, forgotten oil town. This town didn't even have sidewalks, much less a fast-food restaurant! After I got over my frustration about traveling such long distances, I began to visit some of my families and started to actually enjoy my time with them. They were so appreciative and open to my suggestions. I really seemed to be making a difference. One older gentleman, Armando, was a diabetic who spoke very little English. He lived with his wife of 45 years, who spoke almost no English. Their children had moved away in order to go to school and get better jobs. His diabetes was not well controlled, and the rural health clinic FNP suggested that he see a specialist (actually an internist) in the county seat. I helped him make arrangements with the doctor for an early afternoon visit, and made sure that he could catch the county bus that ran between the smaller communities and the county seat. When I came back for a follow-up visit the next week, I was shocked to learn that Armando's appointment had been pushed back to 4:30 p.m. because of the doctor's involvement in hospital emergencies and, by the time Armando was finished with his appointment, the county bus service had ended. Armando, with no money and no one to call for a ride, began walking back to his home—over 52 miles away! About halfway home, the driver of a farm truck gave him a lift to a large cotton farm a few miles from his home. You can imagine my horror and embarrassment when I learned of this ordeal! I never realized how difficult it was for rural people to get to their medical appointments. I always had a car and could drive wherever my gas allowance could take me. I thought that the bus would not be a problem, but I learned my lesson. Now, I make sure that the physician's office understands the patient's circumstances and the importance of getting them back to the bus stop in time to make the last bus.

*Andrea, Senior Nursing Student*

issues faced by rural public health departments, and all of these issues affect the health of the populations served.

### Barriers to Access

In rural areas, numerous access barriers to health care exist. The physical distance between place of residence and location of health care services can be considerable. Rural clients may be referred to a distant urban medical center for cancer therapy or other sophisticated care. Members of the population may be frustrated if they travel to a faraway site for care and do not have their problem resolved. Rural clients must be advised before they travel to make sure that the health care provider is not behind schedule or unable to see them; see From the Case Files I for a hard lesson learned by one PHN student.

Transportation can also be an issue, especially for people who do not drive or who lack dependable vehicles. Unpredictable weather adds to potential barriers for rural clients. Snow, ice, wind, and rain can make travel dangerous, even over short distances. Parents may decide not to risk driving on poorly maintained roads to get their children immunized or to have their own hypertension evaluated. Elderly people may choose to delay health care when long travel times, especially in isolated rural areas, are involved. As the seriousness of a condition increases, however, people often reverse their decisions (Basu & Mobley, 2006), and travel in emergency situa-

tions can be life-threatening, not only because of the emergency itself, but also because of the distance involved to get the ill or injured person to the nearest health care facility. According to a study by Branas and colleagues (2005), almost 47 million rural Americans do not have access to either Level I or Level II trauma centers within an hour's driving time, leaving them at higher risk for death from injuries. However, almost 43 million urban Americans can access 20 or more trauma centers (Level I or Level II) within an hour's time.

Limited choice of health care providers is a barrier for some rural residents. Fewer physicians, nurses, dentists, and other providers work in rural areas (AHRQ, 2007; HRSA, 2002). Those with special needs often must travel to urban medical centers to get required care. One study of disabled adults noted that they found their local rural physicians to be less familiar with their conditions, thus requiring these disabled patient to "teach" their health care provider. They also described rural public transportation as often unreliable and inaccessible (Iezzoni, Killeen, & O'Day, 2006). Another study involving children with special health care needs found that they were 17% more likely to have an unmet need for dental care than their urban counterparts, often because of difficulty accessing dental services, poverty, low levels of education, and lack of insurance (Skinner, Slifkin, & Mayer, 2006). As mentioned earlier, concerns about confidentiality or provider expertise sometimes cause clients to seek care from even more distant providers.

### New Approaches to Improve Access

The *Healthy People 2010* objectives (USDHHS, 2000) mandate improvements in health education, health screening, immunizations, and disease morbidity for the United States. Creative ways of delivering these and other services to rural clients need to be explored. Access to care is a social justice issue: clients who live in rural areas should receive quality health care, regardless of where they choose to live.

One approach that has been successful in numerous rural areas is the use of *mobile clinics*. These clinics bring health care providers to remote places for health screenings, immunizations, dental care, mental health visits, and other services. Mobile health clinics are frequently staffed by NPs, and can improve access to health care for low-income residents. They often are available to residents on evenings and weekends and offer culturally sensitive and bilingual outreach, as well as care for uninsured clients (Santana, 2005).

*School-based clinics* are another approach that improves access, but may be less prominent in rural areas. These clinics provide available, community-based, affordable, and culturally acceptable care to well and sick children. Often grant-supported, school-based clinics facilitate the receipt of health education and primary care by children who are otherwise without easy access to health services (Gamm, Castillo, & Williams, 2004).

**Telehealth**, another approach to increasing access to care, provides electronically transmitted clinician consultation between the client and the health care provider. This option is especially useful for connecting home health nurses with their patients who need close monitoring at home. It is also useful for patient and professional health education, public health applications, and health administration. Specialty health care also may be accessed, with patients and providers connected via two-way audiovisual transmission over telephone lines or the Internet, thus obviating the need for patients to leave their residences. Streaming media, video conferencing, and store-and-forward imaging are just some of the applications commonly utilized (HRSA, 2007b). Clients can also be assessed quickly by interactive communication from physician offices, hospitals, and other sites. Telehealth technology may decrease visits to emergency departments and hospitalizations. Grants and other funding are available to promote the use of this technology (HRSA, 2007b; USDA, 2005).

### Healthy People 2010 Goals

The two broad objectives of *Healthy People 2010* are (1) to increase quality and years of healthy life and (2) to eliminate health disparities. The report noted specific rural disparities: injury-related death rates are 40% higher in rural communities and 20% of the rural population is uninsured, compared with 16% of urban residents (USDHHS, 2000). Because of the unique health issues facing rural America, *Rural Healthy People 2010: A Companion Document to Healthy People 2010* was developed. Using surveys, literature reviews, and other methods of data collection and analysis, the 28 *Healthy People 2010* focus areas were examined for relevance to rural health. The following list represents a consensus of the top

priorities addressed in *Rural Healthy People 2010* (Gamm, Hutchison, Dabney, & Dorsey, 2003):

- ◆ Access to health care:
  - Access to insurance
  - Access to primary care
  - Access to emergency medical services (EMS)
- ◆ Heart and stroke
  - Diabetes mellitus
  - Oral health
  - Tobacco use
  - Substance abuse
  - Maternal, infant, and child health
  - Nutrition and overweight
  - Cancer

Access issues ranked highest because of the disparity in insurance and availability of health care providers between urban and rural populations, as well as the unequal access to emergency medical services (Patterson, Probst, & Moore, 2006). Heart disease, stroke, and diabetes are significant problems among rural populations, leading to avoidable hospitalizations because of inadequate care and follow-up (Hartley et al., 2002; Okon et al., 2006; Gamm et al., 2003).

Oral health in rural areas is affected by the shortage of dentists (Gordon, 2007). Rural adults over age 65 more often report total tooth loss than do their urban counterparts, and dental visits for rural adults between the ages of 18 and 64 are fewer than for urban adults (Gamm et al., 2003; HRSA, 2002). Smoking prevalence in rural areas is higher than in urban areas, and the prevalence rate has changed little from the mid-1990s, despite tobacco education and cessation programs (Doescher et al., 2006). Alcoholism is more common in rural than suburban areas (Borders & Booth, 2007). Prevalence of illicit drug use is higher in rural America; rural eighth graders were found to be more likely to have used marijuana, alcohol, cocaine, and crack than urban eighth graders. They were twice as likely to use methamphetamines (National Center on Addiction & Substance Abuse, 2000; HRSA, 2002). Latino, American Indian, and Asian rural adolescents have more chronic illnesses than do adolescents in other racial/ethnic groups (Wickrama, Elder, & Abraham, 2007).

Children who have special health care needs and who live in rural areas are less likely to have their health care provided by a pediatrician and more likely to have unmet health care needs due to unavailability of services or transportation problems (Skinner & Slifkin, 2007). Adolescent mortality is higher in rural areas, and early prenatal care among rural women, especially minorities and teens, continues to be low (Eberhardt et al., 2001; HRSA, 2002). Studies demonstrate that rural residence is a risk factor for obesity and overweight in children and women (Lutfiyya, Lipsky, Wisdom-Behounek, & Inpanbutr-Martinkus, 2007; Bove & Olson, 2006).

Cancer disparities are found in rural populations. For example, cervical cancer rates for rural women are statistically higher than for women living in urban areas (Bernard, Coughlin, Thompson, & Richardson, 2007). Both rural Blacks and Whites were found to be at increased risk for colon cancer when compared with urban populations (Kinney, Harrell, Slattery, Martin, & Sandler, 2006). One Iowa study found that less than half of rural residents were screened for colorectal cancer by their family physicians (Levy, Dawson,

Hartz, & James, 2006). Rural community health nurses need to consider the *Healthy People 2010* objectives and *Rural Healthy People 2010* priority areas as guides for improving the health status of rural communities throughout the decade.

## MIGRANT HEALTH

You may never have seen migrant workers, yet you are a direct beneficiary of their labor. Have you ever thought about the people who harvest the fruits and vegetables that you eat? What would happen to the complex system of agricultural production and distribution if workers were not available to pick crops at peak harvest times? Have you ever thought about exactly who these people are, where they come from, where they live, or what their health is like? Migrant farmworkers are an integral part of the farming community in the United States and across the world (Cholewinski, 2005). The agricultural industry relies heavily on migrant workers to harvest the almost endless array of fresh produce that appears year-round in supermarkets across the United States as fresh, frozen, and canned fruits and vegetables. More than 3 million seasonal and migrant farmworkers provide labor for the \$28 billion vegetable and fruit crops of the United States (National Center for Farmworker Health [NCFH], 2007a).

Despite their importance to American agriculture, migrant workers are rarely visible members of our society. They go unnoticed beyond the fringes of the camps and farms to which they travel to pursue their livelihood. Most come to the United States from other countries (93%), and of those, about 90% are from Mexico (Evans, Lantigua, Stapleton, Daughtery, & Piloto, 2005). They come with the hope of improving their impoverished lives. Some are legal residents, but most are undocumented aliens and live in fear of deportation. All endure backbreaking, menial labor for low wages and are often deprived of basic rights to safe working conditions, adequate sanitation, decent housing, quality education for their children, and health care.

### MIGRANT FARMWORKERS: PROFILE OF A NOMADIC AGGREGATE

Maintaining a low public profile, migrant workers are, for the most part, marginalized from mainstream society. They remain unseen, unheard, poorly understood, and excluded from many programs that provide health care assistance for low-income people. The migrant worker is a kind of disenfranchised person, for whom no one wants to take responsibility. Yet the needs of these workers are great. They are plagued with different, more complex, and more frequent health problems than the general population (Formichelli, 2008). Common ailments include infectious diseases (e.g., tuberculosis [TB], parasites), gastrointestinal disorders, dermatitis due to pesticide exposure, emotional distress and depression, vision and eye problems, cancer, and chronic illnesses, such as asthma, bronchitis, diabetes, and hypertension. They are plagued by poverty, poor nutrition, substandard housing conditions, long hours and grueling, often unsafe, working conditions. Their demographics, socioeconomic conditions, and lifestyle resemble those of a Third World country despite the fact that they live and work in one of the most prosperous nations on Earth. Although migrant families are in dire need of health resources, various

economic, cultural, and language barriers prevent this aggregate from accessing available health services. According to the Kaiser Commission (Rosenbaum & Shin, 2005), only 15% of migrant farmworkers have full health insurance—compared with 63% of all low-income adults—and only 20% of seasonal and migrant workers reported accessing any health care services between 1998 and 2000. Another study found that less than 10% of Mexican immigrants (documented and undocumented) who were in the United States less than 10 years reported ever going to an emergency department for care, compared with 20% of native-born Mexican Americans and Whites (King, 2007).

Migrant workers live and work in areas where health care practitioners are generally in short supply. In one study of California agricultural communities, 20% had no primary care physician available, while others had a ratio of one physician to 3,000 people (cited in Villarejo, 2003). These astounding facts makes it essential to understand the history, demographics, environment, culture, and health care needs of the migrant worker, so that PHNs can better assist them in protecting their health and the health of all citizens.

## Historical Background

Both historically and internationally, farmers have rarely been able to permanently employ the large workforces needed to harvest their crops. Throughout the 19th century, however, the small, family-owned farms typical in the United States got through the harvest by using school children, neighbors, and local day laborers. As time went by, this became more and more difficult to accomplish. During the decade ending in 1929, over half a million Mexicans migrated to the United States, many drawn to work in seasonal agriculture. With the Great Depression, many of the small, independently run farms went bankrupt, and citizens were concerned about scarce employment opportunities. Because of this, state and federal governments were lobbied by civic groups to “round up Mexican Americans indiscriminately . . . and to ‘repatriate’ them to Mexico” (University of California, 2008a). Within a few years, the outbreak of World War II caused an increased need for food production and additional workers, as many U.S. workers joined the military. To keep abreast of the demand for produce, the larger surviving farms turned to migrant labor for help. The Emergency Labor Program—known as the Bracero Program—was enacted in 1942 to permit temporary Mexican immigration to provide needed workers for American agriculture and industry (University of California, 2008a). Between 1942 and 1964, more than 4 million Mexican workers participated in this program, leaving their families behind and coming to work in Californian fields. When this program ended, workers continued to cross the border to seek employment, often bringing along their families. Employers hired needed undocumented workers from Mexico, as well as Central and South America. Living apart from society, the plight of migrant farmworkers was largely ignored until exposure on a 1960 television documentary—Edward R. Murrow’s *Harvest of Shame*—created a national outcry (Moyers, 2004). This led to the passage of the Migrant Health Act of 1962, which addressed the specific health needs of migrant workers for the first time in U.S. history.

The Migrant Health Act authorized delivery of primary and supplementary health services to migrant farmworkers

(HRSA, 2008). Federally funded migrant health clinics serve areas in the United States where significant numbers of migrant farmworkers gather. In 2004, these clinics served more than 675,000 seasonal and migrant farmworkers, a number far below the estimated 3+ million noted earlier (King, 2007). Services may be provided seasonally, on a temporary basis, or year-round. Staffing usually includes doctors, nurses, NPs, PAs, outreach workers, social workers, and dental and pharmacy workers, along with health educators. Transportation may also be a component in some areas. Primary and preventive health care services are provided to migrant workers and their families throughout more than 800 clinic sites (see Internet Resources at the end of this chapter for a map of your state). However, funding is often inadequate, and many clinics are not sufficiently staffed or operated to meet the health needs of migrant farmworkers and their dependents. Only a few centers are funded exclusively by migrant grant funding, and most are designated as “mixed grant” centers receiving funding from a variety of sources, including Medicaid in some instances (Rosenbaum & Shin, 2005, p. 16). Additionally, although these clinics exist throughout the United States, large geographic regions are not served well or at all. Other services, such as *promotora programs* that employ Hispanic lay health workers or nursing voucher programs providing NP services at participating clinics and nurse referrals to specialists, are available in some areas (King, 2007; Formichelli, 2008). Migrant workers in areas without migrant clinics or other targeted services must rely on local health departments and emergency rooms for health care, or they may simply go without needed care.

## Demographics

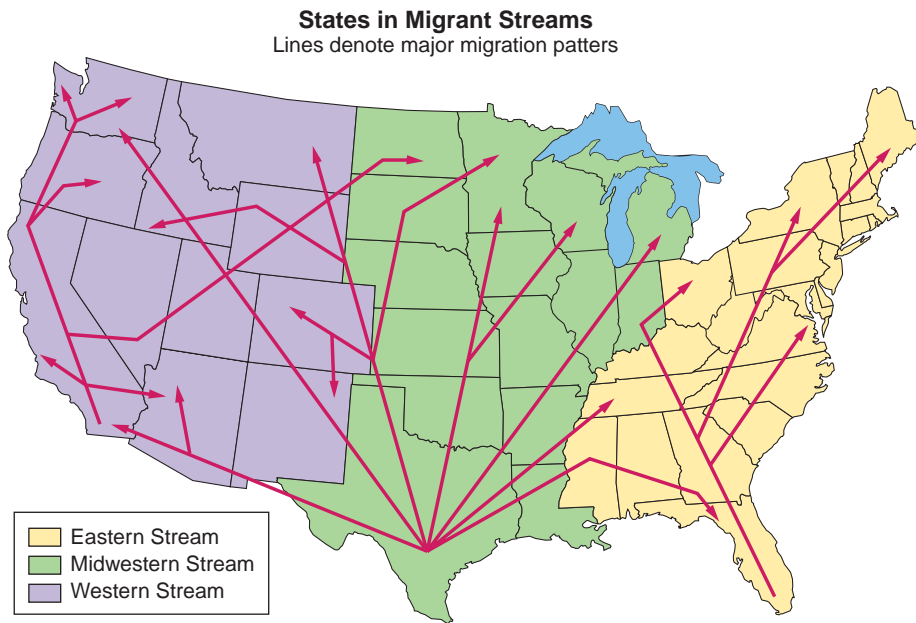

Because migrant farmworkers constitute a mobile population with shifting composition, it is difficult to precisely determine their numbers or origins. Estimates of the number of migrant workers vary also because of the influx of illegal and undocumented workers. Approximately 70% of seasonal and migrant farmworkers permanently reside in the United States (Rosenbaum & Shin, 2005). Most of the estimated 3 to 5 million migrant farmworkers tend to be either newly arrived immigrants, with few connections, or established legal residents with limited opportunities and skills, who rely on farm labor for survival (NCFH, 2007a; 2007b). It is estimated that 1.3 million U.S. citizens are agricultural workers who move between states (Moyers, 2004). The majority of migrant and seasonal farmworkers (81%) were born outside the United States—mostly in Mexico (95%) and Latin America (2%)—although roughly 2% come from Asia and other countries (NCFH, 2007c). African Americans, Jamaicans, Haitians, and other ethnic groups are also represented (NCFH, 2007b). The pool of farmworkers is increasingly diverse in California, with people coming from Latin American and Asia, such as Hmong from Southeast Asia, Mixtec and Zapotec from Mexico, and Maya from Guatemala (Alderete, Vega, Kolody, & Aguilar-Gaxiola, 2000). Many of them speak little English (NCFH, 2007c). Most of the migrant workers are young, with an average age of 31, and half of them are under age 29. Roughly half of all farmworkers are married, and just under 50% of them are parents; about half of them have their families with them. Fifty percent of farmworkers are either citizens (22%), legal permanent residents of the United States

(24%), or workers who possess temporary work permits (2%), according to the most recent government survey (U.S. Department of Labor, 2000). Eighty percent of them are male, and 84% report that they speak Spanish. Twelve percent speak English, and the reported median level of education was sixth grade (NCFH, 2007c). In addition, many mothers bring infants and young children to work with them, and the children spend their days strapped to their mother’s back or playing among the pesticide-laden fields (Alderete et al., 2000; McCauley et al., 2006).

Farmworkers are defined as having income derived primarily from work in the agricultural industry (e.g., field and orchard crops, packing houses, food processing, horticulture, livestock). In a government survey, over 60% reported working in vegetable, fruit, or nut crops (U.S. Department of Labor, 2000).

**Seasonal farmworkers** generally live in one geographic location and are principally employed in agriculture (51% or more of their time), whereas **migrant farmworkers** meet that classification while moving to find agricultural work throughout the year, usually from state to state, and establishing temporary residences (Larson, 2000). Some live apart from their families, forming groups of single men; others travel with their entire families. The average migrant farmworker spends from June to September doing seasonal harvesting, with about 8 weeks on the road traveling from farm to farm for work, and is then unemployed unless other work, such as hauling or canning, is found (Sandhaus, 1998; Bacon, 2006). The main reason migrant workers immigrate is to find work, and most migrant farmworkers end up in areas where they already have social networks, such as family or acquaintances from their own areas of Mexico (Lindstrom & Lauster, 2001). Recent studies show that farmworkers reported being employed only 47% of the previous year in agriculture, and the number of weeks of farm work available to them dropped from 28 weeks to 25 weeks over a 6-year period for workers born outside the United States and from 24 to 23 weeks for native-born workers (Das, Steege, Baron, Beckman, & Harrison, 2001). Migrant workers with less than a year of experience in U.S. agriculture reported only 17 weeks of farm work (U.S. Department of Labor, 2000). Reports of annual income vary, from between \$7,500 and \$10,000 (Formichelli, 2008; U.S. Department of Labor, 2000), to a higher estimate of just under \$15,000 in 2000 (Rosenbaum & Shin, 2005). Most farm workers have incomes below the federal poverty level—76% in 1993 and 60% in 2000 (Rosenbaum & Shin, 2005; NCFH, 2007c).

As an illustration of the working conditions and wages in the tomato fields of Florida, pickers work “10 to 12 hours a day picking tomatoes by hand, earning a piece-rate of about 45 cents for every 32-pound bucket” (Schlosser, 2007). An average work day consists of picking, carrying, and unloading about 2 tons of tomatoes. In Florida, abuses of migrant farm workers have included nonpayment of wages and forcing workers into debt, chaining workers in trailers at night, and charges of slavery. The U.S. Department of Justice has prosecuted roughly “a half a dozen cases of slavery” in the last decade (Schlosser, 2007). Families working in the cotton fields of Arizona report working long hours—from 3 a.m. to 2 p.m.; those working peak season in lettuce and broccoli fields have been known to work 14-hour days with only a half-hour lunch and two 15-minute breaks (Human Rights Watch, 2000).

**FIGURE 29.4** States in migrant streams.

## Migrant Streams and Patterns

Migrant farmworkers usually have their permanent residence, or *home base*, states with a traditionally high number of immigrants, like California, Texas, Florida, New York, or Illinois (King, 2007). From their home base, they mobilize as each new crop is ready for harvest. Following the harvest seasons of agricultural crops, migrant farmworkers move from place to place, usually along predetermined routes called **migrant streams** (Fig. 29.4). Some migrant farmworkers are multigenerational; that is, their families have been farmworkers for several generations, traveling the same streams for many years.

Three principal streams formulate the agricultural routes that migrant laborers follow. The *eastern stream* originates in Florida, where most of their time is spent, and extends up the East Coast through North Carolina, Tennessee, Kentucky, Virginia and other states east of the Mississippi, as far as north as Ohio, New Jersey, New York, Connecticut, Massachusetts, New Hampshire, Vermont, and Maine. The *midwestern stream* begins in southern Texas or northern Mexico and fans out across the United States, ending in the northwestern and midwestern states bordering Canada, both east and west of the Mississippi. The *western stream* originates in California and moves up the West Coast to all western states and from central California into North Dakota (Formichelli, 2008; Evans et al., 2005). Workers move from areas with cotton, tree fruits and nuts, and vegetable crops to other areas where they harvest watermelons, cantaloupes, and potatoes. About 17% of seasonal farmworkers “follow-the-crop” (Villarejo, 2003, p. 177).

Weather conditions and employment opportunities affect movement and patterns of migration. Because of the unpredictable nature of farm work, the three streams are not clearly delineated, pointing to more complex patterns of movement. In addition to the migrant streams, **patterns of migration** exist, with varying lengths of stay. In a *restricted circuit*, many people travel throughout a season within a small geographic area, following the crops. *Point-to-point*

*migration* entails leaving a home base for part of the year to travel to the same place or series of places along a route during the agricultural season, usually returning on a yearly basis. Almost 40% of seasonal farmworkers shuttle back and forth this way (Villarejo, 2003).

*Nomadic* migrant workers travel away from home for several years, working from farm to farm and crop to crop, relying on word of mouth about job opportunities. Nomadic workers are often younger males who send money home to their families (McLaurin & Morrison, 2006). Some of these workers eventually settle in the areas to which they have migrated, whereas others return to their home base. A given ethnic group usually follows its own particular stream and pattern of migration. New growth states, like Utah, Minnesota, Wisconsin, Nebraska, Kansas, Tennessee, and Arkansas, have seen immigrant populations double in the last 15 years (King, 2007). Some migrant workers find work in service-sector jobs and others labor in construction or landscaping, thus ending their need to constantly move with the crops.

## Migrant Lifestyle

To understand the health needs of migrant farmworkers and their families, it is important to understand their lifestyle. Migrant workers and their families endure a transient and uncertain life, with long hours, stressful working conditions, low wages, and poor health care. Substandard housing, often unsafe working conditions, and language barriers make life even more difficult.

Migrant workers must confront the vagaries of an unpredictable world. Migrants typically remain in an area for only 6 to 8 weeks, working the fields 6 days a week from sunrise to sunset. Depending on weather and crop conditions, work may be plentiful one week and virtually gone the next. Because yearly income must be earned during the harvest season, all family members contribute to harvesting. Children are essential to the core group’s economy and must help in the fields and at home (American Academy of Pediatrics,

2005). Migrant workers often drive night and day as they move from crop to crop. Typically, they travel with their children and only their most essential possessions, in aging cars, vans, and trucks. Occasionally, van loads of *solos*, or single men, migrate together. Their status is even more precarious, because they lack family support systems.

Depending on the economy and the crop, a migrant farmworker may earn as little as 40 cents per 5-gallon bushel of harvested crops. At that rate, a worker can earn up to \$100 on a good day, but rain, poor harvest, injury, and disease make the average earnings only \$30 to \$60, causing annual income to fall below the poverty level (NCFH, 2007a). Men, women, and older children all work in the fields. Because inexpensive child care is seldom available, mothers often leave very young children alone playing in fields, where they are exposed to sun, chemicals, and dangerous machinery. Sometimes children are brought to the fields and left in cars or in cardboard boxes. Often a teenage girl or the mother of an infant may remain in the camp to baby-sit all the children; she is usually stranded there, because all available cars are used to take workers to the fields.

Migrant laborers learn about employment opportunities from recruiters, farm labor contractors, and crew leaders, as well as from other migrants. About one-third of California farm workers and 20% of those nationwide are usually employed through farm labor contractors (University of California, 2008b). Migrant laborers who travel in crews, or groups, are often employed by farm labor contractors, who act as the mediator between workers and the farmer (Bureau of Labor Statistics, 2007). They may also provide transportation, housing, and meals for the workers; they may also supervise their work in the fields (Farmworker Justice, 2007). The farmer usually pays the labor contractor, who, in turn, pays the workers. This can be viewed as a way for farmers to remove themselves from the responsibility of paying minimum wages to workers, providing worker's compensation, or meeting legal responsibilities (e.g., state and federal worker safety rules), and preventing union organizing because they employ the contractor, not the individual workers (Ruckelshaus & Goldstein, 2002). An unscrupulous crew leader can withhold payment and keep the migrant workers in constant debt.

## Migrant Hero

César Chavez founded the National Farm Workers Association (NFWA; later changed to United Farm Workers [UFW]), the first union in agricultural labor history to successfully organize migrant farmworkers. As a child, he traveled with his family to harvest crops, but they rarely had enough food to eat and often lived in shacks. Work was frequently scarce, wages were low, and labor contractors cheated the family out of the money they earned. Moving to California during the Great Depression, the family became part of the migrant community. Chavez attended as many as 65 different schools, and after completing eighth grade, he dropped out of school to help support his family by working full-time in the fields.

Chavez organized many successful strikes and boycotts, the most famous one being the boycott of California grapes as a protest against the indiscriminate use of pesticides by growers. This boycott lasted for longer than 5 years,

and on two occasions he fasted as a protest against the use of agricultural pesticides. His efforts united people who, as individuals, had no significance in the power structure. His legacy is an example of how people build power together. He achieved great recognition, although he never owned a home or a car and never made more than \$6,000 a year (United Farm Workers, 2006; Bruns, 2006). Throughout his life, he ignored personal hardships to continue the struggle with union victories and losses.

## HEALTH RISKS OF MIGRANT WORKERS AND THEIR FAMILIES

A community with varied and profound health needs complicated by disease and social isolation, migrant farmworkers and their families are at risk. Migrant workers, often paid piece work, labor at a fast pace, largely without breaks, in order to take advantage of the short growing season (Connor, Rainer, Simcox, & Thomisee, 2007). Because seasonal earnings must last the entire year, the migrant farmworker generally avoids or delays seeking health care until illness becomes debilitating. When work is primary, health is eclipsed (King, 2007). Migrant farmworkers and their families suffer illnesses caused by poor nutrition, a lack of resources to seek care early in the disease process, and infectious diseases due to overcrowding and poor sanitation. National statistics on migrant seasonal workers are sparse, with much of the data regional and only sporadically collected. Some of the most shocking statistics include:

- ◆ The life expectancy of a migrant worker is much lower than the general population, with proportionally increased mortality from “injuries, tuberculosis, mental disorders, cerebrovascular disease, respiratory diseases, ulcers, hypertension, and cirrhosis” (Villarejo, 2003, p. 180).
- ◆ The migrant infant mortality rate is 25% to 30% higher than the national average (cited in Triantafillou, 2003).
- ◆ Migrant children are delayed for immunizations; one national study noted 75% of migrant children were behind on immunization or unimmunized (cited in Triantafillou, 2003).
- ◆ Parasites were reported in 20% to 80% of migrant farmworkers in North Carolina studies (cited in Triantafillou, 2003).
- ◆ Migrant workers have the highest rates of skin disorders; and chemicals, dust, and constant sun exposure are also a continual source of eye hazards (Connor et al., 2007).

## Occupational Hazards

The hazards of agricultural employment, coupled with limited legal protection, jeopardize the health of the migrant farmworker. As mentioned earlier, agriculture ranks second, behind mining, in occupational death rate (Smith, 2007). Falls, cuts, muscle strains and sprains, and repetitive motion injuries (e.g., carpal tunnel syndrome) commonly afflict migrant laborers.

Migrant and seasonal farm work typically requires stooping, long hours working in wet clothes, working with sometimes contaminated soil and water, climbing, carrying

heavy loads, and exposure to the sun and the elements. Failure to perform these activities on a rigid timetable dictated by seasons and weather can result in crop loss. This urgency compels farmworkers to work in all weather conditions, including extreme heat or cold, rain, bright sun, and humidity (Cooper et al., 2005).

In a small study of migrant workers, 41% of those reporting an injury were not provided medical care within 24 hours, and 24% got no care at all (NCFH, 2007d). Eye injuries (from tree branches, tools, or irritants) can cause serious problems. Some research suggests that farmworkers may be six times more likely than the general public to become infected with TB. Parasitic infections have been found to be 28% higher in migrant workers, and higher cancer rates have also been noted (NCFH, 2007d). Extreme cold can lead to frostbite, and overexposure to the sun may result in heat stroke; farm laborers are more often at risk for these conditions. Some plants, like tobacco and strawberries, release chemicals that are toxic to farmworkers who come in close contact with them (NCFH, 2007b).

## Pesticide Exposure

Migrant farmworkers are at greater risk for pesticide poisoning when fields are sprayed or during initial reentry into the field. Many migrant camps are located within large open fields or on the periphery of crop land. Overhead pesticide sprayings then endanger not only those at work in the fields, but also those in the camp. If fields are not posted with warning signs, mass poisoning of farm workers can occur: one example in the central San Joaquin Valley of California involved lengthy exposure for 34 workers and necessitated subsequent hospital treatment (Villarejo, 2003). Two nurses, who as children worked alongside their families in the fields, noted “as the planes sprayed the fields, you could feel the drifts” and when the spray mixed with the early morning dew “the pesticide residue would be on your clothes and your skin—it looked like a white film” (Formichelli, 2008).

Contaminated water sources in the field enhance the absorption and spread of pesticides and organic compounds. Environmental Protection Agency (EPA) standards that bar entry to sprayed fields for at least 24 hours are often ignored. Pesticides can drift from the fields to contaminate food, yards, or children playing nearby. Children are at greater risk for pesticide-induced illnesses because of their higher metabolic rate, greater surface absorption, still developing organs, and possibility for chronic long-term exposure. It is estimated that 300,000 farmworkers suffer pesticide poisoning each year (NCFH, 2007b). Surveillance systems are only in place in eight states; only 30 states require that pesticide-related illnesses be reported. Reporting of pesticide-induced morbidity and mortality are not often required. California has the oldest pesticide surveillance system in the United States (McCauley, Anger, Keifer, Langley, Robson, & Rohlman, 2006), but, even with reporting laws, many cases are never recognized because workers do not seek medical care. Pesticide burns and rashes often go untreated because of lack of education about the dangers of pesticides and lack of available services. Migrant workers are often unaware of the hazards of pesticides. A study among adolescent Latino farmworkers found that 64.7% were traveling and working in the United States independent of their parents, and few reported having received

pesticide training; however, 21.6% of the sample reported that their current work involved mixing or applying agricultural chemicals (McCauley et al., 2006).

A Florida study indicated that farmworkers had a rather extensive lay knowledge of pesticide exposure, and that this could be combined with more required ethnical training to reduce poor health effects (Flocks, Monaghan, Albrecht, & Bahena, 2007). Even though it may be required of health care providers to report pesticide poisoning, it is often misdiagnosed because the symptoms can mimic those of viral infections or heat-related illness (Das et al., 2001; Triantafillou, 2003).

Symptoms of pesticide exposure include sore throat, runny nose, headache, watery eyes, drowsiness, itchy skin, abdominal pain, and nausea or vomiting. More severe symptoms may include sweating, salivation, blurred vision or pinpoint pupils, muscle twitching, or weakness and incontinence (especially with organophosphate or carbamate exposures). Finally, with the most severe exposures, seizures, respiratory depression, and unconsciousness or coma can occur (Migrant Clinician’s Network, n.d.a; McCauley et al., 2006). Only a few categories of pesticides account for more than half of the cases of acute illness; these include inorganic compounds, carbamates, pyrethroids, and organophosphates (Das et al., 2001). Although the impact of acute pesticide poisoning is widely recognized, little is understood about the long-term effects of the repeated low-level exposures to which migrant farmworkers are constantly subjected. Some studies have noted memory problems, depression, neurologic deficits, miscarriages, and birth defects, along with respiratory problems, as being linked to chronic pesticide exposure (McCauley et al., 2006). A study of California agricultural counties found “an increased risk of death among developing babies, ranging from 40% to 120% among those whose mothers lived near crops where certain pesticides were sprayed” (“Living near where pesticides used may boost fetal deaths due to birth defects,” 2001). Numerous studies have examined the link between exposure to pesticides and various neurologic problems and cancer—most often with organophosphate-based pesticides. Some pesticides have been suspected of leading to depression (Stallones & Beseler, 2002). Non-Hodgkin lymphoma, leukemia, prostate cancer, sarcomas and multiple myelomas have been associated with organophosphates, herbicides, and insecticides (Alavanja, Hoppin, & Kamel, 2004; Mahajan, Bonner, Hoppin, & Akavanja, 2006).

A large body of supportive research has indicated a link between Parkinson’s disease, other neurologic disorders and pesticide exposure, but specific mechanisms have been difficult to pinpoint (Alavanja et al., 2004). One study revealed a 70% chance of development of Parkinson’s disease for farm workers exposed to pesticides (“Study links pesticide exposure to Parkinson’s disease,” 2006). Display 29.3, Environmental Exposure History, is a helpful assessment tool for community health nurses working with migrant and seasonal workers to use to determine pesticide exposure. When a client presents with symptoms that may be suggestive of pesticide exposure, mnemonic prompts may help to clarify common symptoms (see Display 29.4).

Pesticide exposure can be a single event, may occur multiple times, or even be continuous. Health effects are thought to be a function of the frequency of exposure and the dose (Hiott, Quandt, Early, Jackson, & Arcury, 2006). Most

## DISPLAY 29.3

## ENVIRONMENTAL EXPOSURE HISTORY

**Do an exposure history to:**

- Identify current or past exposures
- Reduce or eliminate current exposures
- Reduce adverse health effects.

**Taking an Exposure History: Questions to Consider**

Use the **I PREPARE** mnemonic:

**I**–Investigate potential exposures

- Have you ever felt sick after coming in contact with a chemical, pesticide, or other substance?
- Do you have any symptoms that improve when you are away from your home or workplace?

**P**–Present work:

- Are you exposed to solvents, dusts, fumes, radiation, loud noise, pesticides, or other chemicals?
- Do you know where to find Material Data Safety Sheets on chemicals that you work with?
- Do you wear personal protective equipment?
- Are work clothes worn home?
- Do co-workers have similar health problems?

**R**–Residence:

- When was your residence built?
- What type of heating system do you have?
- Have you recently remodeled your home?
- What chemicals are stored on your property?
- Where does your drinking water come from?

**E**–Environmental concerns

- Are there environmental concerns in your neighborhood (e.g., air, water, soil)?
- What types of industries or farms are near your home?
- Do you live near a hazardous waste site or landfill?

**P**–Past work

- What are your past work experiences?

- What is the longest job held?
- Have you ever been in the military, worked on a farm, or done volunteer or seasonal work?

**A**–Activities

- What activities and hobbies do you and your family engage in?
- Do you burn, solder, or melt any products?
- Do you garden, fish, or hunt?
- Do you eat what you catch or grow?
- Do you use pesticides?
- Do you engage in any alternative healing or cultural practices?

**R**–Referrals and resources (use these key referrals and resources)

- Agency for Toxic Substances & Disease Registry: [www.atsdr.cdc.gov](http://www.atsdr.cdc.gov)
- Association of Occupational & Environmental Clinics: [www.aoec.org](http://www.aoec.org)
- Environmental Protection Agency: [www.epa.gov](http://www.epa.gov)
- Material Safety Data Sheets: [www.hazard.com/msds](http://www.hazard.com/msds)
- Occupational Safety & Health Administration: [www.osha.gov](http://www.osha.gov)
- Local health department, environmental agency, poison control center

**E**–Educate (a checklist)

- Are materials available to educate the patient?
- Are alternatives available to minimize the risk of exposure?
- Have prevention strategies been discussed?
- What is the plan for follow-up?

migrant workers come into contact with pesticides through their work. However, exposure to pesticides does not affect only those working in the fields. A Washington state study revealed that workers who thinned trees and plants were more likely to have higher levels of pesticide residues in their house and dust in their vehicles than were those working in other areas (e.g., picking or harvesting, planting or transplanting, pruning, loading plants, or even mixing or applying pesticides). These higher levels were not only present in the homes and vehicles of farmworkers, but pesticide metabolites were also found in their children's urine as well (Coronado, Thompson, Strong, Griffith, & Iuslas, 2004). A study of Virginia- and North Carolina-based farmworkers and their families found higher levels of organophosphate pesticide metabolites in the urine of these children and adults compared to national reference samples (Arcury, 2005). Organophosphates decrease the levels of acetylcholinesterase, found in nerve endings, and can be absorbed through the skin, inhaled, or ingested. All study participants had metabolites present, and farm work and housing close to agricultural

fields were the common factors associated with exposure. Drifts from sprayed fields, residues on farmworker clothing, shoes, tools and skin, as well as food brought from the fields, are all potential sources of exposure. Vehicles can also become contaminated, as can carpeting and furniture. Contaminated clothing should be kept in separate hampers and laundered separately; workers need to be encouraged to leave boots and shoes outside their homes and to change clothing and shower before eating and playing with their children. In homes where more male workers were present, higher levels of pesticide metabolites were found (Arcury, 2005). Substandard housing was also a factor.

### Substandard Housing and Poor Sanitation

In a classic article by Cole and Crawford (1991), a vivid example of one migrant camp in Alabama highlighted workers living in a converted chicken house. An upper portion of the wall had been removed for ventilation, creating easy access for insects and birds. A dirt floor, a single light bulb, and two portable toilets located a distance away were some of the other features. Two sinks in a common living area provided the only water for the almost 60 people who lived in the chicken house. Many did not have mattresses, and because the workers were harvesting potatoes, potato baskets conveniently served as the only furniture. Such living situations still exist today. A nurse who was the child of a migrant farmworker family noted that they “lived in houses that had been condemned,” and that she once “fell into a well that was covered up by grass and dirt” (Formichelli, 2008).

Migrant farmworkers move frequently and often have great difficulty securing adequate housing. In the past, many growers or owners provided housing to migrant workers and their families. This practice has now become much less common, and only limited numbers of government-sponsored housing units are available for migrant workers. When private housing is available, it is often only offered at prices that outpace worker’s wages (Ziebarth, 2006). Data are scant, but a large survey of migrant workers in the eastern, midwestern, and western migrant streams conducted by the Housing Assistance Council (HAC, 2001) revealed that only a quarter of the housing units were owned by employers. However, for those lucky enough to find employer-owned housing, over half of those units were offered without charge. Single-family homes (46%) and apartments (21%) are most common, but workers and their families also are housed in barracks or dormitories and in mobile homes (HAC, 2001; Ziebarth, 2006). The most serious housing problems were found in the Northwest region and in Florida. Over one-quarter of housing units were located adjacent to agricultural fields; in the eastern stream, this figure was much higher at 65% (HAC, 2001).

Families with children occupied 65% of both severely substandard and moderately substandard units (HAC, 2001). Eastern stream units were more often found to be severely or moderately substandard. Many of these included mobile homes. Substandard housing is far more common in the migrant population, as national surveys of U.S. households find only 5% to 2% of the total population, respectively, live in moderately or severely substandard housing (HAC, 2001). Dilapidated conditions were common, with 22% of units having at least one of four appliances or fixtures broken (e.g., bathtub, toilet, stove, refrigerator). Over half had

no working washing machine, compared to national estimates of fewer than one-quarter of households without washing machines (HAC, 2001). Structural problems, such as holes in the roof (15%), sagging frames or roofs (22%), or damage to foundations (15%), were common. Broken glass or window screens were noted in 36% of units, and peeling external paint was found in over 40% of units (HAC, 2001). Evidence of water damage was found in 29% of units, and 19% of them had rodent or insect infestations or other unsanitary conditions.

Crowding is also a problem, as many farmworkers, unable to find sufficient numbers of rental units, share housing—sometimes paying per-person costs. One Minnesota study found that construction trailer barracks, housing 15 to 20 single migrant workers, rented for \$90 per month per person. Cinder-block duplexes cost \$40 per month per worker, and some residential hotels, lacking hot water, rented rooms for almost \$600 per month. Over 75% of respondents earned less than \$7.50 per hour (Ziebarth, 2006). In the HAC study, almost one-third of migrant workers paid rental costs that were in excess of 30% of their gross incomes—the median income was \$860 and the median housing cost was \$380—defined as a “housing cost burden” (p. 10). The costs led to further crowding, as families doubled up to save expenses; 52% of all units were considered crowded. In those crowded units, 74% were occupied by adults and children. Nationally, only 2% to 3% of U.S. households live in housing that is characterized as crowded (HAC, 2001).

In the Minnesota study, 21% of workers experienced “discrimination when trying to find housing,” and noted that landlords “don’t rent to Hispanics” or families with large numbers of children (Ziebarth, 2006, p. 349). When housing cannot be found, workers and families may have to resort to paying rent to live in garages, barns, sheds, or chicken coops, or they may be forced to stay in their cars.

Agricultural fields are usually located in isolated areas on the outskirts of rural communities. While in these isolated fields, migrant workers often are not provided with sanitation facilities or fresh drinking water. The Occupational Safety and Health Administration (OSHA) mandates field sanitation (one toilet) and fresh drinking water for farms with 11 workers or more working together within a quarter-mile stretch of field (OSHA, 2008). Large corporate farms can, however, simply space workers out and legally avoid this regulation. Furthermore, one in six migrant or seasonal workers are employed on farms hiring 10 or fewer workers, where toilets and drinking water do not have to be provided.

### Migrant Family Health

Because of frequent moves, migrant children are often educationally, socially, and physically disadvantaged. Their academic performance may be 10% to 30% below that of other students, as they are often called upon by their families to stay home from school to work, care for younger children, or attend to other household chores (Cooper et al., 2005). They are often socially estranged, constantly moving, and have difficulty finding health-promoting recreational activities. Some research has shown that children of Latino and Black migrant farmworkers exhibit a high degree of psychiatric problems—mostly anxiety-related—including separation anxiety and phobias (Triantafyllou, 2003).

The children of migrant farmworkers receive only fragmented health care. Health problems of migrant children include general poor nutrition, anemia, vitamin A deficiency, increased risk for respiratory and ear infections, dental problems, lead and pesticide poisoning, intestinal parasites, skin infections, TB, and delayed development (American Academy of Pediatrics, 2005). Lack of awareness that minor symptoms, such as diarrhea or fever, may indicate a more serious underlying problem can cause delays in seeking medical attention, as can poverty and a lack of health insurance. An earache is minor, but it can lead to a major problem, such as deafness, if left untreated. Deafness is a frequently mentioned major health problem in the migrant population (Kerr, Lusk, & Ronis, 2002).

Migrant adolescents may be more likely to abuse substances, as they are more often “in contact with adult cultural environments” and under a good deal of stress related to poverty and frequent moves (Cooper et al., 2005, p. 7). They are less likely to graduate from high school, because their education is often interrupted. Stress from acculturation, poor working conditions, deficient social support, and poor family functioning have been associated with greater anxiety and depressive symptoms among farmworkers in the Midwest (Hiott, Grzywacz, Davis, Quandt, & Arcury, 2008).

A North Carolina study of farmworker stress found that 38% had “significant levels of stress”; the most stressful factors were identified as “difficulty finding a place to live,” “not enough water to drink when I am working,” “my partner is no longer with me,” and being bothered “that other people use drugs” (Hiott et al., 2008, p. 36). Display 29.5 lists some stressors from the Hispanic Stress Inventory evaluation tool. Social isolation factors ranked slightly lower, but being away from friends and family were often mentioned. In this study of farmworkers immigrating mostly from Mexico, almost 42% met the classification as depressed, and over 18% had anxiety levels consistent with impaired functioning. The researchers concluded that social isolation had a stronger potential effect on anxiety, whereas poor working conditions were associated more with depression. The need for migrant workers to congregate in neighborhoods with others from their cultural background is an attempt to counter this social isolation. When they are surrounded by others who share their culture and speak their language, and when they can find familiar music, television, entertainment, and food, it helps to allay feelings of anxiety and depression. It is easy to understand why many migrant workers in specific migrant streams originate from the same states or communities in Mexico or other countries; it is an attempt to hold onto some semblance of their social networks as they migrate to the United States (Lindstrom & Lauster, 2001).

In the earlier cited study by Hiott and colleagues (2008), over one-third of respondents met the criteria for alcohol dependence. Alcohol use has been noted to be common among male migrant workers, and the stressors migrant farmworkers face related to their employment and acculturation put them at a higher risk for drug and alcohol abuse (Alderete et al., 2000; Finch, Catalano, Novaco, & Vega, 2003). Drugs and alcohol may be used as a means of coping with separation from family and social isolation (Florida International University, 2005).

Problems with substance abuse may also be associated with violence. Some studies report that 46% of children

From Garcia, D. (1997). Assessing stress among migrant and seasonal farmworkers. *Streamline: The Migrant Health News Source*, 3(5), 1–5.

have witnessed some form of violence; 20% had witnessed a shooting and 11% had witnessed a murder (Triantafyllou, 2003). Domestic violence affects migrant worker families, and childhood exposure to family violence has been found to be associated with behavioral and emotional problems, as well as carrying weapons (Villarejo, 2003). Also, recent surveys show that half of men who are frequent wife abusers also abuse their children (Family Violence Prevention Fund, 2008). Research on domestic violence in this vulnerable population is scant, but more than 1,000 battered farmworker women in a multicenter study were interviewed and researchers identified the typical profile as:

- ◆ Childbearing age (15–40)
- ◆ Hispanic
- ◆ Afraid of their partner
- ◆ Married or living with partner
- ◆ Drug or alcohol use by partner

The overall incidence was 20.6%. Fifty percent of abused women were pregnant at the time of the abuse (Migrant Clinician’s Network, n.d.b). Nationally, just over 30% of women report sexual or physical abuse by a boyfriend or husband during their lifetime (Family Violence Prevention Fund, 2008). (See Chapter 20 for a more complete discussion of domestic violence.) What makes farmworker domestic violence so significant is the fact that these women often experience language barriers, do not have adequate access to health care, live isolated lives with little social support, and fear deportation if they report the abuse—all factors that lead them to endure their violent situation in silence. An example is related by one migrant women who shared one room with her husband, infant, and five single men. Her husband became increasingly violent and unpredictable. He began to beat her and the baby, and she was unable to predict what would initiate a violent attack. She finally fled when one of the men living with them also began beating her. She attributed the aggressive behavior to the powerlessness felt by the men. The Violence Against Women Act of 1994 affords protection for undocumented battered women and children by allowing them to seek legal immigration status without the help of their abusers (Migrant Clinician’s Network, n.d.b). Public health nurses must be aware of these issues and what resources are available in the community (see Levels of Prevention Pyramid).

## Infectious Diseases

As noted earlier, TB is a common infectious disease among farmworkers. Some studies find that between 37% and 44% of farmworkers tested positive for TB in mass screenings throughout the United States (NCFH, 2007d). Discussing the concern for TB, one epidemiologist said, “A Mexican farmworker with TB who begins treatment in New Mexico might travel during the summer all the way to Canada after the harvests, and, even if successfully treated, may well go home to Mexico in the winter, only to be reinfected by an untreated family member” (McCarthy, 2000, p. 1021). Because of frequent moves, poor access to health care, and social isolation, it is often difficult for migrant farmworkers to be accurately diagnosed and treated. Many factors may prevent them from successfully completing a treatment regimen, and language barriers, along with cultural differences,

may preclude them from fully understanding the impact of their disease on themselves and others.

Migrant workers are at greater risk of HIV infection for many of the same reasons. HIV-positive status may be misunderstood and, because of stigmatization and fears of deportation, may be purposely hidden from health officials. Estimated HIV rates are reported to be between 2% and 13%, depending on geographic area and personal risk factors like drug abuse (McCoy, 2005). Others have noted that the rate of HIV infection in migrant farmworkers was 10 times greater than the national average, and that knowledge of HIV transmission in this population was deficient (Fitzgerald, Chakraborty, Shah, Khuder, & Duggan, 2003).

## Economic Barriers and Limited Health Resources

Most migrant workers are unable to qualify for basic health and disability benefits such as Workers’ Compensation, Social Security, occupational rehabilitation, and disability compensation because of undocumented status (NCFH, 2003). Only 7% to 11% of migrant workers have been granted Medicaid coverage (Villarejo, 2003), and federal legislation passed in 2006 requires proof of U.S. citizenship (e.g., passport, birth certificate) when applying for or renewing Medicaid coverage (King, 2007). As a group, migrant farmworkers have more difficulty accessing Medicaid than any other population.

Medicaid benefits have little value in the face of constant mobility, because they are not transferable from state to state. On one hand, although the low income of migrant workers meets the guidelines for state medical assistance, few families remain in one state long enough for the 30-day residency requirement. On the other hand, farmworker families may not qualify for Medicaid because, during certain months of the year, they earn more than the state’s poverty limits. Ironically, migrant workers suffer from preventable and treatable diseases covered under Medicaid, but they are unable to obtain treatment. Some undocumented workers may be eligible for emergency Medicaid—a very limited benefit.

Although many are eligible for public programs such as Medicaid, food stamps, and the Women Infants, and Children (WIC) program, migrant farmworkers as a whole generally do not participate. They may fear immigration penalties or be totally unaware of the available benefits. Some are eligible for Social Security benefits but do not possess the ability to process their claim (NCFH, 2003). Workers who do not have valid Social Security numbers, but still have taxes withheld from their wages, are estimated to contribute \$7 billion in Social Security taxes and about \$1.5 billion in Medicare taxes—and most of them will never qualify for either Medicare or Social Security benefits (King, 2007).

Some think that undocumented workers are a drain on the U.S. economy, and illegal immigration is a hot-button topic. However, a substantial amount of research demonstrates that immigrants generally pay more money into the system than they extract from it. In 2005, approximately 7% of the Texas population were undocumented immigrants, and Texas spent \$58 million that year for health care for undocumented immigrants. However, state revenues from undocumented immigrants exceeded what was spent on health care and education costs by almost \$425 million (King, 2007).

## LEVELS OF PREVENTION PYRAMID

**SITUATION:** Domestic Violence in the Migrant Population. Research is scant, however informal discussions occur among women and health care providers. Outreach workers sometimes possess lists of men who are abusive and their victims. Although the migrant lifestyle and experience is difficult for the entire family, women and children suffer most from family violence that the migrant way of life promotes. Isolation and subjugation to a patriarchal system usually prohibit migrant women from seeking help if they are abused. Fear of consequences and difficulty expressing negative views about husbands prevent women from speaking out. (Migrant Clinician’s Network. *Domestic violence in the farmworker population*. Monograph Series, n.d.)

**GOAL:** Using the three levels of prevention, negative health conditions are avoided, promptly diagnosed and treated, and/or the fullest possible potential is restored.

<b>Tertiary Prevention</b>	
<b>Rehabilitation</b>	<b>Primary Prevention</b>

\*Secondary prevention is difficult because of limited financial resources, lack of transportation, no nearby friends or relatives for support, language barriers (e.g., non-English speaking), and limited safe shelters for battered women in rural areas.

Whatever your viewpoint on this issue, it is important to the public's health that basic health care services be available to vulnerable populations. Continued efforts must be made to conduct research assessing risks and hazards, especially those of pesticide exposure. Many government publications document the despair and isolation of migrant workers, yet very little has been done to address the living and working environments that contribute to diminished health. Although migrant workers are difficult to study as a mobile population, they are important as an integral part of our economy and because infectious disease in their sector increases health risks for all (Hirsch et al., 2002; Glasgow, Johnson, & Morton, 2004).

### Unique Methods of Health Care Delivery and Primary Prevention

Because migrant health centers do not adequately meet the health needs of the entire migrant community, several innovative methods of health care delivery have been developed and implemented by community health nurses. Although changes are often minor and slow to occur in the migrant population, even minute changes are a milestone, because the migrant lifestyle does not support any type of health stability. Any progress made must be welcomed with recognition and support.

Mobile health vans staffed with bilingual community health nurses and lay workers can travel directly to migrant camps and are an effective strategy for outreach health screening and education. By going to migrant camps and delivering care where the clients live and work, especially during nonwork hours such as evenings and weekends, community health nurses increase health access and overcome barriers of culture and lack of child care. Although migrant families receive only fragmented acute care, a nurses' outreach team can succeed in encouraging migrant farmworkers to prevent illness with immunizations, good nutrition, and healthy lifestyles. A viable alternative to traditional medical clinics, the mobile nursing clinic provides primary care to an underserved population through health promotion, disease prevention, and early treatment. Mobile dental vans also provide services to migrant worker's children, often with arrangements made through school nurses, and dental care provided by dental schools or through partnerships (State of California, 2006). Migrant workers suffer from dental problems at a rate higher than the national average; dental caries and periodontal disease are twice the rate of the total population (Lukes & Miller, 2002).

The use of *promotoras*, lay community outreach workers, or *doulas*, usually trained childbirth assistants, have promoted health in migrant communities (Migrant Health, 2006). Some programs use *doulas* to provide classes on childbirth and other perinatal subjects in an interactive manner; these provide extensive case management services along with the traditional duties of childbirth coach. Because *doulas* and *promotoras* are generally members of the migrant community, they are readily accepted. Some *promotoras* teach parenting classes to avert child abuse and neglect, others may work with special populations to deter domestic violence or substance abuse. Some deal with prevention and early diagnosis of infectious diseases, and others facilitate early screening and treatment for cancer (Coughlin & Wilson, 2002). One program in South Texas, *Nuestra Salud*, specifically served women in the *colonias*—or unincorporated border areas between the

United States and Mexico—to promote early detection and treatment of breast and cervical cancer (Migrant Health, 2006). Some *promotoras* migrate with workers and families to provide year-round support and resources.

### Information Tracking Systems

Mobility impedes continuity of care, and the inadequate system of medical record keeping for the migrant population is particularly frustrating and challenging. Data information systems are vital components for monitoring the health status of individual farmworkers as they migrate. Furthermore, these data are essential for generating research and follow-up care as well as long-range health planning. They also help justify appropriation of monies to migrant health agencies. The Migrant Clinician's Network has instituted several tracking systems (2008). *TBNet* promotes the completion of TB treatment among migrant populations, and *Diabetes Track II* is geared toward those with diabetes and helps with monitoring and control. *CAN-Track* is a system for coordination of cancer care, and the newest tracking system, *Prenatal Health Network Project*, offers greater continuity for pregnant migrant women. *Heart Fax* is another system of tracking for those with cardiovascular disease.

Migrant children are susceptible to medical “feast or famine” and may be either overtreated or undertreated simply because their medical histories are unknown to current providers. One method for tracking the health status of migrant school-age children is through the Migrant Student Record Transfer System (MSRTS), a computerized system that collects and maintains health and academic records for migrant children (Branz-Spall, Rosenthal, & Wright, 2003). Records of migrant children collected by school nurses include data on personal and family history; immunization status; visual, auditory, and dental problems; nutritional status; and general physical condition. Although this tracking system does serve to enhance the health of migrant children, many do not attend school or do so only on a sporadic basis. The ability to track these children in the migratory lifestyle from work location to work location is often inadequate. Early intervention for migrating children is not always feasible, although it has been proven to greatly improve outcomes. The creation of a national database for information on the health status of adult migrant workers, paralleling the information included in the MSRTS, has also been suggested.

One such system, MiVIA (“my way” in Spanish), is putting health records online and making them available to migrant workers and their health care providers. Workers get a photo identification card, and their records can be accessed only by the use of a personal password. They can access their medical files, medications, a medical reference guide (bilingual), and other resources, such as local clinics and doctors, public transportation, and housing online, no matter their location (Barbassa, 2006). The program began in California's wine country, but is spreading to more distant locations.

### THE ROLE OF COMMUNITY HEALTH NURSES IN CARING FOR A MOBILE WORKFORCE

Beyond barriers to health care, such as lack of health services, language, and cultural impediments; inadequate to non-existent transportation; financial strains; underinsurance;

and questionable residency status, which are by themselves formidable obstacles, the migrant lifestyle is fraught with challenges. Because of the insecurity and instability inherent in a mobile lifestyle, long-term health goals are difficult to establish and long-term follow-up of any chronic illness is doubtful. Nonetheless, community health nurses provide much-needed services using community resources, innovative thinking, tenacity, and sensitivity.

Strategies for improving the health status and resource use of migrant workers and their families include:

- ◆ Improving existing services
- ◆ Advocating and networking
- ◆ Practicing cultural sensitivity
- ◆ Using lay personnel for community outreach
- ◆ Utilizing unique methods of health care delivery
- ◆ Employing information tracking systems

Community health nurses are the major providers of migrant health services and have a crucial role in the development and management of interventions. In response to the growing need for available, accessible, and affordable health care for farmworker families, nurses are called on not only to understand the migrant lifestyle but also to help migrant families overcome the barriers to health care (see Perspectives: Voices from the Community).

An aggregate at risk, migrant workers suffer higher frequency of illness, more complications, and more long-term debilitating effects. Exacerbated by a magnitude of environmental and work stressors, the health of migrant families is also compromised by limited access to health care, mobility, language and cultural barriers, low educational levels, and few economic and political resources. Because migrant health needs are largely manageable within community settings, community health nurses are ideal health providers. Implementing health education at migrant camps, training lay health workers, and providing clinic hours to accommodate late workdays are successful interventions. Learning the language of the migrant workers and their unique cultures is also helpful in reaching this population. Community health nurses must advocate for the health of migrant workers, who have very little economic or political power, and also guide them through the complexities of a changing health care system.

In the past, male migrant workers traveled primarily in organized crews; now they are most often traveling in family units with women and children. Added attention must be given to family members exposed to the hazards of the migrant lifestyle. Even as many migrant workers settle into communities, the cycle of poverty continues as other workers arrive from impoverished countries. With a paucity of health

## PERSPECTIVES: VOICES FROM THE COMMUNITY

“First of all, a nurse should expect the unexpected. Because of the migratory way of life . . . they do not always know where they will be next week or next month. Therefore we must understand that they do not always have their medical records, immunization records, or income records. Hours are very irregular, depending on what time the workers get in from the fields and what time the shifts are. Because of the distances we travel, we work anywhere from 8 to 12 hours a day. The most rewarding part of the job is bringing health services to the underserved and uninsured. The people are so gracious and appreciative of whatever services we provide.”

*J. S., RN, Michigan*

“Since farmworkers come to our area for only 4 months of the year, it is rare that I care for a migrant woman through her entire pregnancy. I may diagnose her pregnancy, I may see her for three or four prenatal visits, or I may meet her only once before she goes into labor and delivers her baby. I struggle with the desire to make a difference in a short period of time and with the disappointment of not being able to follow-through.”

*C. K., CNM, RN, Pennsylvania*

“Encourage clinicians to trust old diagnostic skills of palpation, auscultation, and careful listening. Exhaustive laboratory work or radiology studies are not likely to be welcomed by farm workers who seek relief of symptoms so

that they may return to work. Be warm and interested in the whole family. If you do not speak Spanish or Creole, work with translators who understand how you work. Use translators as . . . vehicles to get the information out and in. Eye contact and touch are crucial. Learning to be clinically relevant as well as competently utilizing a translator is an art, and takes time and experience to hone. Learning some phrases or some of the most frequently asked questions in the language of the farm worker should be encouraged. Even the attempt to speak the patients’ language will build trust and confidence. These harvesters of the nation’s food are very bright and resourceful people who travel great distances and undergo severe deprivation in order to work. The nobility of this pursuit is getting short shrift in the press and legislative bodies today, but the sheer enormity of the service [that] this group of oppressed people do for the rest of us needs to be acknowledged and honored by the clinicians who will provide primary health care to them and theirs.”

*W. H., RN, Michigan*

“I’m dealing right now with Hispanic women, migrant workers, who do not have any access to prenatal care, none whatsoever. What I’m doing is creative financing, a lot of begging, a lot of pleading, a lot of being nice to people I don’t even want to be nice to because it means that much to me for them to get help. So I find myself in situations that are sometimes uncomfortable, but nonetheless I do it because I feel that as a nurse that’s my job. Having been a farmworker myself, I would want someone to do that for my mother, and they did.”

*Unidentified female nurse, Idaho Falls, Idaho*

## USING THE NURSING PROCESS WHEN WORKING WITH MIGRANT FAMILIES

### Background Data and Assessment

Elena Vasquez is a community health nurse in rural Central California. She had two migrant camps in her service area and realized that during her normal working hours she was missing the adults in the camps. She met with several farmworker families one evening and brainstormed with them. They discussed their health needs and what type of services they needed most. A similar meeting was held at the other camp. At both camps, the families were willing to work with the nurse to enhance needed health care services. The information gathered helped Elena formulate nursing diagnoses which led to innovative planning and implementation.

### Nursing Diagnoses

1. Alteration in family health status related to hazardous working conditions, poverty, and mobility.
2. At risk for occupational and situational injury, illness, and stress due to poverty-level working and living conditions.
3. Inadequate and inaccessible health care services related to poverty, work hours, and mobility.

### Plan and Implementation

Elena enthusiastically approached the health department administration with the innovative ideas she was formulating. The administrator agreed to try the plan Elena proposed for 3 months if Elena could find the personnel she needed and the results were positive.

She enlisted four other community health nurses, two social workers and several bilingual students from the local university's community health nursing class, which used the agency as a clinical site. Each team of nurses, a social worker, and three students drove to a camp once a week on a Tuesday or Thursday evening from 5 to 9 PM

(the professionals started their day at 1 PM on that day). They completed a family assessment for each family; established a health record for each person; conducted health appraisals; administered immunizations; enrolled families in the Women, Infants, and Children Supplemental Food Program (WIC); made early-evening dentist and doctor appointments and arranged transportation if needed; and held brief teaching sessions on safety, infant and child care, family planning, and any topic the people requested or Elena and her colleagues felt the families needed.

The students became as innovative as Elena. They gathered used clothing and household items from their fellow nursing students for distribution and got valuable practice teaching and delivering health care services. The volunteers' enthusiasm overflowed to the farmworkers. Some of the women planned an informal "day care" program after receiving child care classes from the nursing students. Some of the men organized a baseball team to play against the other camp on Sunday afternoons. Additional donations were solicited—toys and books for the day care program and bats and gloves for the ball teams.

### Evaluation

The interventions were so successful that the program became a permanent service of the health department. In the following months, a nurse practitioner was added, along with a preschool teacher and students from the early elementary education program at the university. The two camps became popular with migrant workers, who stayed healthier and were more productive. In addition, the camp managers found the grounds being kept cleaner and had fewer complaints and less abuse of the cabins and shower areas. With improved health and productivity, several families were motivated to establish a permanent home in the community and not continue the migrant lifestyle.

resources, the community health nurse is sometimes the only health provider who can and will care for this population.

Providing care for migrant workers presents a challenge, requiring nurses to be innovative and to go beyond the boundaries of traditional health services (see Using the Nursing Process). Although many resources and programs exist to help migrant families, the needs are still overwhelming. By aligning with the goals of *Healthy People 2010* to improve the health of one of the most underserved populations, the community health nurse will also be improving the health of the nation as a whole.

## URBAN HEALTH

**Urban health** considers those characteristics of the environment as they relate to the health of the population living within large cities. According to Galea and Vlahov (2005), the factors responsible for the health of urban residents reflect three broad themes: the physical environment, the

social environment, and access to health and social services. As opposed to rural areas, there is a noted "lack of connectedness in urban life," and lower overall levels of trust, along with weaker family and community ties (Leviton, Snell, & McGinnis, 2000, p. 864). Connectedness has been shown to be a protective factor, especially for adolescent risk behaviors. Inner-city neighborhoods are often observed to have "both conventional culture and street culture" (p. 865). Community involvement and social networks, often deficient in densely populated areas, are components of social capital (discussed in Chapter 25) and have been associated with positive health outcomes, such as mental and physical health and a longer lifespan (Leyden, 2003). Urban communities may be marked by negative social support, such as that found associated with drugs and gangs. Moreover, the "high concentration of poverty (in central cities) leads to social exclusion" and high stress levels from violence and social isolation (Vlahov et al., 2007). Urban communities are made up of multiethnic and diverse racial communities, and these groups

are often socially and economically separate from what one might believe to be mainstream urban communities.

In 2000, The Johns Hopkins University founded the Urban Health Institute as a means to bolster support among an inner-city population. This “interface between the university and the Baltimore community” was created to improve the health and well-being of the residents of East Baltimore (Urban Health Institute, 2007). Its mission is to promote evidenced-based interventions to solve local, as well as national, health problems encountered in urban America. The New York Academy of Medicine has organized the Center for Urban Epidemiologic Studies to promote research that improves the health and well-being of urban populations by studying the social, biologic, and environmental influences on health (2007). The Academy sponsors the *Journal of Urban Health*, a “collaborative, multi-disciplinary, population-based research, with a special focus on low-income, disadvantaged populations” (2007). But how did the health of these urban communities evolve to such a state that targeted efforts are now required? It began in the 1800s.

## HISTORY OF URBAN HEALTH CARE ISSUES

Urban living has a long and checkered history in the United States. Arriving immigrants increased population density, especially in the large eastern and midwestern cities. Millions of immigrants arrived in the United States between the mid-1800s and the early 1900s. Because most had some family or distant relatives who had arrived here earlier, they made their ways to where these people lived, hoping to receive temporary shelter while they sought work (Garb, 2003). Many came with large families and roomed with other large European and Eastern European families in tenements. Others came alone or as a nuclear family without close ties to others already living here. Nonetheless, they gathered in **ghettos**, thickly populated sections of cities inhabited predominantly by members of the same minority group. This enabled them to be with people from their homeland—people who knew the same language and the same ways.

As time went on, many families left ghetto communities and found housing in smaller towns or in the beginnings of suburbs. As described in the classic work by Cutler, Glaeser, and Vigdor (1997), the Irish left New York City in the early 20th century; then Blacks, coming from the South, moved in. Many Black families later left for outlying suburban areas, and Puerto Rican families moved in. Today, Haitian and Middle Eastern families inhabit some of the same neighborhoods. After 100 years, many of the same buildings continue to provide less than optimal shelter for a new group of immigrants. Although ghetto living provides a sense of belonging, for many it is temporary because it engenders more negatives than positives. Children and grandchildren of the original immigrants seek out a different life for themselves, away from the urban areas that are often riddled with crime, unsafe housing, and disease. Others, because of poverty, drugs, or being near-homeless, remain in urban slum areas (Cutler et al., 1997; Waltzer, 2000).

In a classic position paper, the American College of Physicians used the term **urban health penalty** to describe the “concentration of economic decline, job loss, and major health problems” afflicting inner-city populations experiencing health problems when healthier and wealthier residents moved

to the suburbs, leaving poverty zones of economic and physical deterioration that act as determinants of health (1997, p. 485). Freudenberg, Galea, and Vlahov (2005) find urban health penalty associated with large cities that “concentrate poor people, and expose residents to unhealthy environments, leading to a disproportionate burden of poor health,” and feel that it inaccurately likens “urbaness with class and race” (p. 2–3).

Who has been responsible for addressing the needs of these communities over the last hundred or more years? Who has been, or should have been, addressing the needs evolving among the urban communities? Two connected disciplines, urban planning and public health, have addressed these issues from the 19th century to the present. **Urban planning** worked to improve the welfare of individuals and communities by creating more healthful, efficient, attractive, and equitable places (Kochtitzky et al., 2006). The activities of urban planners usually include addressing the community’s needs related to transportation, housing, commercial areas, natural resources, environmental protection, and health care infrastructure (Johansson, Svedung, & Andersson, 2006; Corburn, 2004).

*Public health*, of course, is directed at improving human well-being through assessing and ensuring the delivery of services at the community level. Together, these disciplines both addressed the needs of the identified vulnerable populations. Initially, during the late 19th and early 20th centuries, these two systems were linked in promoting health by facilitating physical activity through the creation of green space. They joined together in preventing infectious diseases by ensuring healthful drinking water and sewage systems. They also protected the community from exposure to hazardous substances related to industry by monitoring land uses and instituting zoning ordinances (Corburn, 2004; Kochtitzky et al., 2006). During the middle of the 20th century, the focus of planning and public health agencies drifted apart, partly because of their successes in limiting injury and health risk caused by inappropriate mixing of land use. The target of public health agencies shifted from investigating ways to improve the infrastructure to a focus on germ theories and immunizations (Corburn, 2004), challenges that were easier for physicians to address than changing environments. On the other hand, Corburn describes urban planning as switching its energy to “promoting economic development through large infrastructure and transportation projects. Planning shifted from attempting to restrain harmful spillovers from private market activities in urban areas to promoting suburban economic development” (p. 542). At about the same time, Rachel Carson’s book *Silent Spring*, published in 1962, described the effects of pesticides on wildlife and the eventual effects on human health, thus initiating the *environmental justice movement*, and focusing environmental health professionals largely on toxic chemical exposures (Frumkin, 2005).

According to Kochtitzky and colleagues (2006), the disciplines of urban planning and public health have begun to collaborate once again, working together to improve transportation and air quality, and addressing national health issues such as injury prevention, physical activity, access to health care, energy use, and greenhouse gas emissions, along with disaster preparedness and response. This team effort is a natural partnership when addressing such concerns as physical activity and the provision of safe and accessible spaces (Geller, 2003). A study by Leyden (2003), for instance, found that “residents living in walkable, mixed-use neighborhoods are more likely

to know their neighbors, to participate politically, to trust others, and to be involved socially,” all components of social capital that have been shown to improve both mental and physical health (p. 1550). These joint ventures are significant in reaching those *Healthy People 2010* objectives directed at the prevention of chronic disease, injury prevention, and health promotion. Leaders at the CDC are concerned with factors that affect people and their environments, and support efforts that address the improvement of both physical and social environments as related to places to live, work, and play. The CDC’s *Healthy Places* describes the components involved: interaction between environment and health, poorly planned growth leading to sprawl and increased use of vehicles, and healthy community design that promotes health and well-being (2007b). See Display 29.6 for a list of community design issues.

## URBAN POPULATIONS AND HEALTH DISPARITIES

The majority of the world’s populace now lives in cities, which is a change from long-held rural dominance (Vlahov et al., 2007; Vlahov, Gibble, Freudenberg, & Galea, 2004).

The greatest growth of large cities around the world is among less-wealthy nations, where urban slums are developing at a rapid rate (Vlahov & Gaklea, 2002). Depending upon the classification used, more than 30% of the U.S. populace still lives in central cities. Central cities with a population under 50,000 in 1990 grew more rapidly than those with more than 1 million people (U.S. Bureau of Census, 2000b). However, metropolitan areas outside central cities have had faster growth in recent years (U.S. Census Bureau, 2000b). More than 220 million people (almost 80% of the U.S. population) live in what are characterized as urban or metropolitan areas (U.S. Census Bureau, 2000c; Fleischman & Barondess, 2004). Roughly half of the populace lives in *suburban areas* (Collins-Perdue, Stone, & Gostin, 2003). About 80% of all North Americans live in towns and cities, and they spend 90% of their time indoors (Hancock, 2002).

Although some metropolitan areas have recorded substantial population losses in central-city areas (e.g., Milwaukee, Racine, and Waukesha, WI losses of 95.3%; Detroit, Warren, and Flint, MI, 91.7%; Rochester, Batavia, and Seneca Falls, NY, 543.7%; and the New Orleans area, 838.8%), others have logged substantial gains (e.g., San

### DISPLAY 29.6

## CENTERS FOR DISEASE CONTROL AND PREVENTION—SIGNIFICANT HEALTH ISSUES RELATED TO LAND USE (2007)

### Accessibility

Absence of ramps for wheelchairs; lack of depressed curbs (periodic breaks in curbs that act as ramps); narrow doorways that cannot accommodate various assistive devices, such as wheelchairs and walkers; lack of access to mass transit routes or other public services

### Children’s Health and the Built Environment

School design, increased obesity and diabetes, asthma, attention deficit hyperactivity disorder, parks and green spaces

### Elders’ Health and the Built Environment

Safe housing, appropriate public transportation, green spaces and recreational facilities, chronic diseases that limit mobility

### Gentrification

Transformation of neighborhoods from low- to high-value, causing displacement of long-time residents due to higher taxes and rents

### Health Impact Assessment

Effects of a policy, program, or projects on the health of a population and the distribution of those effects judged by tools, procedures, or methods. *The major steps in conducting a health issue assessment (HIA) include*

- screening (identify projects or policies for which an HIA would be useful)
- scoping (identify which health effects to consider)
- assessing risks and benefits (identify which people may be affected and how they may be affected)
- reporting (present the results to decision-makers)
- evaluating (determine the affect of HIA on the decision process)

### Injury

Transportation planning and safety, bicycle- and motor vehicle-related unintentional injuries

### Mental Health

Effect of community design and the built environment on stress levels and cognitive functioning

### Physical Activity

Aspects of the home, workplace, and community environments influence a person’s level of physical activity—the availability and accessibility of attractive stairwells, bicycle paths, walking paths, exercise facilities, and swimming pools, as well as the overall aesthetics of an environment, may play a role in determining the type and amount of physical activity people engage in

### Respiratory Health and Air Pollution

Air quality and air pollutants’ effects on asthma and other health conditions

### Social Capital

Individual and communal time and energy available for such things as community improvement, social networking, civic engagement, personal recreation, and other activities that create social bonds between individuals and groups

### Water Quality

Pollution of surface and groundwater; increased runoff from paved surfaces (streets, parking lots) causes increased erosion and silt and may affect water treatment plants

Source: CDC, 2007. *Designing and building healthy places*. Retrieved August 20, 2008 from <http://www.cdc.gov/healthyplaces/>.

Antonio, TX, a gain of 59%; Oklahoma City and Shawnee, OK, 39.3%; Jacksonville, FL, 37.4%; and Raleigh-Durham and Cary, NC, 29.1%) (Demographia, 2006). One example of how changes in population can adversely affect large cities is Cleveland, Ohio. Between 1950 and 2000, the population dropped from 915,000 to fewer than 500,000 people. This led to a smaller tax base and a greater proportion of poor residents, yet the city had the same maintenance expenses for sewers, water lines, and streets. Detroit, Michigan, lost roughly one-third of its population between 1975 and 1995, but the poverty rate doubled (Galea, Freudenberg, & Vlahov, 2005).

After the automobile became the mainstay of transportation, and with the housing boom and highway expansion occurring after WWII, the suburbs became “the place to be.” People moved from large cities to more suburban areas, and shopping malls and schools followed. Cars became even more essential, because public transportation did not always extend into suburban areas thereby leading to long commute times, traffic congestion, and increased motor vehicle and pedestrian injuries and deaths (Frumkin, 2005; Srinivasan, O’Fallon, & Dearth, 2003). Although not all suburban areas have remained attractive and vital, an income gap persists between city and suburban residents. Poverty is two times greater in cities than in suburban areas (18.2% versus 8.6%); unemployment is also higher (8% versus 5%). In the 2000 Census, per capita income was \$1,000 more for suburban residents than for city dwellers, despite the almost equal percentage of college-educated and professionally employed residents (Logan, 2002).

Today, the declining urban situation is not confined to a few large cities. To achieve the vision of “healthy people in healthy communities,” as discussed throughout the *Healthy People 2010* document, more must be done to promote health and prevent disease in urban areas. Although some significant improvements have been made in the last decade, no more than 15% of the goals identified in *Healthy People 2000* have been achieved (Freudenberg, 2000; Duchon, Andrulis, & Reid, 2004). The primary reason for health disparity, as mentioned in Chapter 25, is the disproportionate burden of certain health and social problems among different populations—in this instance, urban areas. This is believed by some authors to be due to stress, economic inequity, perceptions of deprivation, racism, and lack of access to quality health care among some residents (Fleischman & Baroness, 2004).

Overcrowding and poor-quality housing have been found to have a direct relationship with poor mental health, developmental delay, and even to shorter stature (Bashir, 2002; Vlahov et al., 2007). In a large-scale study, Galea, Ahern, Rudenstine, Wallace, and Vlahov (2005) found that people living in neighborhoods “characterized by poorer features of the built environment” were between 29% and 58% more likely to report depression in the past 6 months, and 36% to 64% more likely to report lifetime depression when compared with people living in better built environments (p. 825). Certain characteristics of the built environment and socioeconomic status have been associated with the prevalence of sexually transmitted diseases/infections and cardiovascular disease mortality rates (Cohen et al., 2000; Diez-Roux et al., 2001). Hazardous waste landfill sites are often located in or near urban areas (Vlahov et al., 2007, p. 119). Air

pollution and noise exposure, often associated with large inner cities, have been linked to asthma, cardiovascular death, hypertension, ischemic heart disease, and hearing impairment (Vlahov et al., 2007). A study of 95 urban communities, comprising about 40% of the U.S. population, revealed a statistically significant relationship between short-term changes in ozone and mortality; the relationship was even higher for respiratory and cardiovascular mortality (Bell, McDermott, Zeger, Samet, & Dominici, 2004). Lead poisoning has been more often reported in older, larger cities, as have poor nutrition and violent crime (Leviton et al., 2000).

Violence is often associated with large metropolitan cities. Urban youth are more likely to engage in violence than those from rural areas, although this varies among cities and neighborhoods (Leviton et al., 2000). U.S. Department of Justice (2007) crime statistics reveal that urban residents had the highest violent victimization rates in 2005 (six per 1,000 compared to four per 1,000 for both suburban and rural residents), and urban households continue to be the most vulnerable to property crime, motor vehicle theft, burglary, and other theft. Some researchers have associated higher crime rates in central cities with unemployment and urban economic change related to a shift from manufacturing to service-sector jobs along with high poverty rates (Oh, 2005).

Inner cities are often thought to be places with “above average . . . unemployment, full-time workers living on low pay, single parents and the sick and . . . disabled . . . living in poor quality and deteriorating housing conditions” (Wasylenki, 2001, p. 214). Dilapidated housing exposes residents to leaking pipes, cracks in walls and ceilings, peeling paint, broken windows, and pests such as cockroaches and rats (Rauh, Chew, & Garfinkel, 2002; Bashir, 2002; Leaderer et al., 2002). There is often limited access to adequate rental properties, and rent is often higher in large cities, making it difficult for low-income residents to find adequate housing. They are often forced to live in neighborhoods that do not facilitate outdoor activity or have markets that provide healthy foods, such as fresh fruits and vegetables (Dannenberg et al., 2003). Low-income housing, when available, is often plagued with construction and maintenance problems and is characterized by crowding, poor quality, high population density, and attendant health problems. Homelessness is more prevalent in urban areas than in rural areas (see Chapter 28). Deteriorated neighborhoods are associated with high crime levels and greater social isolation (Srinivasan et al., 2003). Sociologists Wilson and Kelling first proposed the “broken window theory” in 1982, noting that if a broken window goes unrepaired, soon all the windows are broken, and this sends a powerful message to residents that no one cares. Public health research has validated that a high “broken window index” (graffiti, litter, blighted housing, and abandoned cars) can independently predict neighborhood gonorrhea rates (Frumkin, 2005, p. A291; Cohen et al., 2000).

Population density, complexity, and racial/ethnic diversity are associated with urban areas. Central cities are often home to a large proportion of poor people and those from different racial and ethnic groups (Srinivasan, O’Fallon, & Dearth, 2003). Almost half of all Hispanics live in central cities (46.4%), most often Puerto Ricans and other Hispanics. Cubans live outside central cities within metropolitan areas (76%); only 21.2% of Whites live in central cities (Therrien & Ramirez, 2001). Problems such as HIV infection, asthma,

cirrhosis, diabetes, violence (including homicide), unintentional injury, heroin abuse, preterm delivery, infant mortality, heart disease, cancer, and stroke affect the poor and people of color more than other groups, and these groups are increasingly concentrated in cities. As an illustration, in 1998, the age-adjusted death rate for heart disease among non-Hispanic Black people was 40% higher than the rate for non-Hispanic Whites (Phillips & Grady, 2002). A classic study by McCord and Freeman (1990) found that the mortality rates of Harlem residents between the ages of 5 and 65 years were higher than those in Bangladesh, which was then noted to have one of the lowest income levels in the world—a shocking finding. As noted in Chapter 25, poverty makes a significant difference in health status. A Canadian study found that those living in wealthier neighborhoods of Ontario had 45% shorter waiting times for angiograms and were 23% more likely to have an angiogram than residents in poorer areas. A larger percentage of patients with myocardial infarctions were from the lowest income level (Wasylenki, 2001).

Over the past 25 years, cities and their suburbs have become more alike, and the demographic and health profiles that were previously uniquely urban are now shared by “edge cities” and suburbs populated by poor and minority families. Political power has shifted to more affluent suburban areas, where the tax base and spending practices are greater, at the expense of these cities. Monies that once came to cities to support new resources have also declined. The U.S. Conference of Mayors (2005) estimates that additional expenses to cities due to unfunded federal mandates, such as the Americans with Disabilities Act (ADA) for example, run in the billions of dollars. While these changes were occurring, power shifted to the states and multinational corporations, which invested tax dollars and incentives in the growing suburbs. In the 20 years between 1970 and 1990, the number of people living in poor inner-city neighborhoods doubled (Freudenberg, 2000). These people live a marginal existence—substance abusers, poor elderly, undocumented immigrants, the very ill, and the disabled. They are economically trapped, as the inner city declines around them.

Urban health disparities present a challenge that can be addressed only by the joint effort of public health and urban planning bodies. Coalitions of public health professionals, planners, builders, and architects, along with transportation engineers and government officials are needed to promote healthy, sustainable communities (Srinivasan et al., 2003). President Clinton’s 1999 Council on Sustainable Development defined *sustainable communities* as healthy places where both natural and historic resources are protected, employment is available, urban sprawl is contained, neighborhoods are safe, lifelong learning is promoted, health care and transportation are easily accessible, and all citizens have the opportunity to improve their quality of life.

As with all good plans, the sustainable development plan requires that the recipient of the planning be involved. Corburn calls this “democratizing the practice” (2004, p. 543). Communities that have been victimized through ineffective planning must be included in the decision-making process. This process will require the inclusion of the practical experience that residents bring to the table, alongside expert input. However, to ensure equitable participation and to level the discussions, the community must have access to all the necessary resources, such as technical, legal, and financial assistance.

The health of communities must be addressed from all levels of environmental impact (individual, community, and systems). Data must be included from the various environments, such as homes, workplaces, schools, and community spaces. These approaches then bring such action in line with what is often referred to as *environmental justice*, or the marriage of environmental health and civil rights (Frumkin, 2005, p. 290). A framework to ensure such justice requires that all individuals and communities have the right to work, play, and live in environments that are safe and healthy. It also requires that polluters are punished and required to provide compensation for damages and/or renovation.

## SOCIAL JUSTICE AND THE COMMUNITY HEALTH NURSE

Justice is concerned with treating people fairly. *Distributive justice* refers to the justified distribution of burdens and benefits throughout society (see Chapter 4 for a discussion of distributive justice). In the United States, the distribution of goods and services is largely determined by the marketplace. Although equality is claimed as a social ideal, dramatic inequities are accepted as being determined by the law of the marketplace. In contrast, community health nursing is grounded in commitment to a just distribution of primary goods for all members of society (Drevdahl, Kneipp, Canales, & Shannon-Dorcy, 2001). The founder of American public health nursing, Lillian Wald, was in the forefront of social reform movements emphasizing just allocation of resources for the immigrant and poor laborer (Wald, 1971). At the start of the 21st century, PHNs have inherited her legacy, but are we living up to it?

The hardships faced by people in decaying urban areas is an example of social injustice. **Social justice** occurs when a society provides for the health needs and health care issues of all people by treating people fairly, regardless of where they live or who they are. It involves an “equitable bearing of burdens and reaping of benefits in society” (Drevdahl, Kneipp, Canales, & Shannon-Dorcy, 2001, p. 23). It is a widely held view that social justice is the foundation of public health nursing, and that premature death and disease or health and illness derive from the political, socioeconomic, and structural workings of society (Drevdahl, 2002; Fahrenwald, Taylor, Kneipp, & Canales, 2007). Community health nurses who practice social justice have broad and holistic views of health; they have strong convictions that health care is a basic human right, and that improving the health of communities is an example of social justice (Couto, 2000). Social justice deals with concepts of inclusion, participation, empowerment, and the recognition that diversity is a strength—not a limitation (Racher, 2007). Social justice “ensures distribution of life resources in a way that benefits the marginalized and constrains the self-interest of the privileged”; at its best, it implies complete impartiality (Schim, Benkert, Bell, Walker, & Danford, 2006, p. 73–74).

Public health nurses must have a heightened sense of the value of cultural, racial, and socioeconomic differences and an awareness that these differences are often turned into discrimination in health care services and policies. They must be determined to “extend the bonds of community to give everyone a firm place to stand as equally entitled to services from a health care system with a single high

standard” (Couto, 2000, p. 4). Two programs represent this commitment to social justice on both national and international levels.

The Community Environmental Health Resource Center (CEHRC) in Washington, D.C., works with grassroots organizations engaged in the fight for social justice for low-income communities (Bashir, 2002; CEHRC, 2007). The primary focus is empowering residents and increasing economic opportunities to address the environmental health hazards posed by substandard housing. Children and other vulnerable persons in low-income urban communities are at greatest risk. The CEHRC addresses the major negative health outcomes of childhood asthma and lead poisoning, along with increased risk for depression and poor mental health, among people living in substandard housing in urban areas.

For more than 20 years, the goal of an international movement, *Healthy Cities*, has been to improve the conditions in urban areas, developing cities in which the focus is on “affordable housing, accessible transportation systems, employment for all who want to work, a healthy and safe environment with a sustainable ecosystem, and accessible health care services that focus on [illness] prevention and staying healthy” (Schim et al., 2006, p. 74). The World Health Organization (WHO) sponsors this program and works with local governments to develop healthy populations through capacity building and projects. It is now in its fourth phase, which focuses on healthy aging, health impact assessment, and healthy urban planning (WHO, 2007).

Where is nursing’s role within the concept of social justice? Schim and colleagues (2006) propose a new paradigm for urban health nursing. They propose a model that not only includes social justice along with the traditional concepts of *person*, *environment*, *health*, and *nursing*, but also places social justice at the center of this new approach. Their view is to interconnect social justice with the four basic constructs and promote its centrality in order to guide both “philosophical orientation (theory) and dynamic implementation process (practice) in nursing” (Schim et al., 2006, p. 74). They view social justice as a population-based concept, and note that having an individual patient focus can lead to “paternalism and racism” (p. 76). In their model, urban health nursing directs its practice to the systems and community- or population-based level, at which both political and economic solutions must be considered. Although most nurses in urban settings continue to provide service on the individual level, nurses should step back and analyze their practice and synthesize recommendations for a plan of action at the community planning table to better address the needs of the city or neighborhood.

For nurses, a key factor in the process is to emphasize the social justice perspective of *impartiality*, as defined originally by Barry (cited in Schim et al., 2006). This impartiality drives planning and action in a more *just* manner (i.e., as if neither side knew which position they were in: the advantageous [stronger bargaining] position or the disadvantageous [weaker bargaining] position). Thus, instead of an intervention or action being deemed *just* simply because it gives an advantage to one side or the other, it is done because its *outcome* is considered just or fair when viewed by a dispassionate outsider. The point of negotiations, then, is to get an equal share and no more. Self-interest is rationally put aside in favor of the greater good.

Therefore, although day-to-day practice usually includes individual services, the overall planning for change and improvement must occur from the perspective of the population level. From this level of practice, the construct of *person* incorporates the population level of aggregates, institutions, communities, states, and nations—not solely the individual. The concept of the *environment* at the individual level is often associated with physical and psychosocial influences. With a population focus, it incorporates economic and political structures that can influence health or illness and addresses community and global systems that must be utilized to initiate change and solutions.

Like the other constructs, *health* is expanded to include a population focus that recognizes sociopolitical influences. By acknowledging the health issues encountered at the individual, as well as the population level, the urban nurse can incorporate interventions that address the “dynamic institutional and societal environment” described by Schim and colleagues. In reflecting on the practice of urban nursing, the profession must believe that it requires more of a “population consciousness,” something that is missing throughout most of undergraduate nursing education (Schim et al., 2006, p. 76).

At the same time, urban nursing practice requires cultural and racial competence in order to advocate for the communities served by nursing. Once nursing again accepts and embraces social justice as a focal concept within the practice, especially in urban and public health practices, it can challenge itself to develop more dynamic forms of advocacy and social responsibility that will not only affect its clients, but shape the education and training of future nursing professionals (Fahrenwald et al., 2007). This, in turn, should lead to an enhancement of the practice and research needed to contribute solutions for addressing health disparities in all settings.

The urban nursing profession must focus, much like public health nursing, on including both primary and secondary prevention—not only at the local or community level, but also include the state, national, and international levels, to enact change for the common good. The role of advocate in these practice settings must include not only the individual level, but also the community or population and systems levels. An example of such actions would include advocating for adequate funding of government health systems, such as Medicare and Medicaid, and helping to ensure that all communities are safe and healthy environments in which to live and work. To connect all populations to fair and just systems “requires available, accessible, affordable, and sustainable health care that is equitably and impartially distributed without regard to personal advantage and disadvantage” (Schim et al., 2006, p. 77). Drevdahl and colleagues (2001) remind us that “health is not something belonging only to those who have the means to pay for education, safe working environments, and health care services,” but should be a benefit for all of us living together on this planet.

## COMMUNITY HEALTH NURSING IN RURAL AND URBAN SETTINGS

The proportion of registered nurses (RNs) living in urban and rural areas mirrors the general population (79% versus 21%). The mean age for urban RNs is 43.4 years, whereas rural nurses average 43.1 years. The proportion of male RNs

is similar in urban and large rural areas, but fewer male nurses work in small, isolated rural areas. Like the general population, the education level for nurses is higher in urban areas (46.6% with a baccalaureate or higher degree) than in rural areas (35.3% for large rural, 30.7% for small rural, 30.6% for isolated rural areas).

## Working in a Rural Community

Rural nurses are more likely to work outside hospital settings than are urban RNs, and are more likely to commute outside their residential areas to work. For instance, while there are 719 RNs per 100,000 residents living in small rural areas, only 411 per 100,000 work there. Many rural RNs commute to larger rural areas or urban centers to earn higher wages (Skillman, Palazzo, Keepnews, & Hart, 2005). Rural community health nurses most often grew up in rural areas or lived for a time in small communities. They frequently have extended family there (Bushy, 2000). Rural PHNs are active members of their community and are highly respected professionals (Bushy, 2003).

The rural community health nurse plays many roles:

1. *Advocate*: Assists rural clients and families in obtaining the best possible care
2. *Coordinator/case manager*: Connects rural clients with needed health and social services, often assisting with information on transportation
3. *Health teacher*: Provides education to individuals, families, or groups on health promotion or other health-related topics (e.g., prepared childbirth, parenting, diabetes maintenance, home safety)
4. *Referral agent*: Makes appropriate connections between rural clients and urban service providers
5. *Mentor*: Guides new community health nurses, nursing students, and other nurses new to the rural community
6. *Change agent/researcher*: Suggests new approaches to solving patient care or community health problems based on research, professional literature, and community assessment
7. *Collaborator*: Seeks ways to work with other health and social service professionals to maximize outcomes for individual clients and the community at large
8. *Activist*: With a deep understanding of the community and its population, takes appropriate risks to improve the community's health

See From the Case Files II for a day in the life of a rural public health nurse.

Rural community health nurses have the opportunity to use autonomy in daily practice. Nurses must rapidly assume independent and interdependent decision-making roles because of the small workforce and large workload. Rural nurses are often generalists out of necessity—serving as a “jack-of-all-trades” and feeling that “you’re it” (Rosenthal, 2005, pp. 42–44). Rural community health nurses learn to prioritize tasks quickly and work efficiently with others to get the job done. Referrals to other rural providers are facilitated because providers frequently know one another. The rural community health nurse has an advantage over urban nurses in that the rural health care system is smaller and easier to influence and change, but specialization is seldom possible and long-distance travel is generally a necessity (Bushy, 2003).

Anonymity is not easy for the rural community health nurse, who is always on duty. A trip to the grocery store on a Saturday morning may include interactions with rural clients

## From the Case Files II

### A Day in the Life of a Rural Public Health Nurse

Carol M. arrives at the Stevens County Public Health Department in rural America. She reviews her caseload for the day and begins her work. First, she telephones the principal of the local high school to let him know that she is able to speak next week to the Parent-Teacher Association about raising healthy adolescents (*health teacher*). Then, she calls the family of a hospitalized patient (*coordinator/case manager*) to plan the discharge of their family member. At 10:00 a.m., Carol makes a home visit to the Wesley family. The family members explain that they have been unable to enroll for needed food stamps because they do not understand the process. Carol gives the family an informational handout with phone numbers and addresses, so that they can contact the appropriate agency (*referral agent*) and even calls her neighbor who works at the office to inform her of the need for special attention for the family (*advocate*). At lunch, Carol runs into a social worker colleague and they discuss their concerns about the hospitalized individual with whom Carol spoke earlier in the day (*collaborator*). Both question whether the family will be able to manage the care needed for the patient without much outside support. After lunch, Carol returns to her office for a staff meeting and discusses a new charting system that she is recommending (*change agent/researcher*) for implementation by the department. At the same meeting, she agrees to work with a visiting community health nursing student during his rural practicum (*mentor*). That evening, Carol, as a concerned citizen, participates in a meeting at the town hall about issues related to local water quality. She addresses the group, giving them data and expresses concern (*activist*), then volunteers to lead others who are concerned about the issue. It is obvious that community health nurses like Carol M. often play many roles during the day. As a nursing student working in a rural community, you may have the opportunity to “try on” many of these roles.

and their families about their pressing health concerns. Rural nurses may experience role conflict, as neighbors often view them in all of their various roles—as nurse, “parent, spouse, and church member” (Rosenthal, 2005, p. 43). Rural community health nurses may have confidentiality and personal/professional boundary issues that have to be addressed. However, rural community health nurses are often respected, known, and trusted by the populations they serve (Bushy, 2000). Also, an “insider/outsider” mentality often exists in rural areas, as rural residents may tend to exclude nurses who have only lived in their communities for a short time or who want to remain less involved (Rosenthal, 2005, p. 43).

Rural community health nurses may experience the challenge of physical isolation from personal and professional opportunities associated with urban areas. Travel to cities for basic and continuing education can be a barrier. Rural nurses may also feel isolated in their clinical practices because of the scarcity of professional colleagues. Many rural community health nurses overcome these barriers and learn to appreciate the benefits of clinical practice in a rural setting by discussing their concerns with peers through professional organizations and seeking ways to combat isolation through online education or discussion groups (Bushy, 2003; Rosenthal, 2005).

The rural community health nurse often receives a salary that is lower than that of urban nurses in comparable positions (Skillman et al., 2005). However, there are benefits to rural nursing. Housing costs are usually lower than in larger cities, and long commutes to and from work on congested highways are often avoided, although rural driving can be hazardous. As a place to live and raise a family, rural communities offer a slower pace of life, open spaces, clean air, and friendly atmosphere. The smaller system of health care in a rural community can be advantageous to the community health nurse. It may be easier to understand the system and initiate planned change. There are many possibilities to enhance rural nursing practice, including continuing education by satellite or Internet, partnerships with larger medical centers, and invitations to clinical experts to provide on-site workshops. Grants can be written to facilitate these endeavors.

## Working in an Urban Setting

Urban public health nursing can be very rewarding, and many nurses are drawn to urban areas where salaries are higher, and opportunities for advancement or additional education greater. In urban areas, there are a larger number of nurses, more schools of nursing, and more intensive recruitment efforts than in rural areas, although, inner-city areas, much like rural settings, have a more difficult time filling nursing vacancies (LaSala, 2000).

A study of three Western states, comparing rural and urban health departments, found similar per capita ratios of PHNs. However, urban health departments had more PHN vacancies (70% versus 21%), and both reported difficulties recruiting NPs. More of the rural health agencies permitted part-time work, and this may have somewhat skewed results. Urban health departments employ a variety of personnel, including epidemiologists and nutritionists, who are not always found in rural health agencies, thus allowing for broader collaboration and in-depth services (Rosenblatt, Casey, & Richardson, 2002). Advanced PHNs are more

prevalent in larger urban areas, and they may assume a more population-focused practice—working at a systems level—in place of, or in addition to, the individual care they can provide (Mondy, Cardenas, & Avila, 2003).

The description of PHN duties in one large Midwestern city includes combinations of “home visiting, school assignments, clinic services, and other programs,” with caseloads averaging between 90 and 140 families (Schulte, 2000, p. 5). Specialized positions are also common, with PHNs staffing TB and sexually transmitted diseases/infection clinics, serving assigned schools, providing staff development, or being assigned special projects such as screenings and disaster preparedness. The urban nurses in this study worked mainly with clients at or below the poverty level, and one nurse described the situation this way:

The problems have gotten to be more. The economic situation—everything’s gotten worse. The medical care is a mess—not as accessible. People are more mobile now, even more so than they were years ago . . . they think they left [home] . . . for a better place (p. 6).

Schulte (2000, p. 6) also noted that PHNs worked largely with “three interacting communities”: the local physical communities to which they were assigned, the communities created by individual clients and families, and resource communities (those organized to provide services and goods to clients in need). The processes used by the urban community health nurses included:

- ◆ Forging working relationships
- ◆ Acting as a resource
- ◆ Detecting/asking the next question
- ◆ Making informed judgments
- ◆ Managing a sense of time
- ◆ Teaching
- ◆ Intervening with conditions influencing health
- ◆ Using physical dexterity.

In *forging a relationship*, PHNs began with creating a “perception of presence” by identifying themselves as a PHN and passing out their card with the instruction to the client to call upon them when needed. *Acting as a resource* involves dealing with “sensitive subjects” and requires “honesty, asking direct questions, and ignoring rude behavior.” *Detecting and asking the next question* “means listening to more than what is said” (Schulte, 2000, p. 7). When a client is truly heard and all information is on the table, *making an informed judgment* is then possible. *Sense of time* includes the awareness of the long-term commitment of the community health nurse to the client and the belief that results can occur, despite the lack of progress or even regression on the part of some clients. An illustration of this concept was reported by one of the PHNs in the study:

I had this one lady where I just sensed that something else was going on. She was . . . separated from her husband, but he would come over and demand his “right”—sex—and then he’d give her money. And I kept seeing this pattern in her life. So I started getting her to talk about what kind of childhood she had . . . and it came out that she had an abusive father who did the same thing—he’d rape her and then give her money. So I talked with her and then got her into counseling. I didn’t see her (for awhile) and then she showed up at one of

my schools . . . and said, “You’re the nurse who saw this and sent me for counseling.” She told me that she went back to school, for her GED, and is now enrolled in college. It really helped change her (Schulte, 2000, pp. 7–8).

*Teaching* is described as an ongoing, interactive process that not only provides information about disease prevention and health promotion, but also helps clients navigate the health care system. *Intervening with conditions* that affect health draws on nursing knowledge and experience and involves interceding to reduce the affect of social, political, and economic determinants of health; it involves a “mix of knowledge, experience, intuition, and sensitivity” (p. 8). *Physical dexterity* is used when completing a health assessment of a client’s physical condition.

Schulte (2000) found that urban PHNs create connections through caring processes and an underlying sense of regard for their clients as human beings. Community health nurses collaborate with their clients to develop their facility for long-term health promotion and improvement of their quality of life. Their ultimate goal is to empower clients to be self-sufficient. The centrality of caring is noted in the following PHN comment:

Public health nursing is more than a job. . . . When I’m out there, I care about the people, about what happens to them. I don’t think I’d make a really good public health nurse if I didn’t care. You get results if they know you care—they’re willing to make some change. If they don’t think you care at all about them, why should they take a risk for you? I think public health nursing is all about caring about people (Schulte 2000, p. 8).

There are many points at which the community health nurse can make a difference in people’s lives. Nurses provide services in deteriorating urban areas, with those living in poverty in all settings, and among all vulnerable populations. Nurses first need to assess themselves for their attitudes and preconceptions. Although access to care can be improved for many low-income people in urban areas, many clients simply need an advocate. The urban communities, and the poor or vulnerable people living in them, need strengthening and interventions that can be initiated by community health nurses using the nursing process as a guide.

### Self-assessment

Confronting poverty and caring for vulnerable people from diverse backgrounds, whether in rural or urban areas, necessitates reflective assessment of one’s own assumptions and beliefs. Because poverty may be prevalent over a lifetime, a good number of nursing students have personal or family experience of living in poverty. However, because the stigma is so great and fault finding is so pervasive in U.S. society, acknowledging and reflecting on this experience may well be painful. In contrast, because poverty is so hidden and frequently denied, some nursing students have lived apart from any knowledge of the human experience of poverty. They may have come to believe many of the negative stereotypes about poor people. Nursing students and practicing nurses need to ask such questions as “How have my judgments been shaped? How can I open myself to caring for those from whom most of society turns away?”

We learn from one another’s stories. First, learn from your classmates, friends, and neighbors who are courageous enough to tell you their own experiences of living in poverty. Ask them and listen intently. Then, let your clients teach you. One honor that nurses have is the opportunity to work with people from all walks of life. You are particularly likely in clinical experiences in community health to meet impoverished, vulnerable individuals and families living outside the mainstream. See From the Case Files III about experiences of students, like yourself, through the eyes of their professors.

### Improving Access

Even when government-sponsored health insurance and services are available, extensive barriers prevent many people from accessing services. The community health nurse serves as an advocate and bridge for families who need to gain access. Barriers to access associated with the clients themselves include reluctance to seek coverage because of feelings of pride, independence, or mistrust; feeling powerless; being unaware that such services exist or are worthwhile; lacking resources such as a telephone, transportation, or fare for children who need to go along because no babysitter is available; being illiterate; and preoccupation with meeting survival needs and competing life priorities instead of health needs (Bamberger et al., 2000).

Barriers associated with applying for health insurance include a system that is unfriendly and complicated. Paperwork is overwhelming and may be returned for correction; presentation of paid utility bills or other statements that are not often saved may be required. Informative materials may be too difficult to understand; programs may seek to restrict enrollments by restricting information. The process may require a car, a telephone, and appointments at inconvenient times. The nurse can intervene as a coach and guide, interpreting the system to the client and the client to the system. Likewise, the nurse can act as change agent to improve the system whenever possible.

### Strengthening Communities

We are all connected. All of us as citizens have a stake in preventing the adverse hardships of poverty and ill health. All of society pays to support community members who do not contribute, to house those who are incarcerated, and to ignore the vulnerable. This weakens us. We fear crime in our homes, schools, businesses, and communities in general. Society is impaired by adults who are incapable of providing nurturing environments for their children. And the alienation of many groups in society erodes our sense of community as a nation.

The common good is enhanced by strengthening community resources, including investing in people of historically low status, developing and strengthening ties within families and among people involved in neighborhood mutual support, and redeveloping neighborhood resources (see Chapter 13). Whenever possible, the PHN voices support of economic redevelopment of neighborhoods to enhance schools, housing, and employment. The community health nurse can also work to promote subsidized carpools, school-to-work transition programs, universal health insurance, and inner-city economic-development programs.

## From the Case Files III

### Examples from Community Health Nursing Instructors

Ann, a nursing faculty member at a small Roman Catholic college, had a one-to-one post clinical conference with a student and relays this conversation. The student had made many visits to an African American teen mother of two thriving children. The young mother lived in a dangerous housing project, and, although she locked him out of her second-floor apartment, her abusive boyfriend had been known to climb up the drainage pipe and over the porch roof. Sometimes, he forced open a window and beat her. The mother worked every day at a fast food establishment; her grandmother took care of the children. After a couple of months of weekly visits, the student exclaimed, “When I read her chart, I saw her as an immoral girl—a slut—and I expected her to be a loser. Now I can’t believe what I’ve learned about how strong she is. She just keeps fighting for herself and for her kids to survive! She’s a great mom and I told her so!”

Another faculty member, Sharon, who taught community health nursing in a Midwestern school of nursing was having an informal discussion with a student who related her experience of trying to get comfortable making home visits with low-income young women. She was making brave attempts at home visits to a pregnant woman, about her age, living in the deteriorating outskirts of a major city. She thought she had established rapport and was making headway developing trust with the client. One day the client asked the student, with concern in her voice, if she had “broken off her engagement.” The flustered student then had difficulty explaining the absence of her engagement ring, which she had never mentioned but the client had obviously noticed. During the previous week, she had suddenly realized she was wearing this special ring in marginal neighborhoods and thought it best to leave it at home. Of course, she thought that she had to fabricate another reason to tell the client, but felt badly for being so judgmental when the client was identifying with the student and noted they had something in common.

Lynn, a new public health nursing faculty member from a large state university in the West was shocked and repulsed by the comment of one of her students during lecture one day. When discussing vulnerable populations in urban centers and rural areas, the point was made that poverty can be a generational phenomenon and that many of our clients may find it difficult to dig out of this circumstance. Social justice was discussed, along with the need for PHNs to become social activists in order to change political and socioeconomic factors that keep the status quo. One student, a Hispanic female from a middle class family, spoke up stating “they should all get jobs at McDonalds.” This spurred further discussion about population-focused versus individual-focused interventions and approaches, and the need for all of us to be aware of our prejudices and stereotypical viewpoints.

Many caution well-intentioned professionals to beware when seeking solutions to vulnerability through the use of service programs alone. First, a whole population of people can become defined in terms of their problems instead of their strengths. In addition, citizens acting to help themselves within their community can be weakened when they are seen as clients requiring professional services. Finally, being dependent on multiple human services often has a disabling effect, reducing self-worth and leads to feelings of powerlessness.

Because human service interventions can have negative as well as positive effects, it is important to consider whether more community agencies are the answer to resolving community hardship. Community health planning should seriously consider an organizing process that builds community and that focuses on developing neighborhood competence to solve problems and create solutions for itself (see the discussion of community development in Chapter 15).

### Summary

Rural clients are a unique aggregate. Community health nurses are key to ensuring the delivery of appropriate health services to this population. There are numerous definitions of

the term *rural*. In this chapter, rural is defined as communities with fewer than 10,000 residents and a county population density of fewer than 1,000 people per square mile. The total number of people living in rural communities has increased over the last century. Since 1995, however, the growth rate in many rural communities has decreased. The elderly are a rapidly growing population in rural communities. Rural areas often have less diversity than urban cities, but that is changing in many areas. Rural clients generally have lower educational levels than urban clients, due in part to less access to higher education and lower-paying jobs. Income levels and housing costs are frequently lower than in larger cities.

*Rural Healthy People 2010* identifies national goals applicable to rural communities. Many at-risk populations live in these communities, where there are often fewer employment opportunities, a lack of adequate housing, and limited access to health and social services. Rural elders may have more limited alternatives for housing if they can no longer live alone. Mental health services are limited, even though the need may be great. Numerous risks are associated with agriculture. The community health nurse must help this population identify hazards and practice injury prevention.

A community health nurse needs to engage in community assessment of the rural area as a part of orientation. It is

helpful to identify the strengths of the community. Rural clients are frequently resourceful and often have a supportive network of people to meet their needs.

Access to health care is an important issue in rural communities. Health insurance may not be easily available, and is often not offered to self-employed and those working for smaller companies. Managed care organizations are diffusing into rural communities, and their long-term impact is uncertain. Barriers to access include distance, weather, transportation, and limited choice of providers. Some ways to improve access in these communities are school-based clinics, mobile health vans, and use of the latest technology. University-sponsored nursing centers that could serve rural populations should be explored.

Migrant farmworkers are an integral part of the farming community in the United States and across the world, however they are rarely visible members of our society. As members of a community with varied and profound health needs complicated by disease, social isolation, exposure to occupational hazards such as pesticide and dangerous farm equipment, substandard housing, and poor sanitation, migrant farmworkers and their families are at risk. Migrant children are often educationally, socially, and physically disadvantaged. Because migrant health centers do not adequately meet the health needs of the entire migrant community, several innovative methods of health care delivery have been developed and implemented by community health nurses, including mobile health vans and information tracking systems.

Rural community health nurses are key members of the professional community. Their roles include advocate, coordinator/case manager, health teacher, referral agent, mentor, change agent/researcher, collaborator, and activist. Community health nurses have challenges and opportunities related to their clinical practices. Confidentiality and personal/professional boundary issues may exist. Salaries for rural nurses may be lower than for nurses in urban areas. Rural community health nurses are highly respected individuals who make a difference in the communities they serve.

Urban health issues have existed for hundreds of years in the United States, and they continue today. Many disenfranchised and minority groups call inner cities home. In some downtown areas, upper-middle-class people are renovating old buildings and returning to the city, in the process moving out the poor literally to the streets. Although nursing services may often be delivered at the individual level, the true impact on health must address the community or population level. Key to recognizing the potential impact for improvement in the health disparities that exist is the acceptance of a social justice orientation that will empower nurses to address the required changes needed within the existing social, political, and economic systems. ■

### ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Look on the Internet for six recent articles in both rural and urban newspapers relating to access to health care. After summarizing the content, identify barriers to access that are common to both and

those that are different. What are the main themes relating to health and access to care?

2. Discuss with a classmate the common characteristics of rural, migrant, and urban clients. How can the PHN be better prepared to meet their unique needs? What are some specific challenges facing the PHN working in a rural area? In an urban area?
3. Describe some of the benefits of rural public health nursing.
4. Compare and contrast health, living, and working concerns between migrant workers and recent immigrants. Discuss how many recent immigrants from places such as Asia, Russia, or Iraq experience the same hardships as migrant workers do. How does nomadic lifestyle affect and differentiate the needs of migrant workers and recent immigrants?
5. If you are from a rural area, interview a peer who was raised in an urban setting (or vice versa). Compare your experiences with family, school, friends, entertainment, etc.
6. Look on the Internet for examples of community needs assessment from both rural and urban areas. What are the main findings of each? How do planned interventions differ? How are they similar?
7. Debate with a classmate the need for ready access to specialist medical care and sophisticated diagnostic equipment in all communities. Is this feasible? If not, how can services best be made available to urban and rural clients?

**SETTINGS FOR  
COMMUNITY HEALTH  
NURSING**

# Public Settings for Community Health Nursing

## LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ Explain the focus of the nursing process and how public health nurses (PHNs) and other nurses working in the public sector use it to provide care in their communities.
- ◆ Describe how federal, state, and local public health infrastructures influence the population's health.
- ◆ Evaluate the potential benefits of school-based health centers, and discuss possible parental or community objections.
- ◆ Compare and contrast common roles and functions of PHNs, school nurses, and corrections nurses.

*“A [community nurse] must first nurse. She must be of yet higher class and yet of fuller training than that of a hospital nurse because she has no hospital appliances at hand at all and because she has to take notes on the case for the doctor who has no one but her to report to him.”*

—Florence Nightingale, 1876 (as cited in Edgecomb, 2001)

## KEY TERMS

Corrections nurses  
 Indian Health Services (IHS)  
 Individualized education plans (IEPs)  
 Individualized health plans (IHPs)  
 Local health departments  
 Public health nurse  
 School nurse  
 School nurse practitioner  
 School-based health centers (SBHCs)  
 Section 504 plan  
 U.S. Public Health Service Commissioned Corps

 Many nursing students are not aware of the vast employment opportunities available outside the hospital in public settings. This chapter will discuss several of these public health settings and the opportunities nurses can garner, particularly in services such as public health nursing, school nursing, or corrections nursing. This chapter is a practical explanation of the work of nurses in the public sector.

Although each of these nursing opportunities differs greatly, they have several characteristics in common. First, community nurses who work in a public setting still use the nursing process, but their client is a population or group of people, rather than an individual. Second, emphasis is placed on prevention of disease or disability. Third, community nurses employed in public settings work with a variety of people. They must be able to network and collaborate with other agencies and disciplines. For example, a nurse working in a correctional facility often collaborates with mental health workers and correctional officers. A nurse working in the public setting has many opportunities to be an advocate for individuals and the community, and may serve on regional task forces or advisory boards. In addition, public health nurses (PHNs) focus on population-based care. Nurses may perform individual care, especially correctional nurses; however, most of the focus is placed on the population as client. Finally, nurses who work in the public setting must be autonomous, flexible, creative thinkers who are self-directed and able to prioritize and use the nursing process to make educated decisions and plan care for their respective populations. Nurses who work in public settings must have the highest level of nursing, communication, problem-solving, and intellectual skills.

## PUBLIC HEALTH NURSING

A **public health nurse** is a nurse who works to promote and protect the health of an entire population (American Nurses Association [ANA], 2007a). The most recent data specify that 448,254 workers comprise the U.S. public health workforce (Gebbie, 2000). This workforce consists of epidemiologists, nurses, environmentalists, laboratory professionals, nutritionists, dental workers, social workers, and other health care providers. Of this group, PHNs are the largest, making up 10% of the workforce (or approximately 49,323 nurses). Most PHNs work for governmental bodies, with the majority (36,921) working for local, state, or territorial agencies. Another 4,300 PHNs work for the federal government, and approximately 8,000 are associated with volunteer agencies, such as the American Red Cross (Gebbie, 2000).

Looking at public health from a nursing perspective, approximately 14.9% of all registered nurses (RNs) work in public/community health settings (Health Resources & Services Administration [HRSA], 2006). Public or community agencies are the second largest employer of RNs, after hospitals (employing 56% of nurses). However, with the struggle to find adequate access to health care, along with its increased costs, more nursing care is being performed in a public or community setting. Unfortunately, you may not know of these wonderful employment opportunities available in the public sector. This section will describe the role and opportunities for RNs at the local, state, and federal levels of government. The focus will be on governmental agencies, because these agencies employ the majority of PHNs.

## EDUCATION

The American Nurses Association (ANA) (2007a) recommends that an entry-level PHN should have a bachelor's degree in nursing. This is important because baccalaureate programs provide additional training in public health and leadership. Some states, such as California, require nurses to take additional classes and obtain certification beyond a bachelor's degree if the BSN program does not offer specific content (e.g., child abuse, public health didactic and practicum). Public health nurses working with specific populations, or in administration, should hold a master's degree. A PHN with a master's degree in community/public health nursing may take a national certification examination offered by the American Nurses Credentialing Center (ANCC) (2008). Many master's programs offer dual nursing and public health degrees, but not all. The emphasis on national certification is due to an ever-increasing need to keep the population protected from health threats, such as bioterrorism (especially after September 11, 2001), emerging diseases (e.g., pandemic flu), or natural disasters (e.g., hurricane Katrina).

## KEY FUNCTIONS OF THE PHN IN THE PUBLIC SETTING

Public health nursing practice consists of many areas of expertise; it

- ◆ Focuses on the health of populations
- ◆ Reflects the needs and priorities of the community
- ◆ Requires caring relationships with individuals, families, communities, and systems
- ◆ Is grounded in cultural sensitivity, compassion, social justice, and a belief in the worth of all people (e.g., vulnerable populations)
- ◆ Encompasses all aspects of health (e.g., physical, emotional, mental, social, spiritual, and environmental)
- ◆ Uses strategies to promote health that are motivated by epidemiologic evidence
- ◆ Involves individual, as well as collaborative, strategies to achieve results

(Minnesota Department of Health, 2007)

In brief, the role of the PHN is to focus on the health of the public. Public health nurses combine their nursing and clinical knowledge of disease and the human response to it, along with public health skills, to accomplish their goals (Quad Council, 2007; ANA, 2007a). They apply the nursing process, not only with individuals but also with populations. Public health nurses are the critical link between data tracking (e.g., epidemiology) and clinical understanding of a disease or condition (Missouri Department of Health & Social Services [DHSS], 2006). Public health nurses use the data to prioritize their interventions to stop the spread of diseases, such as measles, and also to intercede with other concerns (e.g., childhood obesity). For example, PHNs may develop a campaign for children to wear bike helmets after an increase of fatal head injuries is noted in their area. A key emphasis of the PHN is prevention, and a key focus is educating and empowering the community. Several other differences exist between PHNs and nursing in general (see Table 30.1 for a comparison).

**TABLE 30.1 Comparing Public Health and General Nursing**

Public Health Nursing	General Nursing
Population-based	Individual-based
Grounded in social justice	Grounded in a relationship of caring
Focuses on the greater good	Focuses on individual good (patient)
Health promotion & disease prevention	Restoration of health & function
Utilize & organize community resources	Manage resources at hand
Seek out clients in need	Take care of clients who come to them
Commitment to the community as a whole	Commitment to individual patient

Adapted from *Cornerstones of Public Health Nursing*, Minnesota Department of Health, 2007.

The population that PHNs focus on can be a geographic community (e.g., a state or municipality) or a focus group (e.g., adolescents or the elderly) spanning all socioeconomic levels. To accomplish this, PHNs often work with individuals or families at highest risk, and their motive is to improve, protect, and promote the health of the entire population. One of the goals that characterize PHNs, and differentiate their goals from those of other specialty disciplines, is achieving the greatest good for the majority of people (ANA, 2007a). (See Chapter 13 for an in-depth discussion of social justice.) This requires priority planning and a basic knowledge of the community.

For example, many issues exist in a community. In one community, a single child may have been hit by a car while riding his bike without a helmet. At the same time, in the same community, there may be 10 births to teen moms, 20 instances of drug overdose, and an outbreak of pertussis. The PHNs in that community must prioritize which issue to address first by deciding which issue impacts the most people and what interventions will help the population thrive (ANA, 2007a). Because each community is different, the priorities will vary among communities, once all factors are taken into account. Hence, *assessment* is a critical component of public health and a key tool for the nurses who work in the public sector (Institute of Medicine, 1988) (see Display 30.1).

Another way public health nursing differs from other areas in nursing is that PHNs must actively seek out and identify potential problems and situations (ANA, 2007a). Nurses who work in a hospital setting address the issues that come to them. If a nurse works in the intensive care unit (ICU) of a hospital, she will work with her assigned patient load. Public health nurses, on the other hand, are out in the community identifying the problems, not waiting for problems to come to them. For example, PHNs may participate

**DISPLAY 30.1****THREE CORE FUNCTIONS OF PUBLIC HEALTH (INSTITUTE OF MEDICINE, 1988)**

1. Assessment
2. Assurance
3. Policy Development

in visits to childcare centers to note any safety hazards, ensure that rules and regulations are being followed, and that children are properly immunized. These visits are part of the priority of *assurance* identified by the Institute of Medicine (1988), noted in Display 30.1.

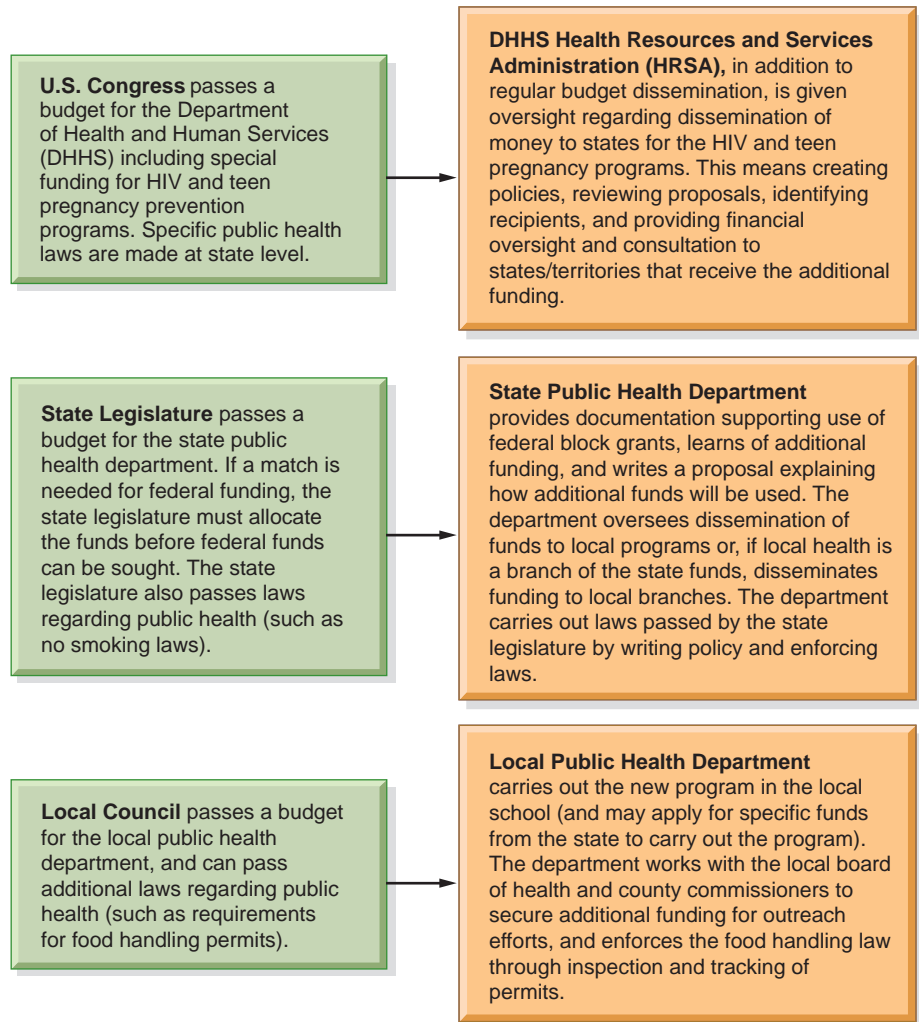

Public health nurses cannot perform all these activities alone. They need to collaborate with other partners and optimally use often limited resources. Public health nurses are in a unique situation because they work with their populations (i.e., clients) and with others to find the best solutions for a situation or problem.

For instance, PHNs may notice an increase in the number of measles cases in their community. They may then work with families to identify where and how the children were exposed to the disease, and with local health care providers to provide treatment and vaccinations for those at highest risk of exposure to and damage from measles. Public health nurses also work with school nurses and other school personnel to exclude from school attendance those children who are not adequately immunized against measles. This helps decrease the spread and potential harm due to measles. Public health nurses educate a variety of groups, such as parent–teacher associations (PTAs) and city or school officials, as to how measles spreads, what can be done to treat the disease, and the importance of herd immunity in protecting the public. Education thus empowers each group to be part of the solution. Finally, PHNs can work with public health officials to develop a policy for all new school entrants to receive a second booster of measles vaccine. *Policy development* is the third critical component of public health identified by the Institute of Medicine (1988) (see Display 30.1).

## PUBLIC HEALTH FUNDING AND GOVERNMENTAL STRUCTURES

Public health nurses can work at any and all levels of government. Hence, it is important to understand the organizational structure, communication, and funding streams between the federal, state, and local levels of government (see Chapter 6 for more on the structure of the public health system). At each level, all three branches of the government are involved in public health, although often the legislative and executive branches play the most important roles, and this discussion will focus on these areas.

The legislative branch (meaning Congress, state legislatures, or local councils) mandates laws or policies and decides how much of the funding in its jurisdiction will be appropriated to public health. Much of the work for public

**FIGURE 30.1** Examples of government organization in relation to public health.

health is carried out in the executive branch of government (Fig. 30.1). Because state and local organizations can be set up in a variety of ways, nurses must check with their local health department for specifics.

## Federal Agencies

The federal government oversees national policy and funding, provides expertise, and sets a national agenda (Novick, Morrow, & Mays, 2008). Several federal organizations are part of the executive branch that oversees the health of the nation. The main organization involved with public health is the Department of Health and Human Services (DHHS), which is overseen by the Secretary of Health and Human Services. The Secretary of DHHS is appointed by the President, and is a member of the President's cabinet. Within DHHS are many agencies, including eight that specifically impact public health (Turnock, 2006). Table 30.2 provides additional detail regarding these eight agencies. Other federal agencies that also impact public health include the Environmental Protection Agency (EPA), the Department of Homeland Security, the Department of Agriculture, the Department of Education and the Department of Veterans Affairs.

These various organizations receive funding and directives from the U.S. Congress (i.e., the legislative branch of the federal government) as part of the DHHS budget process. In 2006, the overall budget of DHHS was \$642 million (USDHHS, 2006). It is the prime responsibility of DHHS and other agencies to ensure that legislative mandates are followed, policies carried out, and funds appropriately disseminated. State health entities receive a large portion of funds as part of *block grant funding*. These funds are lumped together to pay for some general use that states have identified (see Chapter 6 for more detailed information). *Healthy People 2010* and state needs assessments help set priorities for state funding. For example, the maternal and child health (MCH) block grants received by states are then used for reproductive health, child health, and immunizations. States with local health departments also disseminate a portion of these funds to the local level. In addition, state and local tax dollars are used to supplement various programs. Thus, the political leanings of state and local officials can strongly influence local health initiatives.

## State Governments

The U.S. Constitution bestows states with the responsibility to safeguard the health of their citizens (Turnock,

**TABLE 30.2 Agencies Within Department of Health and Human Services**

Agency	Headquarters	Responsibility & Bureaus
Health Resources and Services Administration (HRSA)	Rockville, Maryland	Medically underserved—includes Medicare/Medicaid, HIV/AIDS, maternal and child, health professions, primary health care
Indian Health Services (IHS)	Rockville, Maryland	Provides health services for Native Americans (including Alaskan Natives)
Centers for Disease Control and Prevention (CDC)	Atlanta, Georgia	Health surveillance and prevention of disease and bioterrorism
National Institutes of Health (NIH)	Bethesda, Maryland	Medical research
Food and Drug Administration (FDA)	Rockville, Maryland	Ensures safety of food, medication, medical procedures, and equipment
Substance Abuse and Mental Health Services Administration (SAMHSA)	Rockville, Maryland	Oversees prevention, diagnosis, and treatment for mental health and substance abuse
Agency for Toxic Substances and Disease Registry (ATSDR)	Atlanta, Georgia	Protects public from environmental exposures
Agency for Health Care Research and Quality (AHRQ)	Rockville, Maryland	Includes research on health care quality and effectiveness

Source: <http://www.dhhs.gov>; Turnock, B.J. (2007). *Essentials of public health*. Sudbury, MA: Jones and Bartlett Publishers.

2007). Much of public health is overseen at a state level. However, the structure of where public health fits into the executive branch of state government varies. More than half of the states have an independent state-level public health agency (Beitsch, Brooks, Menachemi, & Grigg, 2006). Another third of the states are part of a “super agency” that may include human services and other state programs (Novick, Morrow, & Mays, 2008). The governor appoints a commissioner, or leading health official, to oversee public health and serve as a member of the governor’s cabinet. These cabinet members are usually medical doctors, appointed by the governor. In recent years, state directors have also included social workers (e.g., Michigan) and public health professionals (e.g., Arkansas). In 2007, Governor Phil Bredesen appointed Susan Cooper, RN, MSN, as the first nurse to serve as public health commissioner for the state of Tennessee. The first nurses appointed to director of state offices of public health were Barbara Sabol and Gloria Smith in Kansas and Michigan (Feldman, 2008).

The purpose of state agencies is to carry forth regulations and policies determined by the federal government. Examples of these programs are the Medicaid, Medicare, and State Children’s Health Insurance Programs (SCHIPs). Many of these programs may have specific federal requirements, but they also allow states the ability to personalize the programs to fit the state’s individual needs. An example of such a program is the MCH block grant, which provides funding and guidelines for the states. However states determine which programs (e.g., reproductive health or children’s health) will be funded and how they will be implemented.

Another example of federal leadership is the *Healthy People 2010* document that provides goals for a variety of health outcomes. States can use these outcomes, or develop additional performance measures, according to state charac-

teristics and needs. In addition, the state agency is influenced by the state legislative body, which oversees the state budget and can pass laws specific to the state. Each state is different due to varying needs, cultures, and political environments. Examples of public health laws at a state level include immunization requirements for school entrance, seat belt safety laws, and regulations regarding parental rights concerning birth control and abortion services for teens.

## Local Public Health

**Local health departments (LHDs)** carry out state laws and policies (Turnock, 2007). They provide the most direct, immediate care of the population (Novick, Morrow, & Mays, 2008). For example, they may provide immunization clinics, track and treat cases of tuberculosis (TB) and other communicable diseases, and provide education on a variety of subjects (e.g., human immunodeficiency virus [HIV]/acquired immune deficiency syndrome [AIDS] prevention, smoking cessation). They often carry out programs with funding from federal and state agencies. For instance, federal funding to address asthma may be obtained through the state agency, and local agencies may organize an educational program on asthma triggers in a local business where many community members work. State and local agencies do not work alone in such endeavors, however. Collaboration is very important in addressing the public health needs of a community. Public health agencies work with private organizations, hospitals, nonprofit groups, universities, and government agencies that oversee food and housing to meet citizens’ needs.

Local health departments work with state health departments, some independently and some as dependent branches of the state agency. The size and services offered

by a local agency also differ depending on state laws, structure, and wealth (Turnock, 2007). Half of LHDs in the United States have fewer than 20 employees (NACCHO, 2007). Thus, the number of LHDs per state can vary dramatically. For example, California has only 62 LHDs, whereas Massachusetts has the most with 324 (NACCHO, 2007). Nearly all LHDs (95%) employ nurses, who make up 24% of the total public health workforce at the local level (NACCHO, 2007).

## NURSING ROLES IN LOCAL, STATE, AND FEDERAL PUBLIC HEALTH POSITIONS

Nurses can work in a variety of capacities at the various levels of government, which may cover most aspects of public health (Novick, Morrow, & May, 2008). Generally speaking, nurses who work at the local level of public health tend to provide direct service care. For example, they often administer immunizations, monitor patients with TB, provide education to school groups, provide cancer screenings, and track communicable disease rates. Local PHNs are the eyes and ears of their communities. Many PHNs working at the local level, especially in rural or small public health departments, may have a variety of responsibilities. For instance, a PHN may be a full-time employee whose time could be split into 50% cancer screening, 25% with the Women, Infant, and Children (WIC) program, and 25% on Medicaid outreach (see Display 30.2 for an example of a PHN's day). Public health nurses also serve in administrative roles within agencies, as well, where they may oversee an entire bureau or program, for example, or serve as supervisors for a group of PHNs.

Within each of the governmental agencies, programs may be arranged according to a particular subject area. For example, a PHN may work in the cardiovascular disease program, overseeing cholesterol screenings and promoting physical health and nutrition. A PHN could also work in the immunization program, promoting and tracking the immunization requirements of school-age children. The nurse may also be in charge of day care licensure requirements, traveling throughout the state and conducting inspections or writing policies. Or, the nurse could oversee a program to decrease sudden infant death syndrome (SIDS) in the state and track SIDS-related deaths. Thus, the variety of locations and programs are limitless for PHNs. The following is a brief overview of some of the main roles of nurses working at state and local health departments. Specific options and means by which PHNs serve as advocates and change agents to protect and promote the health of all are discussed, using the nursing process as an outline. Figure 30.2 provides a practical model of how PHNs use the nursing model and public health principles in their everyday functions.

### Assess

An assessment of the situation is key to any nursing care. Public health nurses assess the situation in a variety of ways. They observe a great deal when they are in the community and when they conduct home visits. They also assess data to identify trends. Often nurses work with other public health personnel when assessing and tracking data, although nurses

### DISPLAY 30.2

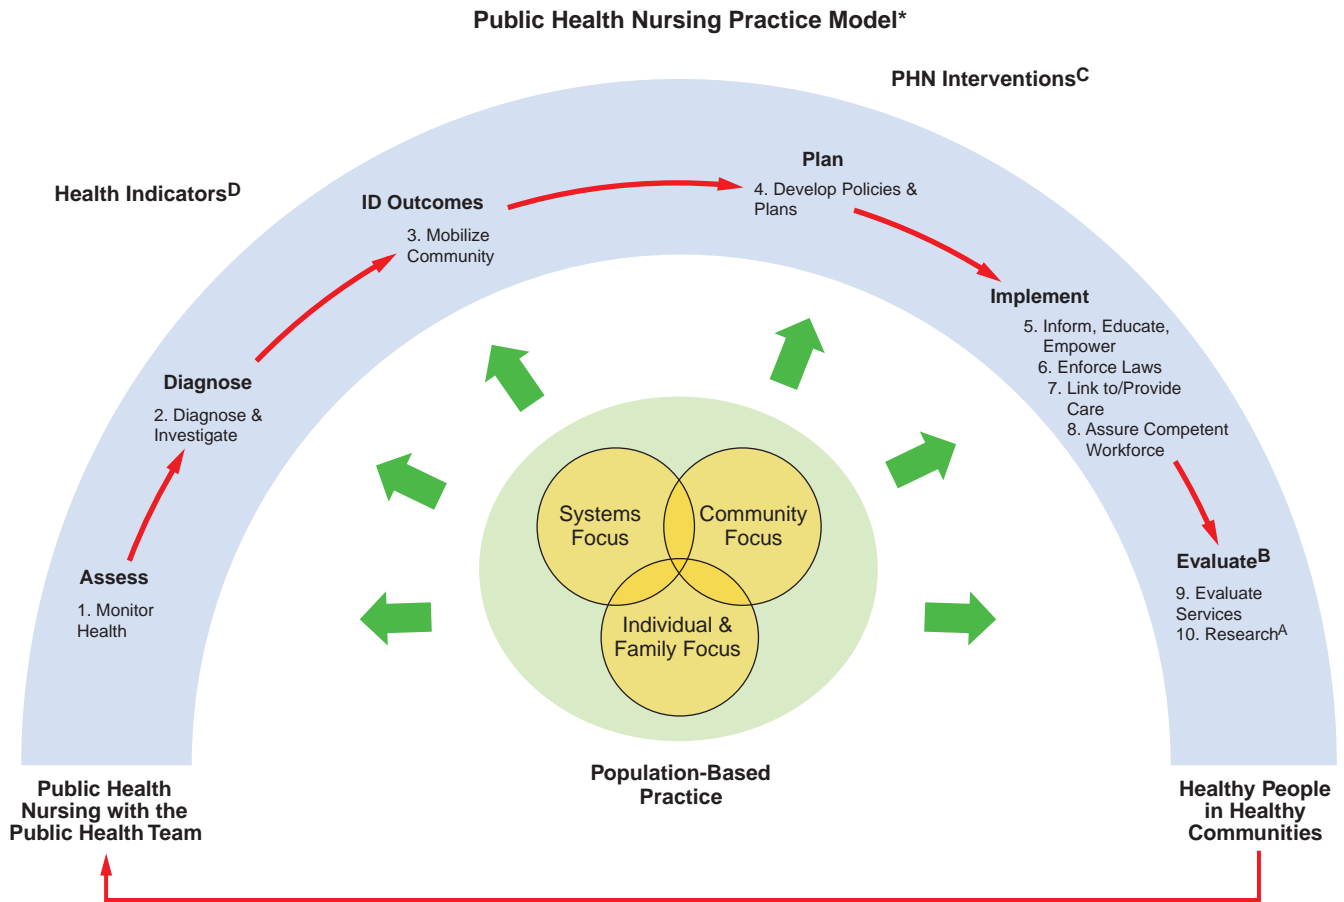

### A TYPICAL DAY IN THE LIFE OF A PHN

- 8:00 a.m.** Staff reproductive health clinic. Provide counseling regarding family planning services, as well as breast and other cancer screenings.
- 10:30 a.m.** Make a home visit to a mother and baby who is not thriving. Conduct an examination of the baby and assess the living situation. Assist the mother regarding breastfeeding, nutrition, newborn care, and parenting.
- 12:30 p.m.** Attend a lunch meeting of a newly formed coalition that is concerned about the increased rate of teen pregnancy in the city. Provide statistics from community, as well as firsthand knowledge of teens participating in the Women, Infants, and Children (WIC) program and the home visiting program. Offer expertise regarding how to approach the problem.
- 2:00 p.m.** Investigate the case of a kindergartner who has TB. With the help of the school nurse, check immunization records of other students and staff. Contact the family to learn who else is exposed and at risk. Provide proper testing and education regarding the signs and symptoms of TB, the need for regular testing, and following the treatment regimen.
- 3:30 p.m.** Staff cancer screening clinic performing Pap smears and providing counseling to women regarding risks of breast and cervical cancer. Follow-up with patients from last week's clinic whose results were questionable.
- 5:00 p.m.** Finish paperwork and go home knowing the community's health was positively impacted today.

Adapted from *Public Health Nursing: Promoting and Protecting Health in Colorado*. Retrieved Sept 21, 2007 from <http://www.cdph.state.co.us/oll/phn/PHNBrochure.pdf>.

may serve as specialists in epidemiology. For example, PHNs can use morbidity and mortality statistics to determine the leading causes of death nationally and locally. They can assess communicable disease rates to identify an outbreak before it becomes too widespread. They track how many people in the community are in compliance with immunizations to keep the herd immunity high and decrease the chance of outbreaks.

Public health nurses use census data to determine population growth. As an example, the census indicates that the number of individuals 65 years or older will double by 2030 (Bergman, 2006). Estimates indicate that in 2030, approximately 72 million, or one in five persons, will be over 65 years of age. This is important in planning for future activities and resources. Public health nurses also use prevalence data to determine which ethnic groups are at higher risk than others. For example, the PHNs at the Utah County Health department noticed an increase in STDs. Upon further investigation, they learned that the greatest increases were within the Hispanic population. Through this assessment they were able to successfully target interventions for this population (Page, 2006).

**FIGURE 30.2** Public health nursing model from Los Angeles Country.

Environmental risks are important to the public’s health and are often assessed by nurses. For example, a PHN conducting blood tests noticed that students living in a mining community had elevated blood lead levels. This assessment information forms the basis for the nurse’s intervention. Each nurse must assess his or her own community, because each has specific characteristics and needs. A community positioned next to a factory that emits fumes will have different issues than a rural community 90 miles away from any industry. At the same time, an outbreak of *Escherichia coli* in one town may identify a risk to the PHN in the neighboring town.

**Diagnose**

Assessment is key to diagnosing a situation or problem. For a PHN, diagnosis also includes identifying priorities for the many concurrent issues. Nurses who work in public settings

may perform skin tests or simple blood work in public clinics to determine TB exposure, or risk of diabetes, or other conditions (Southern Nevada Health District, 2005) (see From the Case Files I). Other nurses utilize microscopes to identify cases of vaginitis and cervicitis (George, 2007). This could all occur on the same day.

As nurses diagnose individual needs, they apply this information and watch for increased or decreased rates (e.g., of disease or injury) among the population. For instance, a nurse working in a public health clinic may notice an increase in the number of people diagnosed with diabetes. The nurse further assesses the situation to determine if it is a population need, and also the degree of the problem. Another PHN may assist with newborn genetic testing. Nurses are in the perfect position to identify issues and trends early on. As more is known regarding genetic trends, the PHN can use this information to advocate policies and laws that will impact a particular population.

## From the Case Files I

### Tuberculosis Exposure

As a PHN you are alerted to a person who has an active TB case. He came into the health department for a chest x-ray after he failed his tuberculin skin test. The person has recently arrived by plane from another state. He stayed for a few weeks with family members in a small house, but now lives with friends in a small apartment. When talking to the patient, you note that he coughs often and does not cover his mouth.

- As a PHN what steps would you take to determine exposure?
- How will you determine who was exposed and will need to be tested?
- What questions can you ask to help determine when and how the patient was exposed to TB?
- What type of education will you provide to him?
- How can you ensure that the patient is compliant with medication treatment?
- Imagine that you are the school nurse of the patient's 8-year-old daughter who has also tested positive. What steps would you take?
- What would you do differently if you were a corrections nurse and the patient was an inmate?

Constant assessment and diagnosis are tools by which PHNs identify critical situations and prioritize issues that must be addressed first. Several documents have helped PHNs prioritize issues. *Healthy People 2010* identifies many of the nation's top priorities (USDHHS, 2000) (see Display 30.3). Public health performance standards also assist nurses in prioritizing needs (CDC, 2001; Quad Council, 2007). The Institute of Medicine (2003) has also identified a need for a greater focus on informatics and genomics.

Improved medical technology has supplied immunizations that have decreased the rates of many communicable diseases. This led to the emergence of new issues and priorities for PHNs, specifically, injury prevention and the management of chronic diseases (Beitsch, Brooks, Menachemi, & Grigg, 2006). World events have also placed additional emphasis on public health roles, including the global spread of TB, bioterrorism, pandemic influenza, and natural disasters (Beitsch, et al., 2006). Because of their nursing and epidemiologic skill, PHNs serve as critical members of emergency response teams, specifically regarding bioterrorism surveillance and preparedness (Atkins, Williams, Silenas, & Edwards, 2005). The nursing and epidemiologic skills they use when tracking outbreaks of communicable diseases, such as TB, are easily transferable to the communicable agents of bioterrorism (e.g., smallpox, anthrax).

### Plan and Implement

Once PHNs have diagnosed and prioritized the needs of their community, they develop and carryout plans to address those needs. Development of care plans is an important function for nurses (Georgia, 2007). Many interventions require collaborating and working with other agencies. Education is also a key to many public health nursing interventions. However, education alone will not change behavior; thus, it is important to address the issue from many different angles, as well as at different levels. Public health nurses cannot solve all issues, but they can serve as advocates to

influence those who can make the changes. The interventions are endless, but here are a few examples:

- ◆ Nurses conduct home visits to mothers at risk. They conduct family assessments to determine the level of psychological issues and education needed by the family regarding specific needs, such as responses to medication. They also help mothers receive needed psychological counseling by linking them to a local mental health agency.
- ◆ A nurse working in risk management develops and teaches an education program about workplace safety and ergonomics. She develops policies regarding shift hours and heavy lifting.
- ◆ A nurse serves as an advocate for a program that will assist children with special health care needs attend a clinic closer to home.
- ◆ A nurse develops a campaign for television, newspaper, and radio regarding the need to receive a flu shot. The nurse also includes incentives that target the elderly community who are at additional risk for developing complications from this illness.
- ◆ The nurse organizes a health clinic at local shelters providing foot care and screenings for blood pressure, diabetes, TB, and cholesterol, as appropriate.
- ◆ The nurse works with schools to educate teens regarding birth control and the impact of teen pregnancy. She includes counseling regarding STDs. She works with the community to ensure that a variety of teen-focused activities are available for this population.
- ◆ The nurse conducts home visits to new mothers who need assistance with breast-feeding and newborn care. The nurse also contacts the housing authority to report hazardous conditions in the housing project she has visited.
- ◆ The nurse helps identify resources for families without insurance to ensure that well-child and adult screenings are performed regularly in order to reduce health care costs associated with illness.

DISPLAY 30.3

**HEALTHY PEOPLE 2010—PUBLIC HEALTH PRIORITIES**

**Healthy People 2010: Public Health**

*Healthy People 2010* provides the direction and goals for all public health nurse (PHNs). *Healthy People 2010* is used to guide prioritizing activities for PHNs. Specifically, PHNs focus on the ten leading indicators, which include:

- Physical activity
- Overweight and obesity
- Tobacco use
- Substance abuse
- Responsible sexual behavior
- Mental health
- Injury and violence
- Environmental quality
- Immunization
- Access to health care

**Healthy People 2010: School Nursing**

One objective directly relates directly to school nurse staffing:

7-4 Increase the proportion of the nation’s elementary, middle, junior high, and senior high schools that have a nurse-to-student ratio of at least 1:750.

Other objectives that school nurses can use to help prioritize activities include:

- 6-9 Increase the proportion of children and youth with disabilities who spend at least 80% of their time in regular education programs.
- 8-20 (Developmental) Increase the proportion of the nation’s primary and secondary schools that have official school policies ensuring the safety of students and staff from environmental hazards, such as chemicals in special classrooms, poor indoor air quality, asbestos, and exposure to pesticides.
- 14-23 Maintain vaccination coverage levels for children in licensed day care facilities and children in kindergarten through the first grade.
- 15-31 (Developmental) Increase the proportion of public and private schools that require use of appropriate head, face, eye, and mouth protection for students participating in school-sponsored physical activities.

- 19-15 (Developmental) Increase the proportion of children and adolescents aged 6 to 19 years whose intake of meals and snacks at schools contributes to good overall dietary quality.
- 22-8 Increase the proportion of the nation’s public and private schools that require daily physical education for all students.
- 22-12 (Developmental) Increase the proportion of the nation’s public and private schools that provide access to their physical activity spaces and facilities for all persons outside of normal school hours (that is, before and after the school day, on weekends, and during summer and other vacations).
- 24-5 (Developmental) Reduce the number of school or work days missed by persons with asthma due to asthma-related illness.
- 26-11 Reduce the proportion of persons engaging in binge drinking of alcoholic beverages.

**Healthy People 2010: Corrections Nursing**

- 13-8 Increase the proportion of substance abuse treatment facilities that offer HIV/AIDS education, counseling, and support.
- 13-9 (Developmental) Increase the number of state prison systems that provide comprehensive HIV/AIDS, sexually transmitted diseases, and tuberculosis (TB) education.
- 13-10 (Developmental) Increase the proportion of inmates in state prison systems who receive voluntary HIV counseling and testing during incarceration.
- 18-8 (Developmental) Increase the proportion of juvenile justice facilities that screen new admissions for mental health problems.
- 25-14 (Developmental) Increase the proportion of youth detention facilities and adult city or county jails that screen for common bacterial sexually transmitted diseases (STDs) within 24 hours of admission and treat STDs (when necessary) before persons are released.
- 26-19 (Developmental) Increase the proportion of inmates receiving substance abuse treatment in correctional institutions.

- ◆ The nurse organizes an immunization clinic at the local school after an outbreak of measles. The nurse also conducts classes at the school regarding communicable disease prevention and tobacco cessation.
- ◆ The nurse organizes a bicycle fair to educate the community regarding the need for bicycle helmets, in hopes of decreasing head injuries. She also works to develop public policy related to car seat usage and collaborates with local businesses in providing vouchers for discounts on car seats for low-income parents.
- ◆ The nurse, who is a paid lobbyist, works to change laws regarding smoking.

- ◆ A nurse, who is an elected member of the state legislature, sponsors a bill to increase funding for school nurses.
- ◆ After a hepatitis outbreak at a local business, the nurse conducts an assessment of the business and provides education classes and suggests policy changes to help guard against future outbreaks.

These interventions are based on evidence-based practice (EBP) (see Chapter 4). Below are some examples of EBP in public health nursing:

- ◆ Media campaigns targeting specific populations have been successfully used to educate and

## EVIDENCE-BASED PRACTICE

### Public Health Nursing

This study investigated the various health sources used by Vietnamese men in the Seattle area (Woodall, Taylor, Yasui, Ngo-Metzger, Burke, Thai, & Jackson, 2006). The sample was determined using the 2001 metropolitan telephone book and 23 last names that investigators at the University of California determined to be shared by 95% of Vietnamese families. From this population, 900 households were randomly selected to participate (509 chose to participate, 79% response rate). Before households were contacted, advertisements about the upcoming survey were publicized on posters in the community Vietnamese grocery stores. The survey was conducted in person by male bilingual and bicultural survey workers (participants had the option to participate in English or Vietnamese). Participants were asked where they received information regarding health and health care. The most common mediums used included Vietnamese newspapers/magazines (73%); English television (67%); Vietnamese television (64%); family members (63%); doctors/nurses and friends (58%); and Vietnamese radio (51%).

### Nursing Implications

Results of past studies indicate Blacks, Hispanics, and Whites rely more on print media and doctors, whereas Korean Americans preferred newspapers. Family and radio were used much less. Thus, when PHNs and others want to target the Vietnamese population, they should include the message in Vietnamese newspapers/magazine. In addition, potentially effective messages can ask “Have you talked to your friends about. . .?” These would be effective because family and friends are often the source of health information for Vietnamese American men.

It is critical for a PHN to understand her population and the best mediums to reach it, as each population or community may be different. Cultural sensitivity is key to successful community outreach. Constant assessment of a community helps PHNs stay up to date with issues and influential media.

Woodall, E.D., Taylor, V.M., Yasui, Y., Ngo-Metzger, Q., Burke, N., Thai, H., & Jackson, J. C. (2006). Sources of health information among Vietnamese American men. *Journal of Immigrant and Minority Health, 8*(3), 263–271.

promote healthy behavior (Beaudoin, Fernandez, Wall, & Farley, 2007).

- ◆ Health screenings have been shown to be a successful outreach effort for the homeless population (Krisberg, 2004).
- ◆ Soloman and Card (2004) have identified several school-based programs that successfully impact sexual activity and teen pregnancy.

- ◆ Bike helmets have been proven to be effective in decreasing head injuries (Berg & Westerling, 2007).
- ◆ Hofler (2006) has described how nurses can effectively impact health policy.
- ◆ The American School Health Association has developed a toolkit to help nurses organize successful immunization programs (Boyer-Chu & Wooley, 2006).

## Evaluate

The world in which PHNs work is always changing. It is crucial to constantly evaluate programs and interventions to determine if goals are reached. For example, a nurse may visit childcare facilities or senior centers to ensure that laws regarding licensure are being followed. Evaluating is often equated with assessing. Public health nurses also can evaluate data to determine whether various rates (e.g., infant mortality, or other health indicators) increase or decrease as a result of their interventions.

Another way that PHNs can determine if their interventions are effective is by becoming involved in research. Numerous researchers have studied the impact that PHNs have on improving population health and societal outcomes (Quad Council, 2007). Corrarino and Little (2006) found that case management and education provided by nurses to families decreased the number of hospital visits for children with asthma. Public health nurses who conducted home visits to these high-risk mothers have also improved the lives of mothers and their babies. Children in the intervention group were found to have increased achievement and intellectual functioning, along with decreased aggression and behavior problems (Olds, et al., 2004; Izzo, et al., 2005).

## PUBLIC HEALTH NURSING CAREERS

Nurses who work at the state and federal levels tend to have consultant, or oversight-type, roles, and some nurses head programs that are specifically funded at the state and/or federal levels (e.g., HIV/AIDS, immunization programs). Some state-employed nurses may work in clinics for children with special health care needs. Some federally employed nurses may provide direct care in Indian Health Service clinics. Public health nurses at all levels may also be called upon to help during a disaster or communicable disease outbreak.

Among distinct opportunities at the federal level are those associated with the Department of Veteran’s Affairs and DHHS. Agencies headed by DHHS include the National Institutes of Health (NIH), the Indian Health Service, the Health Resources and Services Administration Services (HRSA), the U.S. Food and Drug Administration (FDA), the Substance Abuse and Mental Health Services Administration (SAMSHA), and the Centers for Disease Control and Prevention (CDC).

Public health nurses in these agencies oversee and carryout the initiatives of *Healthy People 2010*, along with other program initiatives. Many of their functions are similar to those mentioned earlier. For example, they may oversee and develop programs, such as national surveys, that collect data used to determine priorities. Examples of these

## PERSPECTIVES VOICES FROM THE COMMUNITY

As an instructor of undergraduate nursing students, I want students to realize *public health nursing* is a wonderful and rewarding employment opportunity. Many students often enter the nursing program not knowing much about public health nursing. They may only get minimal exposure to public health and thus not understand who or what is involved in public health nursing. In so doing, they miss out on a wonderful opportunity to work with a variety of people. It may be helping new moms, or working with children and adolescents or the elderly. They may help give vaccinations or prepare for community disasters. They might teach about breastfeeding or conduct cancer screening clinics. They are out with the people ensuring the public's health.

Public health nurses are able to use the science of nursing because they need to understand the pathophysiology, anatomy, human development, and disease transmission. They may not do as many hands-on procedures as hospital nurses, but they still must keep up to date in knowledge, as they are often teaching. In addition, they must be quick and receptive thinkers who can work independently and creatively. Public health nurses also are the essence of the “art” of nursing. They must understand and relate to people, and understand social systems and human behavior. They are the voice for the most vulnerable and the champion of all.

Although PHNs may not see an immediate reward for their actions, as a nurse who works in the hospital does, PHNs make a long and lasting impact not just to an individual but to an entire society. They also have the opportunity to really be a patient advocate. They do this by helping well people stay well and by preventing illness. They also help those who are sick obtain medical access. Public health nurses can also be involved in public policy change that can help an entire community. Public health nursing encompasses the entire art and science of nursing.

Erin M.

surveys include the Behavioral Risk Factor Survey (BRFS), the Youth Risk Behavior Survey (YRBS), and the National Health Interview Survey (NHIS). Federally employed PHNs may also review state funding proposals for projects and ensure that guidelines are met. They are a resource for state and local health departments, and often are called upon as consultants. Nurses working at the NIH may assist in conducting research. For example, a nurse may study the effects of applying chemotherapy directly to a tumor, instead of through intravenous or central lines (U.S. Public Health Service Commissioned Corps, 2007). In addition to these opportunities, PHNs may work as clinicians for the Indian Health Services.

## Indian Health Services

**Indian Health Services (IHS)** is responsible for providing healthcare to Native Americans (American Indians and Alaska Natives) (Turnock, 2007). The IHS provides services for approximately 1.5 million American Indians in 35 states (Turnock, 2007). Employment with the IHS allows a nurse to live in a variety of rural and urban settings and to work specifically with Native Americans, a vulnerable population. These nurses work and oversee health care services in clinics run by IHS. The clinics are usually focused on primary care and focus on general practice. They may work with patients who have diabetes, providing nutritional counseling and education; they may also provide immunizations, perform well-child examinations, or conduct HIV/AIDS screenings. Unique aspects of these jobs are that most clinics are located in remote areas of the country and face unique challenges. Some houses on Native American reservations may not have a telephone or consistent electricity, and these clients may have numerous special needs. This type of nursing is very challenging but can also be extremely rewarding.

## Uniformed Public Health Nursing

Nurses can serve in each of the seven uniformed services of the U.S. Department of Defense (Army, Navy, Marine, Air Force); U.S. Department of Homeland Security (Coast Guard); U.S. Department of Commerce (National Oceanic and Atmospheric Administration [NOAA] Commissioned Corps); and the U. S. Public Health Services Commissioned Corps (USPHSCC) (NOAA, 2007; USPHSCC, 2007).

The **U.S. Public Health Service Commissioned Corps (USPHSCC)** is a group of 6,000 specially trained public health members who serve their country with the goal of protecting and promoting the health of the nation. The Corps was established in 1798, as part of an act to treat sick seaman in Marine hospitals. Over the years, the Corps expanded to oversee the health of immigrants entering the country and to assist in preventing/treating communicable disease outbreaks. The U.S. Surgeon General oversees the Commissioned Corps, and many of its officers are stationed at other federal agencies, such as the CDC and the FDA (USPHSCC, 2007).

Nurses are an integral part of the Corps. They provide nursing care and health care leadership around the world. Their focus is on improving health for the entire community by providing care, conducting research, or reviewing new medications. These nurses work in a variety of federal agencies, many of them listed earlier. On a daily basis, they may perform tasks similar to civilian nurses. However, as commissioned officers they can also be deployed to protect the nation's health. For example, USPHSCC nurses were some of the first on the scene to assist in the aftermath of hurricane Katrina (see Display 30.4). They may also be deployed in the case of a widespread communicable disease outbreak. Their activities can be international as well, in providing expertise and support on global issues such as the Asian tsunami or the worldwide spread of HIV/AIDS.

As commissioned officers, USPHSCC nurses are compensated in addition to their regular salaries and receive veteran's benefits, health insurance, access to military base lodging and recreational facilities, and other benefits. Officers are supported with tuition and other training opportunities to fur-

## DISPLAY 30.4

## UNITED STATES PUBLIC HEALTH SERVICE COMMISSIONED CORPS AND HURRICANE KATRINA

Here is an example from an account in the *Journal of Professional Nursing* of how nurses from the United States Public Health Service Commissioned Corps (USPHSCC) are called upon to help during a national crisis. The authors of the article have “regular” positions with the federal government. At the time the article was written, two authors (Debisette and Brown) worked for the Bureau of Health Professions, part of the Health Resources and Services Administration (HRSA) in the U.S. Department of Health and Human Services. The third author (Chamberlain) worked as a nurse medical evaluations officer in the Office of Commissioned Corps Support Services.

As the threat of hurricane Katrina was imminent the USPHSCC nurses were deployed to Louisiana; they arrived the day before the storm hit land, and were some of the first to respond. In fact, nearly half of the 37 member team ( $n = 15$ ) were nurses. The team was deployed to Baton Rouge to assist local personnel in setting up an 800-bed field hospital (including an intensive care unit) at the Pete Maravich Assembly Center at Louisiana State University. The USPHSCC nurses helped provide nursing care that included triage, treatment, stabilization, and transport to permanent facilities. They addressed the psychological, as well as physiologic, needs of the people as evacuees.

Having lost everything, the evacuees streamed into the center. Many of these evacuees, in addition to the trauma and shock associated with their losses, had special medical needs. Some needed dialysis, some were physically disabled, and some had diabetes.

USPHSCC nurses also ensured the safety and security of the people. For example, it was a USPHSCC nurse who realized that the electrical outage would create a failure of the water pump system, and alerted the command-

ing officer. Knowing they would soon lose water, the nurses then filled bathtubs with water that was later needed for flushing toilets. The USPHSCC nurses covered gaps in care and worked long hours to ensure that the needs of everyone were met.

After working 3 weeks in the Baton Rouge area, the USPHSCC nurses traveled for 3 days with the American Red Cross and the Louisiana Department of Health and Hospitals to other parts of Louisiana to assess needs. They visited 270 shelters. They worked in teams of four (an environmental officer, a health provider trained in epidemiology, a local American Red Cross representative, and an RN). Each member had specific responsibilities. The nurses assessed the ability of the shelters to address the acute and chronic health care needs of the residents, either within the shelter or by accessing local health resources. They accomplished this assignment by interviewing various shelter staff using a standardized survey tool, as well as by direct observation.

The authors concluded from their experience with Katrina:

Nurses are often caregivers, nurturers, and advocates. In addition, they are frequently called upon to take on the roles of educators, counselors, and as evidenced here, researchers. As representatives of the USPHS, they stood with strength and courage in the face of devastation. Most of all, they [were] leaders of compassion who appreciate[d] the love, sense of community, and love for their country that emanated from the people of Louisiana in the aftermath of Hurricane Katrina. (p. 272)

From Debisette, A.T., Brown, C.R., & Chamberlain, N. (2006). A nursing perspective from United States Public Health Service Nurses. *Journal of Professional Nursing*, 22(5), 270–272.

ther their education and advance their careers. Student tuition reimbursement and loan payment options are also available.

To qualify as a nurse in the Commissioned Corps, one must be a U.S. citizen, less than 44 years old, able to pass a physical examination, possess a bachelor’s or higher degree from an accredited nursing program, pass the National Council Licensure Examination (NCLEX), and hold a valid nursing license from one of the 50 states, the District of Columbia, Puerto Rico, Guam, or the U.S. Virgin Islands. For more information on the USPHSCC, see the Internet Resources at the end of this chapter.

## SCHOOL NURSING

School nurses save lives and assist in helping children so that they are able to learn and reach their greatest potential.

School nursing is a specialized practice of professional nursing that advances the well-being, academic success, and life-long achievement of students. To that end, school

nurses facilitate positive student responses to normal development; promote health and safety; intervene with actual and potential health problems; provide case management services; and actively collaborate with others to build student and family capacity for adaptation, self-management, self-advocacy, and learning. (National Association of School Nurses [NASN], 2007a)

A **school nurse** works primarily with the students who attend the nurse’s assigned schools, as well as with the families of those schoolchildren, members of the school staff and administration, health care providers, and other helping professionals within the school and community. In 2005, approximately 14.8 million school-age children attended over 95,000 public schools (U.S. Department of Education, 2006). These children are the parents, workers, leaders, and decision-makers of tomorrow, and their future success depends in good measure on achieving their educational goals today. Their school success is intertwined, to some degree, with the state of their health (Mitchell, 2000).

Think back to your own elementary and secondary schooling. Did you have access to a school nurse? If so, how did that person influence your health and the health of your peers? If you did not have a school nurse, how do you think a school nurse might have improved your school environment or educational experience? The school nurse is a key provider of a variety of services.

## HISTORY OF SCHOOL NURSING

Beginning in the mid-1800s and continuing through the early years of the 20th century, mandatory education was instituted in the United States. The early years included health services often conducted by “medical inspectors,” usually physicians. In New York City, where communicable disease was rampant, inspectors sent notes home with children with the message “you are sick—go home” and citing the reason for their exclusion from school (Vessey & McGowan, 2006, p. 255). The reasons for exclusion were largely the contagious illnesses commonly found among the tenements and crowded slums of the growing city. However, parents often did not receive these notes, or couldn’t read them, and because families lacked resources, most children were left untreated and simply remained out of school as truants. No efforts were made by medical inspectors to follow up on excluded children. Because these excluded children played with healthy children after school hours, the levels of contagious illness actually worsened (Vessey & McGowan, 2006; Wolfe & Selekman, 2002). The absentee children promoted the spread of various communicable diseases (Woodfill & Beyrer, 1991). In 1902, the New York Board of Education contracted with Lillian Wald’s Henry Street Settlement to provide a PHN to work with the families and schools to facilitate the return of healthy children to school. The nurse was Lina Rogers (she later married and added the name Struthers). She made home visits to follow-up on excluded children and was assisted by other Henry Street nurses in providing care, educating families about diseases and the need for hygiene, and working with other organizations to provide needed food, shoes, and clothing (Vessey & McGowan, 2006). In the first month of the school nurse experiment, 98% of children previously excluded from school for medical reasons were treated and readmitted (Woodfill & Beyrer, 1991). The board hired 12 more school nurses, and over the next few years, other cities and states began hiring nurses to work in the schools. School nurses have historically advocated for hot lunches, breakfast programs, and the need for increased health education in schools and for families (Abrams, 2005).

School nurses continue as a specialty branch of professional nursing that serves the school-age population. More than 50,000 school nurses are estimated to be working in schools today (Zaslow, 2006). However, according to the 2006 School Health Policies and Programs Study (SHPPS), many school nurses oversee multiple schools, and less than half of the schools had the nationally recommended ratio of one school nurse for every 750 students (Brener, Wheeler, Wolfe, Vernon-Smiley, & Caldart-Olson, 2007). Most schools (86.3%) had at least a part-time nurse, although some schools still report not having any school nursing services.

School nurses deliver services to students from birth through age 21 years. They also work with students’ families and the school community in regular and special education schools, as well as other educational settings (e.g., preschools, court, and other community schools). Studies show that having a school nurse present increases health and social services and improves absentee rates (Guttu, Engelke, & Swanson, 2004; Telljohann, Price, Dake, & Durgin, 2004; Telljohann, Dake, & Price, 2004).

The role of the school nurse has expanded over the years, along with the increase in chronic conditions and challenges in accessing health care (Lear, 2007; Brousard, 2004). Federal law requires school systems to provide care for children with disabilities. The Individuals with Disabilities Education Act (IDEA), the Rehabilitation Act of 1973, and Title II of the Americans with Disabilities Act all mandate equal educational opportunities for all students, including children with complex medical conditions.

Legislative mandates and technology that has allowed low-birth-weight babies to survive, have led to a steady increase in the number of children with special health care needs attending school (U.S. Department of Education, 2006; Lakdawalla, Bhattacharya, & Goldman, 2004). It is now commonplace for children to attend school accompanied by feeding tubes, catheters, insulin pumps, and glucose monitors, as well as ventilators (Wolfe & Selekman, 2002). More children with life-threatening conditions have required schools to consider “do not resuscitate” orders and provide emergency care plans (Wolfe et al., p. 404).

In addition, the lack of access to health care has added extra burdens on schools as children come to school sick or miss additional days of school resulting from complications of illnesses that could have been easily treated in earlier stages. In 2006, approximately 6.9 million children (10%) did not have health insurance (Bloom & Cohen, 2006). Many children can access health care services only at school (Vessey & McGowan, 2006). Results from the most recent National Health Survey indicate that 5% of children missed 11 days of school or more in the past year because of illness. Children from families of lower socioeconomic status were twice as likely to miss 11 days of school or more than were children from families with higher income levels (9% versus 4%).

## KEY ROLES OF THE SCHOOL NURSE

To understand the role of the school nurse, one must first realize that school health, like all health programs in the community, requires a great degree of collaboration (Brener et al., 2007). School nursing services are part of a coordinated school health program that provides school health services, health education, and health promotion programs for faculty and staff.

### Liaison with the Interdisciplinary School Health Team

The nurse collaborates with counseling and psychological services, as well as physical education and nutrition services, working to provide a healthy school environment with family and community involvement (CDC, 2007a). Although the

school nurse plays a central role, collaboration with many other individuals is important. The coordinated school health program includes eight components and involves a variety of professionals and other people ranging from teachers, administrators, and school staff to families. The components are:

- ◆ School health services (preventive services, referral)
- ◆ Health education (kindergarten through 12th grade curricula)
- ◆ Health promotion for faculty and staff (employee health)
- ◆ Counseling, psychological, and social services
- ◆ School nutrition services
- ◆ Physical education programs
- ◆ Healthy school environment
- ◆ Family and community involvement (partnership among school, families, community groups)

### Positive Working Relationship with Administrators and Teachers

The school principal influences all phases of the school health program by promoting good school health through active support of the school's health services, participation in setting health-related policies, and tapping into community resources. The principal can reinforce positive efforts within the school, ranging from the health teaching in the classroom to the cleaning activities of the custodian. Because of the principal's influential position, it is absolutely essential for the nurse and principal to maintain a positive and cooperative working relationship.

Teachers, whether they are involved in regular instruction, physical education, or special education, play a major role in school health. Because they spend the most time with students, their observations, health teaching, and personal health habits have a profound effect on student health and the quality of school health services. The school nurse and teachers must collaborate constantly, as the school nurse provides information and guidance to teachers regarding students in their classrooms with specific health conditions and concerns and teachers report on students' health concerns and behaviors.

Other health team members, such as health educators, health coordinators, psychologists, audiologists, speech therapists, occupational therapists, physical therapists, counselors, health care providers, dentists, dental hygienists, social workers, security and juvenile justice personnel, health aides, and volunteers, may also be involved, depending on the size and financial resources of the school. All team members, including students, parents, bus drivers, and custodians, have a specialized role complementary to that of the school nurse. Consultation and referral among team members are crucial to the successful implementation of the school health program (Guttu, Engelke, & Swanson, 2004).

If the school system desires such services, a physician may work on a part-time consultative basis; however, fewer than 16% of school systems reported having a school physician (Brener et al., 2007). This role focuses largely on advising and consulting related to policy and medical-legal matters. A community physician may serve on a school advisory panel, acting as a liaison between the community, other health

agencies, and the school. The physician or a nurse practitioner (NP) may become involved in student health appraisals, re-screenings, health problem interventions, sports physical examinations, or first aid support at sporting events.

Funding for school nursing comes from a variety of sources. School districts use support services funding for school nurses. Public health departments may also contribute funding, along with hospitals and other organizations. Federal Medicaid funding has been used to support some of the administrative and nursing services provided to children with special health care needs. Over the last 10 to 15 years, school districts have billed Medicaid for specific services provided in the school setting (e.g., case management of children with chronic illnesses such as diabetes and asthma). However, a recent ruling found that Medicaid funds were being misused and such reimbursement was stopped (USDHHS, Centers for Medicare and Medicaid, 2007). Many schools relied heavily on this funding, and school nurse positions will undoubtedly be eliminated if other funding is not forthcoming (NASN, 2007b).

### RESPONSIBILITIES OF THE SCHOOL NURSE

The primary responsibilities of the school nurse are to prevent illness and to promote and maintain the health of the school community. The school nurse serves not only individuals, families, and groups within the context of school health, but also the school as an organization and its membership (students and staff) as aggregates. The school nurse identifies health-related barriers to learning, serves as a health advocate for children and families, and promotes health while preventing illness and disability (NASN, 2007a).

School nursing activities include care of children with special health needs, including nasogastric tube feedings, catheterization, insulin pumps, and suctioning; general and emergency first aid; vision, hearing, scoliosis, and TB screenings; height, weight, and blood pressure monitoring; oral health and dental education; immunization assessment and monitoring; medication administration; assessment of acute health problems; health examinations (especially for athletic participation or school entry); and referrals.

Other duties that a school nurse may have include training school staff in cardiopulmonary resuscitation (CPR), universal precautions, and first aid, and overseeing the health and wellness of school staff members. Many of these activities may be performed concurrently. See Display 30.5 for a typical day in the life of a school nurse. Each school nurse must assess and prioritize how to address the specific needs in each individual school and determine the order. This largely autonomous practice requires specific skills and training.

### EDUCATION: SPECIAL TRAINING AND SKILLS OF THE SCHOOL NURSE

School nurses operate from one of two administrative bases: the school system or the public health department. In most localities, public or private school systems or districts hire school nurses, and they maintain a specialized, school-based practice. In this specialized role, the nurse can concentrate

## DISPLAY 30.5

## A DAY IN THE LIFE OF A SCHOOL NURSE

**8:00 a.m.** The nurse begins work at her assigned middle school. A parent brings in a controlled medication (narcotic) for her son who fractured his arm the day before. The school nurse works with the parent regarding the medication protocol of the school. The nurse advises that narcotics will affect the student's concentration and ability to learn.

**8:15 a.m.** Two students come into the office to take medications (dextroamphetamine [Dexedrine] and an antidepressant for concentration and focusing).

**8:20 a.m.** First acute illness of the day! A girl has vomited and is very nervous about being in middle school. The nurse calls home to learn that the student has been to her health care provider twice this week because of anxiety. The nurse helps to calm her and talk about the situation and then walks her back to class. The nurse talks to the teacher about the student's situation.

**8:45 a.m.** Three pupils come to the nurse's office complaining of sickness. The nurse assesses them and calls the parents to explain the situation and tells them of the current illness in the school.

**9:00 a.m.** A student arrives in the office holding her nose. She was playing volleyball when she collided with another student. She is afraid her nose is broken. The nurse assesses the situation, and determines that there is a possible fracture. The student's parents are contacted, and arrangements are made for the student to visit the doctor, where the diagnosis (fracture) is confirmed and the student is treated.

**9:15 a.m.** Nurse leaves the middle school and heads for her assigned elementary school (three blocks away). She has a meeting for an individualized education program (IEP). One student has attention deficit disorder and bipolar disorder, and so the student's parents and the educational team (which includes the school nurse) meet to determine how to best serve the student's needs while in school and set goals and objectives. The nurse's role includes educating teachers and staff about how to handle mood swings and outbursts. The nurse works with the student's health care provider regarding

medications and monitors the impact of the medications. The nurse also works with the parents regarding strategies and coping skills to use at home.

**10:30 a.m.** The nurse returns to the middle school and finds six students in her office. One has a bloody nose (and is applying pressure to stop the bleeding); two collided while in physical education class (and have ice on their heads); and three have fevers and upset stomachs and are waiting for parents to arrive. The students who have head injuries are assessed for concussions and neurologic concerns. Parents are contacted regarding signs to watch for when the students return home. One of the student's parents cannot be reached, so a note will be sent home with the same information.

**11:00 a.m.–1:00 p.m.** Lunch time! Ten students come in for their medications. Students arrive with playground injuries to assess and monitor, and parents return calls and arrive to sign out their children.

**1:00 p.m.** The nurse receives a call from the assistant principal requesting the nurse to come to the main office. A student has been found with cigarettes and lighters. The student is given information regarding smoking and drugs. The student lives with surrogate parents who need assistance in setting limits at home and at school.

**1:30 p.m.** All immunizations have been documented and entered for the year. The nurse prints the immunization report and identifies 177 students who are not up-to-date with state requirements. The nurse will need to contact and work with the parents of these students to help them achieve compliance. Students will not be allowed to return to school until the situation is resolved.

**2:30 p.m.** The nurse attends a meeting to create a behavior modification plan for a student who is having difficulty completing assignments.

**3:00 p.m.** The school day ends.

Adapted from Weirick, K. (2003). A typical day in the life of a school nurse. *New Mexico Nurse*.

time and effort solely on the school health program and develop specialized skills in school health assessment and intervention. Today, with the emphasis on delivery of health care at community sites where clients spend most of their time (e.g., schools for children, the workplace for adults), the nurse whose specialty is school health care seems better prepared to meet the complex needs of the school-age population.

In contrast, the school nurse who operates under the board of health's jurisdiction provides services to schools as one part of generalized public health nursing services to the community. The community health nurse working through the health department usually devotes only a portion of the workday to the school; she may have additional responsibilities, such as clinic nursing and home visits. This broader base

allows contact with preschoolers and their families, provides a stronger knowledge of the community and its resources, and promotes integration of in-school and out-of-school care.

Depending on the state of residence, a school nurse is usually an RN—frequently with additional education beyond the bachelor's degree in nursing, sometimes including a master's degree—who has primary responsibility for the health care of school-age children and school personnel in an educational setting. In some areas of the country, licensed practical nurses (LPNs) or licensed vocational nurses (LVNs) may be hired by school districts, but they must generally work under the supervision of an RN. *The Scope and Standards of School Nursing Practice* (2005) indicate that school nurses should, at minimum, possess a bachelor's degree. A

school nurse functions as a promoter of health, an educator, counselor, advocate, manager, and deliverer of care (Brener et al., 2007). And these functions require a knowledge base derived from a baccalaureate nursing program. Many states (39.6%) require state school nurse certification and 29.2% of states have a policy indicating that school nurses must perform continuing education (Brener et al., 2007).

As the needs of school-aged populations become increasingly complex, some states require even more specialized training for school nurses. In California, for instance, school nurses are expected to hold a school health services credential. This credential is obtained through a post-baccalaureate program that includes a minimum of 24 semester units of course work in audiology, guidance and counseling, exceptional children, school health principles and practice, a practicum in school nursing, child psychology, and health curriculum development, in addition to other courses. However, most school nurse credential programs are now available only as part of a master's degree program. A national certification is available as well (*Careers in Focus*, 2006).

**School nurse practitioners** (SNPs) are RNs with advanced academic and clinical preparation (generally certification and a master's degree in nursing) along with a guided experience in physical assessment, diagnosis, and treatment, so that the SNP may provide primary care to school-age children. Many school districts see the advantage of having an SNP on staff, rather than using the limited services of a physician. Assessment, diagnosis, treatment, and referral of injuries, communicable diseases, or other health problems can be managed more efficiently by a NP who is educationally prepared to work holistically with the school-age population and is part of the educational setting. If this arrangement is impractical, an SNP who is available to school nurses for consultation or who is employed on a part-time basis can become the impetus for comprehensive school-based health services. Some school districts utilize SNPs to provide services to teachers and staff to promote wellness or to handle job-related injuries. Some research findings cite cost savings related to SNP services, as students and staff served by them experience fewer days of absenteeism (Perrin, Goad, & Williams, 2002).

As the population continues to become more diverse and the problems of children and their families grow in complexity, the school nurse with specialized training in school health, the education system, case management, and advanced practice nursing (e.g., NPs, clinical nurse specialists) becomes even more essential.

## FUNCTIONS OF SCHOOL NURSING PRACTICE

The three main functions of school nursing practice are health services, health education, and promotion of a healthy school environment.

Health services include caring for individual students who have chronic conditions or acute situations, while at the same time thinking of the entire population and tracking trends. For example, the school nurse observes an increase in the number of students diagnosed with asthma and investigates ways to help all students with asthma. One way of doing this may be to organize an *Open Airways* course (developed by the American Lung Association) to assist students in iden-

tifying triggers and managing their own care. The goal of this course would be to decrease student asthma attacks.

## Health Services for Chronic Conditions

The number of children afflicted with chronic diseases is rising, and 45% of those students are reported to have fallen behind in their schoolwork, whereas 58% are routinely reported absent from school (Guttu, Engelke, & Swanson, 2004). Commonly seen chronic problems include hay fever, sinusitis, dermatitis, tonsillitis, asthma, diabetes, seizure disorders, and hearing difficulties. In addition, acute illnesses such as stomachaches, headaches, colds, and flu are frequent complaints of school-age children. School nurses develop **individualized health plans (IHPs)** to ensure that students with special needs (e.g., chronic conditions) have these needs met. If these students attend the regular classroom, the plans may be known as **Section 504 plans**, named after the section of the Individuals with Disability Education Act that specifically allows for school accommodations with this population. For students in special education programs, nurses can coordinate IHPs with **individualized education programs (IEPs)** to develop health management goals for students. Medically fragile or technology-dependent students, who may require procedures such as suctioning or tube feeding, would have plans developed for *specialized physical health care procedures*. The four chronic conditions most often seen in school-age children are asthma, diabetes, seizures, and severe food allergies (Wolfe & Selekman, 2002).

## Asthma

Asthma is the most common chronic disease of childhood. Although reports indicate morbidity and mortality from asthma has stabilized in the past few years, in 2006, an estimated 14% of children younger than age 18 were diagnosed with asthma (Bloom & Cohen, 2006). Non-Hispanic Blacks exhibit the highest asthma attack rates, and boys more often than girls reported an episode within the past year (Bloom & Cohen). Over half (54%) the children, ages 4 to 18, with asthma experienced school absences—missed “some school”—due to their asthma (Schulman, Ronca, & Bucuvalas, Inc. [SRBI], 2004). Children with asthma also tend to show comorbidities, such as depression and behavioral disorders (Blackman & Gurka, 2007). In such situations, school nurses work with students, their families, and their doctors to develop an *asthma action plan* to control, prevent, or minimize untoward effects of acute asthma episodes. Peak flowmeters can be used regularly to determine early signs of asthma problems. The activities of nurses acting as case managers have been found to decrease the number of emergency room visits and hospitalizations of school-age children with asthma (Levy, Heffner, Stewart, & Beeman, 2006).

Monitoring asthma medications and teaching proper methods of inhaler use are also vital school nursing functions. Many states (88%) allow students to carry quick-acting inhalers on their person (Brener et al., 2007). It often falls to school nurses to ensure that proper protocols and training are accomplished. A study of 19 school districts in North Carolina found a significant difference in outcomes for students with asthma in districts with a nurse-to-student ratio of more than one to 1,000 when compared to districts

with a ratio of less than one to 1,000 (Guttu, Engelke, & Swanson, 2004).

### Diabetes

Diabetes is another common chronic illness in young people: approximately 176,500 under age 20 have diabetes. This translates into one in every 400 to 600 children having type I diabetes (National Diabetes Education Program, 2006), and experts now conclude that both type 1 and type 2 diabetes mellitus are found in school-age children. One report estimates a 45% increase in adolescents with type 2 diabetes over the past 15 years (Pinhas-Hamiel & Zeitler, 2005). Type 2 diabetes is rising almost exponentially in adolescents, leading some scientists to frame it as a major public health crisis caused largely by obesity, sedentary lifestyle, and the predisposition to diabetes of certain ethnic groups.

Working with families and health care providers, school nurses assess and develop a care plan for diabetic students (Clark, Clasen, Stolfi, & Jaballas, 2002). School nurses work closely with the family to maintain confidentiality and at the same time ensure that the school is a safe environment for the child. A multidisciplinary team approach is needed, with family, school, and physician collaboration. Training for teachers and fellow classmates is also important. Teachers are often called upon to assist students with their insulin pumps or food management. Younger children with type 1 diabetes, especially those who use insulin pumps, may need careful monitoring—something that is not always possible for the school nurse, who may not be present where and when problems arise. If the child has an insulin reaction, fellow students should be taught to quickly get the teacher. A current initiative of the American Diabetes Association is to ensure that glucagon can be administered by nonlicensed personnel, such as teachers (NASN, 2006b). However, many school nurses do not feel comfortable delegating this task or others like it. Delegation has become a safety issue that has reached many state boards of nursing and legislatures (Heschel, Crowley, & Cohen, 2005).

Testing blood sugar and taking insulin at school can be frustrating and can cause children to feel singled out or different from their peers. One study found that adolescents with type 1 diabetes have significantly higher rates of depression than those without diabetes (Guzman, 2004). Also, some schools do not permit blood sugar testing and insulin administration in classrooms, so that school health offices are often a place of refuge for diabetic students (Wolfe & Selekmán, 2002). It is important for school nurses to understand each child's concerns and to alert teachers and school personnel to the signs and symptoms (as well as the treatment) of hypoglycemia. In addition to the obvious emergency health-related concerns for diabetic children, a classic study showed that diabetes-related severe hypoglycemia does affect memory tasks (Hershey, Bhargava, Sadler, White, & Craft, 1999). Over time, memory deficits can affect learning and progress in school.

### Seizure Disorders

Seizure disorders are not uncommon in the school-age population. Epilepsy is a disorder of the brain in which neurons

sometimes give abnormal signals. A person who suffers from epilepsy may have comorbidities including autism, depression, and anxiety (National Institute of Neurological Disorders and Stroke [NINDS], 2007). For almost 80% of those diagnosed, seizures can usually be controlled with medication (e.g., antiepileptic drugs specific to the pediatric population), surgical treatment, or a diet rich in proteins and fats and low in carbohydrates (a *ketogenic diet*) (NINDS, 2007).

It is important for school nurses to develop care plans to address seizure concerns during school hours. Care plans include monitoring medication compliance and teaching school staff about first-aid measures for seizure victims. Children and adolescents with seizure disorders may feel embarrassed or be the victims of teasing or bullying. They may exhibit signs of school avoidance. Nurses need to work with these children and to teach all students about the disease process and the need for empathy and understanding.

### Food Allergies

The fourth leading chronic condition found in school settings is severe food allergies that can lead to anaphylactic shock. Such severe allergies result in approximately 30,000 emergency room visit each year (Food Allergy and Anaphylaxis Network, 2006). Eight common foods account for 90% of severe food allergies. They are fish, shellfish, soy, milk, egg, wheat, peanuts, and tree nuts (e.g., cashews, walnuts). Many common foods and school supplies (e.g., play dough) can contain hidden allergens, and care must be taken to prevent exposure. School nurses coordinate and work with students and their families, along with school personnel, to raise awareness and enlist caution. They also work with families and health care providers to ensure that epinephrine via an auto-injector (EpiPen) is available for the child in case of emergencies. Epinephrine reverses the body's allergic reaction to the allergen (Dey, 2008). Many states (66%) allow students to carry an EpiPen on their person because reactions can occur very quickly (Brener et al., 2007). School nurses coordinate and ensure that proper protocol is followed. School nurses also work with teachers and lunch room personnel to alert them of the allergy, explain what can happen in a case of anaphylaxis, and provide training on how to use the EpiPen or other needed medication.

### Behavioral Problems and Learning Disabilities

Other often chronic childhood health problems are those of emotional, behavioral, and intellectual development. These are not always easy to detect and measure, and they can be debilitating. Although these problems are not new, awareness and concern have increased as the rates of occurrence for other life-threatening childhood diseases have diminished. Emotional or behavior problems and learning disabilities are prevalent during childhood, with approximately 22% of adolescents ages 14 to 17 years having a special health care need (Okumura, Pheeters, & Davis, 2007).

The causes of learning disabilities and emotional behavioral problems appear to have genetic, environmental, and cultural influences. The number of children with learning disabilities in the lowest economic group is twice that in the highest group (Bloom & Cohen, 2006). Children

who were characterized as being in fair or poor health were more than five times as likely to have a learning disability and three times as likely to have attention deficit–hyperactivity disorder (ADHD) as children with excellent, very good, or good health status (Bloom & Cohen, 2006). High-risk children often come from families with a high incidence of child abuse (physical and sexual) and neglect. The number of children affected by parental drug use has surpassed that of children with disabilities caused by lead poisoning, another major contributor to developmental problems in children.

ADHD is a cluster of problems related to hyperactivity, impulsivity, and inattention (Dang, Warrington, Tung, Baker, & Pan, 2007). The CDC estimates 4.4 million school-age children between the ages of 4 and 17 have been diagnosed with ADHD (CDC, 2004). School nurses must be aware of the signs and symptoms and serve as an advocate for these children and their families. At each stage of development, those with ADHD are presented with distinct challenges. For example, children in elementary school may often have difficulty and conflict with peers, as well as problems organizing tasks. They may be more accident prone and may have more school-related problems, such as grade retention and suspension or expulsion.

They often have problems with grooming and with handwriting, and they exhibit difficulty sleeping. ADHD is sometimes found with associated disorders, such as communication or language disorders and learning disabilities. Common comorbid conditions are depression, anxiety disorders, and conduct disorders (Dang et al., 2007).

Behavioral and emotional problems of school-age children stem from many causes. School nurses can be alert to early symptoms and refer families for counseling. Some schools are also now offering support groups for children of divorce.

Collaboration is needed between the child's family, the school, and the child's health care provider to diagnose ADHD and effectively plan appropriate interventions and educational accommodations. Teacher confirmation of ADHD-related behaviors is very important. Numerous checklists and assessment tools are available, and school psychologists typically serve as a source for additional information and resources. School nurses can assist parents in recognizing the symptoms of ADHD and obtaining appropriate treatment and follow-up (Dang et al., 2007). A multimodal treatment approach may include stimulant medication, usually methylphenidate (Ritalin or Concerta), dextroamphetamine (Dexedrine) and amphetamine (Adderall), or antidepressants (such as Wellbutrin). Other treatment includes school accommodations for learning problems and social skills training for the child with ADHD (Dang et al., 2007). Family and individual counseling, parent support groups, and training in behavior management techniques, as well as family education about the condition, are also essential features of this method of treatment.

Not all children and adolescents respond to medication, and medication dosage must be carefully monitored and titrated. School nurses can assist parents in this task. The main goal of medication for school-age children is academic improvement. If this does not occur, medication may need to be changed or discontinued. School nurses and community health nurses can work closely with school

staff, parents, and physicians in determining the efficacy of treatment regimens.

### Medication Administration

Medication administration for a variety of conditions is an important responsibility for school nurses. In schools where a nurse is present every day, the nurse can personally oversee medication administration. Unfortunately, many nurses cover more than one school and so other school personnel (e.g., secretaries, health aides) oversee medication administration. Over half the states have laws allowing teachers or health aides to administer medication (Brener et al., 2007). In these situations, it is ideal for school nurses to provide training and audit records to ensure that proper guidelines are followed. Multiple studies show that medication errors increase when school nurses cover multiple schools and unlicensed personnel assist in medication administration (McCarthy, Kelly, & Reed, 2000; Ficca & Welk, 2005). Problems commonly occur with omission of doses because students fail to come to the office for medication administration. This is especially problematic with students taking insulin or antidiabetic drugs, antibiotics, and medication for ADHD.

### Health Services to Prevent Illness and Injury

School nurses emphasize prevention, and focus many of their efforts on prevention of communicable disease (via immunizations) and of injuries.

#### Immunizations

Among schoolchildren, the incidence rates of measles (rubeola), rubella (German measles), pertussis (whooping cough), infectious parotitis (mumps), and varicella (chickenpox) have dropped considerably because of widespread immunization efforts, although these communicable diseases do still occur, and sometimes with serious complications such as birth defects from rubella and nerve deafness from mumps. Although the number of cases of *Haemophilus influenzae* infection and hepatitis B decreased between 2003 and 2004, there was an increase in the number of cases of pertussis, measles, mumps, and hepatitis A. In fact, during this time period (2003–2004), the number of pertussis cases was at its highest point since 1959 (Maternal and Child Health Bureau, 2006).

Low immunization levels in many areas, particularly among poor populations, and increased disease rates signal the need for constant surveillance, outreach programs, and educational efforts. School nurses are deeply involved in each of these preventive activities. Health departments and schools often work collaboratively to provide immunization services. Compulsory immunization laws for school entrance, which vary among states, have enabled public health personnel to carry out these preventive services. Nearly all states (94%) have a policy of excluding students from school if they are not adequately immunized (Brener et al., 2007). Only about 17% of states require TB skin testing before entering school.

School nurses often oversee and ensure that children are in compliance with school entrance laws regarding

## EVIDENCE-BASED PRACTICE

### School Nursing

A study was conducted to determine if the rates of absenteeism were lower at schools where students who received FluMist than at schools where students were not offered the treatment. FluMist was offered free of charge to students at the two experimental schools (64% compliance in school 1 and 46% compliance in school 2). Two other schools with school populations and attendance rates similar to the experimental schools were used as controls. Attendance rates were reviewed from all four schools once FluMist was offered. Those schools where students were offered FluMist statistically ( $p < .001$ ) increased their attendance rates (95.3% to 96.1% and 93.9% to 95.8%) compared to the control schools' rates (94.6% to 94.4% and 94.6% to 94.7%). No significant differences were found in the number of absenteeism due to influenza. However this was self-reported and difficult to track. Wiggs-Stayner, Purdy, Go, McLaughlin, Tryzynka, Sines, and Hlaing (2006) concluded that on-site school immunization programs can be a positive primary prevention.

#### Nursing Implications

Although school nurses often work with individual children, they also look at the school community as a whole and should conduct interventions that will benefit the whole. School nurses must also collect data and determine the effectiveness of their treatments. Finally school nurses must also remember the goals of the institution in which they work (education) and strive to meet these goals (i.e., increased attendance) while at the same time protecting the public's health.

Wiggs-Stayner, K. S., Purdy, T. R., Go, G. N., McLaughlin, N. C., Tryzynka, P. S., Sines, J. R., & Hlaing, T. (2006). The impact of mass school immunization on school attendance. *Journal of School Nursing*, 22(4), 219–222.

immunizations. They may call parents directly when they note that the student is out of compliance. They may also arrange to help the student get immunized by facilitating appointments or, in some school districts, providing the immunizations directly. The American School Health Association has developed a toolkit for school nurses and others to follow when developing successful immunization outreach programs in secondary schools where compliance is always difficult (Boyer-Chu & Wooley, 2006).

### Safety

School nurses are also involved in ensuring that injury prevention efforts are encouraged. Emphasis on a healthful physical environment includes proper selection, design, organization, operation, and maintenance of the school building and playground equipment. Although no national

database collects information about school injuries, one study in Indiana found school injury rates of 2.5 per 100 students (Kaldahl & Blair, 2005).

Custodial personnel assist in the maintenance of school grounds, but school nurses must be aware of conditions and make recommendations to remedy unsafe situations. As school nurses provide first aid treatment for playground injuries they may observe trends (e.g., a high number of injuries where faulty playground equipment or other factors influence higher injury rates) and request action. When injury trends are noted, school nurses work with maintenance departments and administration to advocate change and prevent future injury. In addition, nearly half of the states have adopted a policy directing schools to complete a report when serious injury occurs on school properties (Brener et al., 2007). School nurses also assist with physical adaptations for students with special needs (e.g., ramps, electric doors); they work to ensure safety in and around schools; and they are mindful of visual, thermal, and acoustic factors in school buildings, as well as aesthetic values. Additionally, they promote sanitation and the safety of the school bus system as well as food services (Food-Safe Schools, 2004).

### Health Education and Health Promotion

Another main function of school nursing practice involves education and health promotion. This includes planned and incidental teaching of health concepts and health curriculum development. In some states, school nurses even teach the regular health classes. Education may be one-on-one to help a child obtain better control over asthma or to explain to a newly diagnosed diabetic student what is occurring in his body. As an educator, the school nurse may also teach an entire class regarding a student's severe food allergy or the need for proper hand hygiene. The school nurse explains in simple terms what allergies are and helps students understand that allergies are not contagious, what to do in the case of an allergic reaction, and the importance of not sharing foods that may contain potential allergens (Wolfe & Selekmán, 2002).

Because school nurses are trusted by students, students listen to them. Educational subjects are limitless, but should always apply to the specific needs of the children in the school. The nurse must use creativity and autonomy to identify and prioritize needs. A school nurse may also teach about basic first aid, nutrition, physical exercise, and seat belt safety, or provide information about careers in the health care professions.

In addition to lecture or verbal teaching, education may also be in the form of bulletin board notices, newsletters, or in-service presentations for educators and parents. These activities integrate health information with students' daily living experiences to build positive attitudes toward health and to establish sound health practices that will carry forward into adulthood.

### Screenings: Opportunities for Teaching

Most local school districts provide some type of health screening services, usually through the school nurse or local health care providers. Although the goal of all screening is to promote early intervention, screening also provides the school nurse many opportunities to teach students and staff. Referral

information resulting from screening results is usually given to parents, and school nurses may contact parents to encourage follow-through. Children who are not present for school screenings may not receive the benefits of these screenings (e.g., home schooled and private school students). School nurses often help to coordinate screening resources and benefits, and they often carry out additional screenings for students who were absent when mass screenings were held.

### Vision

The 2006 School Health Policies and Programs Study (SHPPS) noted that 93.4% of reporting school districts offered vision screening (Brener et al., 2007). School nurses often oversee routine vision screenings at periodic intervals, so that vision problems that can interfere with learning may be detected and treated early (e.g., nearsightedness, farsightedness, strabismus, amblyopia). School nurses also are involved in follow-up to ensure that corrective eyewear is obtained. Local Lion's Clubs may be involved in paying for area optometrists to assist with or direct screenings or to provide follow-up care.

### Hearing

Hearing screenings were reported by 92% of districts (Brener et al., 2007). These mass screenings are done to detect any serious hearing deficits that may be related to recurrent ear infections or some type of sensorineural hearing loss. (*Sensorineural hearing loss* involves the inner ear or the nerves leading from the inner ear. It is permanent and cannot be surgically or medically corrected [American Speech-Language Hearing Association, 2007]).

### Miscellaneous Health Screenings

Height, weight, and sometimes blood pressure and cholesterol screenings are done on a regular basis to monitor normal growth and development and allow for early intervention with populations who are especially susceptible to hypertension and heart disease.

In some areas, scoliosis screening is also done, frequently during middle school years or in fifth grade, to permit early detection and referral for medical intervention (e.g., bracing, surgery). Scoliosis may be congenital, but is often idiopathic (Lewis & Bear, 2002). Some 66% of districts reported performing scoliosis screenings (Brener et al., 2007). In Texas and some other areas of the country, acanthosis nigricans (hyperpigmentation from various causes, but sometimes a symptom of diabetes) screenings are being done to look for early markers of type 2 diabetes, especially in high-risk populations (Texas Department of Health Services, 2005).

### Oral and Dental Health: Teaching and Referral

Dental caries affect more than half of school-age children and are the most common chronic disease for that age group. In 2006, about 7% of children ages 2 to 17 had unmet dental needs because their families could not afford dental care (Bloom & Cohen, 2006). An estimated 16.3 million children do not have any dental insurance, a rate 2.6 times greater than those who do not have medical insurance (Lewis,

Mouradian, Slayton, & Williams, 2007). Minority groups tend to have worst rates of dental caries. School days are lost to dental problems and dental visits, with poor children reporting almost 12 times more restricted-activity days from dental-related illness than children from families with higher incomes (CDC, 2005). The cost for dental services in 2006 was estimated to be \$94 billion (CDC, 2007b).

School nurses can address dental health issues in a variety of ways. At a community level, they can educate the public about the benefits of dental fluoride treatments. They can advocate for fluoridation of drinking water, school-provided fluoride rinses or gels, and dental sealant programs. These are all cost-effective, proven methods of reducing dental caries in school-age children. At the classroom level, school nurses can provide dental education and provide toothbrushes, toothpaste, and floss to ensure that students are able to practice good dental hygiene habits. (Local organizations and businesses often will donate such supplies.) Many programs from the American Dental Association, the CDC, and other organizations provide resource materials. At an individual level, school nurses can assist in finding resources for those with no dental health insurance. Finally, school nurses can successfully educate parents, especially those who are immigrants or have different cultural beliefs, regarding the importance of oral and dental health (Brown, Canham, & Cureton, 2005).

Dental screenings or clinics may be conducted to determine the incidence of dental caries, especially in elementary school children, and to encourage follow-up with local dentists for necessary restorations. Only 29% of districts reported performing some type of oral health screening (Brener et al., 2007).

### Promotion of a Healthful School Environment

A third function of school nursing practice includes maintaining and promoting a healthful school environment. Promotion of healthful school living emphasizes planning a daily schedule for monitoring healthful classroom experiences, extracurricular activities, school breakfasts and lunches, emotional climate, discipline programs, and teaching methods. It also includes screening, observing, and assessing to identify needs early and to report illegal drug use, suspected child abuse, and violations of environmental health standards. Health promotion involves the nurse in supporting the physical, mental, and emotional health of school personnel by being an accessible resource to teachers and staff regarding their own health and safety.

### Proper Nutrition and Exercise

Many factors can affect the school environment—heating, cooling, lighting, safe playgrounds, and policies and practices to limit bullying and social aggression or other forms of school violence. The school cafeteria and physical education activities can promote health or contribute to obesity and sedentary lifestyles.

### Obesity

Obesity rates have increased for all children. They have doubled for children between ages 2 and 5 and adoles-

<b>LEVELS OF PREVENTION PYRAMID</b>		
<b>HEALTH ISSUE:</b> Obesity in a school setting

cents (ages 12–19) and tripled for those between ages 6 and 11 years. Approximately 9 million children over the age of 6 are considered obese (Institute of Medicine, 2005). Obesity-related hospital costs for children have tripled over the past two decades and have reached \$129 million a year (Institute of Medicine, 2005). Obesity often begins in childhood and becomes a risk factor for cardiovascular disease and diabetes later in life. With the increase in child obesity rates, the number of children diagnosed with type 2 diabetes continues to rise. One report estimates a 45% increase in adolescents with type 2 diabetes over the past 15 years (Pinhas-Hamiel & Zeitler, 2005).

As children become older, families have less impact on food choices, and peers begin to have more influence. Results of the 2005 Youth Risk Behavior Survey (YRBS) indicate that 80% of those surveyed ate fewer than five servings of fruits and vegetables the day before the survey, and 84% drank fewer than three glasses of milk per day in the previous week (CDC, 2006).

School nurses can do many things to assist with the obesity epidemic. They can advocate for health and physical activity classes. Speroni, Earley, and Atherton (2007) found that a nurse-implemented program in the school decreased obesity among students. The 2005 YRBS revealed that 46% of children surveyed were not enrolled in physical education classes (CDC, 2006). Parents are supportive of increasing physical exercise and emphasizing nutritional foods in the school setting (Murphy & Polivka, 2007). A number of weight control programs for overweight children and adolescents are available through schools, health departments, community health centers, HMOs, and private groups.

**Undernutrition**

Poor nutrition and obesity are not uncommon among adolescents, whose diets often consist of snacks with limited nutritional value interspersed among unhealthful meals. *Undernutrition* can also have serious consequences, one

being an impact on the academic performance of children. Irritability, lack of energy, and difficulty concentrating are only some of the problems that arise from skipped meals or consistently inadequate nutrition (Sweeney & Horishita, 2005). Infection and illness that lead to loss of school days can affect academic progress and interfere with the acquisition of basic skills, such as reading and mathematics. Undernutrition is frequently associated with poverty and hunger, but social pressure to be thin can also spark purposeful undernutrition.

School nurses can advocate for better nutritional choices in the lunch room and vending machines. This may include approaching the legislature to limit soft drink sales in public schools. They can also teach all grade levels regarding proper nutrition, and they can educate students and parents alike about nutritious snacks in contrast to snacks with little food value. School nurses may also work with staff to provide nutrition and exercise programs.

### Eating Disorders

Eating disorders are another area of concern. Issues with body image and control are at the heart of *anorexia nervosa* and *bulimia nervosa*, common problems for adolescent girls. These diseases have emotional causes that pose complex challenges to treatment. School nurses must be aware of the signs and symptoms of eating disorders and be proactive in identifying students at risk. Scoliosis screenings are an optimal time to also observe for eating disorders, as examination of the spine allows for visualization of the body core. School nurses can work with students to develop a healthier self-concept and identify outside treatment resources (NASN, 2002).

### Adolescent High-risk Behaviors

Mortality and morbidity rates for adolescents are low overall and demonstrate considerable improvement since the early 1900s. Many of the health issues that modern adolescents face are a result of their own choices and high-risk activity; for example, sexual activity, substance abuse, injury, and violence are all high-risk behaviors in which adolescents can choose to participate or not. The effects of such choices may not be discovered for many years. From 2003 to 2006, a good number of states developed policies to address alcohol and drug use (22% to 42%), sexually transmitted disease (STD) prevention (17.6% to 32%), suicide prevention (16% to 28%), and tobacco-use (19.6% to 40%) (Brener et al., 2007).

### Sexual Activity: Teen Pregnancy and Sexually Transmitted Diseases

Sexual activity is a sensitive issue. However, the YRBS indicates that close to half of the 12th graders and one-third of all students who participated in the study were sexually active (CDC, 2006). Each year, about half of new STD cases in the United States occur among those between the ages of 15 and 24 (CDC, 2007c). The overall rates of syphilis, gonorrhea, chlamydia, human papillomavirus (HPV), and herpes simplex virus are climbing.

Providing STD services and HIV/AIDS education can be a daunting task. Young people with STDs are often afraid or embarrassed to seek help. Those who have been exposed to the HIV virus may not know that they are infected.

Although in some communities, the school-based clinic dispenses condoms, in other areas school nurses may be restricted in what safe-sex products they can provide. However, nurses *can* provide teens with education and with information about resources that are available outside of school property. School nurses can promote, at the local and state level, the HPV vaccine that guards against cervical cancer. They can also promote abstinence or delaying sexual initiation, as well as fostering safer-sex messages that promote the use of condoms. Sex education is effective at both delaying the onset of sexual activity and decreasing sexual activity in adolescents who are already sexually active. It is also effective in increasing safer-sex practices, knowledge of the efficacy of birth control methods, and overall sexual knowledge (Soloman & Card, 2004).

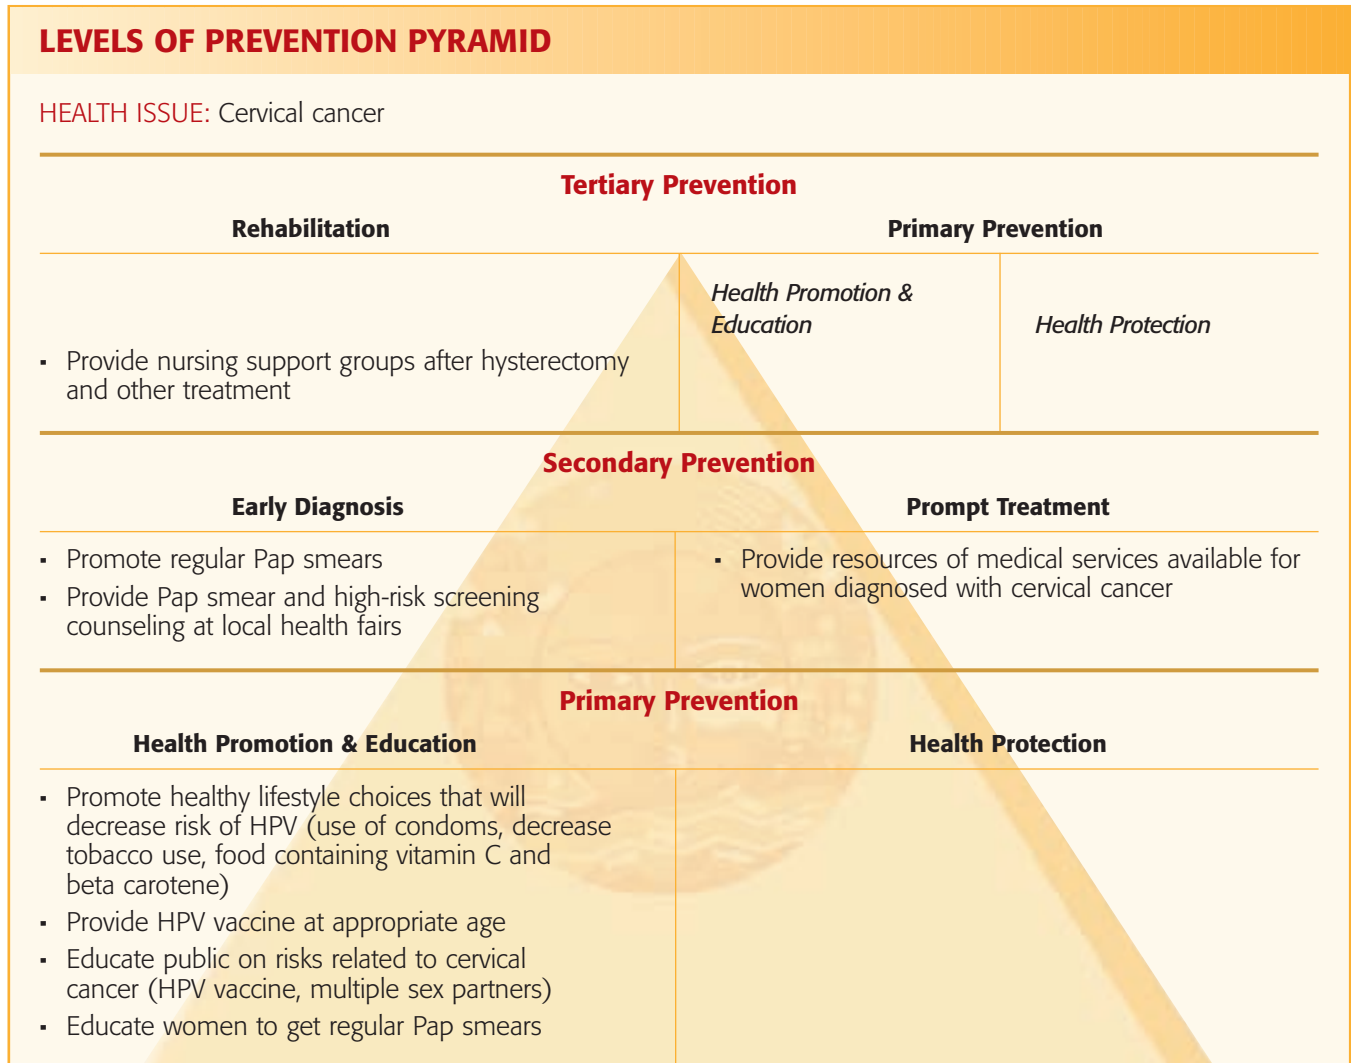

School nurses are sometimes restricted by state and/or district policies from addressing the issues of sex education and STD (including HIV) prevention. However, they can inform students and others in the community about the existence of multimodal youth development programs and family planning programs, which are often stationed strategically in inner cities, near schools, or in school-based clinics. These agencies are empowered to provide birth control information and counseling to young people.

### Substance Abuse

Substance abuse among young people was almost unknown before 1950, and rare before 1960. Now, adolescent drug experimentation and use poses serious physical and psychological threats. By the time they complete high school, 20% of teens report having tried marijuana, 54% have used tobacco, and 74% have consumed alcohol (CDC, 2006). Over half (54%) of those who smoke have tried to quit, and 25% of those who have consumed alcohol tried it before they were 13 years old.

School nurses can assist in programs targeting all substance abuse. Successful programs focus on protective factors, instead of just high-risk behaviors. The programs focus more on the root causes, or why youth choose high-risk activities. When school nurses focus on developing and advocating for protective factors that assist youth to feel part of their community (Graves, Fernandez, Shelton, Frabutt, & Williford, 2005), they can help teens avoid the onset of substance abuse.

School nurses can also provide resources for smoking cessation and substance abuse programs. Hamilton, O'Connell, and Cross (2004) found that school nurses can be successful members of school smoking-cessation programs. In addition to school-based education, programs of peer leadership and parental education/involvement, and community-wide task forces have been developed to lobby for local legislation and strengthen community-school ties. School nurses can be advocates at a community level by lobbying the city council for tougher ordinances controlling advertising content and zoning (especially

near schools). School nurses often work in conjunction with law enforcement officials, school district administrators, and other community agencies to ensure compliance with local regulations and prevent or delay tobacco use. Other groups, such as 4-H clubs, religious congregations, the Catholic Youth Organization, and Boy Scouts, use peer counseling to influence young people to assume responsibility for healthy lifestyles, with the goal of developing decision-making skills that lead to healthy lifestyle choices in adolescence and through adulthood. The school nurse participates in and supports existing programs in addition to counseling and referring young people who need help.

**Mental Health Issues and Suicide**

Depression, schizophrenia, and eating disorders may first appear during adolescence. It is estimated that one of 10 children suffers from a mental illness severe enough to impair them in some way (National Institute of Mental Health, 2008). Many adolescents are reluctant to seek

help for emotional problems, or help may not be readily available to them. It is estimated that only one of five of those who need treatment actually receives it. Common mental health disorders in adolescence include anxiety, depression, ADHD, eating disorders, bipolar disorder, and schizophrenia (NIMH, 2008). Suicide is the third leading cause of death for young people between ages 15 and 24; it is the sixth leading cause of death in children between ages 5 and 14 (American Academy of Child & Adolescent Psychiatry [AACAP], 2004). In 2005, 20% of all high-school students reported that they had either seriously considered or attempted suicide in the past year (CDC, 2006). Girls attempt suicide more frequently than boys, but the actual suicide rate (those who successfully kill themselves) is higher among boys (AACAP, 2004). School nurses must be aware of the signs and symptoms of mental illness and suicidal intentions. They can work with school psychologists, social workers, and other mental health workers to address the needs of the students. They can also provide grief counseling to peers after a student commits suicide.

## Abuse

In 2005, a total of 12 children in every 1,000 had substantiated reports of maltreatment, with younger children (0 to 13 years of age) at the greatest risk (Federal Interagency Forum on Child and Family Statistics, 2007). Girls tended to be maltreated more often than boys. Black, non-Hispanic youth were also at greater risk. Most victims suffered from neglect (USDHHS, 2008). Child abuse prevention education programs can be found in many school districts as a primary preventive intervention. School nurses are required by law to report suspected or confirmed cases of abuse. In addition, school nurses can educate teachers and other school personnel regarding the signs and symptoms of abuse. Abuse can also include issues related to bullying and school violence. For more information on health problems and issues concerning children and adolescents, see Chapter 22.

## School-based Health Clinics

Because of the complex and intertwined emotional, physical, and educational needs of school-age children and adolescents, a more comprehensive interdisciplinary approach to services is needed than the piecemeal approaches attempted previously. School nurses are able to do much to influence school children's health. However, often they need to refer the children to a health care provider. Yet, more parents are working and less available to take care of their children's health care needs during the day. **School-based health centers (SBHC)** provide ready access to health care for large numbers of children and adolescents during school hours, reducing absences from school due to health care appointments. School-based health centers provide a variety of services in a user-friendly manner at a convenient location.

In 2005, there were more than 1,700 SBHCs in the United States, up from only 200 in 1990 (National Assembly on School-Based Health Care [NASBHC], 2007). These clinics are generally established inside the schools. They are distributed in high schools (39%), middle schools (18%), and elementary schools (23%). Some clinics provide services only to school children, whereas others extend services to their families and to other families with preschool-age children in the neighborhood. Most centers are open full time. Those located in middle or high schools may provide pregnancy testing and STD diagnosis and treatment, as well as birth control. However, many SBHCs do not provide contraceptive services on the school site because of school district policy or state law (NASBHC, 2007).

School-based health centers are staffed by interdisciplinary teams of helping professionals, paraprofessionals, and other staff and can include nurses, nurse practitioners, and social workers. Many hospitals, HMOs, and health departments are sponsors of these school clinics, because it is a cost-effective way to decrease visits to the emergency department and promote health, especially to underserved groups such as adolescents. Third-party billing, especially to access Medicaid funding, is increasingly more common among SBHCs, and private foundations have also been instrumental in providing financial and technical support.

School nurses support the clinics by referring students who need additional attention. In some areas, school-linked health centers are utilized. These clinics are not on school property, but may be nearby or easily accessible through mass transit. Schools refer students to these centers and have established collaborative, working relationships that promote information sharing and support.

Evaluation research has demonstrated that SBHCs are effective in increasing student access to health care. The majority (60%) of clients surveyed in Oregon indicated they would have not been able to receive care that day had it not been for the SBHC, and 68% said their health was improved due to the SBHC (Oregon State Government, 2007). School-based health centers also have been found to decrease absenteeism and school dropout rates of teenage mothers who attended the clinic (Barnet, Arroyo, Devoe, & Duggan, 2004).

## SCHOOL NURSING CAREERS

School nurses must be able to work autonomously. They need excellent communication skills and the ability to prioritize and collaborate with many others. The pay for school nurses depends on location and employer (health department or school district). In some places, the wage may be lower than acute care nurses, but the health insurance and benefits package is usually quite extensive. School nurses are sometimes frustrated working in an educational setting, in which health may be a secondary priority, but their expertise is usually highly valued. In addition, school nurses may become involved with other issues in the school, such as violence prevention, that extend beyond the traditional role of the nurse.

There are many positive reasons to work as a school nurse: School nurses generally do not work on weekends, many have contracts that give them the summer off, and the daily work schedule and holidays often coincide with those of the nurse's own school-age children, thus allowing a parent to be home with children during off-school hours. Finally, for most of those employed as school nurses, it is a wonderful and rewarding experience to work with children whose eagerness and innocence can often refresh the soul. It is an opportunity to protect and heal our future leaders, who may become the ones who will protect and heal the world.

## CORRECTIONS NURSING

Nurses who work within the criminal justice system—correctional facilities, prisons, jails, detention centers, substance abuse treatment programs—work with clients in a range of ages from juvenile to elderly, both male and female (ANA, 2007b). The facilities in which they work can hold just a few inmates or may house over 30,000 at one time (Office of Justice Programs [OJP], 2007). In 2006, there were 181,622 federal prisoners; 1,290,200 state prisoners; and 766,010 inmates in local jails, and the number of inmates is steadily rising (OJP, 2007). Tracking the number of nurses who work in correctional facilities is difficult. The last attempt, made in 2000, estimated the number to be 18,033 RNs (Spratley, Johnson, Sochalski, Fritz, & Spencer, 2002).

## PERSPECTIVES VOICES FROM THE COMMUNITY

A great aspect of being a *school nurse* is being able to work with many different people. I like being able to work with people who aren't necessarily sick, but can benefit from my help. Additionally, school nurses must become familiar with resources and people in the community and surrounding areas. By making friends and connections in multiple facilities, occupations, and the like, school nurses can involve local resources as well as specific individuals in improving the population. That is an essential aspect to recognize: nurses shouldn't be alone in working with the community, they should involve as many people as possible, because community members should be active in improving their own area.

Unfortunately, working as a school nurse takes a lot of effort and is time-consuming. Even with the work that has been done at the school, it makes me wonder just how long our interventions will last. Unlike working in a hospital, where results come in just a few days, school nurses must work tirelessly for long periods of time to see the fruits of their labors. Resources aren't as readily available as they are for other types of nursing. Being a school nurse requires learning how to get funding for projects. School nurses often don't have models to work from, as each situation may be unique. They must be innovative, resourceful, and dedicated in order to stick with a project long enough for it to be beneficial to the population.

My overall opinion in working as a community nurse the past few weeks has changed. Being a school nurse has been hard, but rewarding. I know several students in my semester who don't really consider community nursing to be truly nursing practice. I would beg to differ; school nursing is probably the epitome of what nursing was meant to be. It is focused on service and improving the health and well-being of the populace. While nursing in the early days mainly dealt with fixing problems and injuries after they happened, everyone knows that an ounce of prevention is worth a pound of cure. Therefore, school nurses are doing the work that should benefit people the most. However, because their focus is on prevention, they seem to get little recognition for their work, since they are saving lives before they are endangered, they are saving teeth before they fall out, they are saving families before they are lost. I believe their work is pivotal to the improvement of society.

*Neil P., School Nurse*

## HISTORY OF CORRECTIONS NURSING

Although the correctional system of prisons and jails has been around for a very long time, it historically provided minimal, if any, health care to inmates. Prison was a punishment, and the inmates were viewed as not deserving of care that was being paid for from public dollars. The situation did not change until 1976, when the U.S. Supreme

Court issued its decision regarding *Estelle v. Gamble*. The Supreme Court ruled that not providing medical services inflicted pain and denied inmates their Eighth Amendment rights. This decision led to major reforms in the corrections health system. Medical providers were hired and inmates' rights were established. These rights included (ANA, 2007b, p 2):

- ◆ The right to access care
- ◆ The right to professional judgment
- ◆ The right to care that is ordered
- ◆ The right to informed consent
- ◆ The right to refuse treatment
- ◆ The right to medical confidentiality

Although the correctional health system is relatively new, it is under intense pressure from the courts to ensure that adequate and humane care is provided (ANA, 2007b). Several lawsuits have occurred, and unsolved issues in the correctional health care setting continue to be highlighted. Some main issues regard the provision of appropriate and timely patient care for inmates. Ensuring that inmates' health needs are met—along with the growing number of inmates and the increasing intensity of their health concerns—has imposed a huge financial burden on systems that are already overtaxed. Funding for correctional health care derives from public tax dollars. Keeping equipment up-to-date and avoiding shortcuts can be challenging. In an attempt to decrease costs and save money, most states utilize managed care organizations to provide some services for inmates. Correctional Medical Services (CMA) is the largest provider of prison health care in the nation. Some states may also utilize local HMOs (Restum, 2005).

Many institutions have a house clinic, medical unit, or infirmary. However, these clinics do not have the capability to provide all the services inmates may need. For example, if imaging procedures, such as magnetic resonance (MRI) or computed tomography (CT) scans are needed, or specialty consultations required, inmates must go to other sources outside of the prison or jail. In these instances, most corrections' facilities use managed health care systems.

**Corrections nurses** work in onsite medical units housed in criminal justice facilities. These facilities can be local jails, or may be at state and federal prison. The staff members in these units focus on the individual, immediate, and ambulatory care needs of the patients. They also attend to emergency needs and may help manage chronic conditions. They often provide screenings and preventive services. Corrections nurses have the potential to assist inmates to obtain optimal health and thus save taxpayer dollars.

The challenge of corrections nursing is to maintain the fundamental nature of nursing in a challenging environment that is not primarily focused on health care, and to remain nonjudgmental toward clients (ANA, 2007b). Today, corrections nurses work with a variety of clients.

Demographically, inmates differ from the general population. First, inmates have all committed some type of crime, with nearly half (52%) being violent crimes (OJP, 2007). National statistics indicate a larger portion of Black (3,042 per 100,000) and Hispanic (1,261 per 100,000) male inmates than White male inmates (487 per 100,000). Although males are still the majority population (88.6%),

trends show an increase in the number of women in state or federal prisons (OJP, 2007). In addition, the inmate population is drawn disproportionately from lower socioeconomic backgrounds when compared with the general public. This increases their chances of having a long trajectory of poorer access to health care and treatment. Statistics show a greater disproportion of inmates who are chronically ill and have infectious diseases than the nonincarcerated population (ANA, 2007b).

## EDUCATION

The preferred educational level for corrections nurses is a bachelor's degree. The level of skill, judgment, and autonomy needed by nurses who work in corrections is supported and developed within baccalaureate education. Some institutions may require additional coursework in criminal justice, decision-making, assessment, and administrative skills. Master's level nurses (specifically NPs) also are working in corrections, providing primary health care to inmates. National certification, through the National Commission on Correctional Health Care (NCCHC) as a certified correctional health professional (CCHP) or the American Correctional Association (ACA) as a certified corrections nurse (CCN), is available (ANA, 2007b).

## FUNCTIONS OF CORRECTIONS NURSE

The prime responsibility of the corrections nurse is to restore and maintain the health of inmates by providing nursing care within correctional settings (ANA, 2007b). The work location does set corrections nurses apart as being the only nurses who enter their workplaces through metal detectors and grill gates and into a locked-down unit (FitzGerald, 2007). Yet, the knowledge and skill set of corrections nurses overlaps the knowledge and skill sets of many other nursing specialties.

Corrections nurses use public, community, and school health nursing skills, along with skills acquired from the emergency room, occupational health, mental health, orthopedics, and ambulatory care specialties. Like public, community, and school health nurses, corrections nurses are autonomous and must make decisions on their own. They track and screen for communicable diseases. They assist in setting up resources so that inmates who are released can continue getting medical treatment. They also educate inmates and promote healthful lifestyles among them.

Corrections nurses often work in clinic settings, assisting the health care provider in assessing medical situations. They review sick call requests to determine what and if any action needs to be taken, and by whom (nurse or physician). They may also oversee the medical unit beds that house patients who suffer from a variety of conditions, such as neurotrauma requiring critical care or kidney disease requiring dialysis. They provide nursing care for inmates with uncontrolled diabetes, those with pneumonia needing IV antibiotics, inmates with mental health issues, or those undergoing withdrawal (“detox”) from years of substance abuse (Laffan, 2005). They participate in administering medications, as many inmates receive a

variety of medications. In addition, by law, inmates must have a physical assessment within 14 days of admittance. Corrections nurses often perform these assessments. Corrections nurses also provide assessment and assistance in occupational safety issues.

Finally, corrections nurses are called upon to assist in medical emergencies, anywhere in the facility, such as helping with an accident in a woodshop or evaluating an inmate too sick to leave his cell. If inmates need to go to a hospital or appointment outside the correctional facility, a correctional officer generally accompanies them, not the nurse. With so many responsibilities and the uncertainty of new issues, it is imperative for corrections nurses to prioritize their day (see Display 30.6).

Several common health concerns face corrections nurses. These concerns are mental health, drug abuse, and communicable diseases. As the inmate population grows, an increase in elderly and female inmates creates additional health concerns for correctional nurses. The following sections briefly describe some of these concerns, along with examples of what corrections nurses may do to address the issue.

## Mental Health Issues

The increasing number of inmates over the years may be attributed to the deinstitutionalization of individuals with mental illness in the 1970s. For example, in 1970, 368,000

### PERSPECTIVES

#### VOICES FROM THE COMMUNITY

The prison is, in my opinion, a very good place to work. I believe that every student should experience nursing within corrections. I have worked floor nursing before, and working at the prison is much better. Although it can get crazy and chaotic from time to time, the atmosphere is much more laid back. Nurses at the prison seem to have a lot more autonomy than do nurses at other facilities or companies. The prison offers nurses a chance to experience many different skills. . . . You might not gain absolute proficiency in any one skill, but you will gain many skills, and you will become very good at many of them. The nice thing is that nurses come from many different backgrounds, and so they can and will certainly help you and teach you what they know to help with your own skill base. I guarantee that if you work at the prison, you will get to see and experience things that people in normal society will never get the opportunity to see. Come to the prison, and you will get to be a medical nurse, a psych nurse, a triage nurse, an orthopedic nurse, and you can get to do the medical/psychiatric intake screenings for all the new or parole violation inmates who come to the prison on a daily basis. There is probably more, but certainly keep your minds and options open for a great and secure career.

*Travis H., correctional nurse*

## DISPLAY 30.6

## A DAY IN THE LIFE OF A CORRECTIONAL NURSE

A day in my life depends on whether or not I am working at the infirmary or on the forensic unit. I will begin with the prison's infirmary.

I work 12-hour day shifts, so my day begins at 0600 and ends at 1830. As on any nursing unit or floor, I take report from the night shift charge RN. Within our infirmary, we have both a medical side and a psychiatric side where report is given. Following report, I decide with the other nurses whether or not I am going to be responsible for the medical or psychiatric patients, or the walk-ins (acute/emergency care patients). If I, for instance, take the medical side for the day, I will set up the medications and then wait for the other nurse to set up his or her medications for the psychiatric in-patients. We usually do what we call "pill line" together. Following pill line, I return to the nursing station and do my charting. Currently, we have a quadriplegic and paraplegic on our medical side who require a lot of personal care. We also have recently had several patients with MRSA (methicillin-resistant *Staphylococcus aureus*) requiring fairly extensive dressing/packing changes along with IV antibiotics. So with this in mind, following my charting, I will have officers escort the MRSA patients out to a trauma bed in order for me to perform the dressing change and/or administration of IV antibiotics (usually Vancomycin) that take 1 to 2 hours to complete. Following care, these inmates return to their medical cells, and I do my usual charting. The quadriplegic and paraplegic inmates have call lights, so I have to attend to their needs when called. This may consist of feedings, diaper changes, and repositioning. Depending on the day, I will administer showers or bed baths for them. We also currently have an inmate with Parkinson's disease and comorbid psychiatric disorder and neuropathy, who also requires a great deal of care. These are the types of inmates for whom we try to get compassionate releases, so that they can be sent out to nursing homes. Unfortunately, that has not happened yet. I say that because we are not staffed for this kind of care. With this kind of patient care, I tend to remain quite busy. Fortunately for me, the other nurses are very kind and help me along the way. Usually the nurse who does the psychiatric side does not have quite the "hands-on" patient care, and is usually very happy to help. In fact, we all help each other with our respective areas. Even though I am responsible for the medical in-patients, I still might take a walk-in or two and do some of the "q30-minute checks" on the psychiatric side. At the end of the day, I make sure that all my charting is done and then go on my way. There is

quite a bit more actually involved, but it is difficult to explain all the situations that may develop.

On the forensic unit, I show up once again at 0600 and take report from the night RN. On this unit I, along with our one LPN, am responsible for passing all the medications and performing all the blood sugars and insulin administrations for the diabetics in the morning, noon, and afternoon. I have to perform an extensive mental health note on all the inmates in the maximum-security unit of this building, which consists of 10 to 12 inmates on average. I then have to do a less extensive mental health nursing note on all the inmates in our B-section bottom tier, which consists of approximately 20 to 24 inmates. Following all my charting, I enter in all the diabetic care and scan all the medications passed on our electronic MAR (medication administration record). Following all of these duties, I usually make sure that all the medications are current and check for any expired critical medications that might need reordering. I may have to do some blood draws and give some shots for those inmates on forced medications. I consider this unit more of a nursing management unit rather than a hands-on patient care unit.

I decided to work at the prison for a number of reasons. First, I began my nursing career at the state hospital and once I got sucked into the state system, I felt like working for the state throughout my career would be a very beneficial decision for me and for my family. The state offers great benefits, security, and a very good retirement. In the process of receiving my RN degree, I worked with a preceptor at the prison and enjoyed the opportunities that it offered. I really enjoyed the staff and the experience that they brought to the environment. Second, the environment was one in which I found a great deal of interest. During my clinical rotations at the prison, I was exposed to a world that many other people don't have the opportunity to experience. The prison environment certainly is not for everyone, but I felt it was for me. Once I received my RN license, I transferred from the state hospital to the prison, along with all my same benefits. Third, I love mental health nursing and that is what I am currently specializing in at the university. I am in my second year in the psych APRN program. It may sound strange that I just didn't stay at the state hospital, but I really wanted to gain the variety of medical experience the prison had to offer—on top of the mental health experience I already had. Once I graduate with my psych APRN, I plan to stay and retire after 20 years—which will only be about 12 more years—then teach perhaps until I fully retire and golf!

*Travis H, Corrections Nurse*

beds were available for mental health services, but by 1992 only 84,000 remained (ANA, 2007b). Many people suffering from mental illness were left without assistance or support. As a result, they became homeless and, in many cases, committed crimes.

Mental health is a major concern in correctional facilities. Mental health problems affect inmates three to five

times more than they do people in the general population (Heines, 2005). At least half of all inmates have some type of mental health problem (James & Glaze, 2006). Those who suffer from mental illness are three times as likely to have been physically or sexually abused in their lifetime, and 4.5% of state and federal inmates experience at least one incident of sexual victimization by staff or other inmates

while in prison (Beck & Harrison, 2007). At a state level, more than 70% of females and 55% of males in state prisons had some type of mental illness, and those with mental illness tended to have longer sentences (James & Glaze, 2006). That 74% of state inmates and 76% of local inmates with mental health concerns also suffer from substance abuse complicates the matter. Mental illness also impacts suicide rates. In 2002, the suicide rate in local jails (47 per 100,000) was three times higher than the rate in state prisons (Mumola, 2005). Inmates who committed violent crimes were twice as likely to commit suicide as those convicted of nonviolent crimes.

Corrections nurses provide a good deal of mental health nursing care and assist in identifying undiagnosed conditions. James and Glaze (2006) found that one in every three state inmates and one in every six local jail inmates indicated that he had received mental health treatment upon admission. A post-arrest diversion program, in which detainees can visit a psychiatrist within 24 hours of entering jail, has reduced recidivism from 70% to 19%, saving \$2.5 million per year (Heines, 2005). A pre-arrest diversion program that trains police officers to identify persons with mental illness has also been successful in assisting with treatment and avoiding arrest.

Correctional nurses assist in multiple medication administrations per day to ensure that inmates receive the medications needed for their mental illnesses. They can also provide counseling regarding medication usage and assist inmates in understanding the side effects of their medication, which for some are many. Corrections nurses advocate for medication changes when they note severe side effects or a change in the mental status of inmates. Nurses can facilitate setting up medication support groups to allow inmates an opportunity to discuss concerns regarding their medications. They also can assist inmates in understanding the importance of taking their medication.

As inmates prepare to leave the institution, corrections nurses assist in finding outpatient mental health clinics and other resources that will provide support and further treatment for the inmate. Finally, corrections nurses can provide education and training to other corrections workers regarding signs and symptoms of mental illness and the impact mental health has on decision-making and the general health of a person.

## Drug Abuse

Drug abuse by inmates is very high. Mumola and Karberg (2007) estimate that half of all federal prison inmates used drugs, which is a 5% increase from 1997. Female drug use increased by 11% during this same period. All types of drug use increased, except crack cocaine, which declined from 25% in 1997 to 21% in 2004. Drug treatment programs are essential in correctional facilities. Corrections nurses can assist in identifying those in need of the treatment and assessing their willingness to participate. Of the drug users in prison, 40% of state and 49% of federal inmates had participated in treatment programs (Mumola & Karberg, 2007). Corrections nurses also provide nursing care as patients withdraw from substances while in prison. Withdrawal can cause life-threatening symptoms that need immediate medical attention.

## EVIDENCE-BASED PRACTICE

### Corrections Nursing

Smith, Gates, and Foxcroft (2006) conducted a literature review to determine if therapeutic communities (TCs) effectively change behavior better than other substance abuse programs. TCs are commonly used in the prison setting as treatment for drug users. The authors searched numerous databases including MEDLINE, Psycinfo, CINAHL, SIGLE, EMBASE, and the Cochrane Central Register of Controlled Trials. Selection criteria for the review included randomly controlled studies (considered the gold standard of research) that compared TCs with other treatment, no treatments, or other types of TC. Seven studies were found to meet the criteria. The studies were difficult to compare due to the diverse populations being compared (TC versus community residence programs; residential versus day TC programs; standard TC versus abbreviated TC; TCs versus no treatment; TC versus mental health treatment). Of these seven studies only two were conducted in a prison setting. The results of both studies indicate that those who participated in TCs had fewer reincarcerations when compared with the comparison group (no treatment in one study and mental health treatment in the other study). However, Smith and colleagues concluded that minimal evidence exists to support TCs over other types of residential treatment programs. However, methodology and minimal numbers of studies contributed to the lack of comparable evidence.

### Nursing Implications

It is important for nurses in any setting to know if the treatment they provide is based on evidence and is effective. It is inappropriate and unprofessional for nurses to perform activities and treatment just because it traditionally has always been done. It is also important for nurses to evaluate current treatment programs to ensure they are the most effective treatment available.

Smith, L.A., Gates, S., & Foxcroft, D. (2006). Therapeutic communities for substance related disorder. *Cochrane Database Systems Review*, 1, CD005338.

In addition, corrections nurses can organize and provide support groups to assist inmates in staying sober and drug-free. They can advocate for the inclusion of Alcoholics Anonymous, Narcotic Anonymous, and Al-Anon services in the correctional facility. Counseling can be offered to assist inmates as they leave the facility, so that they do not return to prior bad habits if and when they return to areas where drug and alcohol use is rampant (Restum, 2005). Returning to this environment increases their chances of returning to substance abuse, and inmates leaving prisons or jails need to be connected to outside resources.

<b>LEVELS OF PREVENTION PYRAMID</b>

<b>Primary Prevention</b>		
<b>Health Promotion &amp; Education</b>	<b>Health Protection</b>	
<ul style="list-style-type: none"> <li>Teach inmates how STDs are transmitted and what can be done to stop transmission (condoms, other preventive measures)</li> <li>Teach signs and symptoms of commonly occurring STDs</li> <li>Teach that gonorrhea and chlamydia are often asymptomatic, and so routine screening is important for individuals at risk</li> </ul>		

### Communicable Disease

Several communicable diseases are of great concern in the correctional community. These include STDs including HIV/AIDS, TB, and hepatitis C. The concern of communicable disease is not only for the health of the inmate with the disease, but the susceptibility of all inmates, and ultimately the general public (if the inmate is released while still infected). Increased rates of these diseases are due to high-risk behaviors and increased rates of abusive behaviors, including rape (Restum, 2005).

A hallmark study, conducted by the RAND Corporation, indicated that inmates were four times as likely to have active TB, nine to ten times as likely to have hepatitis C, and five times as likely to be infected with HIV as the general population (Davis & Pacchiana, 2003). Data from the end of 2005 indicated that 18,953 male and 1,935 female inmates in state prisons have HIV/AIDS, and 176 state inmates died from AIDS (Maruschak, 2007). On a positive note, the rates of HIV infection have been steadily declining among inmates since 1999. The number of inmates suffering from

hepatitis C varies, but is estimated to be between 20% and 40% (Marcalino, Dhawan, & Rich, 2005). Inmates are at risk for hepatitis C because of the heavy drug use among prisoners.

Tuberculosis is widespread among prisoners and rates are much higher than in the general population. In 2003, TB rates of federal prison inmates were 6.9 times greater than the rates in the general public for a variety of reasons (MacNeil, Lobato, & Moore, 2005). Because many inmates are homeless and abuse alcohol and/or drugs, they are more susceptible to TB; to compound the problem, the closeness of living conditions in jails and prisons facilitates the quick spread of TB (Restum, 2005).

Correctional nurses must track rates of communicable diseases and provide education regarding the spread and treatment of those diseases. They must provide data on the number of cases of reportable diseases to the state health department. Corrections nurses can provide preventative care by offering immunizations to inmates. In addition, they can provide the necessary treatment for TB, STDs, and other diseases, and can assist in advocating for

measures to decrease the spread of disease within correctional facilities.

Corrections nurses can assist institutions by providing initial screenings upon arrival of inmates and periodic screening for certain diseases. Beck and Maruschak (2004) found that 66% of state facilities had policies for regular hepatitis C screenings. However, these screenings should not necessarily be for only those high at risk, such as drug abusers. Marcalino, Dhawan, and Rich (2005) found 66% of those who tested positive for hepatitis C did not report drug use. Screening based on risk may miss many of these inmates. Although female inmates are traditionally screened for *Chlamydia*, Tebb and colleagues (2005) found that a successful screening program tests for *Chlamydia* among adolescent males as well.

Corrections nurses can also evaluate inmates for complications, such as retinal hemorrhage and liver problems, especially in those suffering from hepatitis C (Heines, 2005). For chronic communicable diseases, such as HIV/AIDS, corrections nurses can facilitate and organize peer educator groups. These have been found to be successful in educating inmates on HIV/AIDS, substance abuse, and low self-esteem (Heines, 2005).

Successful programs also exist to assist inmates as they prepare for release. Corrections nurses can facilitate programs that empower inmates not to return to behaviors that increase their chance of contracting HIV (Myers, Zack, Kramer, Gerdner, Rucobo, & Costa-Taylor, 2005). Corrections nurses can also identify resources for inmates suffering from TB, so that they can continue their medication and treatment upon their release.

### Future Trends

Due to advances in health care, longer prison terms, and more restrictive policies, inmates are older, sicker, and remain in prison longer than they did even 20 years ago. And historically, inmates have not taken good care of themselves. Hence, a 50-year-old inmate may have the health of a typical 65-year-old in the general public (ANA, 2007b). This surge in the inmate population is creating a lack of resources and beds for the aging inmate population.

Corrections nurses can increase efforts to empower inmates to take control of their health and can provide them with resources for health care access outside the prison, so that inmates will continue their care upon release. Corrections nurses can also be advocates and lobby state and federal legislatures to allocate funding for the additional resources needed within the prison system.

The female inmate population is also increasing. In addition to women's reproductive health issues, females tend to have higher rates of diabetes, HIV, STDs, mental illness, drug abuse, and emotional issues (ANA, 2007b). One study indicated that female inmates were also more likely to develop cervical cancer due to a lack of cancer screenings when in prison (Magee, Hult, Turalba, & McMillan, 2005). Corrections nurses can begin providing routine cervical and breast cancer screenings for female inmates. They can also provide counseling and emotional support.

Chronic disease, such as diabetes, heart disease, and asthma, are also increasing in the incarcerated population. Corrections nurses can facilitate chronic disease clinics to educate and empower inmates to better control their chronic

conditions. To this end, corrections nurses need to conduct thorough family health histories, as many health conditions tend to have a genetic component, and employ screenings to identify conditions as soon as possible, so that early intervention can decrease complications and stop disease progression. They can follow-up by promoting better nutrition and exercise habits, and medication management.

### CORRECTIONS NURSING CAREERS

Corrections nurses must have good mental health and assessment skills. They must be able to communicate well and be strong nursing advocates and strong advocates for their clients. They work in an intense environment where their safety could be threatened, and they must deal with clients who may be noncompliant, combative, and manipulative. Corrections nurses must also be very flexible and knowledgeable about a variety of nursing specialties.

Salaries depend upon the state, although they tend to be higher salaries than in other nursing fields. Moreover, corrections nurses usually receive extensive employee benefits and insurance packages as government employees. Despite this, nursing shortages still occur (California Department of Personnel Administration, 2005). Corrections nurses have the ability to see amazing and awe-inspiring recoveries from illnesses and injuries because they work with the same patients for a longer time than hospital-based nurses. Correctional nursing provides an opportunity to work with a vulnerable population and practice the true art and science of nursing. You use every nursing skill you have learned and advocate for a population that is in need. It is a challenging, rewarding career.

### Summary

Nurses who work in public settings are critical to the health and well-being of their communities. Public health nursing interventions are essential in keeping our nation healthy. They may not be as visible as hospital nurses, who interact with each patient in the hospital, because PHNs often work from behind the scenes. Those who come in contact with them directly know of their worth, but much of the general population remains unaware of the role and the need for PHNs. Public health nurses deal with a number of issues including communicable diseases, chronic diseases, injuries, STDs, and substance abuse. They work with all ages, ethnicities, socioeconomic groups, and populations. Their emphasis is on health prevention and promotion.

School nurses work with school populations including students, their families and the school staff. They provide individual care and are the bridge between medical providers and schools. School nurses provide health care services, such as direct nursing care, first aid, and specialized health care for children with special needs. They also provide health protection measures such as immunizations and environmental assessments. Finally, school nurses provide health promotion activities including education, health screenings, immunizations, and staff wellness programs. School-based clinics are another means of providing care for the school population. Children and adolescents are important population groups for community health nurses because their physical and emotional health is vital to the future of society and because they require guidance and direction.

Corrections nurses work with inmates in federal, state, or local facilities, including drug treatment and juvenile detention centers. They provide individual care in facility clinics and infirmaries, while also identifying and developing programs to address major health concerns of inmates, including mental illness, drug and alcohol abuse, and communicable diseases. The inmate population is growing older, staying longer, and suffering more from chronic disease. This, along with an increase in female inmates, brings additional challenges for corrections nurses.

All three specialty areas impact the health of our communities. Due to the high level of nursing knowledge, communication skills, autonomy, and leadership needed for these nursing specialties, entry level should be at least a baccalaureate degree. Community nurses who work in public settings provide a valuable service needed to keep our nation healthy. ■

### ACTIVITIES TO PROMOTE CRITICAL THINKING

1. As a government employee, a PHN must be careful not to lobby as part of her work duties. However, knowing the greatest health concerns of the population, how can PHNs serve as advocates for their clients (i.e., population) while remaining politically neutral?
2. What is the major cause of death among adolescents and children? What community-wide interventions could be initiated to prevent these deaths? Select one intervention and describe how you and a group of community health professionals might develop this preventive measure in your community. (Think outside the school setting.)
3. As a correctional nurse, you deal with people from a variety of backgrounds, social classes, and past crimes. How can your values and attitudes toward criminal activity impact your treatment of inmates? Does social class, race, age, or gender make any difference in how you feel about them?
4. One of the concerns expressed by correctional facility nurses is the antisocial behavior and manipulativeness of inmates, along with potential violence. How can a nurse working in a state prison effectively determine the health care needs of inmates?
5. Discuss possible methods of doing nutritional assessments in school-age children. What programs could be instituted to encourage healthier diets and increased exercise? What other factors might need to be considered? How could you, as a school nurse, work with schools and parents to increase physical activity and improve nutrition for school-age children and adolescents?
6. Describe possible benefits of school-based health centers (SBHCs). What are the most common mis-

perceptions? What are frequent barriers to starting SBHCs? What steps can community health nurses take to promote community awareness and facilitate development of SBHCs in local schools?

7. Many of the chronic diseases plaguing society are attributable to people's behavior (such as eating habits, lack of exercise, tobacco use, etc.). Within your clinical group, debate the pros and cons of passing laws that restrict a person's right to behave as they wish, even if it impacts the overall population (increasing health care costs for all).
8. Most schools require that children entering school show proof of being fully immunized for a variety of communicable diseases. With a partner, discuss what would happen if schools no longer had this requirement. How else can immunizations be reinforced in the public?
9. Do you think that schools should require children with behavioral problems to be evaluated and required to take medication? Should taking that medication be a condition of their continuing enrollment? Who should pay for that evaluation and medication?
10. Many prisoners suffer from mental illness. List types of programs and/or support groups that the nurse could provide for these inmates. What about inmates not formally diagnosed with a mental illness?
11. Should inmates be required to pay for their health care (via work programs or other options) while in prison? Would it make them more accountable?

# Private Settings for Community Health Nursing

## LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- ◆ State the historical roots of nurse-managed health centers.
- ◆ Identify the distinctiveness of various nurse-managed health center models.
- ◆ Describe funding sources for nurse-managed health centers.
- ◆ Articulate the importance of sustainability for nurse-managed health centers.
- ◆ State at least two roles of nurses in nurse-managed health centers.
- ◆ Describe the evolution of faith community nursing.
- ◆ Describe and differentiate among the roles of the faith community nurse.
- ◆ Identify the steps for establishing a practice as a faith community nurse.
- ◆ Describe the role of the occupational health nurse and other members of the occupational health team in protecting and promoting workers' health and safety.

*“To insure good health: eat lightly, breathe deeply, live moderately, cultivate cheerfulness, and maintain an interest in life.”*

—William Londen

## KEY TERMS

Best practices  
 Comprehensive primary care center  
 Congregational nurse  
 Contracts  
 Faith community  
 Faith community nurse  
 Federally qualified health center (FQHC)  
 Grant  
 Health ministry nurse  
 National Nursing Centers Consortium (NNCC)  
 Nurse-managed health center (NMHC)  
 Occupational and environmental health nurse  
 Outcomes  
 Parish nurses  
 Request for proposal (RFP)  
 Safety-net provider  
 Sustainability  
 Wellness center

 *Healthy People 2010: Understanding and Improving Health* (U.S. Department of Health and Human Services [USDHHS], 2000) provided clear objectives for promoting health and preventing disease for the past decade. The next 10 years will see unprecedented changes and challenges in the nation's health. As we ponder what those changes will be, the preparation of *Healthy People: The Road Ahead* is in the beginning stages of development. This initiative will “reflect assessments of major risks to health and wellness, changing public health priorities, and emerging issues related to our nation's health preparedness and prevention” (USDHHS, 2008). With this new initiative, there will be ever increasing opportunities for community health nurses to make a difference in their communities. This chapter examines three distinct areas of practice in the community as potential options for your own professional road ahead.

Chapter 30 discussed a wide variety of practice opportunities in the public sector. This chapter will examine three unique private sector roles and practice environments available in the United States and in many other countries: nurse-managed health centers, faith community nursing, and occupational and environmental health nursing. Nurse-managed centers offer the opportunity for more autonomous practice and present excellent learning venues for nursing students. Many such centers are connected to academic nursing programs. Faith community nursing, begun in the mid-1980s, has gained increasing attention in many religious communities. Although the positions are frequently held by volunteers, there are increasing opportunities for paid employment. Occupational and environmental health is a specialty health practice that focuses on the health and well-being of the working population, including both paid and unpaid laborers, and therefore covers most of the country's able adults. This role provides the vital link between nursing and sound business practices. Each of these areas of practice offers community health nurses an avenue to address health disparities in their communities, increase years of healthy life, and provide holistic, client-centered care to meet the current and emerging health needs in their communities, as indicated in *Healthy People 2010*.

## NURSE-MANAGED HEALTH CENTERS

Nursing centers, more recently termed **nurse-managed health centers (NMHC)**, are organizations that give clients access to professional nursing services, and are administered by nurses in partnership with the community in which they serve. In the mid-1980s, The American Nurses Association (ANA) Nursing Centers Task Force developed a definition of nursing centers that is still applicable today (Aydelotte, et al., 1987). Display 31.1 shows a modified version of that original definition. Although all NMHCs share the core elements of the ANA definition, they vary in their practice models. Services offered at NMHCs range from health promotion and wellness to conventional primary care (Torrissi & Hansen-Turton, 2005) (see Fig. 31.1).

Nurse-managed health centers have emerged as vital “safety net” health care providers in America's health care delivery system (Hansen-Turton & Miller, 2006). A “**safety-net provider**” is defined as one that, by mandate or mission, organizes and delivers a significant level of health care and other health-related services to the uninsured, Medicaid

### DISPLAY 31.1

### DEFINITION OF NURSING CENTER

Nursing centers—sometimes referred to as community nursing organizations, nurse-managed centers, nursing clinics, and community-nurse-managed health centers—are organizations that give clients and communities direct access to professional nursing services. Professional nurses in these centers diagnose and treat human responses to actual and potential health problems, and promote health and optimal functioning among target populations and communities. The services provided in these centers are holistic, client-centered, and affordable. Overall accountability and responsibility remain with the nurse executive/director. Nurse-managed health centers are not limited to any particular organizational configuration. Nurse-managed health centers can be free-standing businesses or may be affiliated with universities or other service institutions, such as home health agencies and hospitals. The primary characteristic of the organization is responsiveness to the health needs of populations. The nurse is responsible for all patient care and business operations.

Source: Aydelotte, M.K., Barger, S.E., Branstetter, E., et al. (1987). *The nursing center: Concept and design*. Kansas City, MO: American Nurses Association; and National Nursing Center Consortium. (2008). Modified version of the ANA 1987 *Nursing Centers Task Force* definition.

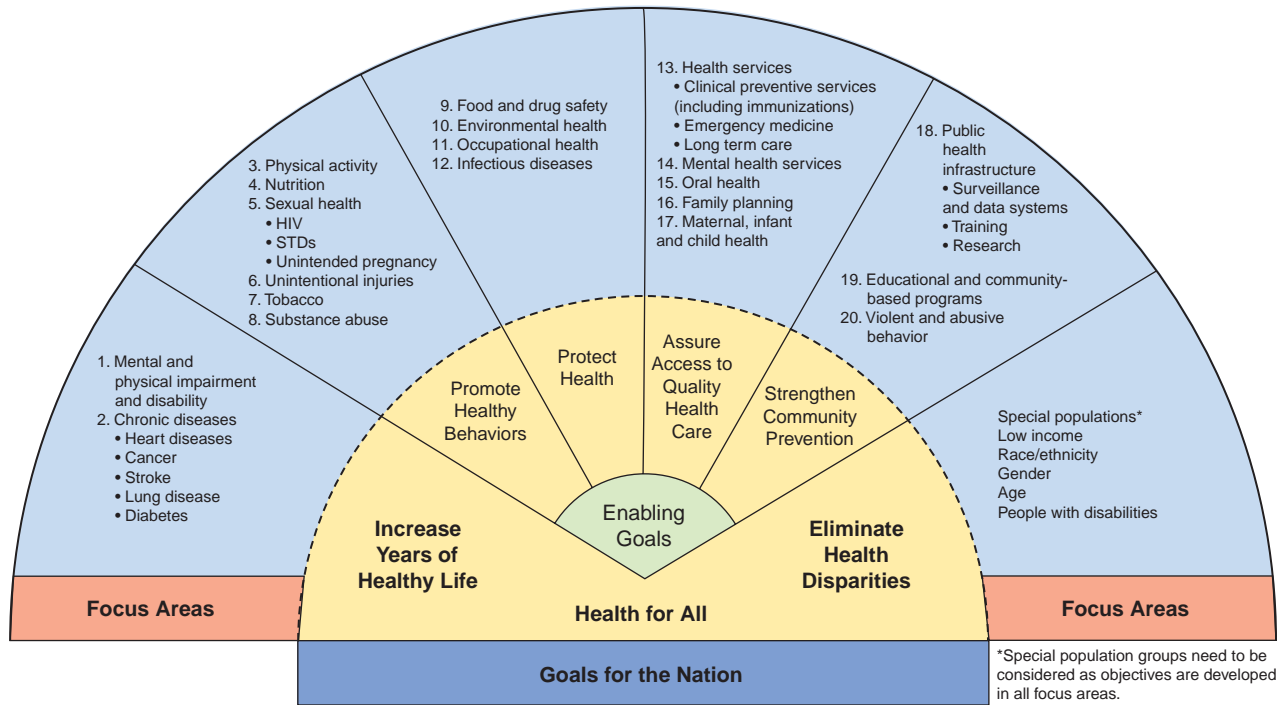

recipients, and other vulnerable populations (Health Resources and Services Administration, 2005).

Located in or near health professional shortage areas and medically underserved areas in both urban and rural communities, NMHCs are found in convenient sites where people live, work, learn, and worship. Oversight is provided by a nurse executive with an advanced degree. Traditionally, targets of service have been those who are least likely to be engaged in ongoing health care services for themselves and their family members. Currently, NMHCs serve both uninsured and underinsured population groups of all age.

NMHCs differ from other public health agencies and tertiary medical care facilities. Although some services overlap, the distinctiveness of NMHCs is found in the community orientation of the nurse-managed centers. This model is depicted by Lundeen's comprehensive community based primary health care model (Lundeen, 2005), in which NMHCs are referred to as *community nursing centers* and are the central figure in the model of health care utilized at the University of Wisconsin, Milwaukee (see Fig. 31.2).

## Healthy People 2010

The publication of *Healthy People: The Surgeon General's Report on Health Promotion and Disease Prevention* (U.S. Department of Health, Education & Welfare, 1979) focused attention on the nation's health promotion and disease prevention activities. The current publication, *Healthy People 2010*, has two main goals: to increase quality of life and to eliminate health disparities (USDHHS, 2000). “Achieving

**FIGURE 31.1** Vision of 2010: Healthy people in healthy communities. From U.S. Department of Health and Human Services, Office of Disease Prevention and Health Promotion. (1997). *Developing objectives for Healthy People 2010*. Washington, DC: U.S. Printing Office, p. 14.

*Healthy People 2010* goals requires a long-term commitment to community collaboration and powerful, productive partnerships among many diverse people and groups” (Kinsey & Buchanan, 2008, p. 414). Nurse-managed health centers are an excellent venue to meet the goals of *Healthy People 2010*.

### History of the Nurse-managed Model

Although today’s NMHCs trace their roots to changes in national health care laws begun in the mid-1960s, the nursing model of holistic care that focuses on vulnerable populations

and integrates primary care and public health dates back to the 19th century. Florence Nightingale’s passion for at-risk populations, as well as her success related to health reform, provides a model for NMHCs today. Lillian Wald, who founded the Henry Street Settlement, and Margaret Sanger, who initiated the first family planning clinic, are two examples of nurses providing holistic care to vulnerable populations (see Chapter 2). These nurse activists sought to resolve the 20th-century problems caused by immigration, urbanization, and industrialization in the United States (Beidler, 2005) (see From the Case Files I).

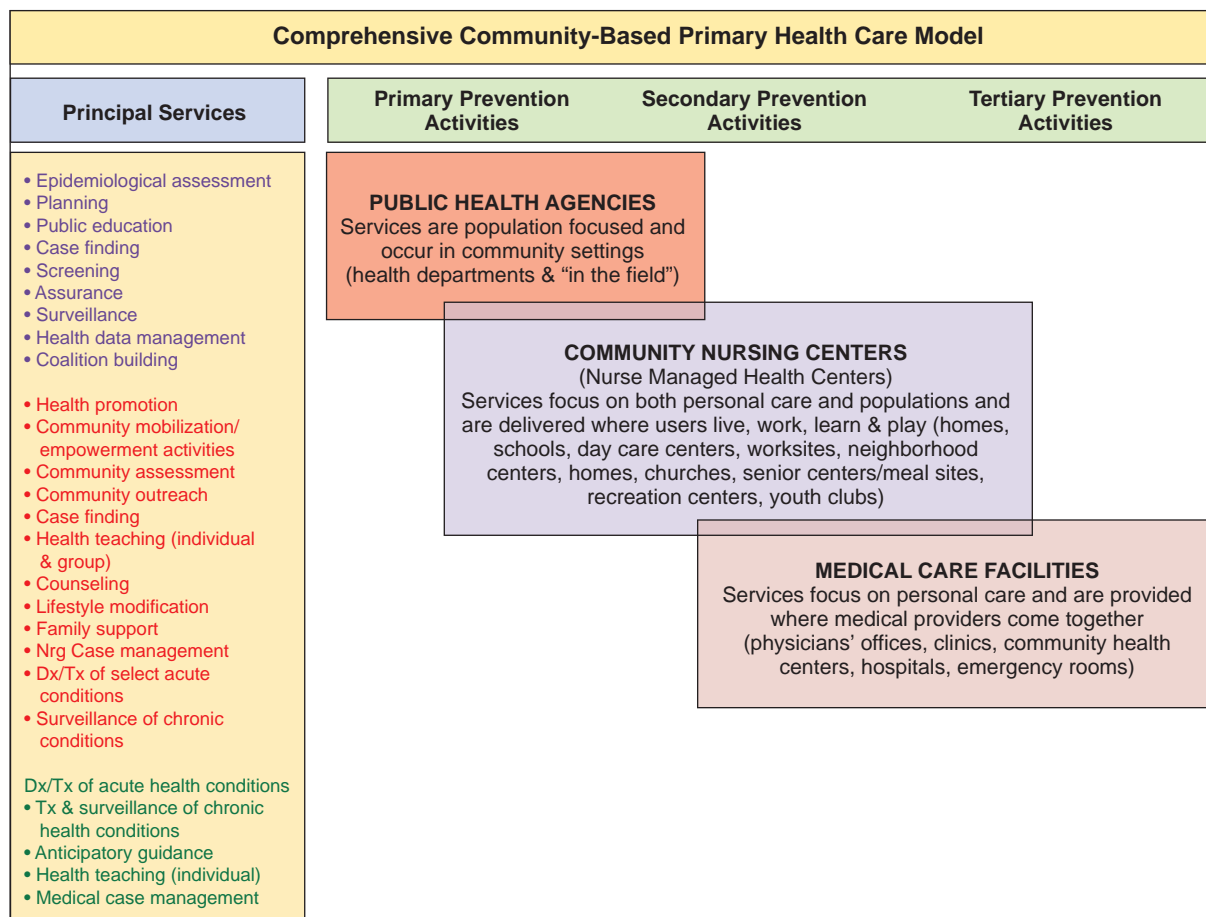

## From the Case Files I

### Caring for Vulnerable Populations at an NMHC

Ms. Jones is a 22-year-old mother of three small children who recently moved to Philadelphia. She brings her oldest child, age 6, to a local comprehensive primary care NMHC for school immunizations. During the course of the history and physical examination, the nurse-practitioner becomes aware that this mother also has two younger children, aged 2 and 3, at home. The family rents a small apartment in housing that was built in the mid-1950s. Ms. Jones reports that her mother (the children’s grandmother) also resides with them. The grandmother is the child care provider while Ms. Jones works at a local hair salon. The grandmother smokes 1.5 to 2 packages of cigarettes daily; Ms. Jones reports that she is a nonsmoker. Upon further questioning, the nurse practitioner learns that the 3-year-old child has a chronic cough and occasional wheezing. Ms. Jones also confides to the nurse-practitioner that she recently missed two menstrual periods and is sexually active.

1. What are some possible health care needs of Ms. Jones? Her mother?
2. What screenings should be performed on Ms. Jones’ children?
3. What other interdisciplinary team members should be involved in this family’s health care?
4. What are some possible referrals that would benefit this family?

**FIGURE 31.2** Comprehensive Community-Based Primary Health Care Model. From Lundeen, S. (2005). *Lundeen's comprehensive community-based primary health care model*. Milwaukee, WI: UW, Milwaukee College of Nursing, with permission.

Since the late 1970s, in conjunction with the development of educational programs for nurse practitioners (NPs), faculties in schools of nursing have established nurse-managed health centers. Linkages have provided clinical sites for educating nurses at all levels and settings, as well as for faculty practice opportunities (Hansen-Turton & Miller, 2006). For example, one urban academic nursing center, La Salle Neighborhood Nursing Center in Philadelphia, Pennsylvania, involves students and faculty in primary and secondary prevention services to the community. Health fairs, immunization outreach and administration, after-school programs, home visiting, health literacy programs, case management for migrant workers, outreach to the homeless, and cable TV health videos are some of the initiatives that undergraduate and graduate students have been engaged in for almost two decades (Miller, 2007).

Today, NMHCs embody the traditional role of nurses, who have historically provided compassionate health care focusing on the special needs of society's most vulnerable: the poor, the aged, those experiencing social injustice, and those living in geographic areas with limited or no access to adequate health care facilities (National Nursing Centers Consortium, 2007). Unlike traditional health care venues that provide primary care and public health services, NMHCs include community participation in program devel-

opment, implementation, and evaluation (Anderko, Bartz, & Lundeen, 2005).

### Nursing Center Models

Several types of nursing centers exist; each reflects the community in which it is located and the particular services it offers (Gerrity & Kinsey, 1999). Academic-based nursing centers, which are located within schools of nursing, are common. In addition, hospital-based and free standing community-based NMHCs offer a mixture of primary care, health promotion, and disease prevention services (Hansen-Turton & Miller, 2006).

Hansen-Turton (2003, p. 150) states that NMHCs meet all of the requirements for **federally qualified health centers (FQHC)**, as defined in Section 330 of the Public Health Service Act. This is an especially important designation, as it enables centers to qualify for many funding sources vital to service provision that would not be available otherwise. To qualify, the centers must:

- ◆ Be located in a medically underserved area or serve a medically underserved population
- ◆ Have a nonprofit, tax-exempt, or public status
- ◆ Have a board of directors, a majority of whom must be consumers of the center's health services

## DISPLAY 31.2

## NURSE-MANAGED HEALTH CENTER MODELS

### Center Types:

- **Wellness Center:** Provides public health as well as health promotion and disease prevention programs
- **Comprehensive Primary Care Center:** Provides traditional primary care and public health programs
- **Specialty Nursing Centers:** Provide programs that target specific health conditions such as HIV or diabetes

### Organizational Structure:

- **Academic Nursing Center:** Located within a school of nursing
- **Free-standing Center:** Independent center with its own governing board
- **Subsidiary:** Part of a larger health care system, such as home health agencies, community centers, schools, and other venues
- **Affiliated Center:** Legal partnership with a health care or human services organization

Adapted from Kinsey, K., & Buchanan, M. (2008). The nursing center: A model for nursing practice in the community. In M. Stanhope & J. Lancaster, *Public health nursing: Population-centered health care in the community* (7th ed., p. 412). St. Louis, MO: Mosby, with permission.

- ◆ Provide culturally competent, comprehensive primary care services to all age groups
- ◆ Offer a sliding scale fee, and provide services regardless of ability to pay

The variety of nursing center models currently being used and their organizational structures demonstrate the diversity of contemporary NMHCs. Display 31.2 describes the three major types of centers (wellness, comprehensive primary care, and specialty nursing centers), along with the various organizational structures that influence their delivery models.

## Funding for Nurse-managed Health Centers

As NMHCs vary in their models, so too do their methods of cost reimbursement, encompassing fee for service, sliding fees, grant support, third-party payments, and the cost-based reimbursement available to FQHCs (Torrise & Hansen-Turton, 2005). Most nursing centers' operational and salary budgets entail a combination of these funding sources.

In the **comprehensive primary care centers**, advanced practice nurses (APNs) provide primary care services. Such services are usually reimbursable under Medicaid and managed care medical insurance plans. In the **wellness centers**, public health nurses and other interdisciplinary team members provide a range of primary and secondary prevention strategies. These services are usually not reimbursed by insurance plans, but are often covered by grants and contracts (Hansen-Turton & Miller, 2006). In addition, foundation support and private donations from community organizations and members provide fiscal support for NMHC initiatives.

It is important to distinguish between grants and contracts as funding sources for NMHCs. Funding organizations usually release guidelines regarding what initiatives they will fund. **Grant** guidelines are frequently termed **requests for proposal**, or **RFP**. Grants can be a source of initial start up funding as well as support for ongoing activities (Kinsey & Buchanan, 2008). A proposal submitted by the NMHC to the funding organization describes how the center would meet the goals and objectives set by the funding organization. **Outcomes**, or the end results at a specific point in time, are becoming increasingly important to funders. Nurse-managed health centers must include measures to collect outcome data and project what outcomes will occur in their submitted proposals. Additionally, funders tend to view initiatives that include interagency collaboration in a more favorable manner. Partnering with one or more NMHCs or other community-based organizations is a strategy that gives additional strength to the proposal when it is under review by the funding organization.

Contracts are another source of funding for NMHCs. **Contracts** are awards establishing a binding legal procurement relationship between a funder and a recipient, obligating the receiver to furnish a product or service defined in detail by the funder (National Institutes of Health, 2007). A contract has specific goals, objectives, and activities as well as a time-frame within which the activities are to be implemented and evaluated. Contracts are awarded on a noncompetitive basis and often are renewable when goals and objectives are met.

Managing the various funding streams that feed the personnel and operations budgets of a NMHC is an arduous task. To ensure that budgetary dollars are spent in the manner specified by the funding organization, meticulous record keeping and itemization of spending is another undertaking that the nurse executive or an operations coordinator of the NMHC must carry out. It is imperative that key personnel from NMHCs maintain precise records and submit accurate quarterly, semi-annual, or annual reports as specified in the grant or contract award.

## Sustainability of Nurse-managed Health Centers

**Sustainability**, or the ability to carry on services and health promotion activities when funding is no longer available, is one of the main challenges of NMHCs. The challenge of sustainability is a common dilemma that funders and grantees both face at the end of an initiative's funding period (Cutler, 2002).

Nurse-managed health centers have much to offer toward resolving the national health care crisis facing vulnerable populations who are uninsured or underinsured. However, without the ability to maintain fiscal sustainability, NMHCs may fail to reach their full potential for positively influencing the future of health care (McBryde-Foster, 2005).

In the past, funders were often confronted either with the task of helping organizations find and secure other resources, or extending their own financial support to ensure the continuity of services. More recently, both public and private funders are stipulating that organizations describe detailed plans for sustainability after the award period ceases in their funding application. Cutler (2002) proposes "Critical Sustainability Questions" that can be used as a preliminary avenue of

## DISPLAY 31.3

## CRITICAL SUSTAINABILITY QUESTIONS

When applying to a funding organization, applicants should consider the following questions:

1. Assuming acceptable results, and assuming that the task will not be fully completed at the end of the grant period, is it expected that this initiative will continue beyond the period for which funding is available?
2. If so, what level of financial and other resources will be needed to continue?
3. What capacity-building measures are needed to make the initiative sustainable? How will these measures be implemented?
4. What is it about this initiative that is likely to attract interest and elicit support?
5. Who are the most likely future funders? (Be specific. If government, what level of government, what agency, what funding stream? If private, which foundation or other source?)
6. Is there a history of this entity supporting efforts (a) of this sort? and (b) of this size?
7. Would success in this effort obviate the need to spend resources on something else, and could that money be diverted to this effort? How?
8. Who within the anticipated funding organization would have to decide to fund, through what processes?

Source: Cutler, I. (2002). *End games: The challenge of sustainability*. Baltimore: Annie E. Casey Foundation Publisher, pp. 23–24.

consideration for organizations such as NMHCs when completing a grant application for funding (see Display 31.3).

## National Organization: The National Nursing Centers Consortium

In 1996, due to interest from several nursing center directors, staff, and community members to address all aspects of operations and to provide ongoing collaboration and continuing education, the Regional Nursing Centers Consortium (RNCC) of Pennsylvania, New Jersey, and Delaware was established. In the short span of 5 years, nursing centers nationwide were contacting the RNCC with inquiries related to all aspects of operations, funding, and sustainability. It soon became evident that the RNCC needed to expand its service area to meet the needs of NMHCs nationwide. In 2001, The **National Nursing Centers Consortium (NNCC)** was formed to represent NMHCs nationwide. Headquartered in Philadelphia, Pennsylvania, the NNCC expanded internationally in 2005 with the addition of a NMHC in Auckland, New Zealand. The vision, mission, and goals of the NNCC are found in Display 31.4.

### Best Practices of Nurse-managed Health Centers

In contemporary health care, evidence-based practice (EBP) is the process of making clinical decisions based upon the best

## DISPLAY 31.4

## NATIONAL NURSING CENTERS CONSORTIUM

#### Vision

Keep the nation healthy through nurse-managed health care.

#### Mission

To strengthen the capacity, growth, and development of nurse-managed health centers to provide access to quality care for vulnerable populations and to eliminate health disparities.

#### Goals

1. Provide national leadership in identifying, tracking, and advising health care policy development.
2. Position nurse-managed health centers as a recognized mainstream health care model.
3. Foster partnerships with people and groups who share common goals.

Source: National Nursing Centers Consortium. (2008). Retrieved August 20, 2008 from <http://www.nncc.us>.

available research evidence, clinical expertise, and client preferences in the context of available resources (Melnik & Fine-out-Overholt, 2005). Nurse-managed health centers implement EBP via **best practices**, or the application of the best available evidence to improve practice (Youngblut & Brooten, 2001). Chapter 4 provides an extensive overview of EBP.

Annually, the NNCC conducts a *Best Practice Conference* at varied locations throughout the nation. This professional conference brings together nurses, staff members, funders, and political leaders to share best practices and participate in networking opportunities. Continuing education credits are awarded for attendance at scientific sessions. This is one example of how NMHCs set standards for quality improvement and promote professional growth among members.

## Role of Students in Nurse-managed Health Centers

Undergraduate and graduate students from several disciplines play a vital part in the activities of NMHCs. These disciplines include, but are not limited to, nursing, social work, mental health, dental, nutrition, and speech-language-hearing science students. When students are assigned to a NMHC for their clinical experience, they become aware of the distinctiveness of nursing centers from other health care delivery systems and of the variety of models and organizational structures that exist, and they are active participants in the vital activities of the particular nursing center to which they are assigned. Most often, students are engaged in primary and secondary prevention strategies via health education, immunization, and screening programs. Students' roles are similar to those of their staff mentors, including advocate, case manager, educator, and referral agent. Faculty roles in NMHC academic models involve clinical supervision of undergraduate and graduate students assigned to the nursing center for their clinical experience (see From the Case Files II).

## EVIDENCE-BASED PRACTICE

### The Role of Community-based Practice Research

The importance of practice-based research networks (PBRNs) in primary health care research and the need for community based primary health research for addressing health disparities experienced by large populations in the United States, is addressed in this article. The unique community-based care delivered by nurses in NMHCs provides a distinct opportunity to combine the strengths of community-based practice research (CBPR) methods, found within a PBRN, to develop and test EBP that benefits health outcomes and decreases health disparities.

The Midwest Nursing Centers Consortium Research Network (MCCRN) was funded by a grant from the Agency for Healthcare Research and Quality in 2002 to begin to develop a collaborative program of PBPR with vulnerable populations across multiple NMHC sites. The research network began with 20 NMHCs, in operation from 3 to 17 years and representing thirteen Midwestern universities. By 2005, the MCCRN had 19 academic NMHCs based in 15 universities.

The original purposes of the MCCRN were to establish a practice-based research network for APNs who practice in NMHCs, establish a web-based system for data collection, and develop a collaborative program of CBPR with vulnerable populations that will inform primary care practitioners about health professional education and health care policy. Additional aims include linkages with other nursing PBRNs, to create a national network to generate knowledge about users of NMHCs, advanced practice nursing in community-based settings, and health outcomes among vulnerable and minority populations served by NMHCs.

The Robert Wood Johnson's Foundation Prescription for Health initiative provided funding for the first MNC-CRN's research study. This study, "Wellness for a Lifetime," took place in eight NMHCs at seven universities in

five states. The primary purpose of this study was to evaluate outcomes of an accessible, culturally, and educationally appropriate physical activity and nutritional intervention for high-risk, low-income, ethnically diverse clients of NMHCs.

Findings included self-reported behavior changes (increase movement and physical activity) as well as intake of a more balanced diet (less junk food and increased fruits and vegetables). The major findings were:

- Twenty-one APNs participated; chart audits before and after the study revealed that APN assessment of physical activity levels (32.9% versus 47.5%) and nutritional status (30.5% versus 56.8%) improved significantly ( $p < .01$ ).
- Clients were predominately women (84%), with an age range between 25 and 83 years and a diverse ethnic distribution of African American (44.4%), White (44.4%), Hispanic (9.9%), and Native American (1.1%).
- Of the 121 clients who signed consent forms, 82 started the program; of those, 20 clients withdrew during the study, for an overall retention rate of 50%.

#### Nursing Implications

Evidence from the first MNCCRN study suggests that a shift in the level of wellness in a large percentage of the population of the nation may depend upon the ability to create new models of health care and promotion that merge the traditional model of primary care with a public health approach to primary prevention and health promotion. Nurse researchers can work with community representatives to identify questions significant to populations served, plan and execute studies that include adequate numbers of participants from underrepresented populations, and generate evidence that can be translated back into best practices at NMHCs.

## From the Case Files II

### Health Screening at an NMHC

Public Health Nurses from an academic wellness NMHC and undergraduate student nurses are conducting blood pressure and glucose screenings at a church-sponsored health fair. For optimum participation, the event is conducted on Sunday from 10 a.m. to 2 p.m., before, during, and after church services. Approximately 50% of adults screened have hypertension and/or hyperglycemia. One African American male participant, who was asymptomatic, had severe hypertension (220/154) and was transported to the nearest hospital for evaluation.

1. What are the possible sequela of untreated hypertension and hyperglycemia?
2. What are some feasible referrals that the PHNs may have made for this aggregate?
3. What types of primary prevention strategies may benefit those attendees who had normal screening results?
4. In what ways do student nurses benefit from participating in this type of screening activity, such as participation at a health fair?

## FAITH COMMUNITY NURSING

Faith community nursing is one of the newest nursing specialties, and one of the oldest means of health care delivery. For hundreds of years, deaconesses, sisters, and lay members of religious communities have been involved in ministering to the sick. This tradition was revitalized through the efforts of Reverend Dr. Granger Westberg, a hospital chaplain and Lutheran minister, in the 1960s. Westberg observed a great need for preventive and holistic health services, especially among the underserved. He estimated that one-third of the illnesses his patients experienced could have been prevented, or the severity reduced, by education and health promotion (Westberg, 1990). To address these needs, he launched several church-based holistic health clinics that were each staffed by a physician, nurse, and chaplain. These clinics provided health services to the underserved in the community for several years. The clinics eventually closed, but the experience led Reverend Westberg to recognize the unique ability of nurses to bridge the disciplines of medicine and religion, and assist the client in understanding the physical and spiritual influences on health. In 1985, Westberg initiated a pilot project in which nurses provided holistic, preventive health care for six Christian congregations in the Chicago area. These nurses were called *parish nurses*.

The surrounding community quickly recognized the positive impact of the parish nurses on the six congregations. More and more churches sought to incorporate a parish nurse into their staff. The parish nursing movement soon spread beyond Christian religious institutions and beyond the borders of the United States to Canada, Australia, and New Zealand. The International Parish Nurse Resource Center, formed in the 1980s, has provided educational programs and resources for nurses seeking to practice as a parish nurse for over two decades. The Health Ministries Association (HMA, 2008) provides additional resources and support for faith community nursing practice and was instrumental in developing the first *Scope and Standards of Parish Nursing Practice* (American Nurses Association/Health Ministries Association [ANA/HMA], 1998).

The original *Scope and Standards of Parish Nursing Practice* defined **parish nurse** as “a registered professional nurse who serves as a member of the ministry staff of a faith community to promote health and wholeness of the faith community . . .” (ANA/HMA, 1998, p.1). The term **faith community** was defined broadly as “an organization of families and individuals who share common values, beliefs, religious doctrine and faith practices . . . such as a church synagogue or mosque . . .” (ANA/HMA, 1998, p. 6). These definitions were carried over to the revised scope and standards published in 2005. In the *Faith Community Nursing: Scope and Standards of Practice* (ANA/HMA, 2005), the title of parish nurse was changed to faith community nurse (FCN) and the name of the specialty was changed to “faith community nursing” (ANA/HMA, 2005). Today, nurses who practice in a faith community may be referred to as a **faith community nurse** (FCN), **parish nurse**, **health ministry nurse**, or **congregational nurse** depending upon preference and the traditions of the faith community. No matter what title is used, a nurse who practices in a faith community is governed by the *Faith Community Nursing: Scope and Standards of Practice* (ANA/HMA, 2005).

## What Do Faith Community Nurses Do?

Activities and interventions used by FCNs are as diverse as their faith communities. Authors have described key aspects of this specialty, which include meeting the emotional and spiritual support needs of the dying (O’Brien, 2006; Redmond, 2006; Weis, Schank, & Matheus, 2006) and serving as an advocate for individuals who are hospitalized, living at home, or in long-term care facilities (Patterson, 2007). Faith community nurses also provide health education by developing ongoing programs that provide essential health information. For example, Redmond (2006) developed a monthly health presentation she coined the “Health Spot,” which was provided in conjunction with a women’s church luncheon. Topics presented were related directly to health concerns common to older women who attended the luncheon. Redmond also developed a competitive walking program framed in a spiritual context to appeal to members of her faith community. Others have described the development of holistic exercise and wellness programs (White, Drechsel, & Johnson, 2006) and health education programs (DeHaven, et al., 2004).

Researchers have also explored what FCNs do. In a review of research, King (2004) concluded that caring, listening, being there, and providing health promotion and health screenings were common and effective interventions provided by the FCN. Anderson’s (2004) study of parish nurses supports King’s conclusions. Anderson found that providing holistic support was a major theme in FCN practice. Holistic support included actions that addressed physical, social, emotional, mental, and spiritual needs such as health education, counseling, referral to community agencies, advocacy on the client’s behalf to meet needs and reduce complications, and mobilizing other members of the faith community to provide support such as visitation, meals, and transportation.

Although some of these interventions may seem different from traditional nursing, which emphasizes physical care, medication administration, and other prescribed treatments, all registered professional nurses including the FCN share the use of the nursing process (ANA, 2004). For the FCN, implementation of a plan of care incorporates actions that fall within one or more of the seven roles of the FCN (see Display 31.5).

## Roles of the Faith Community Nurse

The goal of the FCN is the “protection, promotion and optimization of health and abilities; prevention of illness and injury; and responding to suffering within the context of the values, beliefs, and practices of the faith community. . . .” (ANA/HMA, 2005, p. 1). Health promotion outcomes may be primary, directed at prevention of disease, illness, or injury; secondary, focused on early detection and appropriate intervention; or tertiary, concerned with promoting a sense of well-being when preventing or curing a condition may not occur. To achieve the goal of faith community nursing, seven diverse nursing roles are central for the FCN to incorporate into practice.

### Health Educator

A primary role of the FCN is as a health educator. Increasing awareness of health issues through health education is

## DISPLAY 31.5

the foundation for health promotion and lifestyle changes. The FCN uses assessment skills to determine the health issues that may be present in the faith community and assesses the educational needs related to these issues. In the role of health educator, the FCN may provide individual and group education strategies such as providing health education materials, leading health education classes, or providing health screenings. The FCN may also develop educational displays or flyers, or write educational articles for the faith community newsletter or website (Patterson, 2006).

**Health Counselor**

When education alone is not sufficient for empowering the individual to initiate a change or seek assistance, health counseling may be indicated. In the health counseling role, the nurse seeks to understand the individual's perceptions, fears, and barriers that prevent the person from taking action. The FCN may use a five-step health counseling process described as the 5 A's: Ask, Advise, Assess, Assist, and Arrange (Fiore, et al., 2000). Using this process, the FCN asks about the person's perceptions related to a specific health concern, advises the person about the health concern and the benefits of taking health promoting actions, assesses the person's readiness to take action, offers assistance and guidance in planning ways to address the health concern, and arranges follow-up support.

**Advocate**

The third role of a FCN is that of an advocate, helping individuals obtain needed services or care whether in the hos-

pital, a long-term care facility, or at home. In the advocate role, the FCN uses knowledge of the health care system and awareness of safe and effective care practices to facilitate appropriate, timely intervention. Advocacy is indicated when dealing with vulnerable populations, such as older adults, children, or the homeless, who may not have the ability to speak for themselves or may lack the knowledge or awareness of what constitutes safe, effective care (Patterson, 2007).

**Referral Agent**

The FCN also functions as a referral agent by assisting and guiding the client through the health care system and connecting the client with needed community resources. Through networking with community agencies, the FCN is often aware of and able to access a variety of community resources that support the client's physical, social, financial, emotional, or spiritual needs.

**Developer of Support Groups**

Receiving emotional support from persons who share similar experiences can provide strength, comfort, knowledge, and a sense of empowerment. When the FCN discovers a need for a support group that is not currently available in the community at large, the FCN may fulfill the role of developer of support groups. The FCN develops groups tailored to the faith community needs such as coping with loss and grief, cancer, caregiver stress, chronic illness, single parenting, addiction recovery, and more. The FCN may lead or facilitate the support groups or may train others to fulfill those positions.

**Coordinator of Volunteers**

The health ministry mission of a faith community typically includes a variety of services and activities to provide holistic support of the physical, social, emotional, mental, and spiritual needs of its members. Such a diverse array of services cannot be provided by the FCN alone. In the role of coordinator of volunteers, the FCN recruits, trains, and coordinates other members of the faith community. Volunteers provide or assist with a variety of services such as home, hospital, or long-term care visitations; respite care; assisting with transportation needs of home-bound individuals; calling or sending cards to ill or injured members; and assisting with health screenings. Health ministry volunteers may include nurses, counselors, physical therapists, pharmacists, and other health care providers, as well as those with no health care background.

**Integrator of Faith and Health**

A distinctly unique role of the FCN is as integrator of faith and health. This role emphasizes the holistic relationship between physical, social, emotional, mental, and spiritual dimensions of the person. The FCN helps the person to improve health or enhance wellness by appreciating how the dimensions of the person are interconnected and by helping the person strengthen or support the weaker aspects, as needed.

## Models of Faith Community Nursing Practice

Models of faith community nursing practice are diverse and may be categorized according to volunteer versus salaried positions with institutional versus faith-based sponsorship. The type of practice model adopted depends upon variables such as the number of faith community members served, the existing health ministry services in place, the faith community's governance structure and financial resources, and existing health care systems in the community at large.

Early in the development of faith community nursing, a large number of FCNs were part-time volunteers who were members of the faith community they were serving. Gradually, as communities experienced the positive effect of FCNs within their organizations and researchers validated the effectiveness of FCNs (Brown, 2006; Rethemeyer & Wehling, 2004; Rydholm, 2006), more and more faith communities began creating salaried positions for FCNs. Salaried FCNs may be employed full- or part-time by the faith community, by a group of faith communities, or by a health care system as part of their pastoral care community outreach.

Regardless of the model of practice utilized, integrating the FCN position into the faith community's organizational structure is recommended (Solari-Twadell & McDermott, 2005; Westberg, 1990; Westberg-McNamara, 2006). One way this integration can be provided is with the formation of a *health cabinet* or health and wellness committee within the faith community. The health cabinet was originally described as a way to provide health ministry for a faith community that is interested in adding a FCN to its staff (Westberg, 1990). The health cabinet includes members from the faith community who are interested in promoting and sponsoring health-related activities and programs for the faith community. Members may be nurses, other health care professionals, or persons with no health care background. The FCN functions as a member of the health cabinet and receives guidance and support from the cabinet in developing, promoting, and delivering programs and services to members of the faith community.

## Becoming a Faith Community Nurse

The FCN practices community nursing with a high degree of independence and autonomy. Often, the FCN deals with clients experiencing complex health care situations who may have limited resources and extensive health-related needs. Recommended educational preparation for a FCN includes a bachelor's degree in nursing with community nursing experience as part of the program (ANA/HMA, 2005), and completion of additional education such as a *basic preparation course*. The basic preparation course addresses the roles of the FCN, and provides information on establishing, promoting, and maintaining a FCN practice. Participants gain experience in resolving complex client situations using scenarios and case studies.

## Establishing a Faith Community Nursing Practice

Several steps are involved in creating a FCN position within a faith community. One of the first things to do is assess the community the nurse plans to serve, identifying the health

needs of the faith community and the roles of the FCN that meet those needs. For example, a nurse might assess the demographics of the community and determine the most common health concerns and what education or health counseling needs the faith community may have. A needs assessment survey of the membership about health concerns, or topics of interest may be used. Questions to explore include: Does the faith community need support groups for members who are experiencing the stress of illness, injury, or loss and grief? Do the members of the faith community need more information or assistance to access existing community resources? Is there a need for health screening, respite care, or visitation for the sick or injured in their home, hospital, or long-term care facility?

Once the nurse has assessed the needs of the faith community, he can then identify how a FCN could help to meet those needs. He uses this information to seek the support of the faith community members and staff, usually through visits with key members of the faith community, including longstanding members and past and present board members. The nurse describes to these key members the roles of a FCN and how specific health needs of the faith community could be addressed by the services of a FCN, then solicits input from the staff and spiritual leaders of the faith community.

After key members and leaders of the faith community have verbalized support for adding a FCN to the organization's health ministry, the nurse must seek formal approval from the organization's governing body. The scope of services to be offered, time commitment expected, process of referral to the FCN, means of contacting the FCN, and other administrative aspects of the position should be negotiated before approval is finalized. The organization's bylaws, committee structure, and spiritual leader will determine the process for obtaining formal approval and will determine where the FCN will fit in the organizational structure. The approval process may require a formal presentation of the nurse's proposal to the board members or to the faith community as a whole.

Launching a FCN practice should begin after formal approval and after the nurse has prepared himself and the community for his role as a FCN. As a community health nurse practicing as a FCN, additional educational preparation such as a basic preparation course (mentioned earlier) is recommended. This course provides foundational knowledge for providing care encompassing the seven roles of the FCN, as well as guidance in establishing and maintaining a practice as a FCN.

Another aspect of preparation involves establishing community contacts and compiling information about community resources. The FCN should visit local health-related agencies, clinics, and hospitals and discuss services they provide and how the services can be accessed by members of his faith community. He may seek out community organizations such as the March of Dimes, American Cancer Society, and American Heart Association, which provide health information and online resources for health promotion activities.

If the faith community is not familiar with FCNs, the nurse will want to educate them about the roles of the FCN by describing specific activities that will be actively pursued, such as visitations, support groups, health classes, health

screening, health counseling, and referral to community resources. The nurse should consider making presentations about faith community nursing to groups within the faith community, such as prayer circles, adult Sunday school, teen groups, and existing support groups. These presentations will provide multiple benefits for the FCN and the faith community: the nurse will become familiar with members of the faith community, and they will become familiar with the nurse and the services he will be offering.

In addition to providing presentations about faith community nursing to groups within the faith community, the nurse should consider other ways to inform members of his presence. If the faith community publishes a newsletter or has a website, including a brief introduction to faith community nursing and providing some personal background and professional experience information will help. The nurse may wish to develop flyers and/or brochures that describe what a FCN does and the services he will offer, distributing these from the faith community's office, bulletin board, or foyer. Business cards that provide name, contact information, and outline FCN services may be made available. Once these steps are completed and the foundation for practice has been laid, the nurse is ready to begin a new career path as a FCN.

## OCCUPATIONAL HEALTH NURSING

Business and industry provide another group of settings for community health nursing practice. Employee health has long been recognized as making a vital contribution to individual lives, productivity of business, and the well-being of the entire nation. Organizations are expected to provide a safe and healthy work environment in addition to offering insurance for health care. More companies, recognizing the value of healthy employees, are going beyond offering traditional health benefits to supporting health promotional efforts. Some businesses, for example, offer healthy snacks such as fruit at breaks and promote jogging during the noon hour. A few larger corporations have built exercise facilities for their employees, provide health education programs, and offer financial incentives for losing weight or staying well. An increasing number of both large and small companies have recognized the benefits of occupational and environmental health nurses as part of their overall health promotion and wellness efforts.

## ROLE OF THE OCCUPATIONAL AND ENVIRONMENTAL HEALTH NURSE

Community health nurses have a long history of involvement in occupational health. In 1895, the Vermont Marble Company hired the first industrial nurse in the United States to care for its employees and their families. At the time, it was an unusual demonstration of interest in employee welfare. The nursing service, which consisted mostly of home visiting and care of the sick, was free to employees and their families. Gradually, that role changed. World War II showed a marked increase in employment of industrial public health nurses, who practiced illness prevention and health education among employees at work.

In addition to emergency care and nursing of ill employees, the activities of many industrial nurses involved

safety education, hygiene, nutrition, and improvement of working conditions. Yet, a significantly high number of industrial injuries and sick employees kept many nurses too busy to do anything but care for the ill. They might see more than 75 patients a day in the plant dispensary, where they provided first aid and medications. Employee health programs have improved as socioeconomic and political pressures have created improved safety and health standards for the work environment. Similarly, these developments have changed and expanded the nurse's role. The role of an **occupational and environmental health nurse** is to ensure that the workforce is healthy and productive, as evidenced by the nursing practice standards developed by the Association of Occupational Health Nurses, Inc. (2008).

## Special Skills and Demands

The nurse's role in occupational health, as previously mentioned, has traditionally focused on illness and injury care. This directly resulted from the knowledge and skills obtained in basic nursing education. During the last decade, a number of nursing education programs (primarily on the graduate level) have developed a specialty focus in occupational and environmental health. In addition, many continuing education programs provide occupational and environmental health nurses with updated information and skill training for identifying and assisting in the management of the physical, chemical, biologic, ergonomic, and psychosocial factors in the work environment that can affect worker health and safety. As a result, the occupational health nurse's role is not universal; it depends on the type and philosophy of the company, type and number of workers, health professionals involved, exposures and potential hazards in the work environment, and knowledge and skills of the nurse.

Internationally, occupational health nursing education is garnering attention. The World Health Organization (WHO), as expressed in the 2007 document *Workers' Health: Global Plan of Action*, takes the position that:

Development of human resources for workers' health should be further strengthened by: further postgraduate training in relevant disciplines; building capacity for basic occupational health services; incorporating workers' health in the training of primary health care practitioners and other professionals needed for occupational health services; creating incentives for attracting and retaining human resources for workers' health, and encouraging the establishment of networks of services and professional associations. Attention should be given not only to postgraduate but also to basic training for health professionals in various fields such as promotion of workers' health and the prevention and treatment of workers' health problems. This should be a particular priority in primary health care. (World Health Organization [WHO], p. 6)

This WHO document was based on the earlier policy statement regarding occupational health disparities and the release in 2003 of a standardized occupational health nursing curriculum. These WHO efforts were the basis of a 2004–2005 study of undergraduate nursing programs in Turkey. Esin, Emiroglu, Aksayan, and Beser (2008) sought to determine the length of time devoted to occupational health nursing and the qualifications of the instructors.

Overall, the research indicated limited time spent in both theory and practical experiences, and faculty, although well qualified in public health nursing, had limited practical experience in the corporate sector, pointing to the need for a standardized curriculum in Turkey and other developing countries, as provided in the WHO documents.

Consistent with the WHO (2003) recommendations that occupational health nursing requires additional training and expertise beyond the basic level, U.S. nurses in this specialty are encouraged to seek certification through the American Board for Occupational Health Nurses, Inc. (ABOHN). Established in 1972, this independent nursing specialty board has the stated purposes of establishing standards and examinations for professional nurses in occupational health, elevating and maintaining the quality of occupational health nursing services, stimulating the development of improved educational standards and programs in the field of occupational health nursing, and encouraging occupational health nurses to continue their professional education (ABOHN, 2008).

Nurses who select the field of occupational health and safety encounter experiences that differ significantly from those found in an acute care setting. To make the adjustment, the nurse should be aware of the factors that make occupational health unique.

Unlike hospitals or ambulatory care centers, the workplace is a non-health care institution in which production or service (not health care) is the primary goal. The occupational and environmental health nurse participates in the organization's goals through activities that contribute to the productivity of the workforce.

An occupational and environmental health nurse in the organization is in a staff position, taking on the role of a consultant, educator, or role model in the workplace, but has no supervisory responsibilities or power to hire or fire workers. The nurse is generally responsible for management of the occupational health unit, serving the needs of employees and management personnel.

The occupational and environmental health nurse, especially in smaller organizations, may be the only nurse in the company. As a result, he has none of the on-site consultation and direction that are needed for comfortable, competent, and independent decision-making. Nurses who use critical thinking skills to develop a framework for independent problem-solving enhance their efficiency. A nurse who works alone may feel isolated and need to collaborate with the occupational health and safety team members.

There are various causes of job stress for the occupational and environmental health nurse, and there may be related personal, professional, and employer factors. The nurse may experience role ambiguity due to a lack of professional preparation or inadequate orientation and continuing education. The corporate culture and leadership may foster work overload, be nonsupportive, and have limited career opportunities for the nurse. Occupational and environmental health nurses need to apply strategies to reduce job stress and potential job strain by modeling health-affirming choices, networking with other nurses and professional organizations in the community, and setting appropriate occupational health standards.

The client base served in occupational health is a well-adult population with whom long-term contact is possible.

Occupational and environmental health nurses, therefore, have the chance to know their clients well and have opportunities to work with them through various stages of personal as well as health service-related incidents. Such continuity of health care can challenge occupational health nurses to use all of the community health nursing model interventions—education, engineering, and enforcement.

Finally, the practice focus is oriented to the aggregate; the nurse serves a worker population. Environmental factors significantly influence the health and safety of workers. Therefore, occupational health nurses need to constantly monitor the work environment and assess the health needs of the entire worker population to identify those at risk, particularly workers in hazardous lines of work, and to develop prevention, promotion, and protection programs (see Display 31.6).

## Community-based Occupational Health Nursing

Agencies external to business and industry also provide occupational and environmental health nursing services. Historically, public health nurses from visiting nurse associations made home visits to sick employees and their families. In subsequent years, public health agencies provided part-time nursing services to small companies. These services included supervising the work environment, conducting health examinations, keeping records, teaching about and counseling on health issues, providing first aid, giving immunizations, and referring workers to community resources. More recently, community health nursing services have offered health screening and health promotion programs. Furthermore, occupational and environmental health nurse consultants based in state departments of health provide consultation and continuing education programs to nurses employed in occupational health settings.

Hospital-based occupational health programs, large medical-industrial health clinics, and insurance companies also provide occupational and environmental health nursing services. These services may be in the form of direct care (rehabilitation of an injured worker) or indirect care (consultation on implementing regulations regarding record keeping or compiling health statistics).

A continuing unmet need is attending to the health of workers in smaller companies. These companies have more hazards because equipment and controls are often inadequate. They seldom, if ever, have a health professional on site. Attempts have been made by some communities to provide needed health protection services, but no sustained efforts exist. Community health nurses are in a position to accept this challenge and develop a system that will ensure ongoing service to this high-risk population.

## Members of the Occupational Health Team

Today, the two professionals who generally provide on-site occupational health services are the occupational and environmental health nurse and the safety engineer. Other members of the interprofessional team may include an industrial hygienist, epidemiologist, toxicologist, and occupational physician. However, these specialists usually are employed only by large corporations, or they provide only selected part-time services on a contractual basis. Therefore, the

## DISPLAY 31.6

## OCCUPATIONAL AND ENVIRONMENTAL HEALTH NURSING CARE PLAN

Evelyn Robbins has been the Occupational and Environmental Health Nurse at ABC Metals for 4 years. She works with management, the company physician (who works at ABC Metals 2 days a week), union representatives, unit foremen, individual employees, and representatives from the community businesses and neighborhoods surrounding the plant. The company employs 400 workers—380 in manufacturing, primarily an assembly line making telephone electrical boxes, and 20 management and administrative staff.

Recently, 12 employees came to the worksite clinic complaining of hand injuries that had not occurred before. Ms. Robbins treated the wounds, reported the occurrences to the foremen involved, and reported the incidents to management. In addition, she wanted to explore the cause of these injuries so that they could be interrupted. She used the nursing process in her exploration.

**Assessment**

- Tour the areas where the incidents occurred
- Inquire among the foremen to determine whether there was a change in routine, equipment, employee assignment, or product being manufactured
- Ask injured employees what they were doing when the injury occurred
- Reassess wounds for likenesses and differences; for example, was it the right or left hand and was it on the same part of the hand in each case?

**Diagnoses**

- Wounds occurred in factory areas where a new piece of equipment had been installed
- Injured employees did not receive orientation to the equipment

**Plan**

- Plan to work with foremen to provide an orientation for all employees who work with the new equipment
- Plan an orientation program (with foremen, union representative, and one employee from each unit in the factory) for all employees before working with new equipment in the future, to prevent further injuries

**Implementation**

- Implement the orientation for employees who work with the new equipment
- Initiate the orientation program as new equipment is introduced into the factory

**Evaluation**

- Have there been any new equipment-related injuries in the factory?
- Has there been any change in general safety in the factory related to the increased focus on safety with new equipment.

position of occupational and environmental health nurse in a large company or of the community health nurse who serves smaller companies is the cornerstone of occupational health.

Collaboration may take time, but it is worth the investment. The occupational health nurse must gain the respect and trust of management and establish open communication to influence company policies regarding the nature and scope of health programs.

Depending on the size of the company and its products or services, the occupational health nurse may also collaborate with any or all of the following people: insurance carriers, union representatives, employee assistance counselors, industrial hygienists, safety engineers, company or outside lawyers, toxicologists, human resources personnel, and the community. Any comprehensive assessment of employee health and safety problems, as well as any health promotion program, requires cooperation and assistance from many people working in various departments within the organization.

Finally, the occupational health team is not complete without the workers themselves. Employees can help identify problems and needs while contributing to decision-making about health programs. Their cooperation in implementing and evaluating programs is essential for an effective health protection and promotion effort.

**Future Trends**

A broad goal for occupational health is to promote and maintain the highest level of physical, social, and emotional

health for all workers. In practice, this goal is only beginning to be realized in selected instances. Nevertheless, it is a worthy and, more importantly, an essential objective in the realization of an energized and productive working community.

However, the rapid and fundamental changes in U.S. businesses and the economy in the 1990s and 2000s have added four critical issues that affect the practice of occupational and environmental health nursing. First, the downturn in the global economy, and in the economy of the United States specifically, has skeletonized many worksites, shut down companies, eliminated night or evening shifts, or moved companies to less expensive communities. In addition, several major scandals have eliminated jobs within hours, such as in the Enron and Worldcom corporations, and in those major banks involved in risky home loans that resulted in unprecedented housing foreclosures across the country. Second, increasing worldwide competition requires businesses to remain competitive by reducing or controlling operating costs at the lowest level possible. Third, an increase in technologic hazards requires a sophisticated approach as well as knowledge of toxicology, epidemiology, ergonomics, and public health principles. Fourth, health care costs continue to escalate at faster rates than most company profits do.

Current occupational and environmental health nurse practices will continue to evolve to meet future needs. The focus will shift from one-on-one health services to a new role involving broader environmental, business, and research skills. One such example of this changing role was an Australian study of nurses' perceptions of their current

and future roles in occupational health practice (Mellor & St. John, 2007). The researchers found that wellness, management, and research were the more important activities identified. Their findings suggest that educational efforts should focus on wellness-based models of practice, research, and negotiating skills for the workplace.

Current occupational health nurse activities include the following:

- ◆ Supervising care for emergencies and minor illnesses
- ◆ Counseling employees about health risks
- ◆ Following up with employees' workers' compensation claims
- ◆ Performing periodic health assessments
- ◆ Evaluating the health status of employees returning to work

Future occupational health nurse activities will involve the following:

- ◆ Analyzing trends (health promotion, risk reduction, and health expenditures)
- ◆ Developing programs suited to corporate needs
- ◆ Recommending more efficient and cost-effective in-house health services
- ◆ Determining cost-effective alternatives to health programs and services
- ◆ Collaborating with others to identify problems and propose solutions

As we move further into the 21st century, occupational and environmental health nurses and management will share the goal of developing a healthy, productive, and profitable company. A healthy company consists of healthy and productive employees, and healthy employees mean lower health care costs. Lower costs result in an increased competitive edge and higher profits. Higher profits can make more resources available to support more programs and to improve employee health.

The occupational and environmental health nurse will particularly need skills in effective communication, leadership, change management, research, business acumen, and assertiveness. These tools will be crucial for effectively interpreting the occupational health nurse's role and promoting ideas. The success of programs developed by the occupational health nurse depends on establishing positive working relationships with the other team members. Nurses involved in occupational health have a unique opportunity to help shape the health profile of the working population. An example of this type of effort was the study by Hyeonkyeong, Wilbur, Kim, and Miller (2007) linking high job insecurity with increased risk for lower-back work-related musculoskeletal disorders among long-haul flight attendants. Their findings point to the need for occupational health nurses in the airline industry to be aware of the potential relationship between job tasks and work-related psychosocial factors.

The degree of the occupational nurse's influence depends on how the nurse defines the occupational and environmental health nurse role. Also, the nurse must be able to overcome the many obstacles found in the occupational setting, including restrictive company policies, misunderstanding of the nurse's role, and lack of time for innovative program development. The nurse's role in occupational health,

therefore, varies considerably. It ranges from providing only emergency care for on-the-job injuries or illness to establishing comprehensive policies and programs covering health promotion, accident and disease prevention, and innovative care for disease and disability.

Occupational and environmental health nursing demands a great deal from the nurse. Individual needs in the workplace always compete for the nurse's time and take attention away from aggregate needs, often to the detriment of the latter. To maintain a proper focus on aggregate needs requires discipline and commitment—commitment based on a different mindset and the realization that the health and productivity of workers are interrelated with the health of the community.

## Summary

*Healthy People 2020* will guide both public and private sector nursing practice well into the next decade. Community health nurses have a number of options available to them as they seek to address the myriad health issues facing our communities. For many, the opportunities may present to assume roles in a variety of nontraditional settings, including nurse-managed health centers, faith community nursing, and occupational and environmental health nursing. All three settings offer the community health nurse the opportunity to address health disparities in their communities, promote healthy lifestyles, and improve the overall health and well-being of their respective populations.

Nurse-managed health centers have emerged as critical safety net providers in America's health care delivery system. Various nursing center models exist and are located in health professional shortage areas or medically underserved areas in urban and rural communities. Interdisciplinary teams of APNs, social workers, substance abuse counselors, community health outreach workers, and students from varied disciplines, provide services that generally focus on primary and secondary prevention strategies. Lundeen's comprehensive community based primary health care model demonstrates how NMHCs are distinct from public health agencies and medical care facilities. Funding sources for NMHCs include reimbursement from various organizations, sliding scale fees, grants, contracts, foundation support, and private support via gifts. Sustainability is an ongoing challenge in all NMHC models. An international organization to strengthen the capacity, growth, and development of NMHCs is The National Nursing Center Consortium. Nurse-managed health centers identify, develop, and share best practices. Nurse leaders and staff from NMHCs engage in sociopolitical activities to raise awareness of the outcomes generated by the nursing center model. These activities are implemented to raise awareness of the role of NMHCs in the health care system and to promote sustainability of the centers. Undergraduate and graduate students from various disciplines engage in all aspects of NMHC activities and augment the interdisciplinary team.

Faith community nurses practice community nursing within a unique setting—a faith community. A FCN may provide services to a single faith community or may coordinate services for multiple communities. The FCN addresses the physical, social, emotional, mental, and spiritual needs of the faith community through the roles of health educator, health counselor, referral agent, advocate, developer of

support groups, coordinator of volunteers, and integrator of faith and health.

Occupational and environmental health nursing applies the philosophy and skills of nursing, community, and environmental health to protect and promote the health of people in their workplaces. The occupational and environmental health nurse's role is evolving as business becomes more competitive and health care costs escalate at a frightening rate. That expanded role will include analyzing current trends, recommending more cost-effective and innovative in-house health services, and collaborating with other members of the multidisciplinary occupational health team, including management, to develop appropriate programs.

Each of these three professional practice areas provides a unique opportunity for community health nursing practice. Escalating health care costs, increasing numbers of uninsured and underinsured, and the many gaps in services experienced by so many in our communities present an unprecedented opportunity for community health nurses. The many unmet needs in our communities can be addressed, but only if nurses are willing to take the "road less traveled," as did Lillian Wald and the other pioneers of nursing. As you ponder your options for practice, consider the challenges and the many benefits of these and the many other practice areas in your community. Perhaps you cannot envision yourself in this type of service at this point in your career. A time may come, however, when you are afforded the chance to participate in your own faith community health education efforts, refer a client to a nurse-managed health center, or possibly collaborate with an occupational and environmental health nurse to address an emerging health issue in your community. ■

### ACTIVITIES TO PROMOTE CRITICAL THINKING

1. You are practicing as a newly hired nurse in a NMHC. What assessments would you conduct to determine the needs for the local community that surrounds the NMHC? What sources of data (qualitative and quantitative) would be useful to you during your assessment?
2. Based upon your findings in the previous question, what public policy issues are apparent in this community? How could you, as a nurse working in this NMHC, impact public policy in the future? What key legislators would you contact? How would you accomplish this?
3. Locate a NMHC in your community. Interview a nurse practitioner or public health nurse employed there. Ask the nurse to describe the type of NMHC model he works in. Ask the nurse about *Best Practices* performed in his role. If you cannot locate a NMHC in your local community, search online via the National Nursing Center Consortium's website at [www.nncc.us](http://www.nncc.us) for a NMHC. E-mail the nurse listed as the contact person and ask him the questions in activity 2.

4. This chapter covers the role of the faith community nurse. Search for information about this area of community health nursing in your community. Do you know a faith community nurse? If so, plan to observe his practice for a few hours and explore what the role entails in this faith community.
5. Figure 31.1 depicts the major focus areas identified to meet the nation's goals of increasing years of healthy life and eliminating health disparities. Which of these focus areas is addressed by each of the three areas of practice discussed in this chapter? Which of these focus areas do you see as most critical to each area of practice?
6. This chapter covers the role of the occupational and environmental health nurse. Search for information about this specialty area of nursing in your community. Do you know an occupational health nurse? If so, plan to observe his practice for a few hours and explore what the role entails in this organization.

# Clients Receiving Home Health and Hospice Care

## LEARNING OBJECTIVES

*Upon mastery of this chapter, you should be able to:*

- ◆ Summarize the history and contemporary circumstances of home health and hospice care.
- ◆ Describe Medicare standards for home health and hospice programs.
- ◆ Explain family caregiver burdens of providing home care.
- ◆ Explain how Medicare reimburses home health and hospice care.
- ◆ Describe essential characteristics of home health and hospice nursing practice.
- ◆ Identify unique challenges of infection control, medication management, fall prevention, use of technology, and nurse safety during home visits.
- ◆ Contrast the goals of home health care and hospice.
- ◆ Explain the gaps in home health care and hospice and the need for a coherent community-based long-term care program in the United States.

*“People from all walks of life agree that someone who is sick deserves, in principle, compassion and care.”*

—Paul Farmer, American anthropologist and physician

## KEY TERMS

CMS (Centers for Medicare and Medicaid Services)  
 Community-based long-term care  
 Home-bound  
 Hospice  
 Medicare Home Health Benefit  
 Medicare Hospice Benefit  
 Medicare Prospective Payment System  
 OASIS (Outcome and Assessment Information Set)  
 Palliative interventions  
 Responsive use of self  
 Visiting nurse associations

 A home health nurse sits in an upscale condominium with a frail, elderly gentleman tethered to his home oxygen unit and suffering air hunger as he struggles to speak of the “good old days” when he was young, full of vigor, and taking on the world. During her next visit to a trailer park, she inspects an infected pressure sore that has become smaller and cleaner with each home visit as the client’s wife carefully follows through with wound care teaching. Next, she monitors the pulmonary and cardiac status of a patient newly discharged to his aging bungalow, detecting early signs of cardiac decompensation, and treating them at home in close collaboration with his physician. At that same time, her hospice nurse colleague walks into family chaos with a mother in pain and vomiting at the end of her life, and then leaves with everyone calm and the patient comfortable. These are the kinds of experiences that make up the daily lives of nurses who work with home care and hospice clients. Indeed, home health and hospice programs allow nurses to practice what some see as the very heart of compassionate and highly skilled nursing care. Home health care and hospice programs are expanding and are the work settings for more and more nurses.

Home health care is discussed in the first section of this chapter, followed by an overview of hospice care. The reader is also referred to the discussions in Chapter 19 on working with families, Chapter 20 on violence in families, Chapter 24 on care of the older adult, and Chapter 26 on chronic illness.

## OVERVIEW OF HOME HEALTH CARE

The need for health care at home continues to accelerate. Drastic changes in financing and more people living with complex illness have contributed to this trend. For example, early hospital discharges resulting from third-party payers’ efforts toward cost containment have forced clients to return home quickly to recuperate from surgeries and severe illnesses. Likewise, a growing population survives and yet suffers from complex chronic and life-threatening illness that they struggle to manage at home. Advanced technologies such as telehealth monitoring, intravenous (IV) antibiotics, total parenteral nutrition (TPN), dialysis, and mechanical ventilation are routinely provided and maintained in the client’s home. As the population ages, and particularly now that the baby boomer generation is entering their elder years, home health nursing is challenged to respond. Professional home health care agencies seek to maximize the client’s level of independence and to minimize the effects of existing disabilities through noninstitutional services. Professional home health services aim to decrease rehospitalization and prevent or delay institutionalization (Martinson, Widmer, & Portillo, 2002; Rice, 2006). The National Association for Home Care and Hospice (NAHC at <http://www.nahc.org>) provides a variety of direct services to members, including the publication *Caring* and monthly newsletters.

This section explores the evolution of home health care in the United States; describes home health agencies, clients, and personnel; and examines Medicare criteria and documentation. Finally, the unique characteristics of home health nursing are explored.

## HISTORY AND POLITICS OF HOME HEALTH

Throughout human history, health care has been provided at home by family members. In the United States, the Ladies Benevolent Society in Charleston, South Carolina, made the earliest known (1813) organized effort to care for the sick poor at home (Buhler-Wilkerson, 2007). Later in the 19th century, it became possible for women to become nurses trained in the manner of Florence Nightingale, and wealthy women began to hire them as visiting nurses and to sponsor visiting nurse services. In 1893, Lillian Wald began home visiting in New York City and is famed for professionalizing visiting nursing. One of her most famous innovations was the establishment of insurance coverage for home care. Between 1909 and 1952, 100 million home visits were made to the policy holders of Metropolitan Life Insurance Company. Then, as now, the needs for cost containment and therefore quick discharge were in diametric opposition to nursing goals of providing needed care at the patient’s side as long as needed.

In the latter half of the 20th century, as hospitals became increasingly effective in providing acute care, more people survived to live with debilitating chronic illness and disability, and referral to home care was used to discharge those nonacute patients from the hospital (Buhler-Wilkerson, 2007). The **visiting nurse associations** (VNAs) struggled with patched-together community support until 1965, which began the era of the **Medicare Home Health Benefit**, designed to respond to the medical needs of those convalescing from acute illness.

The Medicare Home Health Benefit was established with certain goals in mind. It was designed to provide intermittent home visits, in which nurses and therapists would instruct clients and families in self care. Home health nursing was clearly differentiated from longer nursing shifts in which nurses stayed in the home for several hours at a time. The period of visiting was to be brief and provide direct personal care just temporarily until patients and families could care for themselves. Neither health promotion nor long-term care was valued or reimbursed. Families were expected to manage long-term care alone. Whereas nurses had previously controlled their own practice, services under the new benefit were viewed as extensions of medical care, with physicians certifying needed services for short-term treatment of sickness.

The number of Medicare-certified home care agencies grew rapidly until enactment of the Balanced Budget Act (BBA) of 1997, which sought explicitly to reduce federal payments for home health care by changing payment from reimbursement for each visit to the **Medicare Prospective Payment System** that determined Medicare payment rates based on patient characteristics and need for services (Kulesher, 2006). The BBA resulted in a closure of 36% of the nation’s Medicare-certified home health agencies and a dramatic decline in the number of patients served, with particular impact on the most vulnerable patients over 85 years old who need intensive services. As a result, some agencies currently deny care to those whose complex nursing needs exceed expected reimbursement. Both cost and number of visits have declined while rates of wound healing failures, incontinence, and psychosocial problems have worsened

(Schlenker, Powell, & Goodrich, 2005). The long-term effect on emergency care and hospitalization is being monitored. The diminished patient contact and increased documentation associated with these restrictive Medicare policies is distressing for home health nurses, who are most satisfied when they have control over their practice and are able to provide quality patient care (Ellenbecker, Boylan, & Samia, 2006).

It is important to be aware that a distinct difference exists between professional and nonprofessional home care services provided to clients. Professional home care is provided by professionals with licenses, certification, or specific qualifications. These professionals typically work for home care agencies with internal and external standards that guide the provision of their services. Nurses, social workers, physical therapists, occupational therapists, and home health aides are examples of professional home care practitioners. In contrast, there are home care organizations that provide nonprofessional home care and those who sell equipment for home care.

## HOME HEALTH AGENCIES

The mix of Medicare-certified home health care agencies includes voluntary nonprofits, hospital-based agencies, proprietary for-profit agencies, governmental agencies, or agencies not federally certified to provide care.

*Voluntary nonprofit agencies* traditionally have a charitable mission and are exempt from paying taxes. They are financed with nontax funds such as donations, endowments, United Way contributions, and third-party provider payments. If nonprofit agencies make any money, they reinvest it back into the agency. Voluntary agencies are usually governed by a voluntary board of directors; they are considered community-based because they provide services within a well-defined geographic location. Whereas in the past VNAs were assured of receiving almost all of the home care referrals in their community, the proliferation of other agencies has eroded their traditional base and put them in a competitive mode. The number of nonprofit home health agencies is diminishing across the country.

*Hospital-based agencies* comprise about one-quarter of Medicare-certified agencies (NAHC, 2004). A hospital may operate a separate department as a home health agency. It may be nonprofit or generate revenue for the hospital. Hospital-based agencies are governed by the sponsoring hospital's board of directors or trustees. The referrals to such hospital-based agencies usually come from the hospital staff itself, and the missions of the agency and the sponsoring hospital are similar. The same is true for rehabilitation and skilled-nursing facilities with home health departments.

*For-profit proprietary agencies* can be governed by individual owners, but many are part of large, regional or national chains that are administered through corporate headquarters. Proprietary agencies are expected to turn a profit on the services they provide, either for the individual owners or for their stockholders. They are required to pay taxes on profits generated. Although some participate in the Medicare program, others rely solely on "private-pay" clients. For-profit home care agencies now comprise over half the number of Medicare-certified agencies (NAHC, 2004).

Some city and county government agencies also provide home care services. They are created and empowered through statutes enacted by legislation. Services are frequently provided by the nursing divisions of state or local health departments and may or may not combine care of the sick with traditional public health nursing services, including health promotion, illness prevention, communicable disease investigation, environmental health services, and maternal-child care. Funding comes from taxes and is usually distributed on the basis of a per capita allocation.

Many agencies providing services in the home remain outside the federal Medicare system that reimburses skilled nursing. These *noncertified* agencies are usually private and derive their funding from direct payment by the client or from private insurers. They may be governed by individual owners or by corporations. For instance, some agencies offer "private duty" shifts of registered nurses, licensed practical nurses, various therapists, or home health aides who are usually paid for "out of pocket" rather than reimbursed by insurance or Medicare. Other services include unskilled assistance in the home with homemaking or housekeeping. Some of these agencies provide live-in personal care. Some organizations provide *durable medical equipment* (DME), such as wheelchairs, commodes, beds, or oxygen. Other services provide high-technology pharmacy services.

## CLIENTS AND THEIR FAMILIES

The client in home health care is not only the individual patient but also the family and any significant others. The nurse must consider how the environmental, political, economic, cultural, and religious dimensions impact the client's illness and ability to meet the goals outlined in the plan of care.

Home care recipients are predominantly white women. More than two-thirds are over age 65 (NAHC, 2004). The most common diagnoses managed at home are cardiovascular, with the five top conditions identified as essential hypertension, heart failure, diabetes, chronic skin ulcers, and osteoarthritis. Most home health clients are admitted after hospitalization.

Individuals recovering from severe illness or living with debilitating chronic illness rely on family members or other sources of unpaid assistance. One in five American households contains a person who provides informal caregiving for an adult family member or friend (Schumacher, Beck, & Marren, 2006). Almost two-thirds are women with an average age of 46, although people can become caregivers at any age. Frail elderly caregivers are especially vulnerable to deterioration of their own health due to their caregiving burden. Family caregiving tasks range from personal care such as bathing and feeding to sophisticated skilled care, including managing tracheostomies or IV lines. Primary caregivers are those who assume the daily tasks of care, while secondary caregivers assume intermittent responsibilities such as shopping or transportation.

These informal caregivers assume a considerable physical, psychological, and economic burden in the care of their loved one at home. When layered on top of existing responsibilities, caregiver tasks compete for time, energy, and attention. As a result, caregivers often describe themselves

as emotionally and physically drained and may very much need information about resources to assist them. Likewise, the economic cost of providing home care places a significant burden on informal caregivers. Out-of-pocket expenditures include medications, transportation, home medical equipment, supplies, and respite services. These costs may be nonreimbursable and are often invisible, but they are very real to families struggling to provide care on a fixed income. While family members compassionately assume their responsibilities, their collective burden in our society as a whole is mounting. Home health nurses must continually assess the strain on caregivers as they seek to develop realistic plans of care.

## HOME HEALTH CARE PERSONNEL

The largest number of home care employees are nurses and home care aides (NAHC, 2004). Registered nurses and licensed practical nurses represent just under half of full time equivalent (FTE) positions in Medicare-certified agencies. Home care aides, physical therapy staff, occupational therapists, social workers, and administrative personnel comprise the rest of the home health team. The business and office personnel of a home health agency are critical to the agency's ability to deliver services to clients. Home health nurses must acquire an understanding of the financial aspects of their clients' care and provide this information to the agency staff, so that appropriate and full reimbursement can be obtained for the services provided.

## REIMBURSEMENT FOR HOME HEALTH CARE

Home health services are reimbursed by both corporate and governmental third-party payers as well as by individual clients and their families. Corporate payers include insurance companies, health maintenance organizations (HMOs), preferred provider organizations (PPOs), and case-management programs. Government payers include Medicare, Medicaid, the military health system (TRICARE), and the Veterans Administration system. These governmental programs have specific conditions for coverage of services, which are often less flexible than those of corporate payers. For a general description of these reimbursement systems, see Chapter 6. The Medicare policies for home health programs set the precedent for all other reimbursement sources and are discussed below.

### Medicare Criteria and Reimbursement

Medicare is the largest single payer for home care services in the United States and has set the standard in establishing reimbursement criteria for other payers. Therefore, it is essential that home care nurses seek to understand the complex Medicare home health requirements and rules for determining eligibility for home care services. It is important to acknowledge that a person may be in dire need of care at home, yet not meet eligibility standards for home health care under Medicare. Five criteria must all be met to be eligible for reimbursement by Medicare (Display 32.1). Consider the implications of these requirements. Documentation must justify that the plan of care is medically "reasonable and necessary." The person must be under the care

#### DISPLAY 32.1

#### MEDICARE HOME HEALTH ELIGIBILITY

1. The type of services and frequency provided must be reasonable and necessary. To determine whether this criterion is met, the client's current health status, medical record, and plan of care are evaluated. If a care plan has been ineffective with a client over a long period of time, continuation of that care plan would not be considered reasonable. Therefore, comprehensive documentation is essential to validate that the provided care was both reasonable and necessary.
2. The client must be **home-bound**. This means that the client leaves the home with difficulty and only for medical appointments or adult day care related to the client's medical care.
3. The plan of care must be entered onto specific Medicare forms. The forms require very specific information regarding the client's diagnosis, prognosis, functional limitations, medications, and types of services needed. The home health nurse often has the primary responsibility for ensuring that the forms are completed appropriately.
4. The client must be in need of a skilled service. In the home, skilled services are provided only by a nurse, physical therapist, or speech therapist. *Skilled nursing services* include skilled observation and assessment, teaching, and performing selected procedures requiring nursing judgment.
5. Services must be intermittent and part-time.

of a physician. He or she must be "homebound" and in need of services that Medicare narrowly defines as "skilled." A person who is "homebound" must be confined to home except for visits to the physician, outpatient dialysis, adult day center, or outpatient chemotherapy and radiation therapy. "Skilled" services are restrictively defined and include selected aspects of nursing, physical therapy, or speech therapy. Home visits must be "intermittent" and time limited. Extensive documentation is required according to Medicare specifications. All of these requirements are subject to contradictory interpretations, which can put an agency's reimbursement at risk.

The Medicare Prospective Payment System (PPS) pays an agency for a 60-day "episode of care." All services and many medical supplies must be provided under the payment amount adjusted to geographic location and determined by the patient's clinical and functional status at the start of care, as well as the projected need for services over the anticipated 60-day period. When the patient is admitted, the patient is comprehensively assessed using a lengthy tool called the **Outcome and Assessment Information Set (OASIS)**. Clinical, functional, and service scores are calculated from selected OASIS items.

In the ongoing campaign to hold down the federal budget by diminishing health costs, home health care faces the ongoing threat of freezes or cuts in payment. For example, in Spring of 2007, the **Centers for Medicare and**

## PERSPECTIVES VOICES FROM THE COMMUNITY

It is vital to develop an expanded vision about the health care needs of frail elders and the kinds of services that are needed in the community. Sometimes, after nurses have been working in Medicare home health for a while, they may begin to identify with the Medicare guidelines. Too often, I have heard experienced home health nurses say about a patient living with severe chronic illness, “She doesn’t deserve services. She doesn’t have skilled needs.” In contrast, I would hope knowledgeable nurses would say to families and decision makers, “She needs and deserves services, but the Medicare home health benefit will not pay for them. Our agency cannot continue to provide care because of the limits imposed on us. We’ll do everything possible to find help for her, but resources are limited.” This kind of insight leads to patient advocacy, development of community networks, and becoming outspoken about needed changes in health policy. Visiting nurses witness the struggles of chronically ill people living at home; we must not abandon them.

*Beth L., Nursing Instructor*

**Medicaid Services (CMS)** proposed reduction in reimbursement, justified by their claim that patients’ needs have been exaggerated in documentation submitted to them (CMS, 2007). They also require payment adjustment based on agency submission of data on selected quality measures. In 2007, the Medicare Payment Advisory Commission (MedPAC) recommended to Congress that payments be frozen and that patients co-pay for each illness visit (Markey, 2007). These proposals overlook the reality that home health care is a cost-effective alternative to hospital and nursing home care. As home health care is restricted to save money and reduce fraud, greater amounts will need to be spent for inpatient care when people cannot cope in the absence of health care assistance at home (see Perspectives: Voices from the Community).

### Medicare Documentation

Initially, every patient must be assessed using the OASIS tool, which determines reimbursement, is integral to agency surveys and certification, and collects information used to measure quality. OASIS assessment requires combining observation and interview to determine functional status, since clients often report what they wish to be true, rather than actual ability (Godfrey, 2005). Selected quality outcomes are measured and data released on the CMS website, which is accessed as “Home Health Compare” (<http://www.medicare.gov/HHCompare>). Display 32.2 identifies selected quality measures. Note that the expectation is that of improving function, not simply stabilizing function, and consider the implications of this standard for very disabled patients.

The Medicare Plan of Care is also completed by the nurse at admission; it must be signed by the physician. It is

### DISPLAY 32.2

## SELECTED HOME HEALTH QUALITY MEASURES

#### Higher Percentages Are Better

- Percentage of patients who get better at walking or moving around
- Percentage of patients who get better at getting in and out of bed
- Percentage of patients who have less pain when moving around
- Percentage of patients whose bladder control improves
- Percentage of patients who get better at bathing
- Percentage of patients who get better at taking their medicines correctly (by mouth)
- Percentage of patients who are short of breath less often
- Percentage of patients who stay at home after an episode of home health care ends
- Percentage of patients with improvement in status of surgical wound

#### Lower Percentages Are Better

- Percentage of patients who had to be admitted to the hospital
- Percentage of patients who need urgent, unplanned medical care
- Percentage of patients with deteriorating wound status

Source: <http://www.medicare.gov/HHCompare>.

then used to assess agency compliance with Medicare and state requirements. Obviously, great pains must be taken to assure accuracy. All follow-up services must match the plan of care. Likewise, OASIS answers and Plan of Care answers must match.

## HOME HEALTH NURSING PRACTICE

The practice of home health nursing has roots in community health nursing (American Nurses Association, 1999). The nurse provides home health nursing care to acute, chronic, and terminally ill clients of all ages in their homes while integrating community health nursing principles that focus on the environmental, psychosocial, economic, cultural, and personal health factors affecting a client’s and family’s health status and well-being. Home health is a unique field of nursing practice that requires a synthesis of community health nursing principles with the theory and practice of medical/surgical, geriatric, mental health, and other nursing specialties. The official journal of the Home Healthcare Nurses Association (HHNA), *Home Healthcare Nurse*, is the primary source of up-to-date nursing knowledge in this rapidly changing field of practice. The stories of home health nurses emphasize shared humanity and promotion of client autonomy (Stulginsky, 1993a, 1993b). The effective home health nurse must

- ◆ Deliberately build trust.
- ◆ Sense “where people are” and suspend judgment.
- ◆ Develop a connection at the first visit.

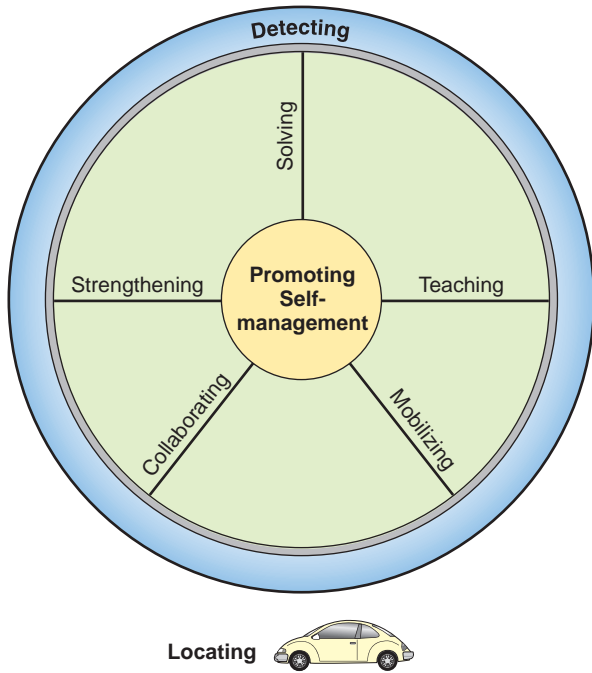

FIGURE 32.1 Home Health Nursing Caregiving Wheel.

- ◆ Develop “giant antennae” to detect cues in the home.
- ◆ Face persistent distractions during home visits.
- ◆ Help people solve their own problems.
- ◆ Keep priorities fluid.
- ◆ Determine how to keep the unstable client safe until the next visit.
- ◆ Thoughtfully maintain boundaries between personal and professional life.
- ◆ “Make do” with limited supplies.
- ◆ Face immense challenges with time management and paperwork demands.
- ◆ Constantly think of personal safety in neighborhoods and homes.

## Nursing Practice During the Home Visit

The practice competencies of home health nurses can be illustrated with the Home Health Nursing Caregiving Wheel (Fig. 32.1).

### Locating the Client and Getting Through the Door

The first step in making a home visit is finding where the person lives, which might involve telephone instructions, a map, or a global positioning system (GPS) unit. For most home health nurses, locating clients involves driving their own cars to the home. Sometimes nurses drive agency cars, and occasionally transportation may involve a bus, subway, boat, or airplane. Directions and household identification can be unclear. In rural areas, tracking down clients can involve vague instructions involving barns, bridges, trees, and other colorful local landmarks (see From the Case Files for an example). When families are unstable, clients may not be staying in households designated on the nurse’s paper-

work. They may have moved in with relatives or friends or back home alone, despite major care needs. Locating is especially challenging when neighbors or even family members live in fear, for whatever reason.

Even when the wheels stop at the correct household, there is the challenge of getting through the closed door and making the connection. *Always remember that you are a guest in the home.* Respect and attentive listening are the foundation. Agendas must be laid aside initially as the nurse focuses on the concerns and realities of both client and family. SmithBattle, Drake, and Diekemper (1997) describe **responsive use of self** as the process expert nurses use to come to understand the lives of vulnerable clients in the community. Assumptions and stereotypes are overturned in the process of discovering how clients live, what they believe, and who comprises their family and community.

Other nursing approaches that build the initial therapeutic nurse–client connection include helping with immediate problems that the family identifies. Start where they want in ways that make sense to them. Emphasize positives to the extent possible, rather than telling people what they are doing wrong and need to change. Autonomy should be respected, and the family should be empowered by actions recognizing that they are in charge of their lives. At the same time, the nurse must be up front and truthful regarding the medical and nursing problems that need resolution. For example, a nurse might say, “You might lose your foot if we cannot work together to figure out a plan of care that works. Let’s think together about what we can do to prevent it.” Since these well-tested relational strategies for developing caring connections run contradictory to the current Medicare requirements for immediate completion of the lengthy OASIS survey tool on admission, the wise nurse needs to focus on sensitively developing initial connections as well as completion of the OASIS.

### Hub of the Family Caregiving Wheel: Promoting Self-management

Home health nursing involves home visits to promote independence rather than dependence on the home health team. Lasting health improvement is only possible when the home health nurse works with the client/family to make decisions that are truly their own. Although financial incentives push home health nurses to minimize the number of visits and duration of service, pressuring a client or family to adopt the agency agenda denies any sense of partnership and can backfire, resulting in nonadherence to the therapeutic regimen. This can place a nurse in a no-win situation.

Every effort is made to develop capacity for self-care, so that the home team can safely withdraw. Obviously, this is quite appropriate for those recovering from an episode of acute illness, but it can be quite difficult when clients are living with severe chronic illness and do not have adequate caregivers to provide needed care without outside nursing assistance. Pressures to discharge are resulting in some patients discharged from home health care agencies while unable to manage care at home; indeed, a proportion of elderly clients are currently discharged from home health agencies with unresolved wound and incontinence issues (Flynn, 2007). Currently, no governmental program assures long-term care for those people unable to care for themselves. The home

## From the Case Files

### Locating the Client's Home

"You can't miss our place," Diane had reassured me on the phone. I slowed in front of the decrepit Sunrise Motel, its roof partially collapsed, and reviewed my notes. I was supposed to turn right on the unmarked gravel road just after the abandoned motel and continue until the road ended. I proceeded slowly through an evergreen tunnel past an old green truck body resting belly up. A little girl perhaps 5 years old, came from around the truck and joined two grade-school-aged boys playing Frisbee in a clearing. I asked them where Diane Quimby lived, and they pointed around a curve in the road. In a moment, I came to a stop near a large wood and metal shed with smoke coming out of a crooked metal pipe in the roof. I knocked. No answer. I heard dialogue from "General Hospital" coming from inside. I knocked again and shouted, "Hello! It's the nurse." "Come on in!" a loud voice responded.

I pushed open the door. There was no knob. Illuminated by one weak lamp, I could just make out a round face with wire rim glasses and a long gray-blond braid. Here was Diane, sitting on a sagging sofa facing a TV tray and watching a flickering black-and-white television. I could see a wooden table in a corner, three mismatched dinette chairs, and a couple of cots against the wall. The air was hazy with the smell of wood smoke.

Diane invited me to pull up a chair. "We're worried about your infections," I began. Diane had unstable, insulin-dependent diabetes and high blood pressure. In June, surgeons had removed her gangrenous left foot with an amputation that ended just below the left knee. Now there was an infection in the wound that had not healed despite extended use of antibiotics.

During the course of the visit, I learned that Diane had no tub or shower for bathing. She also had no money for dressings and no supplies. Since Diane's vision was impaired, her 9-year-old grandson was doing the dressing changes. Until the latest surgery, Diane worked as a cook in a local "boarding home" for frail elders. She was 66 years old and had Medicare coverage. I learned that Diane was the legal guardian for two grandchildren, ages 5 and 9.

Apply the nursing process to comprehensively identify and prioritize nursing diagnoses and propose interventions. Use the Home Health Nursing Caregiving Wheel to guide your care planning.

health nurse must work closely with agency social workers to mobilize resources to care after the agency leaves.

### Rim of the Home Health Caregiving Wheel: Detecting

Nurses in the home are challenged by an extraordinarily complex environment with much to investigate and frequently many distractions to ignore. Detecting is an all-encompassing, never-ending assessment process as the nurse seeks to understand the client's health in the context of home (Zerwekh, 1991). The nurse keeps her ears and eyes "wide open." The home environment surrounds the nurse with sounds, sights, and scents that need to be comprehended in light of the client's needs. Who lives in the home? How do they interact? Who are the caregivers, and how do they care? What is the relevance of culture and religion in the life of the household? How does the physical environment impact patient safety and security? Is there drug paraphernalia in the living room? Can the bathroom tub be used? The questions are endless. Sometimes the underlying etiologies of illness can be discovered by scrutinizing the "big picture" in the home. The OASIS format provides the baselines for the first visit, and then the nursing assessment broadens with each visit as the nurse continually widens her lens to take it all in. Home visits reveal discoveries that can never be imagined in clinic or hospital settings. Take for example the client whose refrigerator no longer chills and whose impaired vision prevents awareness of the expanding family of roaches in the kitchen.

### Spokes of the Home Health Caregiving Wheel: Collaborating, Mobilizing, Strengthening, Teaching, Solving Problems

Home health nursing competencies that radiate from the hub and contribute to promotion of self-care and family care include *collaborating* with multiple team members and *mobilizing resources* in the community that can sustain the client after discharge. The home health care nurse usually is the coordinator of all other home health team members. Working with the social worker, she proposes needed connections with community services. Likewise, *strengthening* involves development of self-management or family caregiving ability. People learn that they can give injections, manage IV lines, safely take complex drug regimens, provide rehabilitation for loved ones after stroke, and perform countless other skills that they do not believe possible until a nurse shows them and they discover that they can do it themselves.

The home health nurse is constantly *teaching* clients and/or family caregivers through concrete explanation, discussion, and modeling behavior. Teaching facts is no assurance of behavior change and improved management of a health problem. Underlying factors influencing health behavior must be diagnosed and addressed. Health coaching, also called *motivational interviewing*, has demonstrated effectiveness in improving chronic disease management by getting patient and family to be actively involved (Huffman, 2007). Instead of telling people what to do, this involves asking people how they would like to change, "What worries you the most?" Those concerns and relevant feelings must

be validated, and the nurse leads the person to consider options for change. The solution develops through a mutual, participatory process. Ultimately, people are responsible for their own health decisions.

Finally, home health nursing competency requires flexibility and creativity in *olving* health care problems and the challenges of everyday living. All outcomes of care can be achieved only by adapting to the skills and resources available in the home. Although people of all socioeconomic backgrounds present with severe health problems requiring home health nursing, many families live on the margins. Inderwies (in Cohen, 2007) vividly describes her 32 years of visiting the “have-nots, can-nots, and will-nots” (p. 15). By this, she refers to people living on the margins of society who have few resources, little capability, and frequent resistance to being told what to do. Their housekeeping may be terrible. Their interactions may be abusive. Witnessing lives in some homes requires an awareness of self and every effort to reach beyond preconception and judgment. Caring in the homes of those living “on the ragged edge” of society necessitates a strong commitment to discovering and honoring shared humanity (Zerwekh, 2000). Sometimes awareness of our own limitations should lead to referral to another home health nurse rather than imposing our own fear and/or anger on vulnerable clients.

## Home Health Nursing Case Management

The home health nurse is the case manager for each client and responsible for coordination of the other professionals and paraprofessionals involved in the client’s care.

She plans visit frequency and duration. Will home visits be made twice weekly, once weekly, or every day? For how long will visits continue? As the care is provided and the client’s condition improves, the home health nurse determines whether the frequency of visits should be reduced or whether the client can be discharged.

She is the primary contact with the client’s physician, collaborating on the initial plan of care, reporting changes in the client’s condition, and securing changes in the plan of care.

The nurse conducts case conferences among team members to share information, discuss problems, and plan actions to effect the best possible outcomes for the client. Medicare mandates such case conferences every 60 days in home care. The nurse case manager supervises the paraprofessionals, such as home health aides, who also serve the home-bound client. This may entail visiting the client at a time when the home health aide is present to observe the care provided.

The home health nurse must know who is going to pay for services from the first visit to the time of discharge from the agency. If the client does not have a source of payment for the care that is needed, the agency must determine whether the client will receive the care free of charge or at a reduced rate. Many agencies have a sliding fee scale, which means that the charge for the services is based on the client’s ability to pay.

## Selected Nursing Challenges in the Home

Working in the home immerses the nurse in challenges unlike anything encountered in controlled institutional environments.

Some of these include infection control, medication safety, risk for falls, technology at home, and nurse safety.

### Infection Control

Home health nurses frequently need to work with the family to prevent infection in clients who are debilitated and may be immunocompromised; in addition, many are now dwelling at home with invasive medical devices that make them especially vulnerable to infection. Likewise, nurses are challenged to consider how to protect the home health care team, family, and community from a client with contagious disease. In such cases, all people living in the home will need instruction. Some households have inadequate facilities to control disease transmission. There may be no access to running water, no heating unit to boil equipment, or inadequate facilities to dispose of contaminated equipment. These conditions necessitate the development of creative solutions to control infection. Complexities of the home environment require the nurse to carefully consider exactly how microorganisms are likely to exit the body, how might they be transmitted, and how are they likely to enter the body of another individual. Households cannot be organized like hospital units with isolation rooms. The nurse must decide when gloves are absolutely essential, when protecting clothing with a gown is needed, when a mask should be worn, and what environmental surfaces are likely to be contaminated and must be scrupulously cleaned. How should soiled tissues or dressings, dishes, and laundry be handled? What is realistic and can actually be carried out by client and family? As in the hospital environment, hands are the main vehicle for transmission of contagion, and hand hygiene is the main intervention that must be emphasized. To guide the nurse, home health agencies have adapted infection control policies and procedures based on the Centers for Disease Control and Prevention’s isolation precautions (Siegel, Rhinehart, Jackson, Chiarello, et al., 2007).

### Medication Safety

Home health nurses assume major responsibility for medication safety. The home health client taking multiple medications is at particular risk of multiple errors in self-administration, including incorrect medication, dose, time, interval, or route. Often doses are missed or doubled. Clients may discontinue a drug or not complete the full course. Sometimes, the drug or drugs ordered are inappropriate considering the patient’s condition at home.

The home presents risks of medication errors that are different from those found in hospital or nursing home (Mager, 2007). Every visiting nurse has stories of finding drawers and cupboards filled with multiple prescriptions from multiple physicians, some current and some many years old. Polypharmacy becomes very obvious at home. Even if the client is well organized and taking every drug prescribed, those prescriptions may have originated from several providers over time and may have contradictory side effects. Sometimes medication errors at home include failure to clearly reconcile hospital or nursing home orders with home discharge orders. Although medication boxes can helpfully organize medications, they can also confuse new or impaired users. Distraction, visual impairment, forgetfulness, depression, and cognitive impairment are common causes of

unintentional medication noncompliance. The home health nurse investigates how the medication is taken by reviewing and reconciling the current list of medications and having the patient explain and demonstrate the process he goes through. Intervention requires clear and repeated instruction, updating the medication list, charting or diagramming the schedule for medication taking, and assuring that the client or caregiver knows how to use the medication box.

Some of the reasons for intentional noncompliance are knowledge deficit, unacceptable side effects, no immediately obvious consequence when the drug is stopped, resistance to authority, perception of personal weakness if needing medication, and prohibitive cost. As the cost of prescriptions is shifted onto people living with chronic illness, drug spending goes down, with partial adherence or total discontinuation of therapy by clients who cannot afford their medication. It is not surprising to note that health then deteriorates and clients with diseases such as congestive heart failure and diabetes come to need intensive medical intervention (Goldman, Joyce, & Zheng, 2007). The home health nurse seeks to nonjudgmentally elicit reasons and mutually figure out solutions that manage medications at home and prevent intensive medical interventions.

### Risk for Falls

Elders living at home have a 35% to 40% chance of falling; fear of falling is a serious problem in the aging, especially in those with debilitating illness (Stanley, Blair, & Beare, 2005). Physiological risk factors include orthostatic hypotension and cardiac dysrhythmias, dizziness, neurologic and musculoskeletal effects on gait and balance, urinary urgency, impaired hearing or vision, alcohol or drug abuse, and medication effects impairing alertness, balance, urinary frequency, and blood pressure. Clients should be observed as they move through their home and carry out activities of daily living. It is important to investigate factors that obstruct movement or threaten balance. The nurse in the home should inspect sidewalks, stairs, and surfaces outside the home; floor, rugs, electrical cords, stairs, lighting, and clutter inside the home; kitchen safety; and bathroom features including grab bars and a raised seat for the toilet and safety modifications for the bathtub. Common home modifications, such as eliminating throw rugs and loose mats and the use of nonslip bath mats have a significant protective effect. Display 32.3 lists teaching guidelines to prevent falls.

### Technology at Home

Home health nurses teach patients and family to manage a wide array of complex technologies. Home regimens often require mini-intensive care units. In the past, the average home had a limited capacity for technology; medication was swallowed and food and fluid were consumed with the aid of fork and spoon. Now, the IV needle has evolved into venous access devices and plastic IV fluid bags can be stacked in the refrigerator and hung from the arm of a lamp. The household becomes home to dialysis, ventilators, enteric and IV nutrition, vasopressors—the list goes on. Nurses teach clients and families to manage it all; we become the guardians and advocates of complex regimens

#### DISPLAY 32.3

### TEACHING TO PREVENT FALLS

- Discuss fear of falling as normal and then urge preventive approaches.
- Identify environmental hazards and explain need for change.
- Encourage highest possible level of physical activity considering ability.
- Explain importance of reporting health status changes that increase risk of falls.
- Explain importance of recognizing sensory changes and correcting immediately.
- Teach regular blood pressure monitoring.
- Emphasize slowing down when moving and changing positions.
- Emphasize safe footwear and foot care.
- Explore strategy for responding to a fall, including calling for help and getting up.
- Demonstrate safe body mechanics to lift heavy objects and to move immobilized family members.

Modified from Stanley, M., Blair, K.A., & Beare, P.G. (2005). *Gerontological nursing: Promoting successful aging with older adults*, 3rd ed. Philadelphia: F.A. Davis, with permission.

that require multiple nursing visits. Paradoxically, our primary mission is to be guardians and advocates for the well-being of client and family. Consider the human impact when the machines and the sickbed become the center of household activities. “We can slip so easily into the struggle to keep the technological regime functioning. However, nurses and other professionals in the home are in the pivotal position to witness the impact, to document the impact, and to assist clients to construct their lives in a meaningful way, so that neither illness nor medical regimes are the only reason for being” (Zerwekh, 1995, p. 12). Sometimes, we can foster dialogue with clients and families to consider the benefits and burdens of continuing technologies. Consider four reasons why technology may be inappropriate: (1) the technology is not achieving a therapeutic purpose, (2) the therapeutic purpose can be met more simply, (3) complications of the intervention outweigh benefits, and (4) the resulting quality of life does not justify the technology.

Recent information technologies being adopted by home health care agencies significantly improve quality of client care. These include medical records available instantly on the nurse’s laptop and daily telemedicine monitoring of electrocardiogram, blood pressure, oxygen saturation, and other vital measures.

### Nurse Safety

Every home health care agency should have a carefully developed program to assure the safety of personnel traveling to homes. Many work closely with local police departments to identify the wisest process for visiting dangerous neighborhoods and isolated rural areas. Display 32.4 lists practices for safe home visiting.

## DISPLAY 32.4

## SAFE HOME VISITS

- Carry a cellular phone.
- Be sure the agency knows your itinerary.
- Clarify directions before travel. Carry a map.
- Make joint visits or request security escort if safety is threatened. Refuse to visit when there is strong evidence of personal danger. Consult the police.
- Call to schedule the visit and do not go into the home without invitation.
- Dress simply without expensive jewelry. Do not carry large amounts of cash. Keep wallet or purse locked in the car.
- Wear an agency badge.
- Follow family directions about how to get by in their neighborhood and when to come in or leave their home. Patients and families usually will protect their nurse.

## THE FUTURE OF CARE IN THE HOME

In conclusion, it can be seen that present-day Medicare home health care intervenes during brief episodes of acute medical trouble, relies on family at home as caregivers, and is expected to get in and out of the home as inexpensively as possible. Consider instead that the true needs of the frail elderly or severely disabled require prolonged psychosocial support, personal care, housekeeping, promotion of health, prevention of deterioration, and early detection of medical problems. In other words, they need case management that extends over months and years. For this to happen, the United States must develop a **community-based long-term care** system. Home health care leaders look to a future of reinventing themselves by moving into new lines of business to meet these needs (Cohen, 2007). Some baby boomers will be able to afford these services by paying out of their own pockets for a network of elder management services. Most baby boomers will need the development of a national community-based long-term care benefit. Refer to Display 32.5 for a list of *Healthy People 2010* objectives related to home health and hospice care (U.S. Department of Health & Human Services [USDHHS], 2000).

## OVERVIEW OF THE HOSPICE MOVEMENT

The contemporary circumstances of death in America are often dehumanizing; most people die in hospitals and long-term care institutions, surrounded by strangers. Uncertainty and denial often prevail during the final stage of life because prognoses are uncertain and many serious illnesses are now treated aggressively until the last breath. The battle against the “evil” of death seems to be the primary emphasis, with patient, family, and professionals wanting to believe that it is possible to win the final struggle. In the 21st century, fatal conditions have been turned into expensive chronic illnesses. Too often, discomfort is not relieved and treatment causes further suffering. And as the period of disability extends and the body deteriorates, social isolation develops. The modern preoccupation with action, productivity, and beauty has little interest in the process of dying. In dramatic

## DISPLAY 32.5

## HEALTHY PEOPLE 2010 HOME HEALTH AND HOSPICE CARE OBJECTIVES

Remember that *Healthy People 2010* has two broad goals: to eliminate health disparities and to increase quality and years of healthy living. A vital concept for elders is that of “compressing morbidity.” This means that we seek to promote healthy lives and to diminish (compress) the time they are suffering with disabling illness. Any health care system developed to provide long-term care for the elderly and those with chronic illness should maximize function and independence. How might such a system work?

### Specific *HP 2010* objectives related to home health and hospice care include:

- 1-4. Increase the proportion of persons who have a specific source of ongoing care.
- 1-5. Increase the proportion of persons with a usual primary care provider.
- 1-6. Reduce the proportion of families that experience difficulties or delays in obtaining health care or do not receive needed care for one or more family members.
- 1-15. Reduce the proportion of adults with long-term care needs who do not have access to the continuum of long-term care services. (Midcourse revision)

contrast to the dehumanization of death, the **hospice** movement has developed to humanize the end-of-life experience and provide palliative care. **Palliative interventions** relieve suffering without curing underlying disease. The hospice movement has emphasized four major changes in end-of-life care: (1) care should attend to body, mind, and spirit; (2) death must not be a taboo topic; (3) medical technology should be used with discretion; and (4) clients have a right to truthful discussion and involvement in treatment decisions (McIntosh & Zerwekh, 2006). Table 32.1 contrasts mainstream medical focus with hospice. This section explores the evolution of hospice care in the United States, describes hospice agencies, and examines Medicare criteria for hospice reimbursement. It concludes with an exploration of the unique characteristics of hospice nursing practice.

## EVOLUTION OF HOSPICE CARE

In medieval Europe, hospices were refuges for the sick and dying. The contemporary hospice movement originated in England, where Dame Cicely Saunders founded St. Christopher's Hospice in 1967 (McIntosh & Zerwekh, 2006). Dr. Saunders was credentialed as a nurse, social worker, and

**TABLE 32.1 Contrasts Between Home Health and Hospice**

Hospice	Home Health
Emphasis is on quality of life and comfort.	Emphasis is on rehabilitation and physiological stabilization.
Focus is on health of whole family.	Focus is on health of client.
Plan of care is guided by client choice.	Plan of care is determined by medical need.
Nurse is case manager until death.	Nurse is case manager until home health discharge.
Client chooses how to live last days.	Priority is given to correcting physiologic imbalances.
Intermittent visits increase in frequency as death become imminent.	Intermittent visits decrease in frequency as client stabilizes.
Nurses are expert in symptom control.	Symptom control is domain of physician with some nurses having expertise.
Sedatives and opioids are expertly adjusted to eliminate suffering.	Sedatives and opioids are used hesitantly to reduce suffering.
End-of-life disease course is managed to avoid crises.	End-of-life problems tend to be seen as medical crises.
Goal is for symptoms at end of life to be managed at home if possible.	Client is brought to hospital for unmanaged symptoms.
Spiritual care is focus of whole team.	Spiritual needs are met by own clergy.
Survivors have bereavement support.	No bereavement support is provided.

Adapted from Zerwekh, J. (2002). Home care of the dying. In I. Martinson, A. Widmer, & C. Portillo. *Home health care nursing*. Philadelphia: W.B. Saunders, with permission.

physician. She developed a unique program based both on compassion and skillful relief of physical discomfort through around-the-clock analgesics administered by mouth. It had been previously assumed that only injections, administered sparingly, could be used for terminal pain control. The first hospice in the United States was established in 1974 in Branford, Connecticut, by Florence Wald, Dean of the Yale School of Nursing. Because even in the 1970s, there was concern about saving money by shortening hospital stays and keeping people out of the hospital, hospices in the United States came to focus on providing care in the home. To that end, Congress established the Medicare hospice benefit in 1982, with the intention of keeping people at home, yet receiving comprehensive services that are less expensive than hospitalization.

Hospice characteristics have changed over time. Initially, nearly all clients suffered from terminal cancer; presently, people with a variety of end-stage diseases are admitted. Diseases that were once rapid death sentences have now turned into chronic life-limiting diseases. With prognoses difficult to predict and denial of death a continuing issue, hospice referrals are now made very late in the disease process. Brief hospice stays make it difficult to significantly help families and clients before death occurs. Another transition in hospice is the move from charity to business (McIntosh & Zerwekh, 2006). With highly reliable Medicare payment, for-profit hospices have expanded and are competing in many communities for the hospice “market share.”

## HOSPICE SERVICES AND REIMBURSEMENT

As in home health care, Medicare has determined the way services are provided. The **Medicare Hospice Benefit** requires that a client who has a prognosis of 6 months or less must sign up for the comfort-focused hospice benefit and waive the reg-

ular hospice benefit. This mandates that the client acknowledges a terminal prognosis and chooses comforting care instead of life-extending care. When this choice is made, the hospice coordinates care in all settings, functioning both as clinical and financial case manager (McIntosh & Zerwekh, 2006). The government pays a flat rate to the hospice for each day the patient receives care. There are four payment levels: (1) routine home care with intermittent visits, (2) continuous home care when the patient’s condition is acute and death is near, (3) inpatient hospital care for symptom relief, and (4) respite care in a nursing home to relieve family members. Eighty percent of care has to be provided at home or in a nursing home that has become the person’s permanent residence.

Hospices coordinate home care and direct inpatient care if needed. The emphasis is on palliation, with a focus on physical, psychosocial, and spiritual comfort. A strong emphasis is placed on caring for the entire family. The hospice team includes nurse, physician, home health aides, physical and occupational therapists, social workers, volunteers, palliative medication and medical equipment specialists, and bereavement counselors. Staff meet regularly to explore together the challenges of assuring comfort at the end of life.

Volunteers fill an important need in hospice care. They act as companions to the client when the family must be somewhere else or is away for short respite. They run errands for family members, shop, organize hot meals prepared by friends and neighbors, baby-sit children in the family, and perform other services as needed.

## HOSPICE NURSING PRACTICE

The nurse’s role is central in the hospice interdisciplinary team. She functions as case manager and visits the client more frequently than other members of the team. Nurses

work in close collaboration with physicians to assure management of symptoms often change rapidly as the end of life nears. In addition to home visits focusing on palliation and interdisciplinary planning, hospice nurses rotate through 24-hour call 7 days a week to assure continuous availability by telephone and visits for emergent problems reported by client or family. Hospice nursing competencies and challenges are similar to those described for home health nurses, with the added expertise needed to relieve physical and emotional suffering of terminally ill people and their families. The American Nurses Association (ANA), in collaboration with other groups, has published standards of practice for hospice and palliative nursing (2007), as well as pain management nursing (2005). These practice standards provide guidance in this specialized field of nursing.

Hospice caregiving can be illustrated as a tree, strongly rooted in the process of nurses deliberately practicing self-care for themselves (Fig. 32.2). This tree has been drawn to explain the expert competencies of hospice nurses who were interviewed to capture the essence of their practice (Zerwekh, 1995, 2006). Each of the hospice nursing practices visualized by the tree diagram is briefly summarized below.

### Roots of Hospice Nursing: Sustaining Oneself

Effective hospice nurses understand that to care for others, they must care for themselves. Without strong healthy roots, the tree will not thrive. *Sustaining oneself* requires deliber-

ate effort to maintain one’s own physical, emotional, and spiritual well-being. Knowing oneself, identifying sources of stress, and learning how to care for oneself are important. Expert hospice nurses keep themselves healthy by maintaining a balance between giving and receiving, letting go of predetermined agendas and idealistic hopes to achieve more than is humanly possible, being emotionally open and clear, and deliberately replenishing themselves to restore their energy (Zerwekh, 2006). “Rooted in self care, we are able to reach out with courage to the broken and terrified at the end of their lives” (p. 60). Examine the Evidence-based Practice feature about the risk of compassion fatigue. Of note: The contemporary work environment of most nurses actually causes more stress than everyday witnessing of suffering and death (Vachon, 2001); emphasis on productivity and finances, with limits placed on nurse empowerment and resources, can be quite disheartening. Leaders must seek to develop a caring culture that respects nurse autonomy in the face of these challenges.

### The Trunk Reaching Upward: Connecting, Speaking Truth, and Encouraging Choice

Rooted in self-care, hospice nurses practice *connecting*, which refers to the centrality of relationships in providing hospice care. The hospice nurse seeks to understand the emotional and spiritual distress common to the end of life, particularly the progressive experience of loss after loss. Guided by that understanding, hospice nurses emphasize attentive

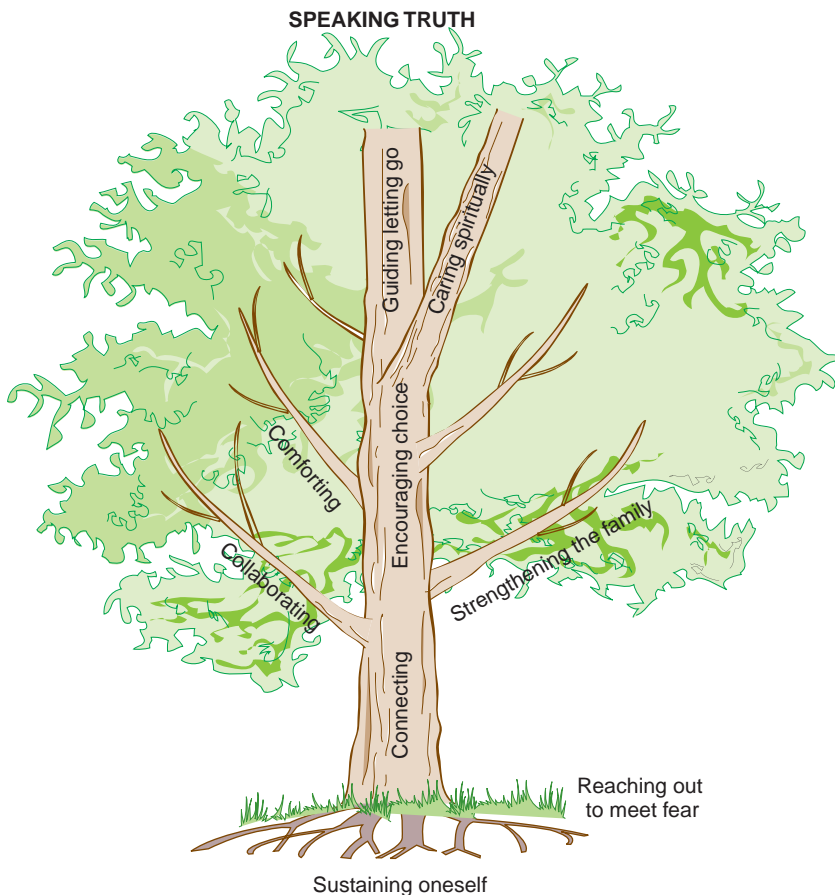

FIGURE 32.2 The Hospice Caregiving Tree.

## EVIDENCE-BASED PRACTICE

### Compassion Fatigue

Do you wonder how hospice nurses sustain compassionate practice as they work day in and day out with suffering patients who always die? Abendroth and Flanery (2006) investigated “compassion fatigue” among 216 nurses in 22 Florida hospices. They defined compassion fatigue as a traumatic stress reaction resulting from helping a person suffering from traumatic events. Symptoms in hospice nurses included being preoccupied with the patient, feeling overwhelmed with work, feeling “on edge” due to helping, losing sleep over patient’s trauma, feeling “bogged down” by the system, depression, memory loss, headaches, and having “frightening” thoughts. The central theme was intense identification with patients that resulted in vicarious experiences of anxiety and pain.

Staying healthy as a hospice nurse requires a high level of self-awareness to “purposefully enter into the world of a suffering person to understand his or her experience, while maintaining enough detachment to be of practical usefulness and to retain our own emotional health” (Zerwekh, 2006, p. 50). Abendroth and Flanery note the value of being able to debrief after experiencing a patient’s death. Nurses working in this area must be supported emotionally by their agency and must also recognize their own need to share stories and speak openly about sorrow, anger, and fear.

listening to understand each individual’s unique story. This requires quieting your own thoughts to truly hear what is being expressed. Sometimes listening involves simply being present in the moment, paying attention. Having heard the client’s story, it is important for hospice nurses to speak honestly when other professionals and family feel obliged to keep being cheerful and positive. Hospice nurses openly seek to speak truthfully about many issues that can be painful to discuss. *Speaking truth* is visualized as encircling the entire top of the caregiving tree. Hospice nurses bring up difficult subjects, so that the client is freed to speak about his greatest fears and concerns. Sometimes it leads to joint problem solving and *encouraging choice* through informed decision making. After truth has been discussed and the client has made a decision, the hospice nurse often advocates for client wishes against the resistance of various authorities. Remember that these are the final decisions in a dying person’s life.

### Collaborating

Interdisciplinary teamwork is an essential branch on the tree. Hospice team members communicate around the table and are constantly consulting each other. The hospice

interdisciplinary team members share information and work interdependently. The hospice nurse coordinates the plan of care and day-to-day efforts to provide physical and psychosocial comfort. She supervises practical nurses and nursing assistants. The physician is responsible for medical care and serves as liaison with the client’s primary care physicians. Social workers, spiritual counselors, and volunteers are integral members of the hospice team. The hospice interdisciplinary team is constantly challenged to work creatively together to find solutions for complex end-of-life suffering with emotional, spiritual, and physical components.

### Strengthening the Family

The death of a family member causes great disruption for all involved. When family members are in a caregiving role in the home, they experience significant personal suffering. They are vulnerable to physical and emotional illness themselves. The process of taking care involves managing the illness and all practical assistance, seeking information and resources, and preparing for death itself (Stetz & Brown, 1997). Family members often are caught up with family issues and struggles with the health-care system. An extremely important hospice nursing role involves strengthening family members’ abilities as caregivers. Teaching caregiving requires creative teaching methods and flexibility. Often the hospice nurse is able to help family members communicate with each other, gather them together, and act as an intermediary if necessary.

### Comforting

Hospice nurses develop extensive expertise in pain and symptom management. Contemporary medical/surgical nursing textbooks discuss the essentials in this field, and advanced knowledge is developed through experience, continued education, and reading. Display 32.6 lists fundamental palliative

#### DISPLAY 32.6

#### FUNDAMENTALS OF PALLIATIVE CARE

- Make no assumptions about what is wrong.
- Believe the patient’s report of symptoms.
- Relieve discomfort to the extent that the patient chooses and finds acceptable.
- Investigate the biologic, psychosocial, and spiritual dimensions of discomfort.
- Anticipate symptoms and relieve them before they occur again.
- Use nursing and complementary (integrative) interventions.
- Become an expert in the use of palliative medication.
- Continually evaluate the effectiveness of interventions.
- Choose the least complex and most manageable interventions that patients and families can manage themselves at home.
- Never give up. Persist in trying different palliative strategies.

## DISPLAY 32.7

**ESSENTIAL COMPONENTS OF PAIN RELIEF**

1. Continually assess the extent of pain and the relief afforded by interventions.
2. Schedule analgesics around the clock to maintain continuous blood levels and prevent the return of pain.
3. Use the least invasive route for analgesic administration, with oral as first choice.
4. Follow the World Health Organization (2007) three-step ladder:
  - Step 1 for mild pain:* Nonopioid (acetaminophen or NSAID) plus adjuvant such as corticosteroid, antidepressant, anxiolytic, or anticonvulsant.
  - Step 2 for persisting pain:* Opioid and perhaps nonopioid and/or adjuvant
  - Step 3 for severe pain:* Strong opioid and perhaps nonopioid or adjuvant

principles and Display 32.7 identifies four important components of pain relief.

### Spiritual Practice and Letting Go

As death draws near, spiritual needs intensify, with the final search for meaning, reconciliation, hope, and transcendence beyond the limits of human lived experience (Touhy & Zerwekh, 2006). Hospice nurses recognize spiritual distress and practice spiritual caring interventions that include respect for beliefs and spiritual practices and fostering reconciliation if there is a problem with estrangement from family, friends, and faith tradition. They deliberately try to keep their minds uncluttered by distracting preoccupations, so that they can listen attentively and promote life review. Cassidy (1998) states that spiritual care at the end of life involves being a companion on the dying person's journey, even when we would rather escape walking with them along the frightening path through darkness.

*Guiding letting go* is a truly unique nursing practice that involves helping the client to let go of former activities and hopes, including life itself. This involves listening to intense emotions and helping the person and family find resolution. Sometimes it involves participating in a vigil at the bedside of the dying person and encouraging loved ones to say their final words of farewell.

### ETHICAL CHALLENGES IN HOSPICE NURSING

The hospice nurse confronts striking ethical challenges at the end of life. "To nurse at the end of life, you need to become conscious of how value-laden the choice of medical and nursing interventions can be. We practice in the middle of an ethical minefield. . . . Naming and clarifying ethical issues is a prominent nursing role. . . . We must strengthen our voice and ask, 'Is what we are doing good for this person and family?'" (Zerwekh, 2006, pp. 180–181). Wide-ranging issues

include respect or disregard for client autonomy, relief or disregard for client suffering, and avoidance of killing at the very end of life. The hospice nurse needs to develop her own knowledge of nursing and medical ethics in order to question the ethical implications of interventions and to advocate for client and family.

### THE FUTURE OF HOME HEALTH AND HOSPICE

Given a rapidly expanding population of elders living longer with challenging chronic illnesses, home health and hospice care in the home will soon need to transform into a community-based long-term care system that doesn't discharge after an acute episode or admit only at the very end of life. In response to out-of-control medical inflation, federal and state governments have sought to hold down expenses in all areas, including restrictions on home health and hospice care. However, costs keep rising in step with technologic and pharmacologic innovation and marketing. Containing costs will eventually force a shift in services from expensive institutional and high-technology interventions to community-based home services.

The entire model for service provision in the home must change to a health care delivery system that continuously serves those living with disabling and terminal illness to maximize well-being at home, anticipate and prevent crises, and minimize emergent and inpatient interventions. The Medicare definitions of home-bound, medical necessity, and skilled nursing must become extinct. Likewise, the current hospice admission requirement that a person must discontinue treatment in order to receive hospice services is outdated. Reception of hospice services should be based on client choice and the reality of a terminal diagnosis. A sustainable, affordable (Callahan, 1999) approach to care in the home will require ongoing case management to coordinate and manage resources with incentives that control cost while assuring quality of life and comfort. Community resources will need to be mobilized to develop interdisciplinary and volunteer teams. Clients and family caregivers will need education and supportive networks. Homemaking and personal care will be the bedrock to keep people at home as long as possible. Nurses, nurse practitioners, and home visiting physicians will need to have the diagnostic and therapeutic resources to monitor physiologic status and intervene in the home. Telehealth and home monitoring will be essential. The focus must change from doing everything possible to prolong physiologic survival to promoting meaningful and comfortable lives. Nurses will have an active role in this process.

### Summary

Community health nurses have an important role in working with elders who receive home care or hospice services. As the population continues to age, the need for nurses to work with older adults where they live, as they are discharged from acute care settings earlier and earlier and, if they are terminally ill, during their final months and days, will only increase.

There are many types of home care agencies: voluntary, proprietary, hospital-based, official, homemaker, and hospice. Care is provided by formal and informal caregivers.

Professional staff members, such as nurses, social workers, therapists, and certified nursing assistants, work in collaboration with family members, and, in some situations, with friends and neighbors.

Hospice is a fairly new concept in the United States, but has a longer history in England. Medicare covers hospice care without the restrictions experienced by nonhospice home care clients. Hospice programs provide holistic care to clients during the last months of life. Many programs are home-based, and they often are a service offered by a home health agency. In addition to in-home hospices, inpatient hospices exist; these can be located in a free-standing building, in part of a skilled nursing facility, or in a section of an acute care facility. The focus of hospice care is not aimed at cure, and it employs holistic caregiving practices that involve family members, professionals, and volunteers.

The nurse provides direct physical nursing care both in home health care and with hospice clients. In addition, the nurse teaches clients, family members, and volunteers; supervises; and case manages. Assessing clients to determine health status and eligibility for additional services and acting as a client advocate occurs with both groups of clients. Determining the frequency and duration of services occurs in home care. With both home care and hospice clients, the nurse must become familiar with the requirements of documentation to promote continuity of care and ensure reimbursement. ■

### ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Go to the *Healthy People 2010* website at <http://www.healthypeople.gov/>. Look up Objective 1.15: *Long-term care and rehabilitative services*. What specific services are included in this objective? Now access the *Healthy People 2010 Midcourse Review* (USDHHS, 2006). Again look up Objective 1.15: Are there changes/revisions to the original objective? How are home health and hospice care addressed in each document? In planning for *Healthy People 2020*, what changes would you propose to this objective to improve access to quality health services?
2. Search the Internet for home health and hospice agencies in your city or town. Select two agencies and compare the employment opportunities of each. How do these job descriptions and the published pay ranges compare to hospitals in your area? What are the benefits of working in home health and hospice? Will the agency hire new graduates, or do they require prior acute care experience?
3. John S., age 58 years, was recently diagnosed with liver cancer following years of heavy alcohol consumption. At the urging of his physician, his wife contacted the local hospice agency for assistance. You have been assigned this case. When you arrive at John's house, his wife tells you that he refuses to see you and is continuing to drink alcohol. She is very distressed and begins to cry. How would you

handle this situation? What are some of the issues inherent in this case?

4. Review your personal health insurance policy or that of a family member. What coverage, if any, is provided for home health or hospice care? What restrictions are stated in the coverage—total reimbursement, source of care, length of service? Do you think this will be adequate to meet your or your family member's needs? What other options might be available to help defray the cost of this type of care?
